- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

## hwsens

Instrument prices and sensitivities from Hull-White interest-rate tree

### Syntax

```
[Delta, Gamma, Vega, Price] = hwsens(HWTree, InstSet)
[Delta, Gamma, Vega, Price] = hwsens( ___, Options)
```

### Description

`[Delta, Gamma, Vega, Price] = hwsens(HWTree, InstSet)` computes instrument sensitivities and prices for instruments using an interest-rate tree created with the `hwtree` function. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

`hwsens` handles instrument types: 'Bond', 'CashFlow', 'OptBond', 'OptEmBond', 'OptEmBond', 'OptFloat', 'OptEmFloat', 'Fixed', 'Float', 'Cap', 'Floor', 'RangeFloat', 'Swap'. See `instadd` for information on instrument types.

`[Delta, Gamma, Vega, Price] = hwsens( ___, Options)` adds an optional input argument for `Options`.

### Examples

#### Compute Instrument Sensitivities Using an HW Interest-Rate Tree

Load the tree and instruments from the `deriv.mat` data file. Compute Delta and Gamma for the cap and bond instruments contained in the instrument set.

```
load deriv.mat;
HWSubSet = instselect(HWInstSet, 'Type', {'Bond', 'Cap'});
```

```
instdisp(HWSubSet)
```

Index	Type	CouponRate	Settle	Maturity	Period	Basis	EndMonthRule	IssueDate	FirstCou
1	Bond	0.04	01-Jan-2004	01-Jan-2007	1	0	1	NaN	NaN
2	Bond	0.04	01-Jan-2004	01-Jan-2008	1	0	1	NaN	NaN

Index	Type	Strike	Settle	Maturity	CapReset	Basis	Principal	Name	Quantity
3	Cap	0.06	01-Jan-2004	01-Jan-2008	1	0	100	6% Cap	10

Compute the Delta and Gamma for the cap and bond instruments.

```
[Delta, Gamma] = hwsens(HWTree, HWSubSet)
```

```
Delta = 3×1
```

```
-291.2580
-374.6368
```

60.9580

Gamma =  $3 \times 1$   
 $10^3 \times$

0.8584  
 1.4609  
 5.5994

## Input Arguments

### **HWTree — Interest-rate tree structure**

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

### **InstSet — Instrument variable**

structure

Instrument variable containing a collection of NINST instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

### **Options — Derivatives pricing options structure**

structure

Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

## Output Arguments

### **Delta — Rate of change of instruments prices with respect to changes in interest rate**

vector

Rate of change of instruments prices with respect to changes in the interest rate, returned as a NINST-by-1 vector of deltas. Delta is computed by finite differences in calls to `hwtree`.

---

**Note** Delta is calculated based on yield shifts of 100 basis points.

---

### **Gamma — Rate of change of instruments deltas with respect to changes in interest rate**

vector

Rate of change of instruments deltas with respect to changes in the interest rate, returned as a NINST-by-1 vector of gammas. Gamma is computed by finite differences in calls to `hwtree`.

---

**Note** Gamma is calculated based on yield shifts of 100 basis points.

---

**Vega — Rate of change of instruments prices with respect to changes in volatility**

vector

Rate of change of instruments prices with respect to changes in the volatility, returned as a NINST-by-1 vector of vegas. Volatility is  $\sigma(t, T)$  of the interest rate. Vega is computed by finite differences in calls to `hwtree`. For information on the volatility process, see `hwvolspec`.

---

**Note** Vega is calculated based on 1% shift in the volatility process.

---

**Price — Price of each instrument**

vector

Price of each instrument, returned as a NINST-by-1 vector. The prices are computed by backward dynamic programming on the interest-rate tree. If an instrument cannot be priced, a NaN is returned in that entry.

# hwtimespec

Specify time structure for Hull-White interest-rate tree

## Syntax

```
TimeSpec = hwtimespec(ValuationDate,Maturity)
TimeSpec = hwtimespec( ____,Compounding)
```

## Description

`TimeSpec = hwtimespec(ValuationDate,Maturity)` sets the number of levels and node times for a hwtree and determines the mapping between dates and time for rate quoting.

`TimeSpec = hwtimespec( ____,Compounding)` adds the optional argument `Compounding`.

## Examples

### Set the Number of Levels and Node Times for a Hull-White Tree

This example shows how to specify a four-period tree with annual nodes and use annual compounding to report rates.

```
ValuationDate = 'Jan-1-2004';
Maturity = ['12-31-2004'; '12-31-2005'; '12-31-2006';
'12-31-2007'];
Compounding = 1;
TimeSpec = hwtimespec(ValuationDate, Maturity, Compounding)
```

```
TimeSpec = struct with fields:
    FinObj: 'HWTimeSpec'
    ValuationDate: 731947
    Maturity: [4x1 double]
    Compounding: 1
    Basis: 0
    EndMonthRule: 1
```

## Input Arguments

### ValuationDate — Pricing date and first observation in the tree

serial date number | character vector date

Pricing date and first observation in the tree, specified as a scalar date using a serial date number or date character vector.

Data Types: double | char

### Maturity — Dates marking the cash flow dates of the tree

serial date number | date character vector

Dates marking the cash flow dates of the tree, specified as NLEVELS-by-1 vector of serial date numbers or date character vectors. Cash flows with these maturities fall on tree nodes. Maturity should be in increasing order.

Data Types: double | char | cell

### Compounding — Rate at which the input zero rates were compounded when annualized

1 (default) | integer with value of 1, 2, 3, 4, 6, 12, 365, or -1

(Optional) Rate at which the input zero rates were compounded when annualized, specified as a scalar integer value.

- If Compounding = 1, 2, 3, 4, 6, 12:

$Disc = (1 + Z/F)^{-T}$ , where F is the compounding frequency, Z is the zero rate, and T is the time in periodic units; for example,  $T = F$  is one year.

- If Compounding = 365:

$Disc = (1 + Z/F)^{-T}$ , where F is the number of days in the basis year and T is a number of days elapsed computed by basis.

- If Compounding = -1:

$Disc = \exp(-T*Z)$ , where T is time in years.

Data Types: double

## Output Arguments

### TimeSpec — Specification for the time layout for hwtree

structure

Specification for the time layout for hwtree, returned as a structure. The state observation dates are [ValuationDate; Maturity(1:end-1)]. Because a forward rate is stored at the last observation, the tree can value cash flows out to Maturity(end).

# hwtree

Build Hull-White interest-rate tree

## Syntax

```
HWTree = hwtree(VolSpec,RateSpec,TimeSpec)
HWTree = hwtree( ____,Name,Value)
```

## Description

HWTree = hwtree(VolSpec,RateSpec,TimeSpec) builds a Hull-White interest-rate tree.

HWTree = hwtree( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Create an HWTree

Using the data provided, create a Hull-White volatility specification (VolSpec), rate specification (RateSpec), and tree time layout specification (TimeSpec). Then, use these specifications to create a Hull-White tree using hwtree.

```
Compounding = -1;
ValuationDate = '01-01-2004';
StartDate = ValuationDate;
VolDates = ['12-31-2004'; '12-31-2005'; '12-31-2006';
'12-31-2007'];
VolCurve = 0.01;
AlphaDates = '01-01-2008';
AlphaCurve = 0.1;
Rates = [0.0275; 0.0312; 0.0363; 0.0415];

HWVolSpec = hwwolspec(ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);

RateSpec = intenvset('Compounding', Compounding,...
'ValuationDate', ValuationDate,...
'StartDates', ValuationDate,...
'EndDates', VolDates,...
'Rates', Rates);

HWTimeSpec = hwtimespec(ValuationDate, VolDates, Compounding);
HWTree = hwtree(HWVolSpec, RateSpec, HWTimeSpec)

HWTree = struct with fields:
    FinObj: 'HWFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 0.9973 1.9973 2.9973]
    dObs: [731947 732312 732677 733042]
```

```

CFlowT: {[4x1 double] [3x1 double] [2x1 double] [3.9973]}
Probs: {[3x1 double] [3x3 double] [3x5 double]}
Connect: {[2] [2 3 4] [2 3 4 5 6]}
FwdTree: {[1.0278] [1.0536 1.0356 1.0178] [1x5 double] [1x7 double]}

```

Use `treeviewer` to observe the tree you have created.

## Input Arguments

### VolSpec — Volatility process specification

structure

Volatility process specification, specified using the `VolSpec` obtained from `hwvolspec`. See `hwvolspec` for information on the volatility process.

Data Types: `struct`

### RateSpec — Interest-rate specification for initial rate curve

structure

Interest-rate specification for initial rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### TimeSpec — Time layout specification

structure

Time layout specification, specified using the `TimeSpec` obtained from `hwtimespec`. The `TimeSpec` defines the observation dates of the HW tree and the compounding rule for date to time mapping and price-yield formulas. See `hwtimespec` for information on the tree structure.

Data Types: `struct`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `HWTree = hwtree(VolSpec, RateSpec, TimeSpec, 'Method', 'HW1996')`

### Method — Hull-White method upon which tree-node connectivity algorithm is based

`HW2000` (default) | character vector with values of `HW1996` or `HW2000`

Hull-White method upon which the tree-node connectivity algorithm is based, specified a character vector with a value of `HW1996` or `HW2000`.

---

**Note** `hwtree` supports two tree-node connectivity algorithms. `HW1996` is based on the original paper published in the *Journal of Derivatives*, and `HW2000` is the general version of the algorithm, as specified in the paper published in August 2000.

---

Data Types: `char`

## Output Arguments

### HWTtree — Hull-White interest-rate tree

structure

Hull-White interest-rate tree, returned as a structure containing time and interest rate information of a trinomial recombining tree.

The HWTtree structure returned contains all the information necessary to propagate back any cash flows occurring during the time span of the tree. The main fields of HWTtree are:

- HWTtree.tObs contains the time factor of each level of the tree.
- HWTtree.dObs contains the date of each level of the tree.
- HWTtree.Probs contains a cell array of 3-by-N numeric arrays with the up/mid/down probabilities of each node of the tree except for the last level. The cells in the cell array are ordered from root node. The arrays are 3-by-N with the first row corresponding to an up-move, the mid row to a mid-move and so on. Each column of the array represents a node starting from the top node of a given level.
- HWTtree.Connect contains a cell array with connectivity information for each node of the tree. The arrangement is similar to HWTtree.Probs, with the exception that it has only one row in each cell. The number represents the node in the next level to which the middle branch connects to. The top branch connects to the value above (minus one) and the lower branch connects to the value below (plus one).
- HWTtree.FwdTree contains the forward spot rate from one node to the next. The forward spot rate is defined as the inverse of the discount factor.

### Introduced before R2006a

## hwvolspec

Specify Hull-White interest-rate volatility process

### Syntax

```
VolSpec = hwvolspec(ValuationDate,VolDates,VolCurve,AlphaDates,AlphaCurve)
VolSpec = hwvolspec( ____,InterpMethod)
```

### Description

`VolSpec = hwvolspec(ValuationDate,VolDates,VolCurve,AlphaDates,AlphaCurve)` creates a structure specifying the volatility for hwtree.

The volatility process is such that the variance of  $r(t + dt) - r(t)$  is defined as follows:  $V = (\text{Volatility}.^2 .* (1 - \exp(-2*\text{Alpha} .* dt))) ./ (2 * \text{Alpha})$ . For more information on using Hull-White interest rate trees, see “Hull-White (HW) and Black-Karasinski (BK) Modeling” on page C-2.

`VolSpec = hwvolspec( ____,InterpMethod)` adds the optional argument `InterpMethod`.

### Examples

#### Create a Structure Specifying the Volatility for hwtree

This example shows how to create a Hull-White volatility specification (`VolSpec`) using the following data.

```
ValuationDate = '01-01-2004';
StartDate = ValuationDate;
VolDates = ['12-31-2004'; '12-31-2005'; '12-31-2006';
'12-31-2007'];
VolCurve = 0.01;
AlphaDates = '01-01-2008';
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve)

HWVolSpec = struct with fields:
    FinObj: 'HWVolSpec'
    ValuationDate: 731947
    VolDates: [4x1 double]
    VolCurve: [4x1 double]
    AlphaCurve: 0.1000
    AlphaDates: 733408
    VolInterpMethod: 'linear'
```

## Input Arguments

### ValuationDate — Observation date of the investment horizon

serial date number | character vector date

Observation date of the investment horizon, specified as a scalar date using a serial date number or date character vector.

Data Types: double | char

### VolDates — Number of points of yield volatility end dates

serial date number | date character vector

Number of points of yield volatility end dates, specified as a NPOINTS-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

### VolCurve — Yield volatility values

decimal

Yield volatility values, specified as a NPOINTS-by-1 vector of decimal values. The term structure of VolCurve is the yield volatility represented by the value of the volatility of the yield from time  $t = 0$  to time  $t + i$ , where  $i$  is any point within the volatility curve.

---

**Note** The number of points in VolCurve and AlphaCurve do not have to be the same.

---

Data Types: double

### AlphaDates — Mean reversion end dates

serial date number | date character vector

Mean reversion end dates, specified as a NPOINTS-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

### AlphaCurve — Positive mean reversion values

positive decimal

Positive mean reversion values, specified as a NPOINTS-by-1 vector of positive decimal values.

---

**Note** The number of points in VolCurve and AlphaCurve do not have to be the same.

---

Data Types: double

### InterpMethod — Interpolation method

'linear' (default) | character vector with values supported by interp1

(Optional) Interpolation method, specified as a character vector with values supported by interp1.

Data Types: char

## Output Arguments

**VolSpec — Specification for the volatility model for hwtree structure**

Structure specifying the volatility model for hwtree.

## See Also

hwcalbycap | hwcalbyfloor | interp1

# impvbybaw

Calculate implied volatility using Barone-Adesi and Whaley option pricing model

## Syntax

```
Volatility = impvbybaw(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike,
OptPrice)
Volatility = impvbybaw( ____, Name, Value)
```

## Description

`Volatility = impvbybaw(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, OptPrice)` calculates implied volatility using the Barone-Adesi and Whaley option pricing model.

`Volatility = impvbybaw( ____, Name, Value)` adds optional name-value pair arguments.

## Examples

### Compute the Implied Volatility for an American Option Using the Barone-Adesi and Whaley Option Pricing Model

This example shows how to compute implied volatility using the Barone-Adesi and Whaley option pricing model. Consider three American call options with exercise prices of \$100 that expire on July 1, 2017. The underlying stock is trading at \$100 on January 1, 2017 and pays a continuous dividend yield of 10%. The annualized continuously compounded risk-free rate is 10% per annum, and the option prices are \$4.063, \$6.77 and \$9.46. Using this data, calculate the implied volatility of the stock using the Barone-Adesi and Whaley option pricing model.

```
AssetPrice = 100;
Settle = 'Jan-1-2017';
Maturity = 'Jul-1-2017';
Strike = 100;
DivAmount = 0.1;
Rate = 0.05;
```

Define the RateSpec.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1, 'Basis', 1)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9753
    Rates: 0.0500
    EndTimes: 0.5000
    StartTimes: 0
    EndDates: 736877
    StartDates: 736696
    ValuationDate: 736696
```

```
Basis: 1
EndMonthRule: 1
```

Define the StockSpec.

```
StockSpec = stockspec(NaN, AssetPrice, {'continuous'}, DivAmount)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: NaN
    AssetPrice: 100
    DividendType: {'continuous'}
    DividendAmounts: 0.1000
    ExDividendDates: []
```

Define the American option.

```
OptSpec = {'call'};
OptionPrice = [4.063;6.77;9.46];
```

Compute the implied volatility for the American option.

```
ImpVol = impvbybaw(RateSpec, StockSpec, Settle, Maturity, OptSpec,...
Strike, OptionPrice)
```

```
ImpVol = 3×1
```

```
0.1802
0.2808
0.3803
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspect`.

`stockspect` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

**Settle — Settlement date**

serial date number | date character vector | datetime object

Settlement date for the American option, specified as a NINST-by-1 matrix using a serial date number, a date character vector, or a datetime object.

Data Types: double | char | datetime

**Maturity — Maturity date**

serial date number | date character vector | datetime object

Maturity date for the American option, specified as a NINST-by-1 matrix using a serial date number, a date character vector, or a datetime object.

Data Types: double | char | datetime

**OptSpec — Definition of option**

character vector with values 'call' or 'put' | string array with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors or string arrays with values 'call' or 'put'.

Data Types: char | string

**Strike — American option strike price value**

nonnegative scalar | nonnegative vector

American option strike price value, specified as a nonnegative scalar or NINST-by-1 matrix of strike price values. Each row is the schedule for one option.

Data Types: single | double

**OptPrice — American option price**

nonnegative scalar | nonnegative vector

American option prices from which the implied volatility of the underlying asset is derived, specified as a nonnegative scalar or NINST-by-1 matrix of strike price values.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: Volatility =

```
impvbybaw(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, OptionPrice)
```

**Limit — Lower and upper bound of implied volatility search interval**

[0.1 10] (or 10% to 1000% per annum) (default) | positive value

Lower and upper bound of implied volatility search interval, specified as the comma-separated pair consisting of 'Limit' and a 1-by-2 positive vector.

Data Types: double

**Tolerance — Implied volatility search termination tolerance**

1e-6 (default) | positive scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of 'Tolerance' and a positive scalar.

Data Types: `double`

## Output Arguments

### **Volatility – Expected implied volatility values**

`matrix`

Expected implied volatility values, returned as a NINST-by-1 matrix. If no solution can be found, a NaN is returned.

**Introduced in R2017a**

## impvbybjs

Determine implied volatility using Bjerksund-Stensland 2002 option pricing model

### Syntax

```
Volatility = impvbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike,
    OptPrice)
Volatility = impvbybjs( ____, Name, Value)
```

### Description

Volatility = impvbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, OptPrice) computes implied volatility using the Bjerksund-Stensland 2002 pricing model.

---

**Note** impvbybjs computes implied volatility of American options with continuous dividend yield using the Bjerksund-Stensland option pricing model.

---

Volatility = impvbybjs( \_\_\_\_, Name, Value) adds optional name-value pair arguments.

### Examples

#### Compute the Implied Volatility Using the Bjerksund-Stensland 2002 Option Pricing Model

This example shows how to compute implied volatility using the Bjerksund-Stensland 2002 option pricing model. Consider three American call options with exercise prices of \$100 that expire on July 1, 2008. The underlying stock is trading at \$100 on January 1, 2008 and pays a continuous dividend yield of 10%. The annualized continuously compounded risk-free rate is 10% per annum and the option prices are \$4.063, \$6.77 and \$9.46. Using this data, calculate the implied volatility of the stock using the Bjerksund-Stensland 2002 option pricing model.

```
AssetPrice = 100;
Settle = 'Jan-1-2008';
Maturity = 'Jul-1-2008';
Strike = 100;
DivAmount = 0.1;
Rate = 0.1;

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1, 'Basis', 1);

StockSpec = stockspec(NaN, AssetPrice, {'continuous'}, DivAmount);

OptSpec = {'call'};
OptionPrice = [4.063;6.77;9.46];

ImpVol = impvbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec, ...
    Strike, OptionPrice)
```

```
ImpVol = 3×1
    0.1500
    0.2501
    0.3500
```

The implied volatility is 15% for the first call, and 25% and 35% for the second and third call options.

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement date

serial date number | date character vector

Settlement date, specified as a NINST-by-1 vector of serial date numbers or a date character vectors.

Data Types: `double` | `char`

### Maturity — Maturity date

serial date number | date character vector

Maturity date for the American option, specified as a NINST-by-1 vector of serial date numbers or a date character vectors.

Data Types: `double` | `char`

### OptSpec — Definition of option

character vector with values 'call' or 'put'

Definition of the option from which the implied volatility is derived, specified as a NINST-by-1 cell array of character vectors with a value of 'call' or 'put'.

Data Types: `char` | `cell`

### Strike — Option strike price value

nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or NINST-by-1 vector of strike price values. Each row is the schedule for one option.

Data Types: double

### **OptPrice — American option price**

nonnegative scalar | nonnegative vector

American option prices from which the implied volatility of the underlying asset is derived, specified as a nonnegative scalar or NINST-by-1 vector.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Volatility =`

```
impvbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, OptPrice, 'Limit',
[0.2 20], 'Tolerance', 1e-5)
```

### **Limit — Lower and upper bound of implied volatility search interval**

[0.1 10] (10% to 1000% per annum) (default) | positive vector

Lower and upper bound of implied volatility search interval, specified as the comma-separated pair consisting of 'Limit' and a 1-by-2 positive vector.

Data Types: double

### **Tolerance — Implied volatility search termination tolerance**

1e-6 (default) | positive scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of 'Tolerance' and a positive scalar.

Data Types: double

## **Output Arguments**

### **Volatility — Expected implied volatility values**

vector

Expected implied volatility values, returned as a NINST-by-1 vector. If no solution can be found, a NaN is returned.

# impvbyblk

Determine implied volatility using Black option pricing model

## Syntax

```
Volatility = impvbyblk(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,
OptPrice)
Volatility = impvbyblk( ____,Name,Value)
```

## Description

`Volatility = impvbyblk(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,OptPrice)` computes implied volatility using the Black option pricing model.

`Volatility = impvbyblk( ____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Implied Volatility Using the Black Option Pricing Model

This example shows how to compute the implied volatility using the Black option pricing model. Consider a European call and put options on a futures contract with exercise prices of \$30 for the put and \$40 for the call that expire on September 1, 2008. Assume that on May 1, 2008 the contract is trading at \$35. The annualized continuously compounded risk-free rate is 5% per annum. Find the implied volatilities of the stock, if on that date, the call price is \$1.14 and the put price is \$0.82.

```
AssetPrice = 35;
Strike = [30; 40];
Rates = 0.05;
Settle = 'May-01-08';
Maturity = 'Sep-01-08';

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1);

StockSpec = stockspec(NaN, AssetPrice);

% define the options
OptSpec = {'put';'call'};

Price = [1.14;0.82];
Volatility = impvbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec,...
Strike, Price,'Method','jackel2016')

Volatility = 2×1

    0.4052
    0.3021
```

The implied volatility is 41% and 30%.

## Input Arguments

### **RateSpec — Interest-rate term structure**

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### **StockSpec — Stock specification for underlying asset**

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### **Settle — Settlement date**

serial date number | date character vector

Settlement date, specified as a NINST-by-1 vector of serial date numbers or a date character vectors.

Data Types: `double` | `char`

### **Maturity — Maturity date**

serial date number | date character vector

Maturity date for the American option, specified as a NINST-by-1 vector of serial date numbers or a date character vectors.

Data Types: `double` | `char`

### **OptSpec — Definition of option**

character vector with values 'call' or 'put'

Definition of the option from which the implied volatility is derived, specified as a NINST-by-1 cell array of character vectors with a value of 'call' or 'put'.

Data Types: `char` | `cell`

### **Strike — Option strike price**

nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or NINST-by-1 vector of strike prices. Each row is the schedule for one option.

Data Types: `double`

### **OptPrice — European option price**

nonnegative scalar | nonnegative vector

European option prices from which the implied volatility of the underlying asset is derived, specified as a nonnegative scalar or NINST-by-1 vector.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Volatility = impvbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, OptPrice, 'Limit', 5, 'Tolerance', 1e-5)`

#### **Limit — Upper bound of implied volatility search interval**

10 (1000% per annum) (default) | positive value

Upper bound of implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a positive scalar.

---

**Note** If you are using `Method` with a value of `'jackel2016'`, the `Limit` argument is ignored.

---

Data Types: double

#### **Tolerance — Implied volatility search termination tolerance**

1e-6 (default) | positive scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of `'Tolerance'` and a positive scalar.

---

**Note** If you are using `Method` with a value of `'jackel2016'`, the `Tolerance` argument is ignored.

---

Data Types: double

#### **Method — Method for computing implied volatility**

`'jackel2016'` (default) | character vector with values `'search'` or `'jackel2016'` | string with values `"search"` or `"jackel2016"`

Method for computing implied volatility, specified as the comma-separated pair consisting of `'Method'` and a character vector with a value of `'search'` or `'jackel2016'` or a string with a value of `"search"` or `"jackel2016"`.

Data Types: char | string

## **Output Arguments**

#### **Volatility — Expected implied volatility values**

vector

Expected implied volatility values, returned as a NINST-by-1 vector. If no solution can be found, a NaN is returned.

## Introduced in R2008b

# impvbybls

Determine implied volatility using Black-Scholes option pricing model

## Syntax

```
Volatility = impvbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike,
OptPrice)
Volatility = impvbybls( ____, Name, Value)
```

## Description

`Volatility = impvbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, OptPrice)` computes implied volatility using the Black-Scholes option pricing model.

`Volatility = impvbybls( ____, Name, Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Implied Volatility Using the Black-Scholes Option Pricing Model

This example shows how to compute the implied volatility using the Black-Scholes option pricing model. Consider a European call and put options with an exercise price of \$40 that expires on June 1, 2008. The underlying stock is trading at \$45 on January 1, 2008 and the risk-free rate is 5% per annum. The option price is \$7.10 for the call and \$2.85 for the put. Using this data, calculate the implied volatility of the European call and put using the Black-Scholes option pricing model.

```
AssetPrice = 45;
Settlement = 'Jan-01-2008';
Maturity = 'June-01-2008';
Strike = 40;
Rates = 0.05;
OptionPrice = [7.10; 2.85];
OptSpec = {'call'; 'put'};

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settlement, 'StartDates', Settlement, ...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);

StockSpec = stockspec(NaN, AssetPrice);

ImpvVol = impvbybls(RateSpec, StockSpec, Settlement, Maturity, OptSpec, ...
Strike, OptionPrice, 'Method', 'jackel2016')

ImpvVol = 2x1

    0.3175
    0.4878
```

The implied volatility is 31.75% for the call and 48.78% for the put.

## Input Arguments

### **RateSpec — Interest-rate term structure**

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### **StockSpec — Stock specification for underlying asset**

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### **Settle — Settlement date**

serial date number | date character vector

Settlement date, specified as a NINST-by-1 vector of serial date numbers or a date character vectors.

Data Types: `double` | `char`

### **Maturity — Maturity date**

serial date number | date character vector

Maturity date for the American option, specified as a NINST-by-1 vector of serial date numbers or a date character vectors.

Data Types: `double` | `char`

### **OptSpec — Definition of option**

character vector with values 'call' or 'put'

Definition of the option from which the implied volatility is derived, specified as a NINST-by-1 cell array of character vectors with a value of 'call' or 'put'.

Data Types: `char` | `cell`

### **Strike — Option strike price**

nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or NINST-by-1 vector of strike prices. Each row is the schedule for one option.

Data Types: `double`

### **OptPrice — European option price**

nonnegative scalar | nonnegative vector

European option prices from which the implied volatility of the underlying asset is derived, specified as a nonnegative scalar or NINST-by-1 vector.

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Volatility = impvbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, OptPrice, 'Limit', 5, 'Tolerance', 1e-5)`

#### Limit — Upper bound of implied volatility search interval

10 (1000% per annum) (default) | positive value

Upper bound of implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a positive scalar.

---

**Note** If you are using `Method` with a value of `'jackel2016'`, the `Limit` argument is ignored.

---

Data Types: double

#### Tolerance — Implied volatility search termination tolerance

1e-6 (default) | positive scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of `'Tolerance'` and a positive scalar.

---

**Note** If you are using `Method` with a value of `'jackel2016'`, the `Tolerance` argument is ignored.

---

Data Types: double

#### Method — Method for computing implied volatility

`'jackel2016'` (default) | character vector with values `'search'` or `'jackel2016'` | string with values `"search"` or `"jackel2016"`

Method for computing implied volatility, specified as the comma-separated pair consisting of `'Method'` and a character vector with a value of `'search'` or `'jackel2016'` or a string with a value of `"search"` or `"jackel2016"`.

Data Types: char | string

## Output Arguments

#### Volatility — Expected implied volatility values

vector

Expected implied volatility values, returned as a NINST-by-1 vector. If no solution can be found, a NaN is returned.

## Introduced in R2008b

# impvbyrgw

Determine implied volatility using Roll-Geske-Whaley option pricing model for American call option

## Syntax

```
Volatility = impvbyrgw(RateSpec, StockSpec, Settle, Maturity, Strike, OptPrice)
Volatility = impvbyrgw( ____, Name, Value)
```

## Description

`Volatility = impvbyrgw(RateSpec, StockSpec, Settle, Maturity, Strike, OptPrice)` computes implied volatility using Roll-Geske-Whaley option pricing model for American call option.

---

**Note** `impvbyrgw` computes implied volatility of American calls with a single cash dividend using the Roll-Geske-Whaley option pricing model.

---

`Volatility = impvbyrgw( ____, Name, Value)` adds optional name-value pair arguments.

## Examples

### Compute the Implied Volatility Using the Roll-Geske-Whaley Option Pricing Model

This example shows how to compute the implied volatility using the Roll-Geske-Whaley option pricing model. Assume that on July 1, 2008 a stock is trading at \$13 and pays a single cash dividend of \$0.25 on November 1, 2008. The American call option with a strike price of \$15 expires on July 1, 2009 and is trading at \$1.346. The annualized continuously compounded risk-free rate is 5% per annum. Calculate the implied volatility of the stock using the Roll-Geske-Whaley option pricing model.

```
AssetPrice = 13;
Strike = 15;
Rates = 0.05;
Settle = 'July-01-08';
Maturity = 'July-01-09';

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1);

StockSpec = stockspec(NaN, AssetPrice, {'cash'}, 0.25, {'Nov 1,2008'});

Price = [1.346];
Volatility = impvbyrgw(RateSpec, StockSpec, Settle, Maturity, Strike, Price)

Volatility = 0.3539
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement date

serial date number | date character vector

Settlement date, specified as a NINST-by-1 vector of serial date numbers or a date character vectors.

Data Types: `double` | `char`

### Maturity — Maturity date

serial date number | date character vector

Maturity date for the American option, specified as a NINST-by-1 vector of serial date numbers or a date character vectors.

Data Types: `double` | `char`

### Strike — Option strike price value

nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or NINST-by-1 vector of strike price values. Each row is the schedule for one option.

Data Types: `double`

### OptPrice — American option price

nonnegative scalar | nonnegative vector

American option prices from which the implied volatility of the underlying asset is derived, specified as a nonnegative scalar or NINST-by-1 vector.

Data Types: `double`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Volatility = impvbyrgw(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, OptPrice, 'Limit', 5, 'Tolerance', 1e-5)`

**Limit — Upper bound of implied volatility search interval**

10 (1000% per annum) (default) | positive value

Upper bound of implied volatility search interval, specified as the comma-separated pair consisting of 'Limit' and a positive scalar.

Data Types: double

**Tolerance — Implied volatility search termination tolerance**

1e-6 (default) | positive scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of 'Tolerance' and a positive scalar.

Data Types: double

## Output Arguments

**Volatility — Expected implied volatility values**

vector

Expected implied volatility values, returned as a NINST-by-1 vector. If no solution can be found, a NaN is returned.

```

## Description

InstSet = instadd(InstSetOld, TypeString, Data1, Data2, ...) adds an instrument to an existing collection.

InstSet = instadd('CashFlow', CFLOWAmounts, CFLOWDates, Settle, Basis) adds an arbitrary cash flow instrument. (See also instcf.)

InstSet = instadd('CashFlow', CFLOWAmounts, CFLOWDates, Settle, Basis) adds an asian instrument. (See also instasian.)

InstSet = instadd('Barrier', OptSpec, Strike, Settle, ExerciseDates, AmericanOpt, BarrierType, Barrier, Rebate) adds a barrier instrument. (See also instbarrier.)

InstSet = instadd('Bond', CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) adds a bond instrument. (See also instbond.)

InstSet = instadd('CBond', CouponRate, Settle, Maturity, ConvRatio, CallStrike, CallStrike, CallExDates, CallExDates, AmericanCall, AmericanCall, PutStrike, PutStrike, PutExDates, PutExDates, AmericanPut, AmericanPut, Period, Period, Face, Face, Spread, Spread, IssueDate, IssueDate, FirstCouponDate, FirstCouponDate, LastCouponDate, LastCouponDate, StartDate, StartDate) adds a convertible bond instrument. (See also instcbond.)

InstSet = instadd('OptEmBond', CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, AmericanOpt, AmericanOpt, Period, Period, Basis, Basis, EndMonthRule, EndMonthRule, Face, Face, IssueDate, IssueDate, FirstCouponDate, FirstCouponDate, LastCouponDate, LastCouponDate, StartDate, StartDate) adds a bond with embedded option instrument. (See also instoptembnd.)

InstSet = instadd('OptBond', BondIndex, OptSpec, Strike, ExerciseDates, AmericanOpt) adds a bond option instrument. (See also instoptbnd.)

InstSet = instadd('Cap', Strike, Settle, Maturity, Reset, Basis, Principal) adds a cap instrument. (See also instcap.)

InstSet = instadd('Compound', UOptSpec, UStrike, USettle, UExerciseDates, UAmericanOpt, COptSpec, CStrike, CSettle, CExerciseDates, CAmericanOpt) adds a compound instrument. (See also instcompound.)

`InstSet = instadd('Fixed', CouponRate, Settle, Maturity, Reset, Basis, Principal, EndMonthRule)` adds a fixed-rate note instrument. (See also `instfixed`.)

`InstSet = instadd('Float', Spread, Settle, Maturity, Reset, Basis, Principal, EndMonthRule, CapRate, FloorRate)` adds a floating-rate note instrument. (See also `instfloat`.)

`InstSet = instadd('Floor', Strike, Settle, Maturity, Reset, Basis, Principal)` adds a floor instrument. (See also `instfloor`.)

`InstSet = instadd('Lookback', OptSpec, Strike, Settle, ExerciseDates, AmericanOpt)` adds a lookback instrument. (See also `instlookback`.)

`InstSet = instadd('OptFloat', OptSpec, Strike, Settle, ExerciseDates, AmericanOpt)` adds a floating-rate option instrument. (See also `instoptfloat`.)

`InstSet = instadd('OptEmFloat', OptSpec, Strike, Settle, ExerciseDates, AmericanOpt, Reset, Basis, EndMonthRule, Principal)` adds a floating-rate embedded option instrument. (See also `instoptemfloat`.)

`InstSet = instadd('RangeFloat', Spread, Settle, Maturity, RateSched, Reset, Basis, Principal, EndMonthRule)` adds a range floating note instrument. (See also `instrangefloat`.)

`InstSet = instadd('OptStock', OptSpec, Strike, Settle, Maturity, AmericanOpt)` adds a stock option instrument. (See also `instoptstock`.)

`InstSet = instadd('Swap', LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType, EndMonthRule, StartDate)` adds a swap instrument. (See also `instswap`.)

`InstSet = instadd('Swaption', OptSpec, Strike, ExerciseDates, Spread, Settle, Maturity, AmericanOpt, SwapReset, Basis, Principal)` adds a swaption instrument. (See also `instswaption`.)

`instadd` stores instruments of types 'Asian', 'Barrier', 'Bond', 'Cap', 'CashFlow', 'Compound', 'Fixed', 'Float', 'Floor', 'Lookback', 'OptBond', 'OptStock', 'Swap', or 'Swaption'. Financial Instruments Toolbox provides pricing and sensitivity routines for these instruments.

## Input Arguments

### `InstSetOld`

Variable containing a collection of instruments. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. For more information on instrument data parameters, see the reference entries for individual instrument types. For example, see `instcap` for additional information on the cap instrument.

## Output Arguments

### InstSet

InstSet is an instrument set variable containing the new input data.

## Examples

### Create a Portfolio with Two Cap Instruments and a 4% Bond

Define the bond:

```
Strike = [0.06; 0.07];
CouponRate = 0.04;
Settle = '06-Feb-2000';
Maturity = '15-Jan-2003';
```

Create a portfolio with two cap instruments and a 4% bond and then display the portfolio:

```
InstSet = instadd('Cap', Strike, Settle, Maturity);
InstSet = instadd(InstSet, 'Bond', CouponRate, Settle, Maturity);
instdisp(InstSet)
```

Index	Type	Strike	Settle	Maturity	CapReset	Basis	Principal
1	Cap	0.06	06-Feb-2000	15-Jan-2003	1	0	100
2	Cap	0.07	06-Feb-2000	15-Jan-2003	1	0	100

Index	Type	CouponRate	Settle	Maturity	Period	Basis	EndMonthRule	IssueDate	FirstCou
3	Bond	0.04	06-Feb-2000	15-Jan-2003	2	0	1	NaN	NaN

## See Also

## instaddfield

Add new instruments to instrument collection

### Syntax

```
InstSet =
instaddfield('FieldName',FieldList,'Data',DataList,'Type',TypeString)
InstSet =
instaddfield('FieldName',FieldList,'FieldClass',ClassList,'Data',DataList,'Type',TypeString)
InstSetNew =
instaddfield(InstSet,'FieldName',FieldList,'Data',DataList,'Type',TypeString)
```

### Arguments

FieldList	Number of fields, specified as a NFIELDS-by-1 cell array of character vectors listing the name of each data field. FieldList cannot be named with the reserved name Type or Index.
DataList	Number of instruments, specified as a NINST-by-M array or NFIELDS-by-1 cell array of data contents for each field. Each row in a data array corresponds to a separate instrument. Single rows are copied to apply to all instruments to be worked on. The number of columns is arbitrary, and data is padded along columns.
ClassList	(Optional) Character vector or NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how DataList is parsed. Valid character vectors are 'dble', 'date', and 'char'. The 'FieldClass', ClassList pair is always optional. ClassList is inferred from existing field names or from the data if not entered.
TypeString	Character vector specifying the type of instrument added. Instruments of different types can have different Fieldname collections.
InstSet	Variable containing a collection of instruments. Instruments are classified by type; each type can have different Data fields. The stored Data field is a row vector or character vector for each instrument.

### Description

InstSet = instaddfield('FieldName',FieldList,'Data',DataList,'Type',TypeString) to create your own types of instruments or to append new instruments to an existing collection. Argument value pairs can be entered in any order.

InstSet = instaddfield('FieldName',FieldList,'FieldClass',ClassList,'Data',DataList,'Type',TypeString) creates an instrument variable.

InstSetNew = instaddfield(InstSet,'FieldName',FieldList,'Data',DataList,'Type',TypeString)

adds instruments to an existing instrument set, `InstSet`. The output `InstSetNew` is a new instrument set containing the input data.

## Examples

Build a portfolio around July options.

```
Strike  Call  Put
   95    12.2  2.9
  100     9.2  4.9
  105     6.8  7.4
```

```
Strike = (95:5:105)'
CallP = [12.2; 9.2; 6.8]
```

Enter three call options with data fields `Strike`, `Price`, and `Opt`.

```
InstSet = instadfield('Type','Option','FieldName',...
{'Strike','Price','Opt'}, 'Data',{ Strike, CallP, 'Call'});
instdisp(InstSet)
```

```
Index Type  Strike Price Opt
  1   Option  95    12.2 Call
  2   Option 100     9.2 Call
  3   Option 105     6.8 Call
```

Add a futures contract and set the input parsing class.

```
InstSet = instadfield(InstSet,'Type','Futures',...
'FieldName',{'Delivery','F'},'FieldClass',{'date','dble'},...
'Data' ,{'01-Jul-99',104.4 });
instdisp(InstSet)
```

```
Index Type  Strike Price Opt
  1   Option  95    12.2 Call
  2   Option 100     9.2 Call
  3   Option 105     6.8 Call
```

```
Index Type  Delivery      F
  4   Futures 01-Jul-1999  104.4
```

Add a put option.

```
FN = instfields(InstSet,'Type','Option')
InstSet = instadfield(InstSet,'Type','Option',...
'FieldName',FN, 'Data',{105, 7.4, 'Put'});
instdisp(InstSet)
```

```
Index Type  Strike Price Opt
  1   Option  95    12.2 Call
  2   Option 100     9.2 Call
  3   Option 105     6.8 Call
```

```
Index Type  Delivery      F
  4   Futures 01-Jul-1999  104.4
```

```
Index Type  Strike Price Opt
  5   Option 105     7.4 Put
```

Make a placeholder for another put.

```
InstSet = instaddfield(InstSet, 'Type', 'Option', ...
'FieldName', 'Opt', 'Data', 'Put')
instdisp(InstSet)
```

Index	Type	Strike	Price	Opt
1	Option	95	12.2	Call
2	Option	100	9.2	Call
3	Option	105	6.8	Call

Index	Type	Delivery	F
4	Futures	01-Jul-1999	104.4

Index	Type	Strike	Price	Opt
5	Option	105	7.4	Put
6	Option	NaN	NaN	Put

Add a cash instrument.

```
InstSet = instaddfield(InstSet, 'Type', 'TBill', ...
'FieldName', 'Price', 'Data', 99)
instdisp(InstSet)
```

Index	Type	Strike	Price	Opt
1	Option	95	12.2	Call
2	Option	100	9.2	Call
3	Option	105	6.8	Call

Index	Type	Delivery	F
4	Futures	01-Jul-1999	104.4

Index	Type	Strike	Price	Opt
5	Option	105	7.4	Put
6	Option	NaN	NaN	Put

Index	Type	Price
7	TBill	99

# instasian

Construct Asian option

## Syntax

```
InstSet = instasian(InstSet,OptSpec,Strike,Settle,
ExerciseDates,AmericanOpt,AvgType,AvgPrice,AvgDate)
[FieldList,ClassList,TypeString] = instasian
```

## Arguments

InstSet	Instrument variable. This argument is specified only when adding asian instruments to an existing instrument set. See <code>instget</code> for more information on the <code>InstSet</code> variable.
OptSpec	NINST-by-1 list of character vector values for 'Call' or 'Put'.
Strike	NINST-by-1 vector of strike price values. Each row is the schedule for one option.
Settle	NINST-by-1 vector of <code>Settle</code> dates.
ExerciseDates	For a European option ( <code>AmericanOpt = 0</code> ):  NINST-by-1 vector of exercise dates. Each row is the schedule for one option. For a European option, there is only one exercise date, the option expiry date.  For an American option ( <code>AmericanOpt = 1</code> ):  NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any tree date between or including the pair of dates on that row. If only one non- <code>NaN</code> date is listed, or if <code>ExerciseDates</code> is NINST-by-1, the option can be exercised between the valuation date of the stock tree and the single listed exercise date.
AmericanOpt	(Optional) If <code>AmericanOpt = 0</code> , <code>NaN</code> , or is unspecified, the option is a European option. If <code>AmericanOpt = 1</code> , the option is an American option.
AvgType	(Optional) Character vector is 'arithmetic' for arithmetic average (default) or 'geometric' for geometric average.
AvgPrice	(Optional) Scalar representing the average price of the underlying asset at <code>Settle</code> . This argument is used when <code>AvgDate &lt; Settle</code> . Default is the current stock price.
AvgDate	(Optional) Scalar representing the date on which the averaging period begins. Default = <code>Settle</code> .

Data arguments are NINST-by-1 vectors, scalar, or empty. Fill in unspecified entries vectors with `NaN`. Only one data argument is required to create the instrument. The others may be omitted or passed as empty matrices `[]`.

## Description

`InstSet = instasian(InstSet,OptSpec,Strike,Settle,ExerciseDates,AmericanOpt,AvgType,AvgPrice,AvgDate)` specifies an Asian option.

`[FieldList,ClassList,TypeString] = instasian` displays the classes.

`FieldList` is a number of fields (NFIELD-by-1) cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` is an NFIELD-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

`TypeString` is a character vector specifying the type of instrument added. For an Asian option instrument, `TypeString = 'Asian'`.

## Examples

### Create an Asian Option Instrument

Load the example instrument set, `deriv.mat`, and set the required values for an asian option instrument.

```
load deriv.mat
```

Create a subportfolio with barrier and lookback options.

```
CRRSubSet = instselect(CRRInstSet,'Type',{'Barrier','Lookback'});
```

Define the asian instrument.

```
OptSpec = 'put';
Strike = NaN;
Settle = '01-Jan-2003';
ExerciseDates = '01-Jan-2004';
```

Add a floating strike asian option to the instrument set.

```
InstSet = instasian(CRRSubSet, OptSpec, Strike, Settle, ExerciseDates);
instdisp(InstSet)
```

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	BarrierSpec	Barrier	Rebat
1	Barrier	call	105	01-Jan-2003	01-Jan-2006	1	ui	102	0

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	Name	Quantity
2	Lookback	call	115	01-Jan-2003	01-Jan-2006	0	Lookback1	7
3	Lookback	call	115	01-Jan-2003	01-Jan-2007	0	Lookback2	9

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	AvgType	AvgPrice	AvgDate
4	Asian	put	NaN	01-Jan-2003	01-Jan-2004	0	arithmetic	NaN	NaN

## instbarrier

Construct barrier option

### Syntax

```
InstSet = instbarrier(OptSpec,Strike,Settle,ExerciseDates,AmericanOpt,
BarrierSpec,Barrier,Rebate)
InstSet = instbarrier(InstSetOld,OptSpec,Strike,Settle,ExerciseDates,
AmericanOpt,BarrierSpec,Barrier,Rebate)
[FieldList,ClassList,TypeString] = instbarrier
```

### Description

`InstSet = instbarrier(OptSpec,Strike,Settle,ExerciseDates,AmericanOpt,BarrierSpec,Barrier,Rebate)` constructs a barrier instrument.

Data arguments are NINST-by-1 vectors, scalar, or empty. Fill in unspecified entries vectors with NaN. Only one data argument is required to create the instrument. The others can be omitted or passed as empty matrices [].

`InstSet = instbarrier(InstSetOld,OptSpec,Strike,Settle,ExerciseDates,AmericanOpt,BarrierSpec,Barrier,Rebate)` adds barrier options to an existing instrument variable `InstSetOld`.

`[FieldList,ClassList,TypeString] = instbarrier` lists field metadata for the barrier instrument.

### Examples

#### Create Two Barrier Option Instruments

Create an instrument set of two barrier options with the following data:

```
OptSpec = {'put';'call'};
Strike = 112;
Settle = '01-Jan-2012';
ExerciseDates = '01-Jan-2015';
BarrierSpec = {'do';'ui'};
Barrier = [101;102];
AmericanOpt = 0;
```

Create the instrument set (`InstSet`) for the two barrier options.

```
InstSet = instbarrier(OptSpec, Strike, Settle, ExerciseDates,AmericanOpt, BarrierSpec, Barrier);
```

Display the instrument set.

```
instdisp(InstSet)
```

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	BarrierSpec	Barrier	Rebat
1	Barrier	put	112	01-Jan-2012	01-Jan-2015	0	do	101	0

2	Barrier call	112	01-Jan-2012	01-Jan-2015	0	ui	102	0
---	--------------	-----	-------------	-------------	---	----	-----	---

## Input Arguments

### OptSpec — Definition of option

character vector with values 'call' or 'put'

Definition of an option as 'call' or 'put', specified as a NINST-by-1 list of character vector values.

Data Types: char

### Strike — Option strike price value

integer

Option strike price value, specified as an NINST-by-1 vector of strike values. Each row is the schedule for one option.

Data Types: double

### Settle — Settlement or trade date

serial date number | date character vector

Settlement date for the barrier option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char

### ExerciseDates — Option exercise dates

date character vector | serial date number

Option exercise dates, specified as a date character vector or a serial date number:

- For a European option (`AmericanOpt = 0`), specified as a NINST-by-1 vector of exercise dates. Each row is the schedule for one option. For a European option, there is only one exercise date, the option expiry date.
- For an American option (`AmericanOpt = 1`), specified as a NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is NINST-by-1, the option can be exercised between the valuation date of the stock tree and the single listed exercise date.

Data Types: double | char

### AmericanOpt — Flag for American option

integer with values 0 or 1

Flag for American option, specified as an integer with values 0 or 1. If `AmericanOpt = 0`, NaN, or is unspecified, the option is a European option. If `AmericanOpt = 1`, the option is an American option.

Data Types: logical

### BarrierSpec — Barrier option type

character vector with values: 'UI', 'UO', 'DI', 'DO'

Barrier option type, specified as a character vector with the following values:

- 'UI' — Up Knock In

This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy/sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option.

- 'UO' — Up Knock Out

This option gives the option holder the right, but not the obligation, to buy/sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying asset passes above the barrier level. Usually, with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.

- 'DI' — Down Knock In

This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy/sell (call/put) the underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option.

- 'DO' — Down Knock Up

This option gives the option holder the right, but not the obligation, to buy/sell (call/put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: char

#### **Barrier — Barrier value**

integer

Barrier value, specified as a vector of values.

Data Types: double

#### **Rebate — Rebate value**

integer

(Optional) Rebate value, specified as a vector of values.

Data Types: double

#### **InstSetOld — Instrument variable**

structure

(Optional) Instrument variable, this argument is specified only when adding barrier instruments to an existing instrument set. See `instget` for more information on the `InstSet` variable.

Data Types: `struct`

## Output Arguments

### **InstSet — Instrument variable for barrier option**

structure

Instrument variable for barrier option, returned as a structure. See `instget` for more information on the `InstSet` variable.

### **FieldList — Fields in InstSet instrument**

cell array of character vectors

Fields in `InstSet` instrument are returned as a (NFIELDS-by-1) cell array of character vectors listing the name of each data field for this instrument type.

### **ClassList — Data class of each field in InstSet instrument**

cell array of character vectors

Data class of each field in `InstSet` instrument, returned as an NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

### **TypeString — Type of instrument added to InstSet instrument**

character vector

Type of instrument added to `InstSet` instrument, returned as a character vector specifying the type of instrument added. For a barrier option instrument, `TypeString = 'Barrier'`.

## More About

### **Barrier Option**

A barrier option has not only a strike price but also a barrier level and sometimes a rebate.

A rebate is a fixed amount that is paid if the option cannot be exercised because the barrier level has been reached or not reached. The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `Barrier`, during the life of the option.

# instbond

Construct bond instrument

## Syntax

```
InstSet =
instbond(CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, First
CouponDate, LastCouponDate, StartDate, Face)
InstSet =
instbond(InstSet, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face)
[FieldList, ClassList, TypeString] = instbond
```

## Arguments

InstSet	Instrument variable. This argument is specified only when adding bond instruments to an existing instrument set. See <code>instget</code> for more information on the <code>InstSet</code> variable.
CouponRate	Decimal annual rate indicating the annual percentage rate used to determine the coupons payable on a bond. <code>CouponRate</code> is a <code>NINST-by-1</code> vector or <code>NINST-by-1</code> cell array of decimal annual rates, or decimal annual rate schedules. For the latter case of a variable coupon schedule, each element of the cell array is a <code>NumDates-by-2</code> cell array, where the first column is dates and the second column is its associated rate. The date indicates the last day that the coupon rate is valid.
Settle	Settlement date. A vector of serial date numbers or date character vectors. <code>Settle</code> must be earlier than <code>Maturity</code> .
Maturity	Maturity date. A vector of serial date numbers or date character vectors.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 1, 2, 3, 4, 6, and 12. Default = 2.

Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
EndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. <b>0</b> = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. <b>1</b> = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
IssueDate	<p>(Optional) Date when a bond was issued.</p>
FirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
LastCouponDate	<p>(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b>, a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b>, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
StartDate	<p>(Optional) Date when a bond actually starts (that is, the date when a bond's cash flows can be considered). To make an instrument forward starting, specify this date as a future date. If <b>StartDate</b> is not explicitly specified, the effective start date is the <b>Settle</b> date.</p>

Face	(Optional) Face or par value. Face is a NINST-by-1 vector or NINST-by-1 cell array of face values, or face value schedules. For the latter case, each element of the cell array is a NumDates-by-2 cell array, where the first column is dates and the second column is its associated face value. The date indicates the last day that the face value is valid. Default = 100.
------	---

Data arguments are number of instruments (NINST)-by-1 vectors, scalar, or empty. Fill in unspecified entries vectors with NaN. Only one data argument is required to create the instrument. The others can be omitted or passed as empty matrices [ ].

## Description

InstSet = instbond(CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) creates a new instrument set containing bond instruments.

InstSet = instbond(InstSet, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) adds bond instruments to an existing instrument set.

[FieldList, ClassList, TypeString] = instbond displays the classes.

FieldList is a number of fields (NFIELDS-by-1) cell array of character vectors listing the name of each data field for this instrument type.

ClassList is an NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

TypeString is a character vector specifying the type of instrument added. For a bond instrument, TypeString = 'Bond'.

## Examples

### Create a Bond Instrument

Create a new instrument variable with the following information:

```
CouponRate= [0.035;0.04];
Settle= 'Nov-1-2013';
Maturity = 'Nov-1-2014';
Period =1;
```

```
InstSet = instbond(CouponRate, Settle, Maturity, ...
Period)
```

```
InstSet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
    Type: {'Bond'}
```

```
FieldName: {{11x1 cell}}  
FieldClass: {{11x1 cell}}  
FieldData: {{11x1 cell}}
```

Display the instrument set.

```
instdisp(InstSet)
```

Index	Type	CouponRate	Settle	Maturity	Period	Basis	EndMonthRule	IssueDate	FirstCou
1	Bond	0.035	01-Nov-2013	01-Nov-2014	1	0	1	NaN	NaN
2	Bond	0.04	01-Nov-2013	01-Nov-2014	1	0	1	NaN	NaN

# instcap

Construct cap instrument

## Syntax

```
InstSet = instcap(Strike,Settle,Maturity,Reset,Basis,Principal)
InstSet = instcap(InstSet,Strike,Settle,Maturity,CapReset,Basis,Principal)
[FieldList,ClassList,TypeString] = instcap
```

## Arguments

InstSet	Instrument variable. This argument is specified only when adding cap instruments to an existing instrument set. See <code>instget</code> for more information on the <code>InstSet</code> variable.
Strike	Rate at which the cap is exercised, as a decimal number.
Settle	Settlement date. Serial date number representing the settlement date of the cap.
Maturity	Serial date number representing the maturity date of the cap.
CapReset	(Optional) NINST-by-1 vector representing the frequency of payments per year. Default = 1.
Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
Principal	(Optional) NINST-by-1 of notional principal amounts or NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid. Default is 100.

## Description

`InstSet = instcap(Strike,Settle,Maturity,Reset,Basis,Principal)` creates a new instrument set containing cap instruments.

`InstSet = instcap(InstSet,Strike,Settle,Maturity,CapReset,Basis,Principal)` adds cap instruments to an existing instrument set.

`[FieldList,ClassList,TypeString] = instcap` displays the classes.

`FieldList` is a number of fields (NFIELDS-by-1) cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` is an NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

`TypeString` is a character vector specifying the type of instrument added. For a cap instrument, `TypeString = 'Cap'`.

---

**Note** Use the optional argument, `Principal`, to pass a schedule for an amortizing cap.

---

## Examples

### Create Two Cap Instruments

Create a new instrument variable with the following information:

```
Strike = [0.035; 0.045];
Settle= 'Jan-1-2013';
Maturity = 'Jan-1-2014';
Reset = 1;
Basis = 1;
Principal = 1000;
```

Create the new cap instruments.

```
InstSet = instcap(Strike, Settle, Maturity, Reset, Basis, Principal)
```

```
InstSet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
    Type: {'Cap'}
    FieldName: {{6x1 cell}}
    FieldClass: {{6x1 cell}}
    FieldData: {{6x1 cell}}
```

Display the cap instruments.

```
instdisp(InstSet)
```

Index	Type	Strike	Settle	Maturity	CapReset	Basis	Principal
1	Cap	0.035	01-Jan-2013	01-Jan-2014	1	1	1000

---

## instcbond

Construct CBond instrument for convertible bond

### Syntax

```
ISet = instcbond(CouponRate,Settle,Maturity,ConvRatio)
ISet = instcbond( ____,Name,Value)
```

```
ISet = instcbond(ISet,CouponRate,Settle,Maturity,ConvRatio)
ISet = instcbond( ____,Name,Value)
```

```
[FieldList,ClassList,TypeString] = instcbond
```

### Description

`ISet = instcbond(CouponRate,Settle,Maturity,ConvRatio)` creates a CBond instrument variable from data arrays.

`ISet = instcbond( ____,Name,Value)` creates a CBond instrument variable from data arrays using optional name-value pair arguments.

`ISet = instcbond(ISet,CouponRate,Settle,Maturity,ConvRatio)` adds a CBond to an existing instrument set.

`ISet = instcbond( ____,Name,Value)` adds a CBond instrument to an existing instrument set using optional name-value pair arguments.

`[FieldList,ClassList,TypeString] = instcbond` lists the field metadata for the CBond instrument.

### Examples

#### Create a CBond Instrument

Create a CBond instrument.

```
CouponRate = 0.03;
Settle = 'Jan-1-2014';
Maturity = 'Jan-1-2016';
CallStrike = 125;
CallExDates = [datenum('Jan-1-2015') datenum('Jan-1-2016')];
```

```
ConvRatio = 1.5;
Spread = 0.045;
```

```
InstSet = instcbond(CouponRate,Settle,Maturity,ConvRatio,...
'Spread',Spread,'CallExDates',CallExDates,'CallStrike',CallStrike,...
'AmericanCall', 1);
```

Display the InstSet for the convertible bond.

```
instdisp(InstSet)
```

Index	Type	CouponRate	Settle	Maturity	ConvRatio	Period	IssueDate	FirstCouponDate
1	CBond	0.03	01-Jan-2014	01-Jan-2016	1.5	2	NaN	NaN

### Add a CBond Instrument to an Existing Portfolio Set

Create a bond instrument using instbond.

```
CouponRate= [0.035;0.04];
Settle= 'Nov-1-2013';
Maturity = 'Nov-1-2014';
Period =1;
```

```
InstSet = instbond(CouponRate,Settle,Maturity, ...
Period);
```

Add a CBond instrument to the existing portfolio set.

```
ConvRatio = 1.5;
InstSet = instadd(InstSet, 'CBond', CouponRate, Settle, Maturity, ConvRatio);
instdisp(InstSet)
```

Index	Type	CouponRate	Settle	Maturity	Period	Basis	EndMonthRule	IssueDate	FirstCouponDate
1	Bond	0.035	01-Nov-2013	01-Nov-2014	1	0	1	NaN	NaN
2	Bond	0.04	01-Nov-2013	01-Nov-2014	1	0	1	NaN	NaN

Index	Type	CouponRate	Settle	Maturity	ConvRatio	Period	IssueDate	FirstCouponDate
3	CBond	0.035	01-Nov-2013	01-Nov-2014	1.5	2	NaN	NaN
4	CBond	0.04	01-Nov-2013	01-Nov-2014	1.5	2	NaN	NaN

```
[FieldList,ClassList,TypeString] = instcbond
```

```
FieldList = 20x1 cell
    {'CouponRate'      }
    {'Settle'          }
    {'Maturity'        }
    {'ConvRatio'       }
    {'Period'          }
    {'IssueDate'       }
    {'FirstCouponDate' }
    {'LastCouponDate' }
    {'StartDate'       }
    {'Face'            }
    {'Spread'          }
    {'CallStrike'      }
    {'CallExDates'    }
    {'AmericanCall'    }
    {'PutStrike'       }
    {'PutExDates'     }
    {'AmericanPut'     }
    {'ConvDates'       }
    {'DefaultProbability'}
    {'RecoveryRate'    }
```

```

ClassList = 20x1 cell
    {'cell'}
    {'date'}
    {'date'}
    {'dble'}
    {'dble'}
    {'date'}
    {'date'}
    {'date'}
    {'date'}
    {'cell'}
    {'dble'}
    {'dble'}
    {'date'}
    {'dble'}
    {'dble'}
    {'date'}
    {'dble'}
    {'date'}
    {'dble'}

```

```

TypeString =
'CBond'

```

## Input Arguments

### CouponRate — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NINST-by-1 positive decimal annual rate or an NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

### Settle — Settlement date

scalar for serial nonnegative date number | scalar for date character vector

Settlement date, specified as an NINST-by-1 scalar using a serial nonnegative date number or date character vector.

---

**Note** The `Settle` date for every convertible bond is set to the `ValuationDate` of the stock tree. The bond argument, `Settle`, is ignored.

---

Data Types: double | char

### Maturity — Maturity date

scalar for serial nonnegative date number | scalar for date character vector

Maturity date, specified as an NINST-by-1 scalar using a serial nonnegative date number or date character vector.

Data Types: double | char

### **ConvRatio — Number of shares convertible to one bond**

nonnegative scalar

Number of shares convertible to one bond, specified as an NINST-by-1 nonnegative scalar.

Data Types: double

### **ISet — Variable containing a collection of instruments**

structure

Variable containing a collection of instruments, specified as a structure. Use this argument to add a CBond (convertible bond) to an existing instrument set (ISet). Instruments within ISet are broken down by type, and each type can have different data fields. For more information on the ISet variable, see `instget`.

Data Types: struct

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `InstSet =`

```
instcbond(CouponRate, Settle, Maturity, ConvRatio, 'Spread', Spread, 'CallExDates', CallExDates, 'CallStrike', CallStrike, 'AmericanCall', 1)
```

### **Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

### **IssueDate — Bond issue date**

scalar for serial date number | scalar for date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 scalar using a serial date number or date character vector.

Data Types: double | char

### **FirstCouponDate — Irregular first coupon date**

scalar for serial date number | scalar for date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 scalar using a serial date number or date character vector.

Data Types: double | char

### **LastCouponDate — Irregular last coupon date**

scalar for serial date number | scalar for date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 scalar using a serial date number or date character vector.

Data Types: double | char

### Face — Face value

100 (default) | scalar of nonnegative value | cell array of nonnegative values

Face value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 scalar of nonnegative face values or an NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is the associated face value. The date indicates the last day that the face value is valid.

Data Types: cell | double

### Spread — Number of basis points over the reference rate

0 (default) | vector

Number of basis points over the reference rate, specified as the comma-separated pair consisting of 'Spread' and a NINST-by-1 vector.

Data Types: double

### CallStrike — Call strike price for European, Bermuda, or American option

nonnegative integer | vector of nonnegative integers

Call strike price for European, Bermuda, or American option, specified as the comma-separated pair consisting of 'CallStrike' and one of the following values:

- For a European call option — NINST-by-1 vector of nonnegative integers
- For a Bermuda call option — NINST-by-NSTRIKES matrix of strike price values, where each row is the schedule for one call option. If a call option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American call option — NINST-by-1 vector of strike price values for each call option.

Data Types: single | double

### CallExDates — Call exercise date for European, Bermuda, or American option

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Call exercise date for European, Bermuda, or American option, specified as the comma-separated pair consisting of 'CallExDates' and one of the following values:

- For a European option — NINST-by-1 vector of serial date numbers or date character vectors.
- For a Bermuda option — NINST-by-NSTRIKES matrix of exercise dates, where each row is the schedule for one call option. For a European option, there is only one CallExDate on the option expiry date.
- For an American option — NINST-by-1 or NINST-by-2 matrix of exercise date boundaries. For each instrument, the call option can be exercised on any tree date between or including the pair of dates on that row. If CallExDates is NINST-by-1, the call option can be exercised between the ValuationDate of the stock tree and the single listed CallExDate.

Data Types: double | char | cell

### AmericanCall — Call option type indicator

0 if AmericanCall is NaN or not entered (default) | scalar | vector of positive integers[0, 1]

Call option type, specified as the comma-separated pair consisting of 'AmericanCall' and a NINST-by-1 positive integer scalar flags with values 0 or 1.

- For a European or Bermuda option — AmericanCall is 0 for each European or Bermuda option.
- For an American option — AmericanCall is 1 for each American option. The AmericanCall argument is required to invoke American exercise rules.

Data Types: single | double

### **PutStrike — Put strike values for European, Bermuda, or American option**

scalar | vector of positive integers [0, 1]

Put strike values for a European, Bermuda, or American option, specified as the comma-separated pair consisting of 'PutStrike' and one of the following values:

- For a European put option — NINST-by-1 vector of nonnegative integers
- For a Bermuda put option — NINST-by-NSTRIKES matrix of strike price values, where each row is the schedule for one put option. If a put option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American put option — NINST-by-1 vector of strike price values for each put option.

Data Types: single | double

### **PutExDates — Put exercise date for European, Bermuda, or American option**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Put exercise date for a European, Bermuda, or American option, specified as the comma-separated pair consisting of 'PutExDates' and one of the following values:

- For a European option — NINST-by-1 vector serial date numbers or date character vectors.
- For a Bermuda option — NINST-by-NSTRIKES matrix of exercise dates, where each row is the schedule for one put option. For a European option, there is only one PutExDate on the option expiry date.
- For an American option — NINST-by-1 or NINST-by-2 matrix of exercise date boundaries. For each instrument, the put option can be exercised on any tree date between or including the pair of dates on that row. If PutExDates is NINST-by-1, the put option can be exercised between the ValuationDate of the stock tree and the single listed PutExDate.

Data Types: double | char | cell

### **AmericanPut — Put option type indicator**

0 if AmericanPut is NaN or not entered (default) | scalar | vector of positive integers [0, 1]

Put option type, specified as the comma-separated pair consisting of 'AmericanPut' and a NINST-by-1 positive integer scalar flags with values 0 or 1.

- For a European or Bermuda option — AmericanPut is 0 for each European or Bermuda option.
- For an American option — AmericanPut is 1 for each American option. The AmericanPut argument is required to invoke American exercise rules.

Data Types: single | double

**ConvDates — Convertible dates**

MaturityDate (default) | scalar for serial date number | scalar for date character vector

Convertible dates, specified as the comma-separated pair consisting of 'ConvDates' and a NINST-by-1 or NINST-by-2 matrix of serial nonnegative date numbers or date character vectors. If ConvDates is not specified, the bond is always convertible until maturity.

For each instrument, the bond can be converted on any tree date between or including the pair of dates on that row.

If ConvDates is NINST-by-1, the bond can be converted between the ValuationDate of the stock tree and the single listed ConvDates.

Data Types: single | double | char

**Output Arguments****ISet — Variable containing a collection of instruments**

character vector | row vector

Variable containing a collection of instruments, returned as a row vector or character vector for each instrument. Instruments are broken down by type and each type can have different data fields. For more information on the ISet variable, see `instget`.

**FieldList — Name of each data field for instrument type**

cell array of character vectors

Name of each data field for instrument type, returned as an NFIELDS-by-1 cell array of character vectors.

**ClassList — Data class of each field**

cell array of character vectors with valid values of 'dble', 'date', and 'char'

Data class of each field, returned as an NFIELDS-by-1 cell array of character vectors with valid character vector values of 'dble', 'date', and 'char'.

**TypeString — Type of instrument added**

character vector

Type of instrument added, returned as character vector. When adding a CBond, the TypeString = 'CBond'.

**Introduced in R2015a**

# instcf

Construct cash flow instrument

## Syntax

```
InstSet = instcf(CFlowAmounts,CFlowDates,Settle,Basis)
InstSet = instcf(InstSet,CFlowAmounts,CFlowDates,Settle,Basis)
[FieldList,ClassList,TypeString] = instcf
```

## Arguments

InstSet	Instrument variable. This argument is specified only when adding cash flow instruments to an existing instrument set. See <code>instget</code> for more information on the <code>InstSet</code> variable.
CFlowAmounts	Number of instruments (NINST) by maximum number of cash flows (MOSTCFS) matrix of cash flow amounts. Each row is a list of cash flow values for one instrument. If an instrument has fewer than MOSTCFS cash flows, the end of the row is padded with NaNs.
CFlowDates	NINST-by-MOSTCFS matrix of cash flow dates. Each entry contains the date of the corresponding cash flow in <code>CFlowAmounts</code> .
Settle	Settlement date on which the cash flows are priced.
Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>

Only one data argument is required to create an instrument. Other arguments can be omitted or passed as empty matrices []. Dates can be input as serial date numbers or date character vectors.

## Description

`InstSet = instcf(CFlowAmounts,CFlowDates,Settle,Basis)` creates a new cash flow instrument set from data arrays.

`InstSet = instcf(InstSet,CFlowAmounts,CFlowDates,Settle,Basis)` adds instruments of type `CashFlow` to an instrument set.

`[FieldList,ClassList,TypeString] = instcf` lists field metadata for an instrument of type `CashFlow`.

`FieldList` is a number of fields (NFIELD-by-1) cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` is an NFIELD-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

`TypeString` specifies the type of instrument added; for example,

```
TypeString = 'CashFlow'
```

.

# instcompound

Construct compound option

## Syntax

```
InstSet =
instcompound(UOptSpec,UStrike,USettle,UExerciseDates,UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates,CAmericanOpt)
InstSet =
instcompound(InstSet,UOptSpec,UStrike,USettle,UExerciseDates,UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates,CAmericanOpt)
[FieldList,ClassList,TypeString] = instcompound
```

## Arguments

InstSet	Instrument variable. This argument is specified only when adding compound instruments to an existing instrument set. See <code>instget</code> for more information on the <code>InstSet</code> variable.
UOptSpec	Character vector with value of 'Call' or 'Put'.
UStrike	1-by-1 vector of strike price values.
USettle	1-by-1 vector of <code>Settle</code> dates.
UExerciseDates	For a European option ( <code>UAmericanOpt = 0</code> ):  1-by-1 vector of exercise dates. For a European option, there is only one exercise date, the option expiry date.  For an American option ( <code>UAmericanOpt = 1</code> ):  1-by-2 vector of exercise date boundaries. The option can be exercised on any tree date. If only one non- <code>NaN</code> date is listed, or if <code>ExerciseDates</code> is 1-by-1, the option can be exercised between the valuation date of the stock tree and the single listed exercise date.
UAmericanOpt	If <code>UAmericanOpt = 0</code> , <code>NaN</code> , or is unspecified, the option is a European option. If <code>UAmericanOpt = 1</code> , the option is an American option.
COptSpec	NINST-by-1 list of character vector values for 'Call' or 'Put' of the compound option.
CStrike	NINST-by-1 vector of strike price values. Each row is the schedule for one option.
CSettle	1-by-1 vector containing the settlement or trade date.

CExerciseDates	<p>For a European option (CAmericanOpt = 0):</p> <p>NINST-by-1 vector of exercise dates. Each row is the schedule for one option. For a European option, there is only one exercise date, the option expiry date.</p> <p>For an American option (CAmericanOpt = 1):</p> <p>NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is NINST-by-1, the option can be exercised between the valuation date of the stock tree and the single listed exercise date.</p>
CAmericanOpt	<p>If CAmericanOpt = 0, NaN, or is unspecified, the option is a European option. If CAmericanOpt = 1, the option is an American option.</p>

## Description

InstSet = instcompound(UOptSpec, UStrike, USettle, UExerciseDates, UAmericanOpt, COptSpec, CStrike, CSettle, CExerciseDates, CAmericanOpt) creates a new instrument set for a compound option.

InstSet = instcompound(InstSet, UOptSpec, UStrike, USettle, UExerciseDates, UAmericanOpt, COptSpec, CStrike, CSettle, CExerciseDates, CAmericanOpt) adds a compound option to an existing instrument set.

[FieldList, ClassList, TypeString] = instcompound displays the classes.

FieldList is a number of fields (NFIELDS-by-1) cell array of character vectors listing the name of each data field for this instrument type.

ClassList is an NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

TypeString is a character vector specifying the type of instrument added. For a compound option instrument, TypeString = 'Compound'.

## Examples

### Create a Compound Option Instrument

Define a compound option instrument with the following data:

```
UOptSpec = 'Call';
UStrike = 130;
USettle = '01-Jan-2012';
UExerciseDates = '01-Jan-2015';
```

```

UAmericanOpt = 0;
COptSpec = 'Put';
CStrike = 5;
CSettle = '01-Jan-2012';
CExerciseDates = '01-Jan-2014';
CAmericanOpt = 0;

```

```

InstSet = instcompound(UOptSpec, UStrike, USettle,UExerciseDates, ...
UAmericanOpt, COptSpec, CStrike, CSettle,CExerciseDates, CAmericanOpt)

```

```

InstSet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
        Type: {'Compound'}
    FieldName: {{10x1 cell}}
    FieldClass: {{10x1 cell}}
    FieldData: {{10x1 cell}}

```

```

InstSet = instcompound(UOptSpec, UStrike, USettle,UExerciseDates, ...
UAmericanOpt, COptSpec, CStrike, CSettle,CExerciseDates)

```

```

InstSet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
        Type: {'Compound'}
    FieldName: {{10x1 cell}}
    FieldClass: {{10x1 cell}}
    FieldData: {{10x1 cell}}

```

Display the instrument set.

```

instdisp(InstSet)

```

Index	Type	UOptSpec	UStrike	USettle	UExerciseDates	UAmericanOpt	COptSpec	CStrike	CSett
1	Compound	Call	130	01-Jan-2012	01-Jan-2015	0	Put	5	01-J

## instdelete

Complement of instrument set by matching conditions

### Syntax

```
ISubSet = instdelete(InstSet,'FieldName',FieldList,'Data',DataList,'Index',IndexSet,'Type',TypeList)
```

### Arguments

InstSet	Variable containing a collection of instruments. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.
FieldList	Number of fields, specified as a NFIELDS-by-1 cell array of character vectors listing the name of each data field to match with data values.
DataList	Number of values, specified as a NVALUES-by-M array or NFIELDS-by-1 cell array of acceptable data values for each field. Each row lists a data row value to search for in the corresponding FieldList. The number of columns is arbitrary and matching ignores trailing NaNs or spaces.
IndexSet	(Optional) Number of instruments, specified as a NINST-by-1 vector restricting positions of instruments to check for matches. The default is all indices available in the instrument variable.
TypeList	(Optional) Number of types, specified as a NTYPES-by-1 cell array of character vectors restricting instruments to match one of TypeList types. The default is all types in the instrument variable.

**Note** Argument value pairs can be entered in any order. The InstSet variable must be the first argument. 'FieldName' and 'Data' arguments must appear together or not at all.

### Description

The output argument ISubSet contains instruments *not* matching the input criteria. Instruments are deleted from ISubSet if all the Field, Index, and Type conditions are met. An instrument meets an individual Field condition if the stored FieldName data matches any of the rows listed in the DataList for that FieldName. See instfind for more examples on matching criteria.

### Examples

Retrieve the instrument set variable ExampleInst from the data file InstSetExamples.mat. The variable contains three types of instruments: Option, Futures, and TBill.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95     12.2 Call    0
2     Option 100     9.2 Call    0
```

```
3   Option 105    6.8  Call  1000
```

```
Index Type    Delivery      F    Contracts
4   Futures 01-Jul-1999  104.4 -1000
```

```
Index Type    Strike Price Opt  Contracts
5   Option 105    7.4  Put  -1000
6   Option 95    2.9  Put    0
```

```
Index Type    Price Maturity      Contracts
7   TBill 99    01-Jul-1999  6
```

Create a new variable, ISet, with all options deleted.

```
ISet = instdelete(ExampleInst, 'Type', 'Option');
instdisp(ISet)
```

```
Index Type    Delivery      F    Contracts
1   Futures 01-Jul-1999  104.4 -1000
```

```
Index Type    Price Maturity      Contracts
2   TBill 99    01-Jul-1999  6
```

## instdisp

Display instruments

### Syntax

```
CharTable = instdisp(InstSet)
```

### Arguments

InstSet	Variable containing a collection of instruments. See <code>instaddfield</code> for examples on constructing the variable.
---------	---

### Description

`CharTable = instdisp(InstSet)` creates a character array displaying the contents of an instrument collection, `InstSet`. If `instdisp` is called without output arguments, the table is displayed in the Command Window.

---

**Note** When using `instdisp`, a value of NaN in one of the columns for an instrument indicates that the default value for that parameter will be used in the instrument's pricing function.

---

`CharTable` is a character array with a table of instruments in `InstSet`. For each instrument row, the Index and Type are printed along with the field contents. Field headers are printed at the tops of the columns.

### Examples

Retrieve the instrument set `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: Option, Futures, and TBill.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1   Option  95    12.2 Call   0
2   Option 100    9.2  Call   0
3   Option 105    6.8  Call 1000
```

```
Index Type   Delivery      F    Contracts
4   Futures 01-Jul-1999  104.4 -1000
```

```
Index Type   Strike Price Opt  Contracts
5   Option 105    7.4  Put  -1000
6   Option  95    2.9  Put   0
```

```
Index Type Price Maturity      Contracts
7   TBill 99    01-Jul-1999  6
```

Create a swap instrument and use `instdisp` to display the instrument. Notice that value of NaN in two columns for this instrument indicates that the default values for `LegReset` and `LegType` parameters will be used in the swap instrument's pricing function.

```
LegRate1 = [0.065, 0];
Settle1 = datenum('jan-1-2007');
Maturity1 = datenum('jan-1-2012');
```

```
ISet = instswap(LegRate1, Settle1, Maturity1);
instdisp(ISet)
```

```
Index Type LegRate   Settle      Maturity    LegReset Basis Principal LegType EndMonthRule
1      Swap [0.065  0] 01-Jan-2007 01-Jan-2012 [NaN]    0    100    [NaN]    1
```

## instfields

List field names

### Syntax

```
FieldList = instfields(InstSet, 'Type', TypeList)
```

### Arguments

InstSet	Variable containing a collection of instruments. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.
TypeList	(Optional) Number of types, specified as a NTYPES-by-1 cell array of character vectors listing the instrument types to query.

### Description

`FieldList = instfields(InstSet, 'Type', TypeList)` retrieves the list of fields stored in an instrument variable.

`FieldList` is a number of fields (NFIELDS-by-1) cell array of character vectors listing the name of each data field corresponding to the listed types.

### Examples

Retrieve the instrument set `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95     12.2 Call   0
2     Option 100     9.2 Call   0
3     Option 105     6.8 Call 1000
```

```
Index Type   Delivery      F      Contracts
4     Futures 01-Jul-1999  104.4 -1000
```

```
Index Type   Strike Price Opt  Contracts
5     Option 105     7.4 Put -1000
6     Option  95     2.9 Put   0
```

```
Index Type Price Maturity      Contracts
7     TBill 99     01-Jul-1999  6
```

Get the fields listed for type 'Option'.

```
[FieldList, ClassList] = instfields(ExampleInst, 'Type', ...
'Option')
```

```
FieldList =
    'Strike'
    'Price'
    'Opt'
    'Contracts'
```

```
ClassList =
    'dble'
    'dble'
    'char'
    'dble'
```

Get the fields listed for types 'Option' and 'TBill'.

```
FieldList = instfields(ExampleInst, 'Type', {'Option', 'TBill'})
```

```
FieldList =
    'Strike'
    'Opt'
    'Price'
    'Maturity'
    'Contracts'
```

Get all the fields listed in any type in the variable.

```
FieldList = instfields(ExampleInst)
```

```
FieldList =
    'Delivery'
    'F'
    'Strike'
    'Opt'
    'Price'
    'Maturity'
    'Contracts'
```

## instfind

Search instruments for matching conditions

### Syntax

```
IndexMatch =
instfind(InstSet, 'FieldName', FieldList, 'Data', DataList, 'Index', IndexSet, 'Type
', TypeList)
```

### Arguments

InstSet	Variable containing a collection of instruments. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.
FieldList	Number of fields, specified as a NFIELDS-by-1 cell array of character vectors listing the name of each data field to match with data values.
DataList	Number of values, specified as a NVALUES-by-M array or NFIELDS-by-1 cell array of acceptable data values for each field. Each row lists a data row value to search for in the corresponding FieldList. The number of columns is arbitrary, and matching ignores trailing NaNs or spaces.
IndexSet	(Optional) Number of instruments, specified as a NINST-by-1 vector restricting positions of instruments to check for matches. The default is all indices available in the instrument variable.
TypeList	(Optional) Number of types, specified as a NTYPES-by-1 cell array of character vectors restricting instruments to match one of TypeList types. The default is all types in the instrument variable.

Argument value pairs can be entered in any order. The InstSet variable must be the first argument. 'FieldName' and 'Data' arguments must appear together or not at all.

### Description

```
IndexMatch =
instfind(InstSet, 'FieldName', FieldList, 'Data', DataList, 'Index', IndexSet, 'Type
', TypeList) returns indices of instruments matching Type, Field, or Index values.
```

IndexMatch is an NINST-by-1 vector of positions of instruments matching the input criteria. Instruments are returned in IndexMatch if all the Field, Index, and Type conditions are met. An instrument meets an individual Field condition if the stored FieldName data matches any of the rows listed in the DataList for that FieldName.

### Examples

Retrieve the instrument set ExampleInst from the data file InstSetExamples.mat. ExampleInst contains three types of instruments: Option, Futures, and TBill.

```
load InstSetExamples;
instdisp(ExampleInst)
```

Index	Type	Strike	Price	Opt	Contracts
1	Option	95	12.2	Call	0
2	Option	100	9.2	Call	0
3	Option	105	6.8	Call	1000

Index	Type	Delivery	F	Contracts
4	Futures	01-Jul-1999	104.4	-1000

Index	Type	Strike	Price	Opt	Contracts
5	Option	105	7.4	Put	-1000
6	Option	95	2.9	Put	0

Index	Type	Price	Maturity	Contracts
7	TBill	99	01-Jul-1999	6

Make a vector, `Opt95`, containing the indexes within `ExampleInst` of the options struck at 95.

```
Opt95 = instfind(ExampleInst, 'FieldName', 'Strike', 'Data', '95')
```

```
Opt95 =
```

```
1
6
```

Locate the futures and Treasury bill instruments within `ExampleInst`.

```
Types = instfind(ExampleInst, 'Type', {'Futures'; 'TBill'})
```

```
Types =
```

```
4
7
```

## instfixed

Construct fixed-rate instrument

### Syntax

```
InstSet =
instfixed(CouponRate,Settle,Maturity,FixedReset,Basis,Principal,EndMonthRule)
InstSet =
instfixed(InstSet,CouponRate,Settle,Maturity,FixedReset,Basis,Principal,EndMonthRule)
[FieldList,ClassList,TypeString] = instfixed
```

### Arguments

InstSet	Instrument variable. This argument is specified only when adding fixed-rate note instruments to an existing instrument set. See <code>instget</code> for more information on the <code>InstSet</code> variable.
CouponRate	Decimal annual rate.
Settle	Settlement date. Date character vector or serial date number representing the settlement date of the fixed-rate note.
Maturity	Date character vector or serial date number representing the maturity date of the fixed-rate note.
FixedReset	(Optional) NINST-by-1 vector representing the frequency of payments per year. Default = 1.
Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>

Principal	(Optional) NINST-by-1 of notional principal amounts or NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid. Default is 100.
EndMonthRule	(Optional) NINST-by-1 vector representing the End-of-month rule. Default = 1.

Data arguments are number of instruments (NINST)-by-1 vectors, scalar, or empty. Fill in unspecified entries vectors with NaN. Only one data argument is required to create the instrument. The others may be omitted or passed as empty matrices [ ].

## Description

InstSet =  
instfixed(CouponRate,Settle,Maturity,FixedReset,Basis,Principal,EndMonthRule)  
creates a new instrument set containing fixed-rate instruments.

InstSet =  
instfixed(InstSet,CouponRate,Settle,Maturity,FixedReset,Basis,Principal,EndMonthRule)  
adds fixed-rate instruments to an existing instrument set.

[FieldList,ClassList,TypeString] = instfixed displays the classes.

FieldList is a number of fields (NFIELDS-by-1) cell array of character vectors listing the name of each data field for this instrument type.

ClassList is an NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

TypeString is a character vector specifying the type of instrument added. For a fixed-rate instrument, TypeString = 'Fixed'.

## Examples

### Create a Fixed-Rate Instrument

Define the characteristics of the fixed-rate instrument.

```
CouponRate = .03;
Settle = datenum('15-Mar-2013');
Maturity = datenum('15-Mar-2018');
FixedReset = 4;
Basis = 1;
Principal = 1000;
EndMonthRule = 1;
```

Create the new cap instrument.

```
ISet = instfixed(CouponRate, Settle, Maturity, FixedReset, Basis, Principal,EndMonthRule)
ISet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
```

```
Type: {'Fixed'}
FieldName: {{7x1 cell}}
FieldClass: {{7x1 cell}}
FieldData: {{7x1 cell}}
```

Display the fixed-rate instrument.

```
instdisp(ISet)
```

Index	Type	CouponRate	Settle	Maturity	FixedReset	Basis	Principal	EndMonthRule
1	Fixed	0.03	15-Mar-2013	15-Mar-2018	4	1	1000	1

# instfloat

Construct floating-rate instrument

## Syntax

```

InstSet =
instfloat(Spread,Settle,Maturity,FloatReset,Basis,Principal,EndMonthRule)
InstSet =
instfloat(InstSet,Spread,Settle,Maturity,FloatReset,Basis,Principal,EndMonthRule)
InstSet =
instfloat(Spread,Settle,Maturity,FloatReset,Basis,Principal,EndMonthRule,CapRate,FloorRate)
InstSet =
instfloat(InstSet,Spread,Settle,Maturity,FloatReset,Basis,Principal,EndMonthRule,CapRate,FloorRate)
[FieldList,ClassList,TypeString] = instfloat

```

## Arguments

InstSet	Instrument variable. This argument is specified only when adding floating-rate note instruments to an existing instrument set. See <code>instget</code> for more information on the <code>InstSet</code> variable.
Spread	Number of basis points over the reference rate.
Settle	Settlement date. Date character vector or serial date number representing the settlement date of the floating-rate note.
Maturity	Date character vector or serial date number representing the maturity date of the floating-rate note.
FloatReset	(Optional) NINST-by-1 vector representing the frequency of payments per year. Default = 1.

<b>Basis</b>	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
<b>Principal</b>	(Optional) NINST-by-1 of notional principal amounts or NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid. Default is 100.
<b>EndMonthRule</b>	(Optional) NINST-by-1 vector representing the End-of-month rule. Default = 1.
<b>CapRate</b>	(Optional) NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array, and the cell array first column is dates, and the second column is associated cap rates. The date indicates the last day that the cap rate is valid.
<b>FloorRate</b>	(Optional) NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array, and the cell array first column is dates, and the second column is associated floor rates. The date indicates the last day that the floor rate is valid.

Data arguments are number of instruments (NINST)-by-1 vectors, scalar, or empty. Fill in unspecified entries vectors with NaN. Only one data argument is required to create the instrument. The others may be omitted or passed as empty matrices [ ].

## Description

**InstSet =**  
**instfloat(Spread,Settle,Maturity,FloatReset,Basis,Principal,EndMonthRule)**  
 creates a new instrument set containing floating-rate instruments.

**InstSet =**  
**instfloat(InstSet,Spread,Settle,Maturity,FloatReset,Basis,Principal,EndMonthRule)**  
 adds floating-rate instruments to an existing instrument set.

`InstSet = instfloat(Spread,Settle,Maturity,FloatReset,Basis,Principal,EndMonthRule,CapRate,FloorRate)` creates a new instrument set containing capped floating-rate instruments.

`InstSet = instfloat(InstSet,Spread,Settle,Maturity,FloatReset,Basis,Principal,EndMonthRule,CapRate,FloorRate)` adds capped floating-rate instruments to an existing instrument set.

`[FieldList,ClassList,TypeString] = instfloat` displays the classes.

`FieldList` is a number of fields (NFIELDS-by-1) cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` is an NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

`TypeString` is a character vector specifying the type of instrument added. For a floating-rate instrument, `TypeString = 'Float'`.

## Examples

### Create a Floating-Rate Instrument

Define the characteristics of the floating-rate instrument.

```
Spread = 2;
Settle = datenum('15-Mar-2013');
Maturity = datenum('15-Mar-2018');
FloatReset = 4;
Basis = 1;
Principal = 1000;
EndMonthRule = 1;
CapRate = 0.35;
FloorRate = 0.27;
```

Create the new floating-rate instrument.

```
ISet = instfloat(Spread, Settle, Maturity, FloatReset, Basis, Principal, ...
EndMonthRule, CapRate, FloorRate)
```

```
ISet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
    Type: {'Float'}
    FieldName: {{9x1 cell}}
    FieldClass: {{9x1 cell}}
    FieldData: {{9x1 cell}}
```

Display the floating-rate instrument.

```
instdisp(ISet)
```

Index	Type	Spread	Settle	Maturity	FloatReset	Basis	Principal	EndMonthRule	CapRate
1	Float	2	15-Mar-2013	15-Mar-2018	4	1	1000	1	0.35

# instfloor

Construct floor instrument

## Syntax

```
InstSet = instfloor(Strike,Settle,Maturity,FloorReset,Basis,Principal)
InstSet =
instfloor(InstSet,Strike,Settle,Maturity,FloorReset,Basis,Principal)
[FieldList,ClassList,TypeString] = instfloor
```

## Arguments

InstSet	Instrument variable. This argument is specified only when adding floor instruments to an existing instrument set. See <code>instget</code> for more information on the InstSet variable.
Strike	Rate at which the floor is exercised, as a decimal number.
Settle	Settlement date. A vector of serial date numbers or date character vectors. <code>Settle</code> must be earlier than <code>Maturity</code> .
Maturity	Maturity date. A vector of serial date numbers or date character vectors.
FloorReset	(Optional) NINST-by-1 vector representing the frequency of payments per year. Default = 1.
Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>

Principal	(Optional) NINST-by-1 of notional principal amounts or NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid. Default is 100.
-----------	--

## Description

`InstSet = instfloor(Strike,Settle,Maturity,FloorReset,Basis,Principal)` creates a new instrument set containing floor instruments.

`InstSet = instfloor(InstSet,Strike,Settle,Maturity,FloorReset,Basis,Principal)` adds floor instruments to an existing instrument set.

`[FieldList,ClassList,TypeString] = instfloor` displays the classes.

`FieldList` is a number of fields (NFIELDS-by-1) cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` is an NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

`TypeString` is a character vector specifying the type of instrument added. For a floor instrument, `TypeString = 'Floor'`.

---

**Note** Use the optional argument, `Principal`, to pass a schedule for an amortizing floor.

---

## Examples

### Create a Floor Instrument

Define the characteristics of the floor instrument.

```
Strike = 0.22;
Settle = datenum('15-Mar-2013');
Maturity = datenum('15-Mar-2018');
FloorReset = 4;
Basis = 1;
Principal = 1000;
```

Create the new floor instrument.

```
ISet = instfloor(Strike, Settle, Maturity, FloorReset, Basis, Principal)
```

```
ISet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
    Type: {'Floor'}
    FieldName: {{6x1 cell}}
    FieldClass: {{6x1 cell}}
    FieldData: {{6x1 cell}}
```

Display the floor instrument.

```
instdisp(ISet)
```

Index	Type	Strike	Settle	Maturity	FloorReset	Basis	Principal
1	Floor	0.22	15-Mar-2013	15-Mar-2018	4	1	1000

## instget

Data from instrument variable

### Syntax

```
[Data_1,Data_2,...,Data_n] =
instget(InstSet,'FieldName',FieldList,'Index',IndexSet,'Type',TypeList)
```

### Arguments

InstSet	Variable containing a collection of instruments. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.
FieldList	(Optional) Number of fields, specified as a NFIELDS-by-1 cell array of character vectors listing the name of each data field to match with data values. FieldList entries can also be either 'Type' or 'Index'; these return type character vectors and index numbers respectively. The default is all fields available for the returned set of instruments.
IndexSet	(Optional) Number of instruments, specified as a NINST-by-1 vector of positions of instruments to work on. If TypeList is also entered, instruments referenced must be one of TypeList types and contained in IndexSet. The default is all indices available in the instrument variable.
TypeList	(Optional) Number of types, specified as a NTYPES-by-1 cell array of character vectors restricting instruments to match one of TypeList types. The default is all types in the instrument variable.

Argument value pairs can be entered in any order. The InstSet variable must be the first argument.

### Description

```
[Data_1,Data_2,...,Data_n] =
instget(InstSet,'FieldName',FieldList,'Index',IndexSet,'Type',TypeList)
```

retrieves data arrays from an instrument variable.

Data\_1 is an NINST-by-M array of data contents for the first field in FieldList. Each row corresponds to a separate instrument in IndexSet. Unavailable data is returned as NaN or as spaces.

Data\_n is an NINST-by-M array of data contents for the last field in FieldList.

### Examples

Retrieve the instrument set ExampleInst from the data file. InstSetExamples.mat. ExampleInst contains three types of instruments: Option, Futures, and TBill.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1      Option  95    12.2 Call    0
```

```

2   Option 100    9.2 Call    0
3   Option 105    6.8 Call  1000

Index Type    Delivery      F    Contracts
4   Futures 01-Jul-1999 104.4 -1000

Index Type    Strike Price Opt    Contracts
5   Option 105    7.4 Put  -1000
6   Option 95    2.9 Put    0

Index Type Price Maturity      Contracts
7   TBill 99    01-Jul-1999 6

```

Extract the price from all instruments.

```
P = instget(ExampleInst, 'FieldName', 'Price')
```

```
P =
```

```

12.2000
 9.2000
 6.8000
    NaN
 7.4000
 2.9000
99.0000

```

Get all the prices and the number of contracts held.

```
[P,C] = instget(ExampleInst, 'FieldName', {'Price', 'Contracts'})
```

```
P =
```

```

12.2000
 9.2000
 6.8000
    Nan
 7.4000
 2.9000
99.0000

```

```
C =
```

```

0
0
1000
-1000
-1000
0
6

```

Compute a value V. Create a new variable ISet that appends V to ExampleInst.

```

V = P.*C
ISet = instsetfield(ExampleInst, 'FieldName', 'Value', 'Data',...
V);
instdisp(ISet)

```

```

Index Type    Strike Price Opt    Contracts Value
1   Option 95    12.2 Call    0          0

```

```

2   Option 100      9.2 Call    0          0
3   Option 105      6.8 Call  1000       6800

Index Type   Delivery      F      Contracts Value
4   Futures 01-Jul-1999  104.4 -1000     NaN

Index Type   Strike Price Opt   Contracts Value
5   Option 105      7.4 Put  -1000    -7400
6   Option  95      2.9 Put    0         0

Index Type Price Maturity      Contracts Value
7   TBill 99      01-Jul-1999  6          594

```

Look at only the instruments that have nonzero Contracts.

```
Ind = find(C ~= 0)
```

```
Ind =
```

```

## instgetcell

Data and context from instrument variable

### Syntax

```
[DataList,FieldList,ClassList] =
instgetcell(InstSet,'FieldName',FieldList,'Index',IndexSet,'Type',TypeList)
```

### Arguments

InstSet	Variable containing a collection of instruments. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.
FieldList	(Optional) Number of fields, specified as a NFIELDS-by-1 cell array of character vectors listing the name of each data field to match with data values. FieldList should not be either Type or Index; these field names are reserved. The default is all fields available for the returned set of instruments.
IndexSet	(Optional) Number of instruments, specified as a NINST-by-1 vector of positions of instruments to work on. If TypeList is also entered, instruments referenced must be one of TypeList types and contained in IndexSet. The default is all indices available in the instrument variable.
TypeList	(Optional) Number of types, specified as a NTYPES-by-1 cell array of character vectors restricting instruments to match one of TypeList types. The default is all types in the instrument variable.

Argument value pairs can be entered in any order. The InstSet variable must be the first argument.

### Description

```
[DataList,FieldList,ClassList] =
instgetcell(InstSet,'FieldName',FieldList,'Index',IndexSet,'Type',TypeList)
```

retrieves data and context from an instrument variable.

DataList is an NFIELDS-by-1 cell array of data contents for each field. Each cell is an NINST-by-M array, where each row corresponds to a separate instrument in IndexSet. Any data which is not available is returned as NaN or as spaces.

FieldList is an NFIELDS-by-1 cell array of character vectors listing the name of each field in DataList.

ClassList is an NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

IndexSet is an NINST-by-1 vector of positions of instruments returned in DataList.

TypeSet is an NINST-by-1 cell array of character vectors listing the type of each instrument row returned in DataList.

## Examples

Retrieve the instrument set `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95     12.2 Call   0
2     Option 100     9.2 Call   0
3     Option 105     6.8 Call 1000
```

```
Index Type   Delivery      F      Contracts
4     Futures 01-Jul-1999  104.4 -1000
```

```
Index Type   Strike Price Opt  Contracts
5     Option 105     7.4 Put  -1000
6     Option  95     2.9 Put   0
```

```
Index Type Price Maturity      Contracts
7     TBill 99     01-Jul-1999  6
```

Get the prices and contracts from all instruments.

```
FieldList = {'Price'; 'Contracts'}
DataList = instgetcell(ExampleInst, 'FieldName', FieldList)
P = DataList{1}
C = DataList{2}
```

P =

```
12.2000
 9.2000
 6.8000
    NaN
 7.4000
 2.9000
99.0000
```

C =

```
0
0
1000
-1000
-1000
0
6
```

Get all the option data: `Strike`, `Price`, `Opt`, `Contracts`.

```
[DataList, FieldList, ClassList] = instgetcell(ExampleInst, ...
'Type', 'Option')
```

DataList =

```
[5x1 double]
[5x1 double]
[5x4 char ]
```

```
[5x1 double]
FieldList =
    'Strike'
    'Price'
    'Opt'
    'Contracts'
ClassList =
    'db1e'
    'db1e'
    'char'
    'db1e'
```

Look at the data as a comma-separated list. Type `help lists` for more information on cell array lists.

```

## instlength

Count instruments

### Syntax

```
NInst = instlength(InstSet)
```

### Arguments

InstSet	Variable containing a collection of instruments. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.
---------	---

### Description

`NInst = instlength(InstSet)` computes `NInst`, the number of instruments contained in the variable, `InstSet`.

# instlookback

Construct lookback option

## Syntax

```
InstSet = instlookback(OptSpec,Strike,Settle,ExerciseDates,AmericanOpt)
InstSet =
instlookback(InstSet,OptSpec,Strike,Settle,ExerciseDates,AmericanOpt)
[FieldList,ClassList,TypeString] = instlookback
```

## Arguments

InstSet	Instrument variable. This argument is specified only when adding lookback instruments to an existing instrument set. See <code>instget</code> for more information on the <code>InstSet</code> variable.
OptSpec	NINST-by-1 list of character vector values for 'Call' or 'Put'.
Strike	NINST-by-1 vector of strike price values. Each row is the schedule for one option.
Settle	NINST-by-1 vector of <code>Settle</code> dates.
ExerciseDates	For a European option ( <code>AmericanOpt = 0</code> ):  NINST-by-1 vector of exercise dates. Each row is the schedule for one option. For a European option, there is only one exercise date, the option expiry date.  For an American option ( <code>AmericanOpt = 1</code> ):  NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any tree date between or including the pair of dates on that row. If only one non- <code>NaN</code> date is listed, or if <code>ExerciseDates</code> is NINST-by-1, the option can be exercised between the valuation date of the stock tree and the single listed exercise date.
AmericanOpt	(Optional) If <code>AmericanOpt = 0</code> , <code>NaN</code> , or is unspecified, the option is a European option. If <code>AmericanOpt = 1</code> , the option is an American option.

Data arguments are number of instruments (NINST)-by-1 vectors, scalar, or empty. Fill in unspecified entries vectors with `NaN`. Only one data argument is required to create the instrument. The others may be omitted or passed as empty matrices [ ].

## Description

`InstSet = instlookback(OptSpec,Strike,Settle,ExerciseDates,AmericanOpt)` creates an instrument set for lookback options.

`InstSet = instlookback(InstSet, OptSpec, Strike, Settle, ExerciseDates, AmericanOpt)` adds lookback options to an existing instrument set.

`[FieldList, ClassList, TypeString] = instlookback` displays the classes.

`FieldList` is a number of fields (NFIELDS-by-1) cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` is an NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

`TypeString` is a character vector specifying the type of instrument added. For a lookback option instrument, `TypeString = 'Lookback'`.

## Examples

### Create a Lookback Option Instrument

Define a floating strike lookback instrument with the following data:

```
OptSpec = 'call';
Strike = NaN;
Settle = '01-Jan-2012';
ExerciseDates = '01-Jan-2015';
```

Create the instrument set.

```
InstSet = instlookback(OptSpec, Strike, Settle, ExerciseDates);
```

Display the lookback instrument.

```
instdisp(InstSet)
```

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt
1	Lookback	call	NaN	01-Jan-2012	01-Jan-2015	0

# instoptbnd

Construct bond option

## Syntax

```
InstSet = instoptbnd(BondIndex, OptSpec, Strike, ExerciseDates)
InstSet = instoptbnd(InstSet, BondIndex, OptSpec, Strike, ExerciseDates)
InstSet =
instoptbnd(InstSet, BondIndex, OptSpec, Strike, ExerciseDates, AmericanOpt)
[FieldList, ClassList, TypeString] = instoptbnd
```

## Arguments

InstSet	Variable containing a collection of instruments. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.
BondIndex	Number of instruments (NINST)-by-1 vector of indices pointing to underlying instruments of Type 'Bond' which are also stored in InstSet. See instbnd for information on specifying the bond data.
OptSpec	NINST-by-1 list of character vector values for 'Call' or 'Put'.
<b>Note</b> The interpretation of the Strike and ExerciseDates arguments depends upon the setting of the AmericanOpt argument. If AmericanOpt = 0, NaN, or is unspecified, the option is a European or Bermuda option. If AmericanOpt = 1, the option is an American option.	
Strike	<p>European option: NINST-by-1 vector of strike price values.</p> <p>Bermuda option: NINST by number of strikes (NSTRIKES) matrix of strike price values.</p> <p>Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.</p> <p>For an American option:</p> <p>NINST-by-1 vector of strike price values for each option.</p>
ExerciseDates	<p>NINST-by-1 (European option) or NINST-by-NSTRIKES (Bermuda option) matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one exercise date, the option expiry date.</p> <p>For an American option:</p> <p>NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is NINST-by-1, the option can be exercised between the underlying bond Settle and the single listed exercise date.</p>

Data arguments are NINST-by-1 vectors, scalar, or empty. Fill in unspecified entries vectors with NaN. Only one data argument is required to create the instrument. The others may be omitted or passed as empty matrices [].

## Description

`InstSet = instoptbnd(BondIndex,OptSpec,Strike,ExerciseDates)` creates a bond option, specified as a European or Bermuda option.

`InstSet = instoptbnd(InstSet,BondIndex,OptSpec,Strike,ExerciseDates)` adds a bond option, specified as a European or Bermuda option, to an existing instrument set.

`InstSet = instoptbnd(InstSet,BondIndex,OptSpec,Strike,ExerciseDates,AmericanOpt)` specifies an American option if `AmericanOpt` is set to 1. If `AmericanOpt` is not set to 1, the function specifies a European or Bermuda option.

`[FieldList,ClassList,TypeString] = instoptbnd` displays the classes.

`FieldList` is a number of fields (NFIELDS-by-1) cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` is an NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

`TypeString` is a character vector specifying the type of instrument added. For a bond option instrument, `TypeString = 'OptBond'`.

## Examples

### Create a Bond Option Instrument

Create a new instrument variable with the following information:

```
BondIndex = 1;
OptSpec = 'call';
Strike= 85;
ExerciseDates = 'Nov-1-2014';
AmericanOpt = 1;
CouponRate= [0.035;0.04];
Settle= 'Nov-1-2013';
Maturity = 'Nov-1-2014';
Period =1;
```

Create the instrument portfolio with two bonds.

```
InstSet = instbond(CouponRate, Settle, Maturity, ...
Period)
```

```
InstSet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
    Type: {'Bond'}
```

```

FieldName: {{11x1 cell}}
FieldClass: {{11x1 cell}}
FieldData: {{11x1 cell}}

```

Create an option on the first bond

```
InstSet = instoptbnd(InstSet, BondIndex, OptSpec, Strike, ExerciseDates, AmericanOpt)
```

```

InstSet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
        Type: {2x1 cell}
        FieldName: {2x1 cell}
        FieldClass: {2x1 cell}
        FieldData: {2x1 cell}

```

Display the instrument set.

```
instdisp(InstSet)
```

Index	Type	CouponRate	Settle	Maturity	Period	Basis	EndMonthRule	IssueDate	FirstCou
1	Bond	0.035	01-Nov-2013	01-Nov-2014	1	0	1	NaN	NaN
2	Bond	0.04	01-Nov-2013	01-Nov-2014	1	0	1	NaN	NaN

Index	Type	UnderInd	OptSpec	Strike	ExerciseDates	AmericanOpt
3	OptBond	1	call	85	01-Nov-2014	1

## instoptembnd

Construct bond with embedded option

### Syntax

```
InstSet = instoptembnd
(CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'AmericanOpt', AmericanOpt, 'Period', Period, 'Basis', Basis, 'EndMonthRule', EndMonthRule, 'Face', Face, 'IssueDate', IssueDate, 'FirstCouponDate', FirstCouponDate, 'LastCouponDate', LastCouponDate, 'StartDate', StartDate)
InstSet = instoptembnd(InstSetOld, CouponRate, ...)
[FieldList, ClassList, TypeString] = instoptembnd
```

### Arguments

CouponRate	Decimal annual rate indicating the annual percentage rate used to determine the coupons payable on a bond. CouponRate is a NINST-by-1 vector or NINST-by-1 cell array of decimal annual rates, or decimal annual rate schedules. For the latter case of a variable coupon schedule, each element of the cell array is a NumDates-by-2 cell array, where the first column is dates and the second column is its associated rate. The date indicates the last day that the coupon rate is valid.
Settle	NINST-by-1 vector of settlement dates.
Maturity	NINST-by-1 vector of maturity dates.
OptSpec	NINST-by-1 vector of character vector values for 'Call' or 'Put'.
For a European or Bermuda option	
Strike	NINST-by-NSTRIKES matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaN's.
ExerciseDates	NINST-by-NSTRIKES matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one ExerciseDate on the option expiry date.
AmericanOpt	(Optional) NINST-by-1 vector of flags. AmericanOpt is 0 for each European or Bermuda option. The default is 0 if AmericanOpt is NaN or not entered.
For an American option	
Strike	NINST-by-1 vector of strike price values for each option.
ExerciseDates	NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is NINST-by-1, the option can be exercised between the underlying bond Settle and the single listed ExerciseDate.

AmericanOpt	NINST-by-1 vector of flags. AmericanOpt is 1 for each American option. The AmericanOpt argument is required to invoke American exercise rules.
Period	(Optional) NINST-by-1 matrix for coupons per year. The default value is 2.
Basis	<p>(Optional) Day-count basis of the instrument. Basis is a vector of integers with the following possible values:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
EndMonthRule	(Optional) NINST-by-1 matrix for the end-of-month rule. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. When the value is 0, the end-of-month rule is ignored, meaning that a bond's coupon payment date is always the same numerical day of the month. When the value is 1, the end-of-month rule is set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) NINST-by-1 matrix for the bond issue date.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

LastCouponDate	(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.
StartDate	(Optional) NINST-by-1 matrix for date when a bond actually starts (that is, the date from which a bond's cash flows can be considered). To make an instrument forward starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the Settle date.
Face	(Optional) Face is a NINST-by-1 vector or NINST-by-1 cell array of face values, or face value schedules. For the latter case, each element of the cell array is a NumDates-by-2 cell array, where the first column is dates and the second column is its associated face value. The date indicates the last day that the face value is valid. Default is 100.

**Note** Data arguments are NINST-by-1 vectors, scalar, or empty. Fill in unspecified entries vectors with NaN. Only one data argument is required to create the instrument. The others may be omitted or passed as empty matrices [ ].

## Description

InstSet = instoptembnd

(CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'AmericanOpt',AmericanOpt,'Period',Period,'Basis',Basis,'EndMonthRule',EndMonthRule,'Face',Face,'IssueDate',IssueDate,'FirstCouponDate',FirstCouponDate,'LastCouponDate',LastCouponDate,'StartDate',StartDate) creates InstSet, a variable containing a collection of instruments.

**Note** instopembnd uses optional parameter name-value pairs such that, 'Name1', Value1, 'Name2', Value2, and so on, are a variable length list of name-value pairs.

Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or character vector for each instrument. See instget for more information on the InstSet variable.

InstSet = instoptembnd(InstSetOld, CouponRate,...) adds 'OptEmBond' instruments to an instrument variable.

[FieldList,ClassList,TypeString] = instoptembnd lists field metadata for the 'OptEmBond' instrument.

FieldList is a number of fields (NFIELDS-by-1) cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` is an `NFIELDS`-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

`TypeString` is a character vector specifying the type of instrument added. For a bond option instrument, `TypeString` = 'OptEmBond'.

## Examples

### Create a Bond With an Embedded Option

This example shows how to create a bond with an embedded option using the following data.

```
Settle = 'jan-1-2007';
Maturity = 'jan-1-2010';
CouponRate = 0.07;
OptSpec = 'call';
Strike = 100;
ExerciseDates = {'jan-1-2008' '01-Jan-2010'};
AmericanOpt = 1;
Period = 1;
```

```
InstSet = instoptembnd(CouponRate, ...
    Settle, Maturity, OptSpec, Strike, ExerciseDates, 'AmericanOpt', AmericanOpt, ...
    'Period', Period);
```

```
% display the instrument
instdisp(InstSet)
```

Index	Type	CouponRate	Settle	Maturity	OptSpec	Strike	ExerciseDates
1	OptEmBond	0.07	01-Jan-2007	01-Jan-2010	call	100	01-Jan-2008 01-Jan-2010

## Introduced in R2008a

## instoptfloat

Create option instrument on floating-rate note or add instrument to current portfolio

### Syntax

```
InstSet = instoptfloat(FloatIndex,OptSpec,Strike,ExerciseDates)
InstSet = instoptfloat(FloatIndex,OptSpec,Strike,ExerciseDates,AmericanOpt)
```

```
InstSet = instoptfloat(InstSetOld, ___)
```

```
[FieldList,ClassList,TypeString] = instoptfloat
```

### Description

`InstSet = instoptfloat(FloatIndex,OptSpec,Strike,ExerciseDates)` to specify a European option for a floating-rate note.

`InstSet = instoptfloat(FloatIndex,OptSpec,Strike,ExerciseDates,AmericanOpt)` to specify an American or Bermuda option for a floating-rate note.

`InstSet = instoptfloat(InstSetOld, ___)` to add instruments to an existing portfolio.

`[FieldList,ClassList,TypeString] = instoptfloat` lists the field metadata for the 'OptFloat' instrument.

### Examples

#### Create an Instrument Portfolio with a Call Option for a Floating-Rate Note

Define the floating-rate note:

```
Settle = 'Nov-1-2012';
Maturity = 'Nov-1-2015';
Spread = 50;
Reset = 1;
```

Create InstSet:

```
InstSet = instfloat(Spread, Settle, Maturity, Reset)
```

```
InstSet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
    Type: {'Float'}
    FieldName: {{9x1 cell}}
    FieldClass: {{9x1 cell}}
    FieldData: {{9x1 cell}}
```

Display the instrument:

```
instdisp(InstSet)
```

Index	Type	Spread	Settle	Maturity	FloatReset	Basis	Principal	EndMonthRule	CapRate
1	Float	50	01-Nov-2012	01-Nov-2015	1	0	100	1	Inf

Add a European call option to the instrument portfolio:

```
OptSpec = 'call';
Strike = 100;
ExerciseDates = 'Nov-1-2015';
```

Create InstSet:

```
InstSet = instoptfloat(InstSet, 1, OptSpec, Strike, ExerciseDates)
```

```
InstSet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
        Type: {2x1 cell}
        FieldName: {2x1 cell}
        FieldClass: {2x1 cell}
        FieldData: {2x1 cell}
```

Display the instrument:

```
instdisp(InstSet)
```

Index	Type	Spread	Settle	Maturity	FloatReset	Basis	Principal	EndMonthRule	CapRate
1	Float	50	01-Nov-2012	01-Nov-2015	1	0	100	1	Inf

Index	Type	UnderInd	OptSpec	Strike	ExerciseDates	AmericanOpt
2	OptFloat	1	call	100	01-Nov-2015	0

## Input Arguments

### FloatIndex — Indices pointing to underlying instruments

vector of nonnegative integers

Indices pointing to underlying instruments of Type 'Float' specified by a NINST-by-1 vector. The instruments of Type 'Float' are also stored in the InstSet variable. For more information, see `instfloat`.

Data Types: double

### OptSpec — Definition of option

character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: char | cell

### Strike — Option strike price values for European, Bermuda, or American option

nonnegative integer | vector of nonnegative integers

Option strike price values for option (European, Bermuda, or American) specified as nonnegative integers using as NINST-by-NSTRIKES vector of strike price values.

- For a European or Bermuda option — NINST-by-NSTRIKES matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American Option — NINST-by-1 vector of strike price values for each option.

Data Types: `single` | `double`

### **ExerciseDates — Exercise date for option (European, Bermuda, or American)**

`serial date number` | `vector of serial date numbers` | `date character vector` | `cell array of date character vectors`

Exercise date for option (European, Bermuda, or American), specified as serial date numbers or date character vectors using a NINST-by-NSTRIKES or NINST-by-2 vector of for the option exercise dates, depending on the option type.

- For a European or Bermuda option — NINST-by-NSTRIKES matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one ExerciseDate on the option expiry date
- For an American option — NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is NINST-by-1, the option can be exercised between the underlying bond Settle date and the single listed ExerciseDate.

Data Types: `double` | `char` | `cell`

### **AmericanOpt — Option type**

0 if AmericanOpt is NaN or not entered (default) | `scalar` | `vector of positive integers[0,1]`

Option type specified as NINST-by-1 positive integer scalar flags with values.

- For a European or Bermuda option — AmericanOpt is 0 for each European or Bermuda option.
- For an American option — AmericanOpt is 1 for each American option. The AmericanOpt argument is required to invoke American exercise rules.

Data Types: `single` | `double`

### **InstSetOld — Variable containing an existing collection of instruments**

`struct`

Variable containing an existing collection of instruments, specified as a struct. For more information on the InstSet variable, see `instget`.

Data Types: `struct`

## **Output Arguments**

### **InstSet — Variable containing a collection of instruments**

`scalar` | `vector`

Variable containing a collection of instruments returned as a scalar or vector with the instruments broken down by type and each type can have different data fields. Each stored data field has a row

vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

**FieldList – Data field for instrument type**

character vector | cell array of character vectors

Data field for instrument type returned as a `NFIELDS`-by-1 cell array of character vectors listing the name of each data field for this instrument type.

**ClassList – Data class of each field**

character vector with value: 'dble', 'date', 'char' | cell array of character vectors with values: 'dble', 'date', 'char'

Data class of each field returned as a `NFIELDS`-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed.

**TypeString – Type of instrument added**

character vector with value 'OptFloat'

Type of instrument added returned as a character vector. The character vector for a floating-rate option instrument is `TypeString = 'OptFloat'`.

## instoptemfloat

Create embedded option instrument on floating-rate note or add instrument to current portfolio

### Syntax

```
InstSet = instoptemfloat(Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates)
InstSet = instoptemfloat( ____,Name,Value)
```

```
InstSet = instoptemfloat(InstSetOld,Spread,Settle,Maturity,OptSpec,Strike,
ExerciseDates)
[FieldList,ClassList,TypeString] = instoptemfloat
```

### Description

`InstSet = instoptemfloat(Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates)` creates an embedded option instrument for a floating-rate note.

`InstSet = instoptemfloat( ____,Name,Value)` adds optional name-value pair arguments.

`InstSet = instoptemfloat(InstSetOld,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates)` to add 'OptEmFloat' instruments to an instrument variable.

`[FieldList,ClassList,TypeString] = instoptemfloat` lists field metadata for the 'OptEmFloat' instrument.

### Examples

#### Create an Instrument Portfolio with a Embedded Option Floating-Rate Note

Define the embedded call option:

```
Settle = 'Nov-1-2012';
Maturity = 'Nov-1-2015';
Spread = 25;
OptSpec = 'call';
Strike = 100;
ExerciseDates = 'Nov-1-2015';
Reset = 1;
```

Create InstSet:

```
InstSet = instoptemfloat(Spread, Settle, Maturity, OptSpec, ...
Strike, ExerciseDates, 'FloatReset', Reset)
```

```
InstSet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
    Type: {'OptEmFloat'}
    FieldName: {{13x1 cell}}
    FieldClass: {{13x1 cell}}
```

```
FieldData: {{13x1 cell}}
```

Display the instrument:

```
instdisp(InstSet)
```

Index	Type	Spread	Settle	Maturity	OptSpec	Strike	ExerciseDates	FloatReset	B
1	OptEmFloat	25	01-Nov-2012	01-Nov-2015	call	100	01-Nov-2015	1	0

## Input Arguments

### Spread — Number of basis points over the reference rate

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: single | double

### Settle — Settlement dates of floating-rate note

ValuationDate of HW Tree (default) | serial date number | character vector | cell array of character vectors

Settlement dates of floating-rate note, specified as serial date numbers or date character vectors using a NINST-by-1 vector or cell array of character vector dates.

Data Types: double | char | cell

### Maturity — Floating-rate note maturity date

serial date number | character vector | cell array of character vectors

Floating-rate note maturity date, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: double | char | cell

### OptSpec — Definition of option

character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: char | cell

### Strike — Embedded option strike price values

nonnegative integer | vector of nonnegative integers

Embedded option strike price values for option specified as nonnegative integers using as NINST-by-NSTRIKES or NINST-by-1 vector of strike price values, depending on the type of option.

- For a European or Bermuda Option — NINST-by-NSTRIKES matrix of strike price values where each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.

- For an American Option — NINST-by-1 vector of strike price values for each option.

Data Types: `single` | `double`

### **ExerciseDates — Exercise date for embedded option**

serial date nonnegative number | vector of serial date nonnegative numbers | date character vector | cell array of date character vectors

Exercise date for embedded option, specified as serial date nonnegative numbers or date character vectors using a NINST-by-NSTRIKES or NINST-by-2 vector of the option exercise dates, depending on the type of option.

- For a European or Bermuda Option — NINST-by-NSTRIKES of exercise dates where each row is the schedule for one option. For a European option, there is only one `ExerciseDate` on the option expiry date.
- For an American Option — NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is NINST-by-1, the option can be exercised between the underlying bond `Settle` date and the single listed `ExerciseDate`.

Data Types: `double` | `char` | `cell`

### **InstSetOld — Variable containing an existing collection of instruments**

struct

Variable containing an existing collection of instruments, specified as a struct. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. For more information on instrument data parameters, see the reference entries for individual instrument types. For example, see `instfloat` for additional information on the float instrument.

Data Types: `struct`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `InstSet = instoptemfloat(Spread, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'FloatReset', Reset)`

### **AmericanOpt — Embedded option type**

0 if `AmericanOpt` is NaN or not entered (default) | scalar | vector of positive integers [0, 1]

Embedded option type, specified as the comma-separated pair consisting of '`AmericanOpt`' and a NINST-by-1 positive integer scalar flags with values:

- For a European or Bermuda option — `AmericanOpt` is 0 for each European or Bermuda option. The default is 0 if `AmericanOpt` is NaN or not entered.
- For an American option — `AmericanOpt` is 1 for each American option. The `AmericanOpt` argument is required to invoke American exercise rules.

Data Types: `single` | `double`

**FloatReset — Frequency of payments per year**

1 (default) | positive integer from the set [1, 2, 3, 4, 6, 12] | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values 1, 2, 4, 6, 12] in a NINST-by-1 vector.

Data Types: single | double

**Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. The Basis value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: single | double

**Principal — Principal values**

100 (default) | nonnegative integer | vector of nonnegative integers | cell array of nonnegative integers

Principal values, specified as the comma-separated pair consisting of 'Principal' and a nonnegative integer using a NINST-by-1 vector of notional principal amounts.

Data Types: single | double

**Options — Structure containing derivatives pricing options**

structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure using derivset.

Data Types: struct

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: single | double

**Output Arguments****InstSet — Variable containing a collection of instruments**

scalar | vector

Variable containing a collection of instruments returned as a scalar or vector with the instruments broken down by type and each type can have different data fields. Each stored data field has a row vector or character vector for each instrument. For more information on the InstSet variable, see `instget`.

**FieldList — Name of each data field**

character vector | cell array of character vectors

NFIELDS-by-1 cell array of character vectors listing the name of each data field for this instrument type.

**ClassList — Determines how arguments are parsed**

character vector with value: 'dble', 'date', or 'char' | cell array of character vectors with values: 'dble', 'date', or 'char'

NFIELDS-by-1 cell array of character vectors listing the data class of each field.

**TypeString — Type of instrument added**

character vector with value 'OptEmFloat'

Character vector specifying the type of instrument added where TypeString = 'OptEmFloat'.

**See Also**`instadd` | `instoptfloat`**Topics**

# instoptstock

Construct stock option

## Syntax

```
InstSet = instoptstock(OptSpec,Strike,Settle,ExerciseDates)
InstSet = instoptstock(InstSet,OptSpec,Strike,Settle,ExerciseDates)
InstSet =
instoptstock(InstSet,OptSpec,Strike,Settle,ExerciseDates,AmericanOpt)
[FieldList,ClassList,TypeString] = instoptstock
```

## Arguments

InstSet	Instrument variable. This argument is specified only when adding stock option instruments to an existing instrument set. See <code>instget</code> for more information on the <code>InstSet</code> variable.
OptSpec	NINST-by-1 list of character vector values 'Call' or 'Put'.
<b>Note</b> The interpretation of the <code>Strike</code> and <code>ExerciseDates</code> arguments depends upon the setting of the <code>AmericanOpt</code> argument. If <code>AmericanOpt</code> = 0, NaN, or is unspecified, the option is a European or Bermuda option. If <code>AmericanOpt</code> = 1, the option is an American option.	
Strike	European option: NINST-by-1 vector of strike price values.  Bermuda option: NINST by number of strikes (NSTRIKES) matrix of strike price values.  Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.  American option: NINST-by-1 vector of strike price values for each option.
Settle	NINST-by-1 vector of settlement dates.
ExerciseDates	NINST-by-1 (European option) or NINST-by-NSTRIKES (Bermuda option) matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one exercise date, the option expiry date.  For an American option:  NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if <code>ExerciseDates</code> is NINST-by-1, the option can be exercised between the underlying bond <code>Settle</code> and the single listed exercise date.

Data arguments are NINST-by-1 vectors, scalar, or empty. Fill in unspecified entries vectors with NaN. Only one data argument is required to create the instrument. The others may be omitted or passed as empty matrices [].

## Description

`InstSet = instoptstock(OptSpec,Strike,Settle,ExerciseDates)` creates a stock option instrument, specified as a European or Bermuda option.

`InstSet = instoptstock(InstSet,OptSpec,Strike,Settle,ExerciseDates)` adds a stock option instrument, specified as a European or Bermuda option, to an existing instrument set.

`InstSet = instoptstock(InstSet,OptSpec,Strike,Settle,ExerciseDates,AmericanOpt)` specifies an American option if `AmericanOpt` is set to 1. If `AmericanOpt` is not set to 1, the function specifies a European or Bermuda option.

`[FieldList,ClassList,TypeString] = instoptstock` displays the classes.

`FieldList` is a number of fields (NFIELDS-by-1) cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` is an NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

`TypeString` is a character vector specifying the type of instrument added. For a stock option instrument, `TypeString = 'OptStock'`.

## Examples

### Create a Stock Option Instrument

Create an instrument set of two stock options with the following data:

```
OptSpec = {'put';'call'};
Strike = [95;98];
Settle = '01-May-2012';
ExerciseDates = {'01-May-2014';'01-May-2015'};
AmericanOpt = [0;1];
```

Create the stock option instruments.

```
InstSet = instoptstock(OptSpec, Strike,Settle, ExerciseDates, AmericanOpt)
```

```
InstSet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
    Type: {'OptStock'}
    FieldName: {{5x1 cell}}
    FieldClass: {{5x1 cell}}
    FieldData: {{5x1 cell}}
```

Display the instrument set.

```
instdisp(InstSet)
```

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt
1	OptStock	put	95	01-May-2012	01-May-2014	0

---

2    OptStock call    98    01-May-2012    01-May-2015    1

## instrangefloat

Construct range note instrument

### Syntax

```
ISet =  
instrangefloat(Spread, Settle, Maturity, RateSched, Reset, Basis, Principal, EndMonthRule)  
ISet =  
instrangefloat(ISet, Spread, Settle, Maturity, RateSched, Reset, Basis, Principal, EndMonthRule)
```

### Description

ISet =  
instrangefloat(Spread, Settle, Maturity, RateSched, Reset, Basis, Principal, EndMonthRule) creates a range instrument from data arrays.

ISet =  
instrangefloat(ISet, Spread, Settle, Maturity, RateSched, Reset, Basis, Principal, EndMonthRule) adds a new range instrument to an existing instrument set.

### Input Arguments

#### Spread

Number of basis points over the reference rate.

#### Settle

NINST-by-1 vector of dates representing the settle date of the floating-rate note.

#### Maturity

NINST-by-1 vector of dates representing the maturity date of the floating-rate note.

#### RateSched

NINST-by-1 vector of structures representing the range of rates within which cash flows are nonzero. Each element of the structure array contains two fields:

- RateSched.Dates — NDates-by-1 cell array of dates corresponding to the range schedule.
- RateSched.Rates — NDates-by-2 array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date RateSched.Dates(*n*) is nonzero for rates in the range RateSched.Rates(*n*,1) < Rate < RateSched.Rate(*n*,2).

#### Reset

(Optional) NINST-by-1 vector representing the frequency of payments per year.

**Default:** 1

### **Basis**

(Optional) Day-count basis of the instrument. A vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

**Default:** 0 (actual/actual)

### **Principal**

(Optional) NINST-by-1 vector of the notional principal amount.

**Default:** 100

### **EndMonthRule**

(Optional) NINST-by-1 vector for end-of-month rule. Values are 1 (in effect) and 0 (not in effect).

**Default:** 1 (in effect)

---

**Note** Data arguments are number of instruments NINST-by-1 vectors, scalar, or empty. Fill in unspecified entries vectors with NaN. Only one data argument is required to create the instrument. You can omit or pass the others as empty matrices [ ]. However, you cannot price the instrument when using the range note pricing function if you are missing any of the required input arguments.

---

## **Output Arguments**

### **ISet**

Variable containing a collection of instruments. Instruments are divided by type and each type can have different data fields. Each stored data field has a row vector or character vector for each instrument. Values are:

- `FieldList` — NFIELDS-by-1 cell array of character vectors listing the name of each data field for this instrument type.
- `ClassList` — NFIELDS-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.
- `TypeString` — Character vector specifying the type of instrument added. `TypeString = 'RangeFloat'`.

For more information, on `ISet` see `instget`.

## Examples

### Create a Range Note Instrument

Create an instrument portfolio with a range note.

```
Spread = 100;
Settle = 'Jan-1-2011';
Maturity = 'Jan-1-2014';
```

```
RateSched.Dates = {'Jan-1-2012'; 'Jan-1-2013' ; 'Jan-1-2014'};
RateSched.Rates = [0.045 0.055; 0.0525 0.0675; 0.06 0.08];
```

```
% Create InstSet
```

```
InstSet = instrangefloat(Spread, Settle, Maturity, RateSched);
```

```
% Display the portfolio instrument
```

```
instdisp(InstSet)
```

Index	Type	Spread	Settle	Maturity	RateSched	FloatReset	Basis	Principal	EndMon
1	RangeFloat	100	01-Jan-2011	01-Jan-2014	[Struct]	1	0	100	1

Add a second range note instrument to the portfolio. Second Range Note:

```
Spread2 = 200;
Settle2 = 'Jan-1-2011';
Maturity2 = 'Jan-1-2013';
RateSched2.Dates = {'Jan-1-2012'; 'Jan-1-2013'};
RateSched2.Rates = [0.048 0.059; 0.055 0.068];
```

```
InstSet = instrangefloat(InstSet, Spread2, Settle2, Maturity2, RateSched2);
```

```
% Display the portfolio instrument
```

```
instdisp(InstSet)
```

Index	Type	Spread	Settle	Maturity	RateSched	FloatReset	Basis	Principal	EndMon
1	RangeFloat	100	01-Jan-2011	01-Jan-2014	[Struct]	1	0	100	1
2	RangeFloat	200	01-Jan-2011	01-Jan-2013	[Struct]	1	0	100	1

## More About

### Range Note Instrument

A range note is a structured (market-linked) security whose coupon rate is equal to the reference rate as long as the reference rate is within a certain range.

If the reference rate is outside of the range, the coupon rate is 0 for that period. This type of instrument entitles the holder to cash flows that depend on the level of some reference interest rate and are floored to be positive. The note holder gets direct exposure to the reference rate. In return for the drawback that no interest is paid for the time the range is left, they offer higher coupon rates than comparable standard products, like vanilla floating notes.

## Introduced in R2012a

## instselect

Create instrument subset by matching conditions

### Syntax

```
InstSubSet =
instselect(InstSet, 'FieldName', FieldList, 'Data', DataList, 'Index', IndexSet, 'Type', TypeList)
```

### Arguments

InstSet	Variable containing a collection of instruments. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.
FieldList	Number of fields, specified as a NFIELDS-by-1 cell array of character vectors listing the name of each data field to match with data values.
DataList	Number of values (NVALUES-by-M) array or NFIELDS-by-1 cell array of acceptable data values for each field. Each row lists a data row value to search for in the corresponding FieldList. The number of columns is arbitrary and matching ignores trailing NaNs or spaces.
IndexSet	(Optional) Number of instruments, specified as a NINST-by-1 vector restricting positions of instruments to check for matches. The default is all indices available in the instrument variable.
TypeList	(Optional) Number of types, specified as a NTYPES-by-1 cell array of character vectors restricting instruments to match one of TypeList types. The default is all types in the instrument variable.

Argument value pairs can be entered in any order. The `InstSet` variable must be the first argument. 'FieldName' and 'Data' arguments must appear together or not at all. 'Index' and 'Type' arguments are each optional.

### Description

```
InstSubSet =
instselect(InstSet, 'FieldName', FieldList, 'Data', DataList, 'Index', IndexSet, 'Type', TypeList)
```

creates an instrument subset (`InstSubSet`) from an existing set of instruments (`InstSet`).

`InstSubSet` is a variable containing instruments matching the input criteria. Instruments are returned in `InstSubSet` if all the `Field`, `Index`, and `Type` conditions are met. An instrument meets an individual `Field` condition if the stored `FieldName` data matches any of the rows listed in the `DataList` for that `FieldName`. See `instfind` for examples on matching criteria.

### Examples

Retrieve the instrument set `ExampleInst` from the data file `InstSetExamples.mat`. The variable contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples
instdisp(ExampleInst)
```

Index	Type	Strike	Price	Opt	Contracts
1	Option	95	12.2	Call	0
2	Option	100	9.2	Call	0
3	Option	105	6.8	Call	1000

Index	Type	Delivery	F	Contracts
4	Futures	01-Jul-1999	104.4	-1000

Index	Type	Strike	Price	Opt	Contracts
5	Option	105	7.4	Put	-1000
6	Option	95	2.9	Put	0

Index	Type	Price	Maturity	Contracts
7	TBill	99	01-Jul-1999	6

Make a new portfolio containing only options struck at 95.

```
Opt95 = instselect(ExampleInst, 'FieldName', 'Strike', ...
'Data', '95')
```

```
instdisp(Opt95)
```

```
Opt95 =
```

Index	Type	Strike	Price	Opt	Contracts
1	Option	95	12.2	Call	0
2	Option	95	2.9	Put	0

Make a new portfolio containing only futures and Treasury bills.

```
FutTBill = instselect(ExampleInst, 'Type', {'Futures'; 'TBill'})
```

```
instdisp(FutTBill) =
```

Index	Type	Delivery	F	Contracts
1	Futures	01-Jul-1999	104.4	-1000

Index	Type	Price	Maturity	Contracts
2	TBill	99	01-Jul-1999	6

## instsetfield

Add or reset data for existing instruments

### Syntax

```
InstSet = instsetfield(InstSet,'FieldName',FieldList,'Data',DataList)
InstSet =
instsetfield(InstSet,'FieldName',FieldList,'Data',DataList,'Index',IndexSet,'
Type',TypeList)
```

### Arguments

InstSet	Variable containing a collection of instruments. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. InstSet must be the first argument in the list.
FieldList	Number of fields, specified as a NFIELDS-by-1 cell array of character vectors listing the name of each data field. FieldList cannot be named with the reserved names Type or Index.
DataList	Number of instruments, specified as a NINST-by-M array or NFIELDS-by-1 cell array of data contents for each field. Each row in a data array corresponds to a separate instrument. Single rows are copied to apply to all instruments to be worked on. The number of columns is arbitrary, and data is padded along columns.
IndexSet	NINST-by-1 vector of positions of instruments to work on. If TypeList is also entered, instruments referenced must be one of TypeList types and contained in IndexSet.
TypeList	Number of types, specified as a NTYPES-by-1 cell array of character vectors restricting instruments worked on to match one of TypeList types.

Argument value pairs can be entered in any order.

### Description

instsetfield sets data for existing instruments in a collection variable.

InstSet = instsetfield(InstSet,'FieldName',FieldList,'Data',DataList) resets or adds fields to every instrument.

InstSet = instsetfield(InstSet,'FieldName',FieldList,'Data',DataList,'Index',IndexSet,'Type',TypeList) resets or adds fields to a subset of instruments.

The output InstSet is a new instrument set variable containing the input data.

## Examples

Retrieve the instrument set ExampleInstSF from the data file InstSetExamples.mat. ExampleInstSF contains three types of instruments: Option, Futures, and TBill.

```
load InstSetExamples;
ISet = ExampleInstSF;
instdisp(ISet)
```

```
Index Type   Strike Price Opt
1   Option  95    12.2 Call
2   Option 100    9.2  Call
3   Option 105    6.8  Call
```

```
Index Type   Delivery      F
4   Futures 01-Jul-1999  104.4
```

```
Index Type   Strike Price Opt
5   Option 105    7.4  Put
6   Option NaN   NaN  Put
```

```
Index Type   Price
7   TBill 99
```

Enter data for the option in Index 6: Price 2.9 for a Strike of 95.

```
ISet = instsetfield(ISet, 'Index',6,...
'FieldName',{'Strike','Price'}, 'Data',{ 95 , 2.9 });
instdisp(ISet)
```

```
Index Type   Strike Price Opt
1   Option  95    12.2 Call
2   Option 100    9.2  Call
3   Option 105    6.8  Call
Index Type   Delivery      F
4   Futures 01-Jul-1999  104.4
Index Type   Strike Price Opt
5   Option 105    7.4  Put
6   Option  95    2.9  Put
```

```
Index Type   Price
7   TBill 99
```

Create a field Maturity for the cash instrument.

```
MDate = datenum('7/1/99');
ISet = instsetfield(ISet, 'Type', 'TBill', 'FieldName',...
'Maturity','FieldClass', 'date', 'Data', MDate);
instdisp(ISet)
```

```
Index Type   Price Maturity
7   TBill 99    01-Jul-1999
```

Create a field Contracts for all instruments.

```
ISet = instsetfield(ISet, 'FieldName', 'Contracts', 'Data', 0);
instdisp(ISet)
```

```
Index Type   Strike Price Opt Contracts
1   Option  95    12.2 Call  0
```

```

2   Option 100    9.2 Call 0
3   Option 105    6.8 Call 0

Index Type    Delivery      F    Contracts
4   Futures 01-Jul-1999  104.4 0

Index Type    Strike Price Opt  Contracts
5   Option 105    7.4 Put  0
6   Option 95    2.9 Put  0

Index Type    Price Maturity    Contracts
7   TBill 99    01-Jul-1999  0

```

Set the `Contracts` fields for some instruments.

```

ISet = instsetfield(ISet,'Index',[3; 5; 4; 7],...
'FieldName','Contracts', 'Data',[1000; -1000; -1000; 6]);

```

```
instdisp(ISet)
```

```

Index Type    Strike Price Opt  Contracts
1   Option 95    12.2 Call  0
2   Option 100    9.2 Call  0
3   Option 105    6.8 Call 1000

Index Type    Delivery      F    Contracts
4   Futures 01-Jul-1999  104.4 -1000

Index Type    Strike Price Opt  Contracts
5   Option 105    7.4 Put  -1000
6   Option 95    2.9 Put   0

Index Type    Price Maturity    Contracts
7   TBill 99    01-Jul-1999  6

```

# instswap

Construct swap instrument

## Syntax

```

InstSet = instswap(LegRate,Settle,Maturity)
InstSet = instswap(InstSet,LegRate,Settle,Maturity)
InstSet =
instswap(InstSet,LegRate,Settle,Maturity,InstSet,LegReset,Basis,Principal,Leg
Type,EndMonthRule)
InstSet =
instswap(InstSet,LegRate,Settle,Maturity,LegReset,Basis,Principal,LegType,End
MonthRule,StartDate)
[FieldList,ClassList,TypeString] = instswap

```

## Arguments

InstSet	Instrument variable. This argument is specified only when adding a swap to an existing instrument set. See <code>instget</code> for more information on the <code>InstSet</code> variable.
LegRate	Leg rate, specified as a NINST-by-2 matrix, with each row defined as:  [CouponRate Spread] (fixed-float), [Spread CouponRate] (float-fixed), [CouponRate CouponRate] (fixed-fixed), or [Spread Spread] (float-float).  CouponRate is the decimal annual rate. Spread is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.
Settle	Settlement date. NINST-by-1 vector of serial date numbers or date character vectors. <code>Settle</code> must be earlier than <code>Maturity</code> .
Maturity	Maturity date. NINST-by-1 vector of dates representing the maturity date for each swap.
LegReset	(Optional) NINST-by-2 matrix representing the reset frequency per year for each swap. Default = [1 1].

<b>Basis</b>	<p>(Optional) Day-count basis representing the basis for each leg. <b>NINST-by-1</b> array (or <b>NINST-by-2</b> if <b>Basis</b> is different for each leg).</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
<b>Principal</b>	<p>(Optional) <b>Principal</b> accepts a <b>NINST-by-1</b> vector or <b>NINST-by-1</b> cell array (or <b>NINST-by-2</b> if <b>Principal</b> is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a <b>NumDates-by-2</b> matrix where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid. Default = 100.</p>
<b>LegType</b>	<p>(Optional) <b>NINST-by-2</b> matrix. Each row represents an instrument. Each column indicates if the corresponding leg is fixed (1) or floating (0). This matrix defines the interpretation of the values entered in <b>LegRate</b>. Default is [1, 0] for each instrument.</p>
<b>EndMonthRule</b>	<p>(Optional) <b>NINST-by-1</b> (or <b>NINST-by-2</b> if <b>EndMonthRule</b> is different for each leg). Default = 1.</p>
<b>StartDate</b>	<p>(Optional) <b>NINST-by-1</b> vector of dates when the swaps actually start. Default is <b>Settle</b>.</p>

Data arguments are number of instruments (**NINST**)-by-1 vectors, scalar, or empty. Fill in unspecified entries vectors with **NaN**. Only one data argument is required to create the instrument; the others may be omitted or passed as empty matrices [ ].

## Description

**InstSet = instswap(LegRate, Settle, Maturity)** creates a new instrument set containing swap instruments.

**InstSet = instswap(InstSet, LegRate, Settle, Maturity)** adds swap instruments to an existing instrument set.

`InstSet = instswap(InstSet, LegRate, Settle, Maturity, InstSet, LegReset, Basis, Principal, LegType, EndMonthRule)` uses optional input arguments to create a new instrument set containing swap instruments or adds swap instruments to an existing instrument set.

`InstSet = instswap(InstSet, LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType, EndMonthRule, StartDate)` to create a new forward swap instrument or to add a forward swap instrument to an existing portfolio.

`[FieldList, ClassList, TypeString] = instswap` displays the classes.

`FieldList` is a number of fields (NFIELDs-by-1) cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` is an NFIELDs-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

`TypeString` is a character vector specifying the type of instrument added. For a swap instrument, `TypeString = 'Swap'`.

## Examples

### Create a Vanilla Swap Instrument

Create a vanilla swap using market data.

Use the following market data to create a swap instrument.

```
LegRate = [0.065, 0]
```

```
LegRate = 1×2
```

```
    0.0650    0
```

```
Settle = 'jan-1-2007';
```

```
Maturity = 'jan-1-2012';
```

```
LegReset = [1, 1];
```

```
Basis = 0
```

```
Basis = 0
```

```
Principal = 100
```

```
Principal = 100
```

```
LegType = [1, 0]
```

```
LegType = 1×2
```

```
    1    0
```

```
InstSet = instswap(LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
InstSet = struct with fields:
    FinObj: 'Instruments'
    IndexTable: [1x1 struct]
        Type: {'Swap'}
    FieldName: {{9x1 cell}}
    FieldClass: {{9x1 cell}}
    FieldData: {{9x1 cell}}
```

View the swap instrument using `instdisp`.

```
instdisp(InstSet)
```

```
Index Type LegRate    Settle      Maturity      LegReset Basis Principal LegType EndMonthRule
1      Swap [0.065  0] 01-Jan-2007  01-Jan-2012  [1 1]  0    100    [1 0]  1
```

### Create a Float-Float Swap and Price with `intenvprice`

Use `instswap` to create a float-float swap and price the swap with `intenvprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([40 20],today,datemnth(today,60),[], [], [], [0 0]);
intenvprice(RateSpec,IS)
```

```
ans =
```

```
0.8644
```

### Create Float-Float, Fixed-Fixed, and Float-Fixed Swaps and Price with `intenvprice`

Use `instswap` to create swaps and price the swaps with `intenvprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([.03 .02],today,datemnth(today,60),[], [], [], [1 1]);
IS = instswap(IS,[200 300],today,datemnth(today,60),[], [], [], [0 0]);
IS = instswap(IS,[300 .07],today,datemnth(today,60),[], [], [], [0 1]);
intenvprice(RateSpec,IS)
```

```
ans = 3x1
```

```
4.3220
-4.3220
4.5921
```

## **More About**

### **Amortizing Swap**

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

### **Forward Swap**

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

## instswaption

Construct swaption instrument

### Syntax

```
InstSet = instswaption(OptSpec,Strike,ExerciseDates,Spread,Settle,Maturity)
InstSet = instswaption(____,AmericanOpt,SwapReset,Basis,Principal)
InstSet = instswaption(InstSetOld,____)
[FieldList,ClassList,TypeString] = instswaption
```

### Description

InstSet = instswaption(OptSpec,Strike,ExerciseDates,Spread,Settle,Maturity) to specify a European swaption.

Fill in unspecified entries vectors with the value NaN. Only one data argument is required to create the instruments; the others may be omitted or passed as empty matrices [ ].

InstSet = instswaption(\_\_\_\_,AmericanOpt,SwapReset,Basis,Principal) to specify an American swaption.

InstSet = instswaption(InstSetOld,\_\_\_\_) to add swaption instruments to an instrument variable.

[FieldList,ClassList,TypeString] = instswaption to list field metadata for the swaption instrument.

### Examples

#### Create Two Swaption Instruments

This example shows how to create two European swaption instruments using the following data.

```
OptSpec = {'Call'; 'Put'};
Strike = .05;
ExerciseDates = 'jan-1-2011';
Spread=0;
Settle = 'jan-1-2007';
Maturity = 'jan-1-2012';
AmericanOpt = 0;
```

```
InstSet = instswaption(OptSpec, Strike, ExerciseDates, Spread, Settle, Maturity, ...
    AmericanOpt);
```

```
% view the European swaption instruments using instdisp
instdisp(InstSet)
```

Index	Type	OptSpec	Strike	ExerciseDates	Spread	Settle	Maturity	AmericanOpt	Swaption
1	Swaption	Call	0.05	01-Jan-2011	0	01-Jan-2007	01-Jan-2012	0	1
2	Swaption	Put	0.05	01-Jan-2011	0	01-Jan-2007	01-Jan-2012	0	1

## Create Two European Swaption Instruments with Receiving and Paying Legs

This example shows how to create two European swaption instruments with receiving and paying legs using the following data.

```
OptSpec = {'Call'; 'Put'};
Strike = .05;
ExerciseDates = 'jan-1-2011';
Spread=0;
Settle = 'jan-1-2007';
Maturity = 'jan-1-2012';
AmericanOpt = 0;
SwapReset = [2 4]; % 1st column represents receiving leg, 2nd column represents paying leg
Basis = [1 3]; % 1st column represents receiving leg, 2nd column represents paying leg
```

```
InstSet = instswaption(OptSpec,Strike,ExerciseDates,AmericanOpt,Spread,Settle,Maturity, ...
SwapReset,Basis);
```

View the European swaption instruments using `instdisp`.

```
instdisp(InstSet)
```

Index	Type	OptSpec	Strike	ExerciseDates	Spread	Settle	Maturity	AmericanOpt	SwapReset
1	Swaption	Call	0.05	01-Jan-2011	0	0	01-Jan-2007	NaN	2 4
2	Swaption	Put	0.05	01-Jan-2011	0	0	01-Jan-2007	NaN	2 4

## Input Arguments

### OptSpec — Definition of option

cell array of character vectors with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors with values 'call' or 'put'. A 'call' swaption entitles the buyer to pay the fixed rate. A 'put' swaption entitles the buyer to receive the fixed rate.

Data Types: char | cell

### Strike — Strike swap rate values

vector

Strike swap rate values, specified as a NINST-by-1 vector.

Data Types: double

### ExerciseDates — Option exercise dates

serial date number | date character vector

Option exercise dates, specified as a vector of date character vectors or serial date numbers, where each row is the schedule for one option and the last element of each row must be the same as the maturity of the tree.

- For a European option, use a NINST-by-1 vector of exercise dates. Each row is the schedule for one option. For a European option, there is only one ExerciseDate on the option expiry date.

- For an American option, use a NINST-by-2 vector of exercise dates. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is NINST-by-1, the option can be exercised between the underlying swap `Settle` and the single listed `ExerciseDate`.

Data Types: double | char

### **Spread — Number of basis points over the reference rate**

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate, specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: single | double

### **Settle — Settle date for each swap**

serial date number | date character vector

Settle date for each swap, specified as a NINST-by-1 vector of date character vectors or serial date numbers.

Data Types: char | double

### **Maturity — Maturity date for each swap**

serial date number | date character vector

Maturity date for each swap, specified as a NINST-by-1 vector of date character vectors or serial date numbers.

Data Types: char | double

### **AmericanOpt — Option type**

0 European (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 integer flags with values:

- 0 — European
- 1 — American

The `AmericanOpt` argument is required to invoke American exercise rules.

Data Types: double

### **SwapReset — Reset frequency per year for each leg**

1 (default) | numeric

(Optional) Reset frequency per year for each leg, specified as a NINST-by-1 vector or NINST-by-2 matrix. If `SwapReset` is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

### **Basis — Day-count basis of instrument**

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis of the instrument, specified as a NINST-by-1 vector or NINST-by-2 matrix representing the basis for each leg. If `Basis` is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Principal — Notional principal amount**

100 (default) | numeric

(Optional) Notional principal amount, specified as a NINST-by-1 vector.

Data Types: double

### **InstSetOld — Variable containing an existing collection of instruments**

struct

Variable containing an existing collection of instruments, specified as a struct. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. The `InstSetOld` argument is specified only when adding swaption instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: struct

## **Output Arguments**

### **InstSet — Variable containing collection of instruments**

vector

(Optional) Variable containing a collection of instruments. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

Data Types: double

### **FieldList — Name of each data field for this instrument type**

cell array of character vectors

Name of each data field for this instrument type, returned as a NFIELDS-by-1 cell array of character vectors.

Data Types: char | cell

**ClassList – Data class of each field**

character vector with value: 'dble', 'date', or 'char'.

Data class of each field, returned as a NFIELDS-by-1 cell array of character vectors. Valid character vectors are 'dble', 'date', and 'char'.

Data Types: char | cell

**TypeString – Type of instrument added**

character vector

Type of instrument added, returned as a character vector (for a swaption, TypeString = 'Swaption').

Data Types: char

# insttypes

List types

## Syntax

```
TypeList = insttypes(InstSet)
```

## Arguments

InstSet	Variable containing a collection of instruments. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.
---------	---

## Description

`TypeList = insttypes(InstSet)` retrieves a list of types stored in an instrument variable.

`TypeList` is a number of types (NTYPES)-by-1 cell array of character vectors listing the Type of instruments contained in the variable.

## Examples

Retrieve the instrument set variable `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1   Option  95    12.2 Call   0
2   Option 100    9.2 Call   0
3   Option 105    6.8 Call 1000
```

```
Index Type   Delivery      F    Contracts
4   Futures 01-Jul-1999  104.4 -1000
```

```
Index Type   Strike Price Opt  Contracts
5   Option 105    7.4 Put  -1000
6   Option  95    2.9 Put   0
```

```
Index Type Price Maturity      Contracts
7   TBill 99    01-Jul-1999  6
```

List all of the types included in `ExampleInst`.

```
TypeList = insttypes(ExampleInst)
```

```
TypeList =
    'Futures'
    'Option'
    'TBill'
```

# intenvget

Properties of interest-rate structure

## Syntax

```
ParameterValue = intenvget(RateSpec,ParameterName)
```

## Description

`ParameterValue = intenvget(RateSpec,ParameterName)` obtains the value of the named parameter `ParameterName` extracted from the `RateSpec`.

## Examples

### Extract Values from a RateSpec

Use `intenvset` to set the interest-rate structure.

```
RateSpec = intenvset('Rates',0.05,'StartDates',...
'20-Jan-2000','EndDates','20-Jan-2001')
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: 0.9518
    Rates: 0.0500
    EndTimes: 2
    StartTimes: 0
    EndDates: 730871
    StartDates: 730505
    ValuationDate: 730505
    Basis: 0
    EndMonthRule: 1
```

Use `intenvget` to extract values from the `RateSpec`.

```
[R, RateSpec] = intenvget(RateSpec,'Rates')
```

```
R = 0.0500
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: 0.9518
    Rates: 0.0500
    EndTimes: 2
    StartTimes: 0
    EndDates: 730871
    StartDates: 730505
    ValuationDate: 730505
    Basis: 0
```

EndMonthRule: 1

## Input Arguments

### **RateSpec — Interest-rate specification**

structure

Interest-rate specification, specified by the RateSpec obtained previously from `intenvset` or `toRateSpec` for an `IRDataCurve` or `toRateSpec` for an `IRFunctionCurve`.

Data Types: `struct`

### **ParameterName — Parameter name to be accessed**

character vector

Parameter name to be accessed, specified as a character vector. The value of the named parameter is extracted from the structure `RateSpec`. It is sufficient to type only the leading characters that uniquely identify the parameter. Case is ignored for parameter names.

Data Types: `char`

## Output Arguments

### **ParameterValue — Value of the named parameter ParameterName extracted from RateSpec**

scalar

Value of the named parameter 'ParameterName' extracted from `RateSpec`, returned as a scalar value.

# intenvprice

Price instruments from set of zero curves

## Syntax

```
Price = intenvprice(RateSpecInstSet)
```

## Description

Price = intenvprice(RateSpecInstSet) computes arbitrage-free prices for instruments against a set of zero coupon bond rate curves.

intenvprice handles the following instrument types: 'Bond', 'CashFlow', 'Fixed', 'Float', 'Swap'. See instadd for information about constructing defined types.

## Examples

### Load Zero Curves and Instruments from Data File

Load the zero curves and instruments.

```
load deriv.mat
instdisp(ZeroInstSet)
```

Index	Type	CouponRate	Settle	Maturity	Period	Basis	EndMonthRule	IssueDate	FirstCou
1	Bond	0.04	01-Jan-2000	01-Jan-2003	1	NaN	NaN	NaN	NaN
2	Bond	0.04	01-Jan-2000	01-Jan-2004	2	NaN	NaN	NaN	NaN

Index	Type	CouponRate	Settle	Maturity	FixedReset	Basis	Principal	Name	Quantity

4	Float	20	01-Jan-2000	01-Jan-2003	1	NaN	NaN	20BP Float	8

Index	Type	LegRate	Settle	Maturity	LegReset	Basis	Principal	LegType	Name
5	Swap	[0.06 20]	01-Jan-2000	01-Jan-2003	[1 1]	NaN	NaN	[NaN]	6%/20BP Swap

Price the instruments.

```
Price = intenvprice(ZeroRateSpec, ZeroInstSet)
```

```
Price = 5x1

    98.7159
    97.5334
    98.7159
   100.5529
     3.6923
```

### Create a Float-Float Swap and Price with `intenvprice`

Use `instswap` to create a float-float swap and price the swap with `intenvprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([400 200],today,datemnth(today,60),[], [], [], [0 0]);
intenvprice(RateSpec,IS)
```

```
ans = 8.6440
```

### Create Float-Float, Fixed-Fixed, and Float-Fixed Swaps and Price with `intenvprice`

Use `instswap` to create swaps and price the swaps with `intenvprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([.03 .02],today,datemnth(today,60),[], [], [], [1 1]);
IS = instswap(IS,[200 300],today,datemnth(today,60),[], [], [], [0 0]);
IS = instswap(IS,[300 .07],today,datemnth(today,60),[], [], [], [0 1]);
intenvprice(RateSpec,IS)
```

```
ans =
```

```
    4.3220
   -4.3220
    4.5921
```

## Input Arguments

### RateSpec — Interest-rate specification

structure

(Optional) Interest-rate specification, specified by the `RateSpec` obtained previously from `intenvset` or `toRateSpec` for an `IRDataCurve` or `toRateSpec` for an `IRFunctionCurve`.

Data Types: `struct`

### InstSet — Instrument variable containing a collection of instruments

structure

Instrument variable containing a collection of instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

## Output Arguments

### Price — Prices of each instrument

matrix

Prices of each instrument, returned as a number of instruments (NINST) by number of curves (NUMCURVES) matrix. If an instrument cannot be priced, a NaN is returned in that entry.

For single-type pricing functions to retrieve pricing information, see the following:

bondbyzero	Price bonds from a set of zero curves.
cfbyzero	Price arbitrary cash flow instrument from a set of zero curves.
fixedbyzero	Fixed-rate note prices from a set of zero curves.
floatbyzero	Floating-rate note prices from a set of zero curves.
swapbyzero	Swap prices from a set of zero curves.

## intenvsens

Instrument price and sensitivities from set of zero curves

### Syntax

```
[Delta,Gamma,Price] = intenvprice(RateSpecInstSet)
```

### Description

[Delta,Gamma,Price] = intenvprice(RateSpecInstSet) computes dollar prices and price sensitivities for instruments that use a zero coupon bond rate structure.

intenvsens handles the following instrument types: 'Bond', 'CashFlow', 'Fixed', 'Float', 'Swap'. See instadd for information about constructing defined types.

### Examples

#### Compute Prices Sensitivities for Instruments Using a Zero Coupon Bond Rate Structure

Load the tree and instruments from the deriv.mat data file and use intenvprice to compute dollar prices and sensitivities for instruments that use a zero coupon bond rate structure.

```
load deriv.mat
instdisp(ZeroInstSet)
```

Index	Type	CouponRate	Settle	Maturity	Period	Basis	EndMonthRule	IssueDate	FirstCou
1	Bond	0.04	01-Jan-2000	01-Jan-2003	1	NaN	NaN	NaN	NaN
2	Bond	0.04	01-Jan-2000	01-Jan-2004	2	NaN	NaN	NaN	NaN

Index	Type	CouponRate	Settle	Maturity	FixedReset	Basis	Principal	Name	Quantity
3	Fixed	0.04	01-Jan-2000	01-Jan-2003	1	NaN	NaN	4% Fixed	80

```

## Input Arguments

### RateSpec — Interest-rate specification

structure

(Optional) Interest-rate specification, specified by the RateSpec obtained previously from `intenvset` or `toRateSpec` for an `IRDataCurve` or `toRateSpec` for an `IRFunctionCurve`.

Data Types: `struct`

### InstSet — Instrument variable containing a collection of instruments

structure

Instrument variable containing a collection of instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

## Output Arguments

### Delta — Rate of change of instrument prices with respect to shifts in the observed zero curve

vector

Rate of change of instrument prices with respect to shifts in the observed zero curve, returned as a number of instruments (NINST) by number of curves (NUMCURVES) matrix. Delta is computed by finite differences.

---

**Note** Delta sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

---

### Gamma — Rate of change of instrument deltas with respect to shifts in the observed zero curve

vector

Rate of change of instrument deltas with respect to shifts in the observed zero curve, returned as a number of instruments (NINST) by number of curves (NUMCURVES) matrix. Gamma is computed by finite differences.

---

**Note** Gamma sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

---

**Price – Prices of each instrument**

vector

Prices of each instrument, returned as a number of instruments (NINST) by number of curves (NUMCURVES) matrix. If an instrument cannot be priced, a NaN is returned in that entry.

# intenvset

Set properties of interest-rate structure

## Syntax

```
RateSpec = intenvset(Name,Value)
[RateSpec,RateSpecOld] = intenvset(RateSpec,Name,Value)
[RateSpec,RateSpecOld] = intenvset
```

## Description

`RateSpec = intenvset(Name,Value)` creates an interest-rate term structure (`RateSpec`) where the input argument list is specified as name-value pairs.

---

**Note** When creating a new `RateSpec`, the set of arguments passed to `intenvset` must include `StartDates`, `EndDates`, and either `Rates` or `Disc`.

---

`[RateSpec,RateSpecOld] = intenvset(RateSpec,Name,Value)` creates an interest-rate term structure (`RateSpec`) where the input argument list is specified as name-value pairs along with the optional argument `RateSpec`. If the optional argument `RateSpec` is specified, `intenvset` modifies the existing interest-rate term structure `RateSpec` by changing the named argument to the specified values and recalculating the arguments dependent on the new values.

`[RateSpec,RateSpecOld] = intenvset` creates an interest-rate term structure `RateSpec` with all fields set to [ ].

## Examples

### Create a RateSpec for a Zero Curve

Use `intenvset` to create a `RateSpec` for a zero curve.

```
RateSpec = intenvset('Rates', 0.05, 'StartDates', ...
'20-Jan-2000', 'EndDates', '20-Jan-2001')
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: 0.9518
    Rates: 0.0500
    EndTimes: 2
    StartTimes: 0
    EndDates: 730871
    StartDates: 730505
    ValuationDate: 730505
    Basis: 0
    EndMonthRule: 1
```

Now change the Compounding argument to 1 (annual).

```
RateSpec = intenvset(RateSpec, 'Compounding', 1)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: 0.9518
    Rates: 0.0506
    EndTimes: 1
    StartTimes: 0
    EndDates: 730871
    StartDates: 730505
    ValuationDate: 730505
    Basis: 0
    EndMonthRule: 1
```

Calling `intenvset` with no input or output arguments displays a list of argument names and possible values.

```
intenvset
```

```
Compounding: [ 0 | 1 | {2} | 3 | 4 | 6 | 12 | 365 | -1 ]
Disc: [ scalar | vector (NPOINTS x 1) ]
Rates: [ scalar | vector (NPOINTS x 1) ]
EndDates: [ scalar | vector (NPOINTS x 1) ]
StartDates: [ scalar | vector (NPOINTS x 1) ]
ValuationDate: [ scalar ]
Basis: [ {0} | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 ]
EndMonthRule: [ 0 | {1} ]
```

### Create a RateSpec for a Forward Curve

Use `intenvset` to create a `RateSpec` for a forward curve.

```
RateSpec = intenvset('Rates', 0.05, 'StartDates', ...
    '20-Jan-2001', 'EndDates', '20-Jan-2002', 'ValuationDate', '20-Jan-2000')
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: 0.9518
    Rates: 0.0500
    EndTimes: 4
    StartTimes: 2
    EndDates: 731236
    StartDates: 730871
    ValuationDate: 730505
    Basis: 0
    EndMonthRule: 1
```

Now change the Compounding argument to 1 (annual).

```
RateSpec = intenvset(RateSpec, 'Compounding', 1)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: 0.9518
    Rates: 0.0506
    EndTimes: 2
    StartTimes: 1
    EndDates: 731236
    StartDates: 730871
    ValuationDate: 730505
    Basis: 0
    EndMonthRule: 1
```

### Create a RateSpec Using Two Curves

Define data for the interest-rate term structure and use `intenvset` to create a `RateSpec`.

```
StartDates = '01-Oct-2011';
EndDates = ['01-Oct-2012'; '01-Oct-2013'; '01-Oct-2014'; '01-Oct-2015'];
Rates = [[0.0356;0.041185;0.04489;0.047741],[0.0325;0.0423;0.0437;0.0465]];
RateSpec = intenvset('Rates', Rates, 'StartDates',StartDates,...
    'EndDates', EndDates, 'Compounding', 1)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [4x2 double]
    Rates: [4x2 double]
    EndTimes: [4x1 double]
    StartTimes: [4x1 double]
    EndDates: [4x1 double]
    StartDates: 734777
    ValuationDate: 734777
    Basis: 0
    EndMonthRule: 1
```

To look at the `Rates` for the two interest-rate curves:

```
RateSpec.Rates
```

```
ans = 4x2
```

```
    0.0356    0.0325
    0.0412    0.0423
    0.0449    0.0437
    0.0477    0.0465
```

### Create a RateSpec to Price Multi-Stepped Coupon Bonds

Price the following multi-stepped coupon bonds using the following data:

```

Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2010';
StartDates = ValuationDate;
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'};
Compounding = 1;

% Create RateSpec using intenvset
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% Create a portfolio of stepped coupon bonds with different maturities
Settle = '01-Jan-2010';
Maturity = {'01-Jan-2011'; '01-Jan-2012'; '01-Jan-2013'; '01-Jan-2014'};
CouponRate = {'01-Jan-2011' .042; '01-Jan-2012' .05; '01-Jan-2013' .06; '01-Jan-2014' .07}};

% Display the instrument portfolio
ISet = instbond(CouponRate, Settle, Maturity, 1);
instdisp(ISet)

```

Index	Type	CouponRate	Settle	Maturity	Period	Basis	EndMonthRule	IssueDate	FirstCou
1	Bond	[Cell]	01-Jan-2010	01-Jan-2011	1	0	1	NaN	NaN
2	Bond	[Cell]	01-Jan-2010	01-Jan-2012	1	0	1	NaN	NaN
3	Bond	[Cell]	01-Jan-2010	01-Jan-2013	1	0	1	NaN	NaN
4	Bond	[Cell]	01-Jan-2010	01-Jan-2014	1	0	1	NaN	NaN

Build a BDTTtree to price the stepped coupon bonds. Assume the volatility to be 10%

```

Sigma = 0.1;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates)));
BDTT = bdttree(BDTVolSpec, RS, BDTTimeSpec);

% Compute the price of the stepped coupon bonds
PBDT = bdtprice(BDTT, ISet)

PBDT = 4x1

    100.6763
    100.7368
    100.9266
    101.0115

```

## Input Arguments

### RateSpec — Interest-rate specification for initial risk-free rate curve

structure

(Optional) Interest-rate specification for initial rate curve, specified by the RateSpec obtained previously from `intenvset` or `toRateSpec` for an `IRDataCurve` or `toRateSpec` for an `IRFunctionCurve`.

Data Types: struct

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `RateSpec = intenvset('Rates',0.05,'StartDates','20-Jan-2001','EndDates','20-Jan-2002','ValuationDate','20-Jan-2000')`

## Compounding — Rate at which the input zero rates were compounded when annualized

2 (default) | integer with value of 0, 1, 2, 3, 4, 6, 12, 365, or -1

Rate at which the input zero rates were compounded when annualized, specified as the comma-separated pair consisting of 'Compounding' and a scalar integer value. The Compounding argument determines the formula for the discount factors (`Disc`):

- Compounding = 0 for simple interest
  - $Disc = 1/(1 + Z * T)$ , where T is time in years and simple interest assumes annual times  $F = 1$ .
- Compounding = 1, 2, 3, 4, 6, 12
  - $Disc = (1 + Z/F)^{-T}$ , where F is the compounding frequency, Z is the zero rate, and T is the time in periodic units, for example,  $T = F$  is one year.
- Compounding = 365
  - $Disc = (1 + Z/F)^{-T}$ , where F is the number of days in the basis year and T is a number of days elapsed computed by basis.
- Compounding = -1
  - $Disc = \exp(-T*Z)$ , where T is time in years.

Data Types: double

## Disc — Unit bond prices over investment intervals

[ ] (default) | matrix

Unit bond prices over investment intervals from `StartDates` (when the cash flow is valued) to `EndDates` (when the cash flow is received), specified as the comma-separated pair consisting of 'Disc' and a number of points (`NPOINTS`) by number of curves (`NCURVES`) matrix.

Data Types: double

## Rates — Interest rates

matrix of decimal values

Interest rates, specified as the comma-separated pair consisting of 'Rates' and a number of points (`NPOINTS`) by number of curves (`NCURVES`) matrix of decimal values. `Rates` can only contain negative decimal values if the resulting `RateSpec` is used with a Normal (Bachelier) model, shifted Black model, or a shifted SABR model.

Data Types: double

## EndDates — Maturity dates ending the interval to discount over

serial date number | date character vector

Maturity dates ending the interval to discount over, specified as the comma-separated pair consisting of 'EndDates' and a scalar or a NPOINTS-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

### **StartDates — Dates starting the interval to discount over**

serial date number | date character vector

Dates starting the interval to discount over, specified as the comma-separated pair consisting of 'StartDates' and a scalar or a NPOINTS-by-1 vector of serial date numbers or date character vectors. StartDates must be earlier than EndDates.

Data Types: double | char | cell

### **ValuationDate — Observation date of the investment horizons entered in StartDates and EndDates**

min(StartDates) (default) | serial date number | character vector date

observation date of the investment horizons entered in StartDates and EndDates, specified as the comma-separated pair consisting of 'ValuationDate' and a specified as a scalar serial date number or date character vector.

Data Types: double | char

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer value.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar integer with a value of 0 or 1. This rule applies only when EndDates is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

## Output Arguments

### **RateSpec** — Interest-rate specification for initial rate curve

structure

Interest-rate specification for initial rate curve, returned as a structure.

### **RateSpecOld** — Properties of an interest-rate structure before the changes introduced by the call to `intenvset`

structure

Properties of an interest-rate structure before the changes introduced by the call to `intenvset`, returned as a structure.

## isafin

True if input argument is financial structure type or financial object class

### Syntax

```
IsFinObj = isafin(Obj,ClassName)
```

### Arguments

Obj	Name of a financial structure.
ClassName	Character vector containing the name of a financial structure class.

### Description

`IsFinObj = isafin(Obj,ClassName)` returns True (1) if input argument is a financial structure type or financial object class, otherwise False (0) is returned.

### Examples

```
load deriv.mat
IsFinObj = isafin(HJMTree, 'HJMFwdTree')

IsFinObj =
     1
```

# ittprice

Price instruments using implied trinomial tree (ITT)

## Syntax

```
[Price,PriceTree] = ittprice(ITTree,InstSet)
[Price,PriceTree] = ittprice( ____,Options)
```

## Description

[Price,PriceTree] = ittprice(ITTree,InstSet) price instruments using an implied trinomial tree (ITT) created with `itttree`. All instruments contained in a financial instrument variable, `InstSet`, are priced.

`ittprice` handles the following instrument types: `optstock`, `barrier`, `Asian`, `lookback`, and `compound`. Use `instadd` to construct the defined types.

[Price,PriceTree] = ittprice( \_\_\_\_,Options) adds an optional input argument for `Options`.

## Examples

### Price Instruments Using Implied Trinomial Tree (ITT)

Load the ITT tree and instruments from the data file `deriv.mat`.

```
load deriv.mat
```

Display the barrier and Asian options contained in the instrument set.

```
ITSubSet = instselect(ITInstSet,'Type', {'Barrier', 'Asian'});
```

```
instdisp(ITSubSet)
```

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	BarrierSpec	Barrier	Rebate
1	Barrier	call	85	01-Jan-2006	31-Dec-2008	1	ui	115	0

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	AvgType	AvgPrice	AvgDate
2	Asian	call	55	01-Jan-2006	01-Jan-2008	0	arithmetic	NaN	NaN
3	Asian	call	55	01-Jan-2006	01-Jan-2010	0	arithmetic	NaN	NaN

Price the barrier and Asian options contained in the instrument set.

```
[Price, PriceTree] = ittprice(ITTree, ITSubSet)
```

```
Price = 3x1
```

```
    2.4074
    3.2052
    6.6074
```

```
PriceTree = struct with fields:
  FinObj: 'TrinPriceTree'
  PTree: {1x5 cell}
  tObs: [0 1 2 3 4]
  dObs: [732678 733043 733408 733773 734139]
```

## Input Arguments

### ITTree — Implied trinomial stock tree structure

structure

Implied trinomial stock tree structure, specified by using `ittree`.

Data Types: `struct`

### InstSet — Instrument variable

structure

Instrument variable containing a collection of NINST instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

### Options — Derivatives pricing options structure

structure

(Optional) Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

## Output Arguments

### Price — Price for each instrument

vector

Price for each instrument, returned as a NINST-by-1 vector. The prices are computed by backward dynamic programming on the stock tree. If an instrument cannot be priced, a NaN is returned in that entry.

For information on single-type pricing functions to retrieve state-by-state pricing tree information, see the following:

- `barrierbyitt` for pricing barrier options using an ITT tree
- `optstockbyitt` for pricing American, European, or Bermuda options using an ITT tree
- `asianbyitt` for pricing Asian options using an ITT tree
- `lookbackbyitt` for pricing lookback options using an ITT tree
- `compoundbyitt` for price compound options using an ITT tree
- `cbondbyitt` for pricing convertible bonds using an ITT tree

### PriceTree — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.

## Introduced in R2007a

## ittsens

Instrument sensitivities and prices using implied trinomial tree (ITT)

### Syntax

```
[Delta, Gamma, Vega, Price] = ittsens(ITTTree, InstSet)
[Delta, Gamma, Vega, Price] = ittsens( ____, Options)
```

### Description

`[Delta, Gamma, Vega, Price] = ittsens(ITTTree, InstSet)` calculates instrument sensitivities and prices using an implied trinomial tree (ITT) that is created with the `itttree` function. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

`ittsens` handles the following instrument types: `optstock`, `barrier`, `Asian`, `lookback`, and `compound`. Use `instadd` to construct the defined types.

`[Delta, Gamma, Vega, Price] = ittsens( ____, Options)` adds an optional input argument for `Options`.

### Examples

#### Compute Instrument Sensitivities Using an Implied Trinomial Tree (ITT)

Load the ITT tree and instruments from the data file `deriv.mat` and display the vanilla options and barrier option instruments.

```
load deriv.mat
ITTSubSet = instselect(ITTInstSet, 'Type', {'OptStock', 'Barrier'});
```

```
instdisp(ITTSubSet)
```

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	Name	Quantity
1	OptStock	call	95	01-Jan-2006	31-Dec-2008	1	Call1	10
2	OptStock	put	80	01-Jan-2006	01-Jan-2010	0	Put1	4

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	BarrierSpec	Barrier	Rebate
3	Barrier	call	85	01-Jan-2006	31-Dec-2008	1	ui	115	0

Compute the Delta and Gamma sensitivities of vanilla options and barrier option contained in the instrument set.

```
[Delta, Gamma] = ittsens(ITTTree, ITTSubSet)
```

Warning: The option set specified in `StockOptSpec` was too narrow for the generated tree. This made extrapolation necessary. Below is a list of the options that were outside of the range of those specified in `StockOptSpec`.

```
Option Type: 'call' Maturity: 01-Jan-2007 Strike=67.2897
```

```

Option Type: 'put'    Maturity: 01-Jan-2007  Strike=37.1528
Option Type: 'put'    Maturity: 01-Jan-2008  Strike=27.6066
Option Type: 'put'    Maturity: 31-Dec-2008  Strike=20.5132
Option Type: 'call'   Maturity: 01-Jan-2010  Strike=164.0157
Option Type: 'put'    Maturity: 01-Jan-2010  Strike=15.2424

```

Delta = 3×1

```

0.2387
-0.4283
0.3482

```

Gamma = 3×1

```

0.0260
0.0188
0.0380

```

## Input Arguments

### ITTree — Stock tree structure

structure

Stock tree structure, specified by using `itttree`.

Data Types: `struct`

### InstSet — Instrument variable

structure

Instrument variable containing a collection of NINST instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

### Options — Derivatives pricing options structure

structure

Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

## Output Arguments

### Delta — Rate of change of instruments prices with respect to changes in the stock price

vector

Rate of change of instruments prices with respect to changes in the stock price, returned as a NINST-by-1 vector of deltas.

For path-dependent options ('Lookback' and 'Asian'), Delta and Gamma are computed by finite differences in calls to `ittprice`. For the rest of the options ('OptStock', 'Barrier', 'CBond',

and 'Compound'), Delta and Gamma are computed from the ITTtree and the corresponding option price tree.

### **Gamma — Rate of change of instruments deltas with respect to changes in stock price**

vector

Rate of change of instruments deltas with respect to changes in the stock price, returned as a NINST-by-1 vector of gammas.

For path-dependent options ('Lookback' and 'Asian'), Delta and Gamma are computed by finite differences in calls to `ittprice`. For the rest of the options ('OptStock', 'Barrier', 'CBond', and 'Compound'), Delta and Gamma are computed from the ITTtree and the corresponding option price tree.

### **Vega — Rate of change of instruments prices with respect to changes in volatility of the stock**

vector

Rate of change of instruments prices with respect to changes in the volatility of the stock, returned as a NINST-by-1 vector of vegas. Vega is computed by finite differences in calls to `itttree`.

### **Price — Price of each instrument**

vector

Price of each instrument, returned as a NINST-by-1 vector. The prices are computed by backward dynamic programming on the stock tree. If an instrument cannot be priced, a NaN is returned in that entry.

# itttimespec

Specify time structure using implied trinomial tree (ITT)

## Syntax

```
TimeSpec = itttimespec(ValuationDate,Maturity,NumPeriods)
```

## Description

`TimeSpec = itttimespec(ValuationDate,Maturity,NumPeriods)` creates the structure specifying the time layout for an ITT tree (`itttree`).

## Examples

### Creates the Structure Specifying the Time Layout for an ITT Tree

This example shows how to specify a four-period tree with time steps of 1 year.

```
ValuationDate = '1-July-2006';
Maturity = '1-July-2010';
TimeSpec = itttimespec(ValuationDate, Maturity, 4)

TimeSpec = struct with fields:
    FinObj: 'ITTimeSpec'
    ValuationDate: 732859
    Maturity: 734320
    NumPeriods: 4
    Basis: 0
    EndMonthRule: 1
    tObs: [0 1 2 3 4]
    dObs: [732859 733224 733589 733954 734320]
```

## Input Arguments

### ValuationDate — Pricing date and first observation in the tree

serial date number | character vector date

Pricing date and first observation in the `itttree`, specified as a scalar date using a serial date number or date character vector.

Data Types: double | char

### Maturity — Date marking the depth of the EQP stock tree

serial date number | date character vector

Date marking the depth of the `itttree` trinomial tree, specified as scalar serial date number or date character vector.

Data Types: double | char

**NumPeriods — Number of time steps in the ITT tree**

integer

Number of time steps in the `itttree` trinomial tree, specified as scalar integer value.Data Types: `double`**Output Arguments****TimeSpec — Specification for the time layout for `itttree`**

structure

Specification for the time layout for `itttree`, returned as a structure.**See Also**`ittprice` | `itttree` | `stockspec`**Topics**

# itttree

Build implied trinomial stock tree

## Syntax

```
ITTTree = itttree(StockSpec,RateSpec,TimeSpec,StockOptSpec)
```

## Description

ITTTree = itttree(StockSpec,RateSpec,TimeSpec,StockOptSpec) builds an implied trinomial (ITT) stock tree.

## Examples

### Create an ITT Tree

Assume that the interest rate is fixed at 8% annually between the valuation date of the tree (January 1, 2006) until its maturity.

```
Rate = 0.08;
ValuationDate = '01-01-2006';
EndDate = '01-01-2008';
```

```
RateSpec = intenvset('StartDates', ValuationDate, 'EndDates', EndDate, ...
    'ValuationDate', ValuationDate, 'Rates', Rate, 'Compounding', -1);
```

To build an ITTTree, create the StockSpec, TimeSpec, and StockOptSpec structures.

```
Sigma = 0.20;
AssetPrice = 50;
DividendType = 'cash';
DividendAmounts = [0.50; 0.50; 0.50; 0.50];
ExDividendDates = {'03-Jan-2007'; '01-Apr-2007'; '05-July-2007'; '01-Oct-2007'}
```

```
StockSpec = stockspec(Sigma, AssetPrice, DividendType, ...
    DividendAmounts, ExDividendDates);
```

```
ValuationDate = '01-01-2006';
EndDate = '01-01-2008';
NumPeriods = 4;
```

```
TimeSpec = itttimespec(ValuationDate, EndDate, NumPeriods);
```

Build a StockOptSpec structure.

```
Settle = '01/01/06';
```

```
Maturity = ['07/01/06';
    '07/01/06';
    '07/01/06';
    '07/01/06'];
```

```
'01/01/07';
'01/01/07';
'01/01/07';
'01/01/07';
'07/01/07';
'07/01/07';
'07/01/07';
'07/01/07';
'01/01/08';
'01/01/08';
'01/01/08';
'01/01/08'];

Strike = [113;
101;
100;
88;
128;
112;
100;
78;
144;
112;
100;
69;
162;
112;
100;

OptSpec = { 'call';
'call';
'put';
'put';
'call';
'call';
'put';
'put';
'call';
'call';
```

```
'put';
'put';
'call';
'call';
'put';
'put'};
```

```
StockOptSpec = stockoptspec(OptPrice, Strike, Settle, Maturity, OptSpec);
```

Use `itttree` to build the `ITTree` structure. Note, in this example, the extrapolation warnings are turned on. These warnings are a consequence of having to extrapolate to find the option price of the tree nodes. In this example, the set of inputs options was too narrow for the shift in the tree nodes introduced by the disturbance used to calculate the sensitivities. As a consequence extrapolation for some of the nodes was needed.

```
warning('on', 'fininst:itttree:Extrapolation');
ITTree = itttree(StockSpec, RateSpec, TimeSpec, StockOptSpec)
```

Warning: The option set specified in `StockOptSpec` was too narrow for the generated tree. This made extrapolation necessary. Below is a list of the options that were outside of the range of those specified in `StockOptSpec`.

```
Option Type: 'call'    Maturity: 02-Jul-2006  Strike=60.7466
Option Type: 'put'    Maturity: 02-Jul-2006  Strike=50.0731

## Input Arguments

### StockSpec — Stock specification

structure

Stock specification, specified by the `StockSpec` obtained from `stockspec`. See `stockspec` for information on creating a stock specification.

Data Types: `struct`

### RateSpec — Interest-rate specification for initial risk-free rate curve

structure

Interest-rate specification for initial risk-free rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### TimeSpec — Tree time layout specification

structure

Tree time layout specification, specified by the `TimeSpec` obtained from `itttimespec`. The `TimeSpec` defines the observation dates of the ITT tree. See `itttimespec` for information on the tree structure.

Data Types: `struct`

### StockOptSpec — Option stock specification

structure

Option stock specification, specified by the `StockOptSpec` obtained from `stockoptspec`. See `stockoptspec` for information on creating a stock specification.

Data Types: `struct`

## Output Arguments

### ITTree — ITT trinomial tree

structure

ITT trinomial tree, returned as a structure specifying the time layout for the tree.

# LiborMarketModel

Create LIBOR Market Model

## Description

The LIBOR Market Model (LMM) is an interest-rate model that differs from short rate models in that it evolves a set of discrete forward rates.

Specifically, the lognormal LMM specifies the following diffusion equation for each forward rate

$$\frac{dF_i(t)}{F_i} = -\mu_i dt + \sigma_i(t) dW_i$$

where:

$W$  is an N-dimensional geometric Brownian motion with

$$dW_i(t)dW_j(t) = \rho_{i,j}$$

The LMM relates drifts of the forward rates based on no-arbitrage arguments. Specifically, under the Spot LIBOR measure, drifts are expressed as

$$\mu_i(t) = -\sigma_i(t) \sum_{j=q(t)}^i \frac{\tau_j \rho_{i,j} \sigma_j(t) F_j(t)}{1 + \tau_j F_j(t)}$$

where:

$\rho_{i,j}$  represents the input argument Correlation.

$\sigma_j(t)$  represents the input argument VolFunc.

$F_j(t)$  represents the computation of the input argument for ZeroCurve.

$\tau_i$  is the time fraction associated with the  $i$  th forward rate

$q(t)$  is an index defined by the relation

$$T_{q(t)-1} < t < T_{q(t)}$$

and the Spot LIBOR numeraire is defined as

$$B(t) = P(t, T_{q(t)}) \prod_{n=0}^{q(t)-1} (1 + \tau_n F_n(T_n))$$

## Creation

### Syntax

```
LMM = LiborMarketModel(ZeroCurve,VolFunc,Correlation)
LMM = LiborMarketModel( ____,Name,Value)
```

### Description

`LMM = LiborMarketModel(ZeroCurve,VolFunc,Correlation)` creates a `LiborMarketModel` (LMM) object using the required arguments for `ZeroCurve`, `VolFunc`, `Correlation`.

`LMM = LiborMarketModel( ____,Name,Value)` sets Properties on page 11-840 using name-value pairs. For example, `LMM = LiborMarketModel(irdc,VolFunc,Correlation,'Period',1)`. You can specify multiple name-value pairs. Enclose each property name in single quotes.

### Input Arguments

#### ZeroCurve — Zero curve used to evolve path of future interest rates

IRDataCurve object | RateSpec

Zero curve used to evolve the path of future interest rates, specified as an output from `IRDataCurve` or a `RateSpec` that is obtained from `intenvset`. The `ZeroCurve` input sets the `ZeroCurve` on page 11-0 property.

Data Types: object | struct

#### VolFunc — Volatility function

cell array of function handles

Volatility function, specified using a `NumRates`-by-1 cell array of function handles and sets the `VolFunc` on page 11-0 property. Each function handle must take time as an input and, return a scalar volatility.

---

**Note** The number of rates to simulate using the `simTermStructs` function is determined by the size of the `VolFunc` and `Correlation` inputs which must be consistent. These can be any value and, together with the `Period` property, determines the kinds and number of rates being simulated. For example, if the `Period` is set to 4 (quarterly) and `VolFunc` has length of 120 and `Correlation` has size 120-by-120, then 120 quarterly rates are simulated. In other words, 30 years of the yield curve are simulated (0-3mos, 3mos-6mos, 6mos-9mos, and so on, all the way up to 30 years). Therefore, if `VolFunc` and `Correlation` have size 120, the output of a call to `simTermStructs` is (nPeriods +1) -by-121-by-nTrials.

---

Data Types: cell

#### Correlation — Correlation matrix

matrix

Correlation matrix, specified using a `NumRates`-by-`NumRates` correlation matrix and sets the `Correlation` on page 11-0 property.

---

**Note** The number of rates to simulate using the `simTermStructs` function is determined by the size of the `VolFunc` and `Correlation` inputs which must be consistent. These can be any value and,

together with the `Period` property, determines the kinds and number of rates being simulated. For example, if the `Period` is set to 4 (quarterly) and `VolFunc` has length of 120 and `Correlation` has size 120-by-120, then 120 quarterly rates are simulated. In other words, 30 years of the yield curve are simulated (0-3mos, 3mos-6mos, 6mos-9mos, and so on, all the way up to 30 years). Therefore, if `VolFunc` and `Correlation` have size 120, the output of a call to `simTermStructs` is (nPeriods +1) -by-121-by-nTrials.

---

Data Types: double

## Properties

### **ZeroCurve – Zero curve**

IRDataCurve object | RateSpec

Zero curve, specified as an output from `IRDataCurve` or a `RateSpec` that is obtained from `intenvset`.

Data Types: object | struct

### **VolFunc – Volatility function**

cell array of function handles

Volatility function, specified using a `NumRates`-by-1 cell array of function handles. Each function handle must take time as an input and, return a scalar volatility.

Data Types: cell

### **Correlation – Correlation matrix**

matrix

Correlation matrix, specified using a `NumRates`-by-`NumRates` correlation matrix.

Data Types: double

### **NumFactors – Number of Brownian factors**

NaN (default) | numeric

Number of Brownian factors, specified as a numeric value. The default is NaN, where the number of factors is equal to the number of rates.

Data Types: double

### **Period – Period of forward rates, specifically number of rates per year**

2 (default) | numeric with value 1, 2, 4, or 12

Period of the forward rates, specifically the number of rates per year, specified as a numeric value of 1, 2, 4, or 12. The default value is 2, meaning forward rates are spaced at 0, .5, 1, 1.5, and so on.

Data Types: double

## Object Functions

`simTermStructs` Simulate term structures for LIBOR Market Model

## Examples

### Create a LIBOR Market Model Using an IRDataCurve

Create a LMM object using an IRDataCurve.

```
Settle = datenum('15-Dec-2007');
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

LMMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
LMMVolParams = [.3 -.02 .7 .14];

numRates = 20;
VolFunc(1:numRates,1) = {@(t) LMMVolFunc(LMMVolParams,t)};

Beta = .08;
CorrFunc = @(i,j,Beta) exp(-Beta*abs(i-j));
Correlation = CorrFunc(meshgrid(1:numRates)',meshgrid(1:numRates),Beta);

LMM = LiborMarketModel(irdc,VolFunc,Correlation,'Period',1)

LMM =
  LiborMarketModel with properties:
    ZeroCurve: [1x1 IRDataCurve]
  VolFunctions: {20x1 cell}
  Correlation: [20x20 double]
  NumFactors: NaN
  Period: 1
```

Simulate the term structures for the specified LMM object.

```
[ZeroRates, ForwardRates] = simTermStructs(LMM, 10, 'nTrials',100);
```

### Create a LIBOR Market Model Using a RateSpec

Create a LMM object using a RateSpec.

```
Settle = datenum('15-Dec-2007');
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

RateSpec = intenvset('Rates',ZeroRates,'EndDates',CurveDates,'StartDate',Settle);

LMMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
LMMVolParams = [.3 -.02 .7 .14];

numRates = 20;
```

```

VolFunc(1:numRates,1) = {@(t) LMMVolFunc(LMMVolParams,t)};

Beta = .08;
CorrFunc = @(i,j,Beta) exp(-Beta*abs(i-j));
Correlation = CorrFunc(meshgrid(1:numRates)',meshgrid(1:numRates),Beta);

LMM = LiborMarketModel(RateSpec,VolFunc,Correlation,'Period',1)

LMM =
  LiborMarketModel with properties:

    ZeroCurve: [1x1 IRDataCurve]
  VolFunctions: {20x1 cell}
  Correlation: [20x20 double]
  NumFactors: NaN
  Period: 1

```

Simulate the term structures for the specified LMM object.

```
[ZeroRates, ForwardRates] = simTermStructs(LMM, 10,'nTrials',100);
```

## More About

### LIBOR Market Model

The LIBOR Market Model, also called the BGM Model (Brace, Gatarek, Musiela Model) is a financial model of interest rates.

The quantities that are modeled are a set of forward rates (also called forward LIBORs) which have the advantage of being directly observable in the market, and whose volatilities are naturally linked to traded contracts.

### Introduced in R2013a

# simTermStructs

Simulate term structures for LIBOR Market Model

## Syntax

```
[ZeroRates,ForwardRates] = simTermStructs(LMM,nPeriods)
[ZeroRates,ForwardRates] = simTermStructs( ____,Name,Value)
```

## Description

[ZeroRates,ForwardRates] = simTermStructs(LMM,nPeriods) simulates future zero curve paths using a specified `LiborMarketModel` object.

[ZeroRates,ForwardRates] = simTermStructs( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Simulate Term Structures for a LIBOR Market Model

Create a LMM object.

```
Settle = datenum('15-Dec-2007');
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

LMMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
LMMVolParams = [.3 -.02 .7 .14];

numRates = 20;
VolFunc(1:numRates-1) = {@(t) LMMVolFunc(LMMVolParams,t)};

Beta = .08;
CorrFunc = @(i,j,Beta) exp(-Beta*abs(i-j));
Correlation = CorrFunc(meshgrid(1:numRates-1),meshgrid(1:numRates-1),Beta);

LMM = LiborMarketModel(irdc,VolFunc,Correlation,'Period',1)

LMM =
    LiborMarketModel with properties:

        ZeroCurve: [1x1 IRDataCurve]
    VolFunctions: {1x19 cell}
    Correlation: [19x19 double]
    NumFactors: NaN
    Period: 1
```

Simulate the term structures for the specified LMM object.

```
[ZeroRates, ForwardRates] = simTermStructs(LMM, 20, 'nTrials', 100);
```

## Input Arguments

### LMM — LiborMarketModel object

object

LiborMarketModel object, specified using the LMM object created using LiborMarketModel.

Data Types: object

### nPeriods — Number of simulation periods

numeric

Number of simulation periods, specified as a numeric value. The nPeriods value is determined by the swaption expiry and the periodicity of the rates of the model. For example, if you were to price a swaption expiring in 5 years with a semiannual LIBOR Market Model (LMM), then nPeriods would be 10.

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: [ZeroRates, ForwardRates] = simTermStructs(LMM, 20, 'nTrials', 100)

### nTrials — Number of simulated trials

1 (default) | positive integer

Number of simulated trials (sample paths), specified as the comma-separated pair consisting of 'nTrials' and a positive scalar integer value of nPeriods observations each. If you do not specify a value for this argument, the default is 1, indicating a single path of correlated state variables.

Data Types: double

### antithetic — Flag indicating whether antithetic sampling is used to generate Gaussian random variates

false (default) | positive integer

Flag indicating whether antithetic sampling is used to generate the Gaussian random variates that drive the zero-drift, unit-variance rate Brownian vector  $dW(t)$ , specified as the comma-separated pair consisting of 'antithetic' and a Boolean scalar flag. For details on the Brownian vector, see simBySolution.

Data Types: logical

### Z — Direct specification of dependent random noise process

generated by simBySolution function (default) | numeric

Direct specification of the dependent random noise process, specified as the comma-separated pair consisting of 'Z' and a numeric value. The Z value is used to generate the zero-drift, unit-variance

rate Brownian vector  $dW(t)$  that drives the simulation. For details, see `simBySolution` for the GBM model.

Data Types: `double`

### **Tenor — Maturities to compute at each time step**

number of rates in `LiborMarketModel` object (default) | numeric vector

Maturities to compute at each time step, specified as the comma-separated pair consisting of 'Tenor' and a numeric vector.

Tenor enables you to choose a different set of rates to output than the underlying rates. For example, you may want to simulate quarterly data but only report annual rates; this can be done by specifying the optional input Tenor.

The default for tenor is the number of rates in the `LiborMarketModel` object as specified by the `Correlation` and `VolFunc` input arguments for the `LiborMarketModel` object.

Data Types: `double`

## **Output Arguments**

### **ZeroRates — Simulated zero-rate term structures**

matrix

Simulated zero-rate term structures, returned as a `nPeriods+1-by-nTenors-by-nTrials` matrix.

### **ForwardRates — Simulated forward-rate term structures**

matrix

Simulated zero-rate term structures, returned as a `nPeriods+1-by-nTenors-by-nTrials` matrix.

## LinearGaussian2F

Create two-factor additive Gaussian interest-rate model

### Description

The two-factor additive Gaussian interest rate-model is specified using the zero curve,  $a$ ,  $b$ ,  $\sigma$ ,  $\eta$ , and  $\rho$  parameters.

Specifically, the LinearGaussian2F model is defined using the following equations:

$$r(t) = x(t) + y(t) + \phi(t)$$

$$dx(t) = -a(t)x(t)dt + \sigma(t)dW_1(t), x(0) = 0$$

$$dy(t) = -b(t)y(t)dt + \eta(t)dW_2(t), y(0) = 0$$

where  $dW_1(t)dW_2(t) = \rho dt$  is a two-dimensional Brownian motion with correlation  $\rho$ , and  $\phi$  is a function chosen to match the initial zero curve.

### Creation

#### Syntax

```
G2PP = LinearGaussian2F(ZeroCurve,a,b,sigma,eta,rho)
```

#### Description

`G2PP = LinearGaussian2F(ZeroCurve,a,b,sigma,eta,rho)` creates a `LinearGaussian2F` (`G2PP`) object using the required arguments to set the Properties on page 11-846.

### Properties

#### ZeroCurve – Zero curve

IRDataCurve object | RateSpec

Zero curve, specified as an output from `IRDataCurve` or a `RateSpec` that is obtained from `intenvset`. This is the zero curve used to evolve the path of future interest rates.

Data Types: object | struct

#### a – Mean reversion for first factor

numeric

Mean reversion for the first factor, specified either as a scalar or function handle which takes time as input and returns a scalar mean reversion value.

Data Types: double

**b — Mean reversion for second factor**

numeric

Mean reversion for the second factor, specified either as a scalar or as a function handle which takes time as input and returns a scalar mean reversion value.

Data Types: double

**sigma — Volatility for first factor**

numeric

Volatility for the first factor, specified either as a scalar or function handle which takes time as input and returns a scalar mean volatility.

Data Types: double

**eta — Volatility for second factor**

numeric

Volatility for the second factor, specified either as a scalar or function handle which takes time as input and returns a scalar mean volatility.

Data Types: double

**rho — Scalar correlation of factors**

numeric

Scalar correlation of the factors, specified as a numeric value.

Data Types: double

**Object Functions**

simTermStructs Simulate term structures for two-factor additive Gaussian interest-rate model

**Examples****Create a Two-Factor Additive Gaussian Interest-Rate Model Using an IRDataCurve**

Create a two-factor additive Gaussian interest-rate model using an IRdataCurve.

```
Settle = datenum('15-Dec-2007');
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

a = .07;
b = .5;
sigma = .01;
eta = .006;
rho = -.7;

G2PP = LinearGaussian2F(irdc,a,b,sigma,eta,rho)
```

```
G2PP =
  LinearGaussian2F with properties:

  ZeroCurve: [1x1 IRDataCurve]
    a: @(t,V)ina
    b: @(t,V)inb
  sigma: @(t,V)insigma
  eta: @(t,V)ineta
  rho: -0.7000
```

Use the `simTermStructs` method to simulate term structures based on the `LinearGaussian2F` model.

```
SimPaths = simTermStructs(G2PP, 10, 'nTrials', 100);
```

### Create a Two-Factor Additive Gaussian Interest-Rate Model Using a RateSpec

Create a two-factor additive Gaussian interest-rate model using a `RateSpec`.

```
Settle = datenum('15-Dec-2007');
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle, 360*CurveTimes, 1);

RateSpec = intenvset('Rates', ZeroRates, 'EndDates', CurveDates, 'StartDate', Settle);

a = .07;
b = .5;
sigma = .01;
eta = .006;
rho = -.7;

G2PP = LinearGaussian2F(RateSpec, a, b, sigma, eta, rho)

G2PP =
  LinearGaussian2F with properties:

  ZeroCurve: [1x1 IRDataCurve]
    a: @(t,V)ina
    b: @(t,V)inb
  sigma: @(t,V)insigma
  eta: @(t,V)ineta
  rho: -0.7000
```

Use the `simTermStructs` method to simulate term structures based on the `LinearGaussian2F` model.

```
SimPaths = simTermStructs(G2PP, 10, 'nTrials', 100);
```

## More About

### Two-Factor Additive Gaussian Interest-Rate Model

Short-rate model based on two factors where the short rate is the sum of the two factors and a deterministic function.

In this case  $\phi(t)$ , which is chosen to match the initial term structure.

## simTermStructs

Simulate term structures for two-factor additive Gaussian interest-rate model

### Syntax

```
[ZeroRates,ForwardRates] = simTermStructs(G2PP,nPeriods)
[ZeroRates,ForwardRates] = simTermStructs( ____,Name,Value)
```

### Description

[ZeroRates,ForwardRates] = simTermStructs(G2PP,nPeriods) simulates future zero curve paths using a specified LinearGaussian2F object.

[ZeroRates,ForwardRates] = simTermStructs( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Simulate Term Structures for the LinearGaussian2F Model

Create a two-factor additive Gaussian interest-rate model.

```
Settle = datenum('15-Dec-2007');
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

a = .07;
b = .5;
sigma = .01;
eta = .006;
rho = -.7;

G2PP = LinearGaussian2F(irdc,a,b,sigma,eta,rho)

G2PP =
    LinearGaussian2F with properties:

    ZeroCurve: [1x1 IRDataCurve]
               a: @(t,V)ina
               b: @(t,V)inb
    sigma: @(t,V)insigma
    eta: @(t,V)ineta
    rho: -0.7000
```

Use the simTermStructs method to simulate term structures based on the LinearGaussian2F model.

```
SimPaths = simTermStructs(G2PP, 10, 'nTrials', 100);
```

## Simulate Term Structures for the LinearGaussian2F Model Using a Vector for deltaTime

Create a two-factor additive Gaussian interest-rate model.

```
Settle = datenum('15-Dec-2007');
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle, 360*CurveTimes, 1);

irdc = IRDataCurve('Zero', Settle, CurveDates, ZeroRates);
a = .07;
b = .5;
sigma = .01;
eta = .006;
rho = -.7;
G2PP = LinearGaussian2F(irdc, a, b, sigma, eta, rho)

G2PP =
  LinearGaussian2F with properties:

  ZeroCurve: [1x1 IRDataCurve]
             a: @(t,V)ina
             b: @(t,V)inb
             sigma: @(t,V)insigma
             eta: @(t,V)ineta
             rho: -0.7000
```

Use the `simTermStructs` method to simulate term structures based on the `LinearGaussian2F` object, where uneven simulation tenors are specified using the optional name-value argument `deltaTime` as a vector of length `NPeriods`.

```
NPeriods = 10;
dt = rand(NPeriods, 1);
SimPaths = G2PP.simTermStructs(NPeriods, 'nTrials', 100, 'DeltaTime', dt);
```

## Input Arguments

### G2PP — LinearGaussian2F object

object

`LinearGaussian2F` object, specified using the `G2PP` object created using `LinearGaussian2F`.

Data Types: object

### nPeriods — Number of simulation periods

numeric

Number of simulation periods, specified as a numeric value. For example, to simulate 12 years with an annual spacing, specify 12 as the `nPeriods` input and 1 as the optional `deltaTime` input (note that the default value for `deltaTime` is 1).

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[ZeroRates, ForwardRates] = simTermStructs(G2PP, NPeriods, 'nTrials', 100, 'deltaTime', dt)`

### `deltaTime` — Time step between `nPeriods`

1 (default) | numeric

Time step between `nPeriods`, specified as the comma-separated pair consisting of `'deltaTime'` and a numeric scalar or vector. For example, to simulate 12 years with an annual spacing, specify 12 as the `nPeriods` input and 1 as the optional `deltaTime` input (note that the default value for `deltaTime` is 1).

Data Types: double

### `nTrials` — Number of simulated trials

1 (default) | positive integer

Number of simulated trials (sample paths), specified as the comma-separated pair consisting of `'nTrials'` and a positive scalar integer value of `nPeriods` observations each. If you do not specify a value for this argument, the default is 1, indicating a single path of correlated state variables.

Data Types: double

### `antithetic` — Flag indicating whether antithetic sampling is used to generate Gaussian random variates

false (default) | positive integer

Flag indicating whether antithetic sampling is used to generate the Gaussian random variates that drive the zero-drift, unit-variance rate Brownian vector  $dW(t)$ , specified as the comma-separated pair consisting of `'antithetic'` and a Boolean scalar flag. For details, see `simBySolution` for the HWV model.

Data Types: logical

### `Z` — Direct specification of dependent random noise process

Gaussian variates generated by `simBySolution` function (default) | numeric

Direct specification of the dependent random noise process, specified as the comma-separated pair consisting of `'Z'` and a numeric value. The `Z` value is used to generate the zero-drift, unit-variance rate Brownian vector  $dW(t)$  that drives the simulation. For details, see `simBySolution` for the HWV model. If you do not specify a value for `Z`, `simBySolution` generates Gaussian variates.

Data Types: double

### `Tenor` — Maturities to compute at each time step

tenor of `LinearGaussian2F` object zero curve (default) | numeric vector

Maturities to compute at each time step, specified as the comma-separated pair consisting of `'Tenor'` and a numeric vector.

Tenor enables you to choose a different set of rates to output than the underlying rates. For example, you may want to simulate quarterly data but only report annual rates; this can be done by specifying the optional input Tenor.

Data Types: double

## Output Arguments

### **ZeroRates — Simulated zero-rate term structures**

matrix

Simulated zero-rate term structures, returned as a `nPeriods+1-by-nTenors-by-nTrials` matrix.

### **ForwardRates — Simulated forward-rate term structures**

matrix

Simulated zero-rate term structures, returned as a `nPeriods+1-by-nTenors-by-nTrials` matrix. The `ForwardRates` output is computed using the simulated short rates and by using the model definition to recover the entire yield curve at each simulation date.

## lookbackbycrr

Price lookback option from Cox-Ross-Rubinstein binomial tree

### Syntax

```
Price = lookbackbycrr(CRRTree,OptSpec,Strike,Settle,ExerciseDates)
Price = lookbackbycrr(___,AmericanOpt)
```

### Description

`Price = lookbackbycrr(CRRTree,OptSpec,Strike,Settle,ExerciseDates)` prices lookback options using a Cox-Ross-Rubinstein binomial tree.

`Price = lookbackbycrr(___,AmericanOpt)` adds an optional argument for `AmericanOpt`.

### Examples

#### Price a Lookback Option Using a CRR Binomial Tree

This example shows how to price a lookback option using a CRR binomial tree by loading the file `deriv.mat`, which provides `CRRTree`. The `CRRTree` structure contains the stock specification and time information needed to price the option.

```
load deriv.mat;

OptSpec = 'Call';
Strike = 115;
Settle = '01-Jan-2003';
ExerciseDates = '01-Jan-2006';

Price = lookbackbycrr(CRRTree, OptSpec, Strike, Settle, ...
ExerciseDates)

Price = 7.6015
```

### Input Arguments

#### CRRTree — Stock tree structure

structure

Stock tree structure for a Cox-Ross-Rubinstein binomial tree, specified by using `crrtree`.

Data Types: `struct`

#### OptSpec — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as 'call' or 'put' using a character vector or a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: char | cell

### **Strike — Option strike price value**

matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using a NINST-by-1 matrix of strike price values. Each row is the schedule for one option.

To compute the value of a floating-strike lookback option, `Strike` must be specified as NaN. Floating-strike lookback options are also known as average strike options.

Data Types: double

### **Settle — Settlement date or trade date**

serial date number | date character vector

Settlement date or trade date for the lookback option, specified as a NINST-by-1 matrix of settlement or trade dates using serial date numbers or date character vectors.

---

**Note** The `Settle` date for every lookback option is set to the `ValuationDate` of the stock tree. The lookback argument, `Settle`, is ignored.

---

Data Types: double | char

### **ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a serial date number or date character vector:

- For a European option, use a NINST-by-1 matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is a NINST-by-1 vector of serial date numbers or cell array of character vectors, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

Data Types: double | char

### **AmericanOpt — Option type**

0 European (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 integer flags with values:

- 0 — European
- 1 — American

Data Types: single | double

## Output Arguments

### Price — Expected prices for lookback options at time 0

vector

Expected prices for lookback options at time 0, returned as a NINST-by-1 vector. Pricing of lookback options is done using Hull-White (1993). Therefore, for these options there are no unique prices on the tree nodes except for the root node.

## More About

### Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-38.

# lookbackbycvgsg

Calculate prices of European lookback options using Conze-Viswanathan and Goldman-Sosin-Gatto models

## Syntax

```
Price = lookbackbycvgsg(RateSpec, StockSpec, OptSpec, Strike, Settle,
ExerciseDates)
```

```
Price = lookbackbycvgsg( ____, Name, Value)
```

## Description

`Price = lookbackbycvgsg(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates)` returns prices of European lookback options using Conze-Viswanathan and Goldman-Sosin-Gatto models. `lookbackbycvgsg` calculates prices of European fixed- and floating-strike lookback options. To compute the value of a floating-strike lookback option, `Strike` must be specified as NaN. The Goldman-Sosin-Gatto model is used for floating-strike lookback options. The Conze-Viswanathan model is used for fixed-strike lookback options.

`Price = lookbackbycvgsg( ____, Name, Value)` adds optional name-value pair arguments.

## Examples

### Compute the Price of a Floating Lookback Option Using the Goldman-Sosin-Gatto Model

Define the RateSpec.

```
StartDates = 'Jan-1-2013';
EndDates = 'Jan-1-2014';
Rates = 0.042;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
```

```
    FinObj: 'RateSpec'
  Compounding: -1
         Disc: 0.9589
         Rates: 0.0420
    EndTimes: 1
    StartTimes: 0
    EndDates: 735600
    StartDates: 735235
  ValuationDate: 735235
         Basis: 0
    EndMonthRule: 1
```

Define the StockSpec.

```
AssetPrice = 50;
Sigma = 0.36;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3600
    AssetPrice: 50
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the floating lookback options.

```
Settle = 'Jan-1-2013';
Maturity = 'April-1-2013';
OptSpec = {'put'; 'call'};
Strike = NaN;
```

Compute the price of the European floating lookback options.

```
Price = lookbackbycvgs(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity)
```

```
Price = 2×1
```

```
7.2581
6.9777
```

### Compute the Price of a Fixed Lookback Option Using the Conze-Viswanathan Model

Define the RateSpec.

```
StartDates = 'Jan-1-2013';
EndDates = 'Jan-1-2014';
Rates = 0.045;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
    'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9560
    Rates: 0.0450
    EndTimes: 1
    StartTimes: 0
    EndDates: 735600
    StartDates: 735235
    ValuationDate: 735235
    Basis: 0
    EndMonthRule: 1
```

Define the StockSpec.

```
AssetPrice = 102;
Sigma = 0.45;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.4500
    AssetPrice: 102
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the fixed lookback options.

```
Settle = 'Jan-1-2013';
Maturity = 'July-1-2013';
OptSpec = {'put'; 'call'};
Strike = [98; 101];
```

Price the European fixed lookback options.

```
Price = lookbackbycvgs(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity)
```

```
Price = 2×1
```

```
18.3130
30.4021
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspect`.

`stockspect` handles several types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with values 'call' or 'put' | cell array of character vectors

Definition of option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors.

Data Types: `char` | `cell`

**Strike — Option strike price values**

`integer` | vector of integers

Option strike price values, specified as an integer using a NINST-by-1 vector of strike price values.

Data Types: `single` | `double`

**Settle — Settlement or trade date**

`serial date number` | vector of serial date numbers | `date character vector` | cell array of character vectors

Settlement or trade date for the lookback option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `double` | `char` | `cell`

**ExerciseDates — European option expiry date**

`serial date number` | vector of serial date numbers | `date character vector` | cell array of character vectors

European option expiry date, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `double` | `char` | `cell`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Price =`

```
lookbackbycvgsg(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates, 'AssetMinMax', AssetMinMax)
```

**AssetMinMax — Maximum or minimum underlying asset price**

if unspecified, the lookback option is newly issued, and `AssetMinMax = StockSpec.AssetPrice` (default) | nonnegative integer

Maximum or minimum underlying asset price, specified as the comma-separated pair consisting of `'AssetMinMax'` and a NINST-by-1 vector.

Data Types: `single` | `double`

**Output Arguments****Price — Expected prices of lookback option**

`vector`

Expected prices of the lookback option, returned as a NINST-by-1 vector.

## More About

### Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-38.

## lookbacksensbycvgs

Calculate prices or sensitivities of European lookback options using Conze-Viswanathan and Goldman-Sosin-Gatto models

### Syntax

```
PriceSens = lookbacksensbycvgs(RateSpec, StockSpec, OptSpec, Strike, Settle,
ExerciseDates)
```

```
PriceSens = lookbacksensbycvgs( ____, Name, Value)
```

### Description

`PriceSens = lookbacksensbycvgs(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates)` returns prices or sensitivities of European lookback options using Conze-Viswanathan and Goldman-Sosin-Gatto models. `lookbacksensbycvgs` calculates prices of European fixed- and floating-strike lookback options. To compute the value of a floating-strike lookback option, `Strike` must be specified as `NaN`. The Goldman-Sosin-Gatto model is used for floating-strike lookback options. The Conze-Viswanathan model is used for fixed-strike lookback options.

`PriceSens = lookbacksensbycvgs( ____, Name, Value)` adds optional name-value pair arguments.

### Examples

#### Compute the Price and Delta of a Floating Lookback Option Using the Goldman-Sosin-Gatto Model

Define the `RateSpec`.

```
StartDates = 'Jan-1-2013';
EndDates = 'Jan-1-2014';
Rates = 0.41;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
```

```
    FinObj: 'RateSpec'
  Compounding: -1
        Disc: 0.6637
        Rates: 0.4100
    EndTimes: 1
    StartTimes: 0
    EndDates: 735600
    StartDates: 735235
  ValuationDate: 735235
        Basis: 0
  EndMonthRule: 1
```

Define the StockSpec with continuous dividend yield.

```
AssetPrice = 120;
Sigma = 0.3;
Yield = 0.045;
StockSpec = stockspec(Sigma, AssetPrice, 'Continuous', Yield)

StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3000
    AssetPrice: 120
    DividendType: {'continuous'}
    DividendAmounts: 0.0450
    ExDividendDates: []
```

Define the floating lookback option.

```
Settle = 'Jan-1-2013';
Maturity = 'July-1-2013';
OptSpec = 'call';
Strike = NaN;
SMinMax = 100;
```

Compute the price and delta of the European floating lookback option.

```
OutSpec = {'price', 'delta'};
[Price, Delta] = lookbacksensbycvgs(RateSpec, StockSpec, OptSpec, Strike,...
Settle, Maturity, 'AssetMinMax', SMinMax, 'OutSpec', OutSpec)

Price = 36.9926
Delta = 0.8659
```

### Compute the Price and Delta of a Fixed Lookback Option Using the Conze-Viswanathan Model

Define the RateSpec.

```
StartDates = 'Jan-1-2013';
EndDates = 'Jan-1-2015';
Rates = 0.1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.8187
    Rates: 0.1000
    EndTimes: 2
    StartTimes: 0
    EndDates: 735965
    StartDates: 735235
    ValuationDate: 735235
```

```
Basis: 0  
EndMonthRule: 1
```

Define the StockSpec.

```
AssetPrice = 103;  
Sigma = 0.30;  
StockSpec = stockspect(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:  
    FinObj: 'StockSpec'  
    Sigma: 0.3000  
    AssetPrice: 103  
    DividendType: []  
    DividendAmounts: 0  
    ExDividendDates: []
```

Define the fixed lookback option.

```
Settle = 'Jan-1-2013';  
Maturity = 'July-1-2013';  
OptSpec = 'call';  
Strike = 99;
```

Price and delta for the European fixed lookback option.

```
OutSpec = {'price', 'delta'};  
[Price, Delta] = lookbacksensbyls(RateSpec, StockSpec, OptSpec, ...  
Strike, Settle, Maturity, 'OutSpec', OutSpec)
```

```
Price = 22.7227
```

```
Delta = 1.1349
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspect`.

`stockspect` handles several types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

**OptSpec — Definition of option**

character vector with values 'call' or 'put' | cell array of character vectors

Definition of option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors.

Data Types: char | cell

**Strike — Option strike price values**

integer | vector of integers

Option strike price values, specified as an integer using a NINST-by-1 vector of strike price values.

Data Types: single | double

**Settle — Settlement or trade date**

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Settlement or trade date for the lookback option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: double | char | cell

**ExerciseDates — European option expiry date**

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

European option expiry date, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of dates.

Data Types: double | char | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `PriceSens =`

```
lookbacksensbycvgsg(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates, 'AssetMinMax', AssetMinMax, 'OutSpec', {'All'})
```

**AssetMinMax — Maximum or minimum underlying asset price**

if unspecified, the lookback option is newly issued, and `AssetMinMax = StockSpec.AssetPrice` (default) | nonnegative integer

Maximum or minimum underlying asset price, specified as a NINST-by-1 vector.

Data Types: single | double

**OutSpec — Define outputs**

{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

`OutSpec = {'All'}` specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}`

Data Types: `char` | `cell`

## Output Arguments

### **PriceSens** — Expected prices or sensitivities of lookback option

vector

Expected prices or sensitivities (defined by `OutSpec`) of the lookback option, returned as a NINST-by-1 vector.

## More About

### **Lookback Option**

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-38.

# lookbackbyeqp

Price lookback option from Equal Probabilities binomial tree

## Syntax

```
Price = lookbackbyeqp(EQPTree,OptSpec,Strike,Settle,ExerciseDates)
Price = lookbackbyeqp( ____,AmericanOpt)
```

## Description

`Price = lookbackbyeqp(EQPTree,OptSpec,Strike,Settle,ExerciseDates)` prices lookback options using an Equal Probabilities binomial tree.

`Price = lookbackbyeqp( ____,AmericanOpt)` adds an optional argument for `AmericanOpt`.

## Examples

### Price a Lookback Option Using an EQP Equity Tree

This example shows how to price a lookback option using an EQP equity tree by loading the file `deriv.mat`, which provides `EQPTree`. The `EQPTree` structure contains the stock specification and time information needed to price the option.

```
load deriv.mat

OptSpec = 'Call';
Strike = 115;
Settle = '01-Jan-2003';
ExerciseDates = '01-Jan-2006';

Price = lookbackbyeqp(EQPTree, OptSpec, Strike, Settle, ...
ExerciseDates)

Price = 8.7941
```

## Input Arguments

### EQPTree — Stock tree structure

structure

Stock tree structure for an Equal Probabilities binomial tree, specified by using `eqptree`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as 'call' or 'put' using a character vector or a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: char | cell

**Strike — Option strike price value**

matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using a NINST-by-1 matrix of strike price values. Each row is the schedule for one option.

To compute the value of a floating-strike lookback option, `Strike` must be specified as NaN. Floating-strike lookback options are also known as average strike options.

Data Types: double

**Settle — Settlement date or trade date**

serial date number | date character vector

Settlement date or trade date for the lookback option, specified as a NINST-by-1 matrix of settlement or trade dates using serial date numbers or date character vectors.

---

**Note** The `Settle` date for every lookback option is set to the `ValuationDate` of the stock tree. The lookback argument, `Settle`, is ignored.

---

Data Types: double | char

**ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a serial date number or date character vector:

- For a European option, use a NINST-by-1 matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is a NINST-by-1 vector of serial date numbers or cell array of character vectors, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

Data Types: double | char

**AmericanOpt — Option type**

0 European (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 integer flags with values:

- 0 — European
- 1 — American

Data Types: single | double

## Output Arguments

### Price — Expected prices for lookback options at time 0

vector

Expected prices for lookback options at time 0, returned as a NINST-by-1 vector. Pricing of lookback options is done using Hull-White (1993). Therefore, for these options there are no unique prices on the tree nodes except for the root node.

## More About

### Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see "Lookback Option" on page 3-38.

## lookbackbyitt

Price lookback option using implied trinomial tree (ITT)

### Syntax

```
Price = lookbackbyitt(ITTTree,OptSpec,Strike,Settle,ExerciseDates)
Price = lookbackbyitt( ____,AmericanOpt)
```

### Description

`Price = lookbackbyitt(ITTTree,OptSpec,Strike,Settle,ExerciseDates)` prices lookback options using an implied trinomial tree (ITT).

`Price = lookbackbyitt( ____,AmericanOpt)` adds an optional argument for `AmericanOpt`.

### Examples

#### Price a Lookback Option Using an ITT Equity Tree

This example shows how to price a lookback option using an ITT equity tree by loading the file `deriv.mat`, which provides the `ITTTree`. The `ITTTree` structure contains the stock specification and time information needed to price the option.

```
load deriv.mat
```

```
OptSpec = 'Call';
Strike = 85;
Settle = '01-Jan-2006';
ExerciseDates = '01-Jan-2008';
```

```
Price = lookbackbyitt(ITTTree, OptSpec, Strike, Settle, ExerciseDates)
```

```
Price = 0.5426
```

### Input Arguments

#### ITTTree — Stock tree structure

structure

Stock tree structure for an implied trinomial tree (ITT), specified by using `itttree`.

Data Types: `struct`

#### OptSpec — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a character vector or a NINST-by-1 cell array of character vectors for `'call'` or `'put'`.

Data Types: char | cell

### Strike — Option strike price value

matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using a NINST-by-1 matrix of strike price values. Each row is the schedule for one option.

To compute the value of a floating-strike lookback option, `Strike` must be specified as NaN. Floating-strike lookback options are also known as average strike options.

Data Types: double

### Settle — Settlement date or trade date

serial date number | date character vector

Settlement date or trade date for the lookback option, specified as a NINST-by-1 matrix of settlement or trade dates using serial date numbers or date character vectors.

---

**Note** The `Settle` date for every lookback option is set to the `ValuationDate` of the stock tree. The lookback argument, `Settle`, is ignored.

---

Data Types: double | char

### ExerciseDates — Option exercise dates

serial date number | date character vector

Option exercise dates, specified as a serial date number or date character vector:

- For a European option, use a NINST-by-1 matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is a NINST-by-1 vector of serial date numbers or cell array of character vectors, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

Data Types: double | char

### AmericanOpt — Option type

0 European (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 integer flags with values:

- 0 — European
- 1 — American

Data Types: single | double

## Output Arguments

### Price — Expected prices for lookback options at time 0

vector

Expected prices for lookback options at time 0, returned as a NINST-by-1 vector. Pricing of lookback options is done using Hull-White (1993). Therefore, for these options there are no unique prices on the tree nodes except for the root node.

## More About

# lookbackbyls

Price European or American lookback options using Monte Carlo simulations

## Syntax

```
[Price,Paths,Times,Z] = lookbackbyls(RateSpec,StockSpec,OptSpec,Strike,
Settle,ExerciseDates)
[Price,Paths,Times,Z] = lookbackbyls( ___,Name,Value)
```

## Description

[Price,Paths,Times,Z] = lookbackbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates) returns prices of lookback options using the Longstaff-Schwartz model for Monte Carlo simulations. lookbackbyls computes prices of European and American lookback options.

For American options, the Longstaff-Schwartz least squares method calculates the early exercise premium.

lookbackbyls calculates values of fixed- and floating-strike lookback options. To compute the value of a floating-strike lookback option, Strike must be specified as NaN.

[Price,Paths,Times,Z] = lookbackbyls( \_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Compute the Price for a Floating Lookback Option Using Monte Carlo Simulation

Define the RateSpec.

```
StartDates = 'Jan-1-2013';
EndDates = 'Jan-1-2014';
Rates = 0.042;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
```

```
    FinObj: 'RateSpec'
  Compounding: -1
         Disc: 0.9589
         Rates: 0.0420
    EndTimes: 1
    StartTimes: 0
         EndDates: 735600
         StartDates: 735235
    ValuationDate: 735235
         Basis: 0
    EndMonthRule: 1
```

Define the StockSpec.

```
AssetPrice = 50;  
Sigma = 0.36;  
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:  
    FinObj: 'StockSpec'  
    Sigma: 0.3600  
    AssetPrice: 50  
    DividendType: []  
    DividendAmounts: 0  
    ExDividendDates: []
```

Define the floating lookback option.

```
Settle = 'Jan-1-2013';  
Maturity = 'April-1-2013';  
OptSpec = 'put';  
Strike = NaN;
```

Compute the price of the European floating lookback option.

```
Price = lookbackbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity)
```

```
Price = 6.6471
```

### Compute the Price of a Fixed Lookback Option Using Monte Carlo Simulation

Define the RateSpec.

```
StartDates = 'Jan-1-2013';  
EndDates = 'Jan-1-2014';  
Rates = 0.045;  
Compounding = -1;  
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...  
    'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:  
    FinObj: 'RateSpec'  
    Compounding: -1  
    Disc: 0.9560  
    Rates: 0.0450  
    EndTimes: 1  
    StartTimes: 0  
    EndDates: 735600  
    StartDates: 735235  
    ValuationDate: 735235  
    Basis: 0  
    EndMonthRule: 1
```

Define the StockSpec.

```
AssetPrice = 102;
Sigma = 0.45;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.4500
    AssetPrice: 102
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the fixed lookback option.

```
Settle = 'Jan-1-2013';
Maturity = 'July-1-2013';
OptSpec = 'call';
Strike = 98;
```

Compute the price of the European fixed lookback option.

```
Price = lookbackbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity)
Price = 30.2368
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspect`.

`stockspect` handles several types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with values 'call' or 'put' | cell array of character vectors

Definition of option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors.

Data Types: `char` | `cell`

### Strike — Option strike price values

integer | vector of integers

Option strike price values, specified as an integer using a NINST-by-1 vector of strike price values.

Data Types: `single` | `double`

### **Settle — Settlement or trade date**

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Settlement or trade date for the lookback option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `double` | `char` | `cell`

### **ExerciseDates — Matrix of exercise callable or puttable dates for European or American options**

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Matrix of exercise callable or puttable dates for European or American options, specified as date character vectors or as serial date numbers as follows:

- European option — NINST-by-1 vector of exercise dates. For a European option, there is only one exercise date which is the option expiry date.
- American option — NINST-by-2 vector of exercise date boundaries. For each instrument, the option is exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is a NINST-by-1 vector of serial date numbers or cell array of character vectors, the option is exercised between `Settle` and the single listed exercise date.

Data Types: `double` | `char` | `cell`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Price =`

```
lookbackbyls(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr, 'AmericanOpt', 1)
```

### **AmericanOpt — Option type**

0 European (default) | scalar with value [0, 1]

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and an integer scalar flag with these values:

- 0 — European
- 1 — American

---

**Note** For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see <https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf>.

---

Data Types: `single` | `double`

### **NumTrials** — Scalar number of independent sample paths

1000 (default) | nonnegative scalar integer

Scalar number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of 'NumTrials' and a nonnegative integer.

Data Types: `single` | `double`

### **NumPeriods** — Scalar number of simulation periods per trial

100 (default) | nonnegative scalar integer

Scalar number of simulation periods per trial, specified as the comma-separated pair consisting of 'NumPeriods' and a nonnegative integer. NumPeriods is considered only when pricing European lookback options. For American lookback options, NumPeriods is equal to the number of exercise days during the life of the option.

Data Types: `single` | `double`

### **Z** — Time series array of dependent random variates

vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of 'Z' and a NumPeriods-by-1-by-NumTrials 3-D array. The Z value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: `single` | `double`

### **Antithetic** — Indicator for antithetic sampling

false (default) | scalar logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified as the comma-separated pair consisting of 'Antithetic' and a value of `true` or `false`.

Data Types: `logical`

## **Output Arguments**

### **Price** — Expected price of lookback option

scalar

Expected price of the lookback option, returned as a 1-by-1 scalar.

### **Paths** — Simulated paths of correlated state variables

vector

Simulated paths of correlated state variables, returned as a NumPeriods + 1-by-1-by-NumTrials 3-D time series array. Each row of Paths is the transpose of the state vector  $X(t)$  at time  $t$  for a given trial.

### **Times** — Observation times associated with simulated paths

vector

Observation times associated with simulated paths, returned as a `NumPeriods + 1`-by-1 column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

### **Z – Time series array of dependent random variates**

vector

Time series array of dependent random variates, returned as a `NumPeriods`-by-1-by-`NumTrials` 3-D array when `Z` is specified as an input argument. If the `Z` input argument is not specified, then the `Z` output argument contains the random variates generated internally.

## **More About**

### **Lookback Option**

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-38.

# lookbacksensbyls

Calculate price and sensitivities for European or American lookback options using Monte Carlo simulations

## Syntax

```
[PriceSens,Paths,Times,Z] = lookbacksensbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)
```

```
[PriceSens,Paths,Times,Z] = lookbacksensbyls( ___,Name,Value)
```

## Description

[PriceSens,Paths,Times,Z] = lookbacksensbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates) returns prices or sensitivities of lookback options using the Longstaff-Schwartz model for Monte Carlo simulations. lookbacksensbyls computes prices of European and American lookback options.

For American options, the Longstaff-Schwartz least squares method calculates the early exercise premium.

lookbacksensbyls calculates values of fixed- and floating-strike lookback options. To compute the value of a floating-strike lookback option, Strike must be specified as NaN.

[PriceSens,Paths,Times,Z] = lookbacksensbyls( \_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Compute the Price and Delta of a European Floating Lookback Option Using Monte Carlo Simulation

Define the RateSpec.

```
StartDates = 'Jan-1-2013';
EndDates = 'Jan-1-2014';
Rates = 0.41;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.6637
    Rates: 0.4100
    EndTimes: 1
    StartTimes: 0
    EndDates: 735600
    StartDates: 735235
    ValuationDate: 735235
```

```

    Basis: 0
    EndMonthRule: 1

```

Define the StockSpec with continuous dividend yield.

```

AssetPrice = 120;
Sigma = 0.3;
Yield = 0.045;
StockSpec = stockspec(Sigma, AssetPrice, 'Continuous', Yield)

StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3000
    AssetPrice: 120
    DividendType: {'continuous'}
    DividendAmounts: 0.0450
    ExDividendDates: []

```

Define the floating lookback option.

```

Settle = 'Jan-1-2013';
Maturity = 'July-1-2013';
OptSpec = 'call';
Strike = NaN;

```

Compute the price and delta of the European floating lookback option.

```

OutSpec = {'price', 'delta'};
[Price, Delta] = lookbacksensbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity,...
'OutSpec', OutSpec)

Price = 27.0768

Delta = 0.2256

```

### Compute the Price and Delta of a European Fixed Lookback Option Using Monte Carlo Simulation

Define the RateSpec.

```

StartDates = 'Jan-1-2013';
EndDates = 'Jan-1-2015';
Rates = 0.1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.8187
    Rates: 0.1000
    EndTimes: 2
    StartTimes: 0

```

```

    EndDates: 735965
    StartDates: 735235
    ValuationDate: 735235
        Basis: 0
    EndMonthRule: 1

```

Define the StockSpec.

```

AssetPrice = 103;
Sigma = 0.30;
StockSpec = stockspec(Sigma, AssetPrice)

```

```

StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3000
    AssetPrice: 103
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []

```

Define the fixed lookback option.

```

Settle = 'Jan-1-2013';
Maturity = 'July-1-2013';
OptSpec = 'call';
Strike = 99;

```

Compute the price and delta of the European fixed lookback option.

```

OutSpec = {'price', 'delta'};
[Price, Delta] = lookbacksensbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity,...
'OutSpec', OutSpec)

```

```

Price = 22.7227

```

```

Delta = 1.1349

```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` can handle several types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### **OptSpec — Definition of option**

character vector with values 'call' or 'put' | cell array of character vectors

Definition of option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors.

Data Types: `char` | `cell`

### **Strike — Option strike price values**

integer | vector of integers

Option strike price values, specified as an integer using a NINST-by-1 vector of strike price values.

Data Types: `single` | `double`

### **Settle — Settlement or trade date**

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Settlement or trade date for the lookback option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `double` | `char` | `cell`

### **ExerciseDates — Matrix of exercise callable or puttable dates for European or American options**

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Matrix of exercise callable or puttable dates for European or American options, specified as date character vectors or as serial date numbers as follows:

- European option — NINST-by-1 vector of exercise dates. For a European option, there is only one exercise date which is the option expiry date.
- American option — NINST-by-2 vector of exercise date boundaries. For each instrument, the option is exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is a NINST-by-1 vector of serial date numbers or cell array of character vectors, the option is exercised between `Settle` and the single listed exercise date.

Data Types: `double` | `char` | `cell`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `PriceSens =`

```
lookbacksensbyls(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr, 'AmericanOpt', 1, 'OutSpec', {'All'})
```

**AmericanOpt — Option type**

0 European (default) | scalar with value [0,1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and an integer scalar flag with these values:

- 0 — European
- 1 — American

---

**Note** For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see <https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf>.

---

Data Types: single | double

**NumTrials — Scalar number of independent sample paths**

1000 (default) | nonnegative scalar integer

Scalar number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of 'NumTrials' and a nonnegative integer.

Data Types: single | double

**NumPeriods — Scalar number of simulation periods per trial**

100 (default) | nonnegative scalar integer

Scalar number of simulation periods per trial, specified as the comma-separated pair consisting of 'NumPeriods' and a nonnegative integer. NumPeriods is considered only when pricing European lookback options. For American lookback options, NumPeriod is equal to the number of exercise days during the life of the option.

Data Types: single | double

**Z — Time series array of dependent random variates**

vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of 'Z' and a NumPeriods-by-1-by-NumTrials 3-D array. The Z value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: single | double

**Antithetic — Indicator for antithetic sampling**

false (default) | scalar logical flag with value true or false

Indicator for antithetic sampling, specified as the comma-separated pair consisting of 'Antithetic' and a value of true or false.

Data Types: logical

**OutSpec — Define outputs**

{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity.

Example: OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}

Data Types: char | cell

## Output Arguments

### PriceSens — Expected price or sensitivities of lookback option

scalar

Expected price or sensitivities (defined by OutSpec) of the lookback option, returned as a 1-by-1 array.

### Paths — Simulated paths of correlated state variables

vector

Simulated paths of correlated state variables, returned as a NumPeriods + 1-by-1-by-NumTrials 3-D time series array. Each row of Paths is the transpose of the state vector  $X(t)$  at time  $t$  for a given trial.

### Times — Observation times associated with simulated paths

vector

Observation times associated with simulated paths, returned as a NumPeriods + 1-by-1 column vector of observation times associated with the simulated paths. Each element of Times is associated with the corresponding row of Paths.

### Z — Time series array of dependent random variates

vector

Time series array of dependent random variates, returned as a NumPeriods-by-1-by-NumTrials 3-D array when Z is specified as an input argument. If the Z input argument is not specified, then the Z output argument contains the random variates generated internally.

## More About

### Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-38.

## lookbackbystt

Price lookback options using standard trinomial tree

### Syntax

```
Price = lookbackbystt(STTTree,OptSpec,Strike,Settle,ExerciseDates)
Price = lookbackbystt(___,AmericanOpt)
```

### Description

Price = lookbackbystt(STTTree,OptSpec,Strike,Settle,ExerciseDates) prices lookback options using a standard trinomial (STT) tree.

Price = lookbackbystt(\_\_\_,AmericanOpt) prices lookback options using a standard trinomial (STT) tree with an optional argument for AmericanOpt.

### Examples

#### Price a Lookback Option Using the Standard Trinomial Tree Model

Create a RateSpec.

```
StartDates = 'Jan-1-2009';
EndDates = 'Jan-1-2013';
Rates = 0.035;
Basis = 1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
    'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.8694
    Rates: 0.0350
    EndTimes: 4
    StartTimes: 0
    EndDates: 735235
    StartDates: 733774
    ValuationDate: 733774
    Basis: 1
    EndMonthRule: 1
```

Create a StockSpec.

```
AssetPrice = 85;
Sigma = 0.15;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
```

```

        Sigma: 0.1500
        AssetPrice: 85
        DividendType: []
        DividendAmounts: 0
        ExDividendDates: []

```

Create an STTtree.

```

NumPeriods = 4;
TimeSpec = stttimespec(StartDates, EndDates, 4);
STTtree = stttree(StockSpec, RateSpec, TimeSpec)

```

```

STTtree = struct with fields:
    FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2 3 4]
    dObs: [733774 734139 734504 734869 735235]
    STree: {1x5 cell}
    Probs: {[3x1 double] [3x3 double] [3x5 double] [3x7 double]}

```

Define the lookback option and compute the price.

```

Settle = '1/1/09';
ExerciseDates = [datenum('1/1/12'); datenum('1/1/13')];
OptSpec = 'call';
Strike = [90;95];

```

```

Price= lookbackbystt(STTtree, OptSpec, Strike, Settle, ExerciseDates)

```

```

Price = 2x1

```

```

    11.7296
    12.9120

```

## Input Arguments

### STTtree — Stock tree structure for standard trinomial tree

structure

Stock tree structure for a standard trinomial tree, specified by using `stttree`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as 'call' or 'put' using a character vector or a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: `char` | `cell`

**Strike — Option strike price value**

matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using a NINST-by-1 matrix of strike price values. Each row is the schedule for one option. To compute the value of a floating-strike lookback option, **Strike** should be specified as NaN. Floating-strike lookback options are also known as average strike options.

Data Types: double

**Settle — Settlement date or trade date**

serial date number | date character vector

Settlement date or trade date for the lookback option, specified as a NINST-by-1 matrix of settlement or trade dates using serial date numbers or date character vectors.

---

**Note** The **Settle** date for every lookback option is set to the **ValuationDate** of the stock tree. The lookback argument, **Settle**, is ignored.

---

Data Types: double | char

**ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a serial date number or date character vector:

- For a European option, use a NINST-by-1 matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one **ExerciseDates** on the option expiry date.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, or if **ExerciseDates** is a NINST-by-1 vector of serial date numbers or cell array of character vectors, the option can be exercised between **ValuationDate** of the stock tree and the single listed **ExerciseDates**.

Data Types: double | char

**AmericanOpt — Option type**

0 European (default) | scalar with values [0, 1]

Option type, specified as NINST-by-1 positive integer scalar flags with values:

- 0 — European
- 1 — American

Data Types: single | double

**Output Arguments****Price — Expected prices for lookback options at time 0**

matrix

Expected prices for lookback options at time 0, returned as a NINST-by-1 matrix. Pricing of lookback options is done using Hull-White (1993). Consequently, for these options there are no unique prices on the tree nodes with the exception of the root node.

## More About

### Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see "Lookback Option" on page 3-38.

## Introduced in R2015b

## lrtimespec

Specify time structure for Leisen-Reimer binomial tree

### Syntax

```
TimeSpec = lrtimespec(ValuationDate,Maturity,NumPeriods)
```

### Description

`TimeSpec = lrtimespec(ValuationDate,Maturity,NumPeriods)` specifies a time structure for a Leisen-Reimer stock tree (`lrtree`).

### Examples

#### Specify the Time Structure for Leisen-Reimer Binomial Tree

This example shows how to specify a 5-period tree with time steps of 1 year.

```
ValuationDate = '1-July-2010';
Maturity = '1-July-2015';
TimeSpec = lrtimespec(ValuationDate, Maturity, 5)

TimeSpec = struct with fields:
    FinObj: 'BinTimeSpec'
    ValuationDate: 734320
    Maturity: 736146
    NumPeriods: 5
    Basis: 0
    EndMonthRule: 1
    tObs: [0 1 2 3 4 5]
    dObs: [734320 734685 735050 735415 735780 736146]
```

### Input Arguments

#### ValuationDate — Pricing date and first observation in Leisen-Reimer stock tree

serial date number | character vector date

Pricing date and first observation in the `lrtree`, specified as a scalar date using a serial date number or date character vector.

Data Types: double | char

#### Maturity — Date marking the depth of the Leisen-Reimer stock tree

serial date number | date character vector

Date marking the depth of the Leisen-Reimer stock tree, specified as scalar serial date number or date character vector.

Data Types: double | char

**NumPeriods — Number of time steps in the Leisen-Reimer stock tree**

odd integer value

Number of time steps in the Leisen-Reimer stock tree, specified as scalar odd integer value.

---

**Note** Leisen-Reimer requires the number of steps to be an odd number.

---

Data Types: double

**Output Arguments****TimeSpec — Specification for the time layout for lrtree**

structure

Specification for the time layout for lrtree, returned as a structure.

**References**

## Lrtree

Build Leisen-Reimer stock tree

### Syntax

```
LRTree = lrtree(StockSpec,RateSpec,TimeSpec,Strike)
LRTree = lrtree( ____,Name,Value)
```

### Description

`LRTree = lrtree(StockSpec,RateSpec,TimeSpec,Strike)` builds a Leisen-Reimer stock tree.

`LRTree = lrtree( ____,Name,Value)` adds a name-value pair argument.

### Examples

#### Build a Leisen-Reimer Stock Tree

This example shows how to build Leisen-Reimer stock tree. Consider a European put option with an exercise price of \$30 that expires on June 1, 2010. The underlying stock is trading at \$30 on January 1, 2010 and has a volatility of 30% per annum. The annualized continuously compounded risk-free rate is 5% per annum. Using this data, create a Leisen-Reimer tree with 101 steps using the PP1 method.

```
AssetPrice = 30;
Strike = 30;

ValuationDate = 'Jan-1-2010';
Maturity = 'June-1-2010';

% define StockSpec
Sigma = 0.3;
StockSpec = stockspeg(Sigma, AssetPrice);

% define RateSpec
Rates = 0.05;
Settle = ValuationDate;
Basis = 1;
Compounding = -1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);

% build the Leisen-Reimer (LR) tree with 101 steps
LRTimeSpec = lrtimespec(ValuationDate, Maturity, 101);

% use the PP1 method
LRMethod = 'PP1';

LRTree = lrtree(StockSpec, RateSpec, LRTimeSpec, Strike, ...
'method', LRMethod)
```

```

LRTree = struct with fields:
    FinObj: 'BinStockTree'
    Method: 'LR'
    Submethod: 'PP1'
    Strike: 30
    StockSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [1x102 double]
        dObs: [1x102 double]
    STree: {1x102 cell}
    UpProbs: [101x1 double]

```

## Input Arguments

### StockSpec — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be 0.

Data Types: `struct`

### RateSpec — Interest-rate specification for initial risk-free rate curve

structure

Interest-rate specification for initial rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### TimeSpec — Time tree layout specification

structure

Time tree layout specification, specified using the `TimeSpec` output obtained from `lrtimespec`.

Data Types: `struct`

### Strike — Option strike price value

nonnegative integer

Option strike price value, specified as a scalar nonnegative integer.

Data Types: `double`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `LRTree = lrtree(StockSpec, RateSpec, LRTimeSpec, Strike, 'Method', 'PP2')`

**Method — Computation method**

'PP1' (default) | character vector with value 'PP1' or 'PP2'

Computation method, specified as the comma-separated pair consisting of 'Method' and a character vector with a value of 'PP1' or 'PP2'. 'PP1' is for Peizer-Pratt method 1 inversion and 'PP2' is for Peizer-Pratt method 2 inversion. For more information on 'PP1' and 'PP2' methods, see “Leisen-Reimer Tree (LR) Modeling” on page C-3.

Data Types: char

**Output Arguments****LRTree — Stock and time information for a Leisen-Reimer tree**

structure

Stock and time information for a Leisen-Reimer tree, returned as a structure.

# maxassetbystulz

Determine European rainbow option price on maximum of two risky assets using Stulz option pricing model

## Syntax

Price =  
`maxassetbystulz(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)`

## Arguments

RateSpec	The annualized, continuously compounded rate term structure. For information on the interest rate specification, see <code>intenvset</code> .
StockSpec1	Stock specification for asset 1. See <code>stockspec</code> .
StockSpec2	Stock specification for asset 2. See <code>stockspec</code> .
Settle	NINST-by-1 vector of settlement or trade dates.
Maturity	NINST-by-1 vector of maturity dates.
OptSpec	NINST-by-1 cell array of character vectors 'call' or 'put'.
Strike	NINST-by-1 vector of strike price values.
Corr	NINST-by-1 vector of correlation between the underlying asset prices.

## Description

Price =  
`maxassetbystulz(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)` computes rainbow option prices using the Stulz option pricing model.

Price is a NINST-by-1 vector of expected option prices.

## Examples

### Compute Rainbow Option Prices Using the Stulz Option Pricing Model

Consider a European rainbow option that gives the holder the right to buy either \$100,000 worth of an equity index at a strike price of 1000 (asset 1) or \$100,000 of a government bond (asset 2) with a strike price of 100% of face value, whichever is worth more at the end of 12 months. On January 15, 2008, the equity index is trading at 950, pays a dividend of 2% annually and has a return volatility of 22%. Also on January 15, 2008, the government bond is trading at 98, pays a coupon yield of 6%, and has a return volatility of 15%. The risk-free rate is 5%. Using this data, if the correlation between the rates of return is -0.5, 0, and 0.5, calculate the price of the European rainbow option.

Since the asset prices in this example are in different units, it is necessary to work in either index points (asset 1) or in dollars (asset 2). The European rainbow option allows the holder to buy the

following: 100 units of the equity index at \$1000 each (for a total of \$100,000) or 1000 units of the government bonds at \$100 each (for a total of \$100,000). To convert the bond price (asset 2) to index units (asset 1), you must make the following adjustments:

- Multiply the strike price and current price of the government bond by 10 (1000/100).
- Multiply the option price by 100, considering that there are 100 equity index units in the option.

Once these adjustments are introduced, the strike price is the same for both assets (\$1000). First, create the `RateSpec`:

```
Settle = 'Jan-15-2008';
Maturity = 'Jan-15-2009';
Rates = 0.05;
Basis = 1;

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', Basis)

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9512
    Rates: 0.0500
    EndTimes: 1
    StartTimes: 0
    EndDates: 733788
    StartDates: 733422
    ValuationDate: 733422
    Basis: 1
    EndMonthRule: 1
```

Create the two `StockSpec` definitions.

```
AssetPrice1 = 950; % Asset 1 => Equity index
AssetPrice2 = 980; % Asset 2 => Government bond
Sigma1 = 0.22;
Sigma2 = 0.15;
Div1 = 0.02;
Div2 = 0.06;

StockSpec1 = stockspec(Sigma1, AssetPrice1, 'continuous', Div1)

StockSpec1 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.2200
    AssetPrice: 950
    DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []

StockSpec2 = stockspec(Sigma2, AssetPrice2, 'continuous', Div2)

StockSpec2 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1500
    AssetPrice: 980
```

```

    DividendType: {'continuous'}
    DividendAmounts: 0.0600
    ExDividendDates: []

```

Calculate the price of the options for different correlation levels.

```

Strike = 1000 ;
Corr = [-0.5; 0; 0.5];
OptSpec = 'call';

Price = maxassetbystulz(RateSpec, StockSpec1, StockSpec2,...
    Settle, Maturity, OptSpec, Strike, Corr)

Price = 3×1

    111.6683
    103.7715
    92.4412

```

These are the prices of one unit. This means that the premium is 11166.83, 10377.15, and 9244.12 (for 100 units).

## More About

### Rainbow Option

A rainbow option payoff depends on the relative price performance of two or more assets.

A rainbow option gives the holder the right to buy or sell the best or worst of two securities, or options that pay the best or worst of two assets. Rainbow options are popular because of the lower premium cost of the structure relative to the purchase of two separate options. The lower cost reflects the fact that the payoff is generally lower than the payoff of the two separate options.

Financial Instruments Toolbox supports two types of rainbow options:

- Minimum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth less.
- Maximum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth more.

For more information, see “Rainbow Option” on page 3-26.

## maxassetsensbystulz

Determine European rainbow option prices or sensitivities on maximum of two risky assets using Stulz pricing model

### Syntax

```
PriceSens =
maxassetsensbystulz(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)
PriceSens =
maxassetsensbystulz(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr, OutSpec)
```

### Arguments

RateSpec	The annualized, continuously compounded rate term structure. For information on the interest rate specification, see <code>intenvset</code> .
StockSpec1	Stock specification for asset 1. See <code>stockspec</code> .
StockSpec2	Stock specification for asset 2. See <code>stockspec</code> .
Settle	NINST-by-1 vector of settlement or trade dates.
Maturity	NINST-by-1 vector of maturity dates.
OptSpec	NINST-by-1 cell array of character vectors 'call' or 'put'.
Strike	NINST-by-1 vector of strike price values.
Corr	NINST-by-1 vector of correlation between the underlying asset prices.

OutSpec	<p>(Optional) All optional inputs are specified as matching parameter name-value pairs. The parameter name is specified as a character vector, followed by the corresponding parameter value. You can specify parameter name-value pairs in any order. Names are case-insensitive and partial matches are allowed provided no ambiguities exist. Valid parameter names are:</p> <ul style="list-style-type: none"> <li>• NOUT-by-1 or 1-by-NOUT cell array of character vectors indicating the nature and order of the outputs for the function. Possible values are 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', or 'All'.</li> </ul> <p>For example, <code>OutSpec = {'Price'; 'Lambda'; 'Rho'}</code> specifies that the output should be Price, Lambda, and Rho, in that order.</p> <p>To invoke from a function: <code>[Price, Lambda, Rho] = maxassetsensbystulz(..., 'OutSpec', {'Price', 'Lambda', 'Rho'})</code></p> <p><code>OutSpec = {'All'}</code> specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying <code>OutSpec</code> as <code>OutSpec = {'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', 'Price'};</code>.</p> <ul style="list-style-type: none"> <li>• Default is <code>OutSpec = {'Price'}</code>.</li> </ul>
---------	--

## Description

`PriceSens = maxassetsensbystulz(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)` computes rainbow option prices using the Stulz option pricing model.

`PriceSens = maxassetsensbystulz(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr, OutSpec)` computes rainbow option prices or sensitivities using the Stulz option pricing model.

`PriceSens` is a NINST-by-1 or NINST-by-2 vector of expected prices or sensitivities values.

## Examples

### Compute Rainbow Option Prices and Sensitivities Using the Stulz Option Pricing Model

Consider a European rainbow option that gives the holder the right to buy either \$100,000 of an equity index at a strike price of 1000 (asset 1) or \$100,000 of a government bond (asset 2) with a strike price of 100% of face value, whichever is worth more at the end of 12 months. On January 15, 2008, the equity index is trading at 950, pays a dividend of 2% annually, and has a return volatility of 22%. Also on January 15, 2008, the government bond is trading at 98, pays a coupon yield of 6%, and has a return volatility of 15%. The risk-free rate is 5%. Using this data, calculate the price and sensitivity of the European rainbow option if the correlation between the rates of return is -0.5, 0, and 0.5.

Since the asset prices in this example are in different units, it is necessary to work in either index points (for asset 1) or in dollars (for asset 2). The European rainbow option allows the holder to buy the following: 100 units of the equity index at \$1000 each (for a total of \$100,000) or 1000 units of the government bonds at \$100 each (for a total of \$100,000). To convert the bond price (asset 2) to index units (asset 1), you must make the following adjustments:

- Multiply the strike price and current price of the government bond by 10 (1000/100).
- Multiply the option price by 100, considering that there are 100 equity index units in the option.

Once these adjustments are introduced, the strike price is the same for both assets (\$1000). First, create the RateSpec:

```
Settle = 'Jan-15-2008';
Maturity = 'Jan-15-2009';
Rates = 0.05;
Basis = 1;
```

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9512
    Rates: 0.0500
    EndTimes: 1
    StartTimes: 0
    EndDates: 733788
    StartDates: 733422
    ValuationDate: 733422
    Basis: 1
    EndMonthRule: 1
```

Create the two StockSpec definitions.

```
AssetPrice1 = 950; % Asset 1 => Equity index
AssetPrice2 = 980; % Asset 2 => Government bond
Sigma1 = 0.22;
Sigma2 = 0.15;
Div1 = 0.02;
Div2 = 0.06;
```

```
StockSpec1 = stockspec(Sigma1, AssetPrice1, 'continuous', Div1)
```

```
StockSpec1 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.2200
    AssetPrice: 950
    DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Sigma2, AssetPrice2, 'continuous', Div2)
```

```
StockSpec2 = struct with fields:
    FinObj: 'StockSpec'
```

```

        Sigma: 0.1500
    AssetPrice: 980
    DividendType: {'continuous'}
    DividendAmounts: 0.0600
    ExDividendDates: []

```

Calculate the price and delta for different correlation levels.

```

Strike = 1000 ;
Corr = [-0.5; 0; 0.5];
OutSpec = {'price'; 'delta'};
OptSpec = 'call';
[Price, Delta] = maxassetsensbystulz(RateSpec, StockSpec1, StockSpec2,...
Settle, Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec)

```

Price = 3×1

```

111.6683
103.7715
92.4412

```

Delta = 3×2

```

0.4594    0.3698
0.4292    0.3166
0.4053    0.2512

```

The output Delta has two columns: the first column represents the Delta with respect to the equity index (asset 1), and the second column represents the Delta with respect to the government bond (asset 2). The value 0.4595 represents Delta with respect to one unit of the equity index. Since there are 100 units of the equity index, the overall Delta would be 45.94 (100 \* 0.4594 ) for a correlation level of -0.5. To calculate the Delta with respect to the government bond, remember that an adjusted price of 980 was used instead of 98. Therefore, for example, the Delta with respect to government bond, for a correlation of 0.5 would be 251.2 (0.2512 \* 100 \* 10 ).

## More About

### Rainbow Option

A rainbow option payoff depends on the relative price performance of two or more assets.

A rainbow option gives the holder the right to buy or sell the best or worst of two securities, or options that pay the best or worst of two assets. Rainbow options are popular because of the lower premium cost of the structure relative to the purchase of two separate options. The lower cost reflects the fact that the payoff is generally lower than the payoff of the two separate options.

Financial Instruments Toolbox supports two types of rainbow options:

- Minimum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth less.
- Maximum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth more.

# minassetbystulz

Determine European rainbow option prices on minimum of two risky assets using Stulz option pricing model

## Syntax

```
Price = minassetbystulz(RateSpec, StockSpec1, StockSpec2, Settle, Maturity,
OptSpec, Strike, Corr)
```

## Description

Price = minassetbystulz(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr) computes option prices using the Stulz option pricing model.

## Examples

### Compute Rainbow Option Prices Using the Stulz Option Pricing Model

Consider a European rainbow put option that gives the holder the right to sell either stock A or stock B at a strike of 50.25, whichever has the lower value on the expiration date May 15, 2009. On November 15, 2008, stock A is trading at 49.75 with a continuous annual dividend yield of 4.5% and has a return volatility of 11%. Stock B is trading at 51 with a continuous dividend yield of 5% and has a return volatility of 16%. The risk-free rate is 4.5%. Using this data, if the correlation between the rates of return is -0.5, 0, and 0.5, calculate the price of the minimum of two assets that are European rainbow put options. First, create the RateSpec:

```
Settle = 'Nov-15-2008';
Maturity = 'May-15-2009';
Rates = 0.045;
Basis = 1;
```

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9778
    Rates: 0.0450
    EndTimes: 0.5000
    StartTimes: 0
    EndDates: 733908
    StartDates: 733727
    ValuationDate: 733727
    Basis: 1
    EndMonthRule: 1
```

Create the two StockSpec definitions.

```
AssetPriceA = 49.75;
AssetPriceB = 51;
SigmaA = 0.11;
SigmaB = 0.16;
DivA = 0.045;
DivB = 0.05;

StockSpecA = stockspeg(SigmaA, AssetPriceA, 'continuous', DivA)

StockSpecA = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1100
    AssetPrice: 49.7500
    DividendType: {'continuous'}
    DividendAmounts: 0.0450
    ExDividendDates: []

StockSpecB = stockspeg(SigmaB, AssetPriceB, 'continuous', DivB)

StockSpecB = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1600
    AssetPrice: 51
    DividendType: {'continuous'}
    DividendAmounts: 0.0500
    ExDividendDates: []
```

Compute the price of the options for different correlation levels.

```
Strike = 50.25;
Corr = [-0.5;0;0.5];
OptSpec = 'put';
Price = minassetbystulz(RateSpec, StockSpecA, StockSpecB, Settle,...
Maturity, OptSpec, Strike, Corr)

Price = 3×1

    3.4320
    3.1384
    2.7694
```

The values 3.43, 3.14, and 2.77 are the price of the European rainbow put options with a correlation level of -0.5, 0, and 0.5 respectively.

## Input Arguments

**RateSpec** — Annualized, continuously compounded rate term structure  
structure

Annualized, continuously compounded rate term structure, specified using `intenvset`.

Data Types: structure

**StockSpec1** — Stock specification for asset 1  
structure

Stock specification for asset 1, specified using `stockspec`.

Data Types: `structure`

### **StockSpec2 — Stock specification for asset 2**

`structure`

Stock specification for asset 2, specified using `stockspec`.

Data Types: `structure`

### **Settle — Settlement or trade dates**

`vector`

Settlement or trade dates, specified as an NINST-by-1 vector of numeric dates.

Data Types: `double`

### **Maturity — Maturity dates**

`vector`

Maturity dates, specified as an NINST-by-1 vector.

Data Types: `double`

### **OptSpec — Option type**

cell array of character vectors with a value of 'call' or 'put'

Option type, specified as an NINST-by-1 cell array of character vectors with a value of 'call' or 'put'.

Data Types: `cell`

### **Strike — Strike prices**

`vector`

Strike prices, specified as an NINST-by-1 vector.

Data Types: `double`

### **Corr — Correlation between the underlying asset prices**

`vector`

Correlation between the underlying asset prices, specified as an NINST-by-1 vector.

Data Types: `double`

## **Output Arguments**

### **Price — Expected option prices**

`vector`

Expected option prices, returned as an NINST-by-1 vector.

### Introduced in R2009a

# minassetsensbystulz

Determine European rainbow option prices or sensitivities on minimum of two risky assets using Stulz option pricing model

## Syntax

```
PriceSens = minassetsensbystulz(RateSpec, StockSpec1, StockSpec2, Settle,
Maturity, OptSpec, Strike, Corr)
PriceSens = minassetsensbystulz( ____, Name, Value)
```

## Description

`PriceSens = minassetsensbystulz(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)` computes option prices using the Stulz option pricing model.

`PriceSens = minassetsensbystulz( ____, Name, Value)` specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute Rainbow Option Prices and Sensitivities Using the Stulz Option Pricing Model

Consider a European rainbow put option that gives the holder the right to sell either stock A or stock B at a strike of 50.25, whichever has the lower value on the expiration date May 15, 2009. On November 15, 2008, stock A is trading at 49.75 with a continuous annual dividend yield of 4.5% and has a return volatility of 11%. Stock B is trading at 51 with a continuous dividend yield of 5% and has a return volatility of 16%. The risk-free rate is 4.5%. Using this data, if the correlation between the rates of return is -0.5, 0, and 0.5, calculate the price and sensitivity of the minimum of two assets that are European rainbow put options. First, create the `RateSpec`:

```
Settle = 'Nov-15-2008';
Maturity = 'May-15-2009';
Rates = 0.045;
Basis = 1;
```

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', Basis)
```

```
RateSpec = struct with fields:
```

```
    FinObj: 'RateSpec'
  Compounding: -1
         Disc: 0.9778
         Rates: 0.0450
    EndTimes: 0.5000
    StartTimes: 0
         EndDates: 733908
    StartDates: 733727
  ValuationDate: 733727
         Basis: 1
  EndMonthRule: 1
```

Create the two StockSpec definitions.

```
AssetPriceA = 49.75;
AssetPriceB = 51;
SigmaA = 0.11;
SigmaB = 0.16;
DivA = 0.045;
DivB = 0.05;
```

```
StockSpecA = stockspec(SigmaA, AssetPriceA, 'continuous', DivA)
```

```
StockSpecA = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1100
    AssetPrice: 49.7500
    DividendType: {'continuous'}
    DividendAmounts: 0.0450
    ExDividendDates: []
```

```
StockSpecB = stockspec(SigmaB, AssetPriceB, 'continuous', DivB)
```

```
StockSpecB = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1600
    AssetPrice: 51
    DividendType: {'continuous'}
    DividendAmounts: 0.0500
    ExDividendDates: []
```

Calculate price and delta for different correlation levels.

```
Strike = 50.25;
Corr = [-0.5;0;0.5];
OptSpec = 'put';
OutSpec = {'Price'; 'delta'};
[P, D] = minassetsensbystulz(RateSpec, StockSpecA, StockSpecB,...
    Settle, Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec)
```

P = 3×1

```
3.4320
3.1384
2.7694
```

D = 3×2

```
-0.4183 -0.3496
-0.3746 -0.3189
-0.3304 -0.2905
```

The output Delta has two columns: the first column represents the Delta with respect to the stock A (asset 1), and the second column represents the Delta with respect to the stock B (asset 2). The value 0.4183 represents Delta with respect to the stock A for a correlation level of -0.5. The Delta with respect to stock B, for a correlation of zero is -0.3189.

## Input Arguments

### **RateSpec — Annualized, continuously compounded rate term structure**

structure

Annualized, continuously compounded rate term structure, specified using `intenvset`.

Data Types: `structure`

### **StockSpec1 — Stock specification for asset 1**

structure

Stock specification for asset 1, specified using `stockspec`.

Data Types: `structure`

### **StockSpec2 — Stock specification for asset 2**

structure

Stock specification for asset 2, specified using `stockspec`.

Data Types: `structure`

### **Settle — Settlement or trade dates**

vector

Settlement or trade dates, specified as an NINST-by-1 vector of numeric dates.

Data Types: `double`

### **Maturity — Maturity dates**

vector

Maturity dates, specified as an NINST-by-1 vector.

Data Types: `double`

### **OptSpec — Option type**

cell array of character vectors with a value of 'call' or 'put'

Option type, specified as an NINST-by-1 cell array of character vectors with a value of 'call' or 'put'.

Data Types: `cell`

### **Strike — Strike prices**

vector

Strike prices, specified as an NINST-by-1 vector.

Data Types: `double`

### **Corr — Correlation between the underlying asset prices**

vector

Correlation between the underlying asset prices, specified as an NINST-by-1 vector.

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[PriceSens] = minassetsensbystulz(RateSpec, StockSpecA, StockSpecB, Settle, Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec)`

### OutSpec — Define outputs

`{'Price'}` (default) | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`-by-1 or 1-by-`NOUT` cell array of character vectors or string array with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}`

Data Types: `cell`

## Output Arguments

### PriceSens — Expected prices or sensitivities

vector

Expected prices or sensitivities, returned as an `NINST`-by-1 or `NINST`-by-2 vector.

## More About

### Rainbow Option

A rainbow option payoff depends on the relative price performance of two or more assets.

A rainbow option gives the holder the right to buy or sell the best or worst of two securities, or options that pay the best or worst of two assets. Rainbow options are popular because of the lower premium cost of the structure relative to the purchase of two separate options. The lower cost reflects the fact that the payoff is generally lower than the payoff of the two separate options.

Financial Instruments Toolbox supports two types of rainbow options:

- Minimum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth less.
- Maximum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth more.

## mkbush

Create bushy tree

### Syntax

```
[Tree, NumStates] = mkbush(NumLevels, NumChild, NumPos, Trim, NodeVal)
```

### Arguments

NumLevels	Number of time levels of the tree.
NumChild	1-by- number of levels (NUMLEVELS) vector with number of branches (children) of the nodes in each level.
NumPos	1-by-NUMLEVELS vector containing the length of the state vectors in each time level.
Trim	(Optional) Scalar 0 or 1. If Trim = 1, NumPos decreases by 1 when moving from one time level to the next. Otherwise, if Trim = 0 (Default), NumPos does not decrease.
NodeVal	(Optional) Initial value at each node of the tree. Default = NaN.

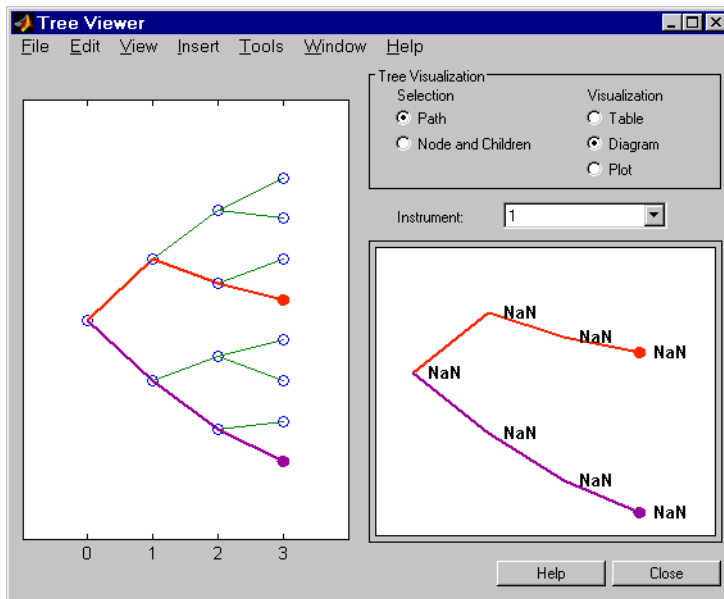

### Description

[Tree, NumStates] = mkbush(NumLevels, NumChild, NumPos, Trim, NodeVal) creates a bushy tree Tree with initial values NodeVal at each node. NumStates is a 1-by-NUMLEVELS vector containing the number of state vectors in each level.

### Examples

Create a tree with four time levels, two branches per node, and a vector of three elements in each node with each element initialized to NaN.

```
Tree = mkbush(4, 2, 3);
treeview(Tree)
```

## mktree

Create recombining binomial tree

### Syntax

```
Tree = mktree(NumLevels, NumPos, NodeVal, IsPriceTree)
```

### Arguments

NumLevels	Number of time levels of the tree.
NumPos	1-by-NUMLEVELS vector containing the length of the state vectors in each time level.
NodeVal	(Optional) Initial value at each node of the tree. Default = NaN.
IsPriceTree	(Optional) Boolean determining if a final horizontal branch is added to the tree. Default = 0.

### Description

`Tree = mktree(NumLevels, NumPos, NodeVal, IsPriceTree)` creates a recombining tree `Tree` with initial values `NodeVal` at each node.

### Examples

Create a recombining tree of four time levels with a vector of two elements in each node and each element initialized to NaN.

```
Tree = mktree(4, 2);
```

# mktrintree

Create recombining trinomial tree

## Syntax

```
TrinTree = mktrintree(NumLevels, NumPos, NumStates, NodeVal)
```

## Arguments

NumLevels	Number of time levels of the tree.
NumPos	1-by- <code>NUMLEVELS</code> vector containing the length of the state vectors in each time level.
NumStates	1-by- <code>NUMLEVELS</code> vector containing the number of state vectors in each time level.
NodeVal	(Optional) Initial value at each node of the tree. Default = NaN.

## Description

`TrinTree = mktrintree(NumLevels, NumPos, NumStates, NodeVal)` creates a recombining tree `Tree` with initial values `NodeVal` at each node.

## Examples

Create a recombining trinomial tree of four time levels with a vector of two elements in each node and each element initialized to NaN.

```
TrinTree = mktrintree(4, [2 2 2 2], [1 3 5 7]);
```

## mmktbybdt

Create money-market tree from Black-Derman-Toy interest-rate tree

### Syntax

```
MMktTree = mmktbybdt(BDTree)
```

### Arguments

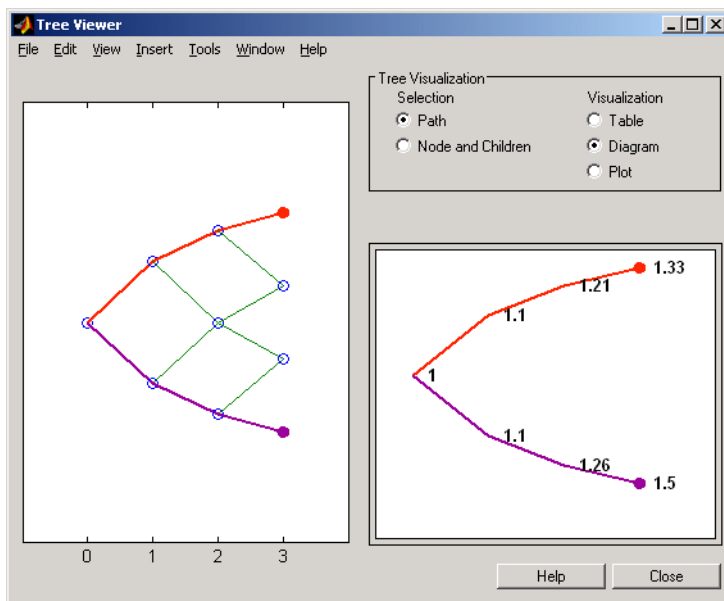

BDTree	Interest-rate tree structure created by <code>bdttree</code> .
--------	--

### Description

`MMktTree = mmktbybdt(BDTree)` creates a money-market tree from an interest-rate tree structure created by `bdttree`.

### Examples

```
load deriv.mat;
MMktTree = mmktbybdt(BDTree);
treeviewer(MMktTree)
```

### See Also

`bdttree`

## mmktbyhjm

Create money-market tree from Heath-Jarrow-Morton interest-rate tree

### Syntax

```
MMktTree = mmktbyhjm(HJMTree)
```

### Arguments

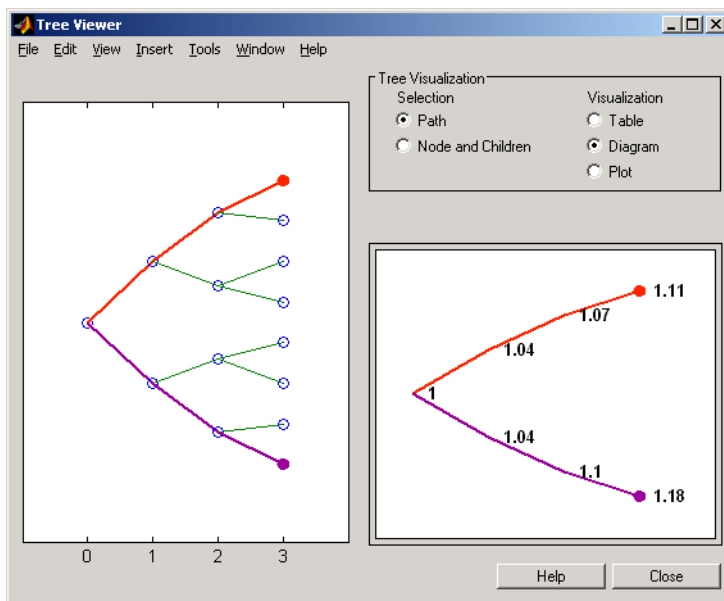

HJMTree	Forward-rate tree structure created by hjmtree.
---------	---

### Description

MMktTree = mmktbyhjm(HJMTree) creates a money-market tree from a forward-rate tree structure created by hjmtree.

### Examples

```
load deriv.mat;
MMktTree = mmktbyhjm(HJMTree);
treeview(MMktTree)
```

### See Also

hjmtree

## normalvolbysabr

Implied Normal (Bachelier) volatility by SABR model

### Syntax

```
outVol = normalvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,Strike)
outVol = normalvolbysabr( ____,Name,Value)
```

### Description

`outVol = normalvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,Strike)` calculates the implied Normal (Bachelier) volatility by using the SABR stochastic volatility model.

`outVol = normalvolbysabr( ____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Implied Normal (Bachelier) Volatility Using the SABR Model

Define the model parameters and option data.

```
ForwardValue = 0.0209;
Strike = 0.02;
Alpha = 0.041;
Beta = 0.5;
Rho = -0.2;
Nu = 0.33;
```

```
Settle = datenum('15-Feb-2018');
ExerciseDate = datenum('15-Feb-2020');
```

Compute the Normal (Bachelier) volatility using the SABR model.

```
ComputedVols = normalvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,Strike)
ComputedVols = 0.0059
```

#### Compute the Implied Normal (Bachelier) Volatility Using the Normal SABR Model

To use the Normal SABR model, set the `Beta` parameter to zero. Negative interest rates are allowed when the Normal SABR model is used in combination with Normal (Bachelier) implied volatility.

Define the model parameters and option data.

```
ForwardValue = -0.00383;
Strike = -0.003;
```

```
Alpha = 0.007;
Beta = 0; % Set the Beta parameter to zero to use the Normal SABR model
Rho = -0.18;
Nu = 0.29;
```

```
Settle = datenum('17-Jan-2018');
ExerciseDate = datenum('17-Apr-2018');
```

Compute the Normal (Bachelier) volatility using the Normal SABR model.

```
ComputedVols = normalvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,Strike)
```

```
ComputedVols = 0.0070
```

## Input Arguments

### Alpha — Current SABR volatility

scalar numeric

Current SABR volatility, specified as a scalar numeric.

Data Types: double

### Beta — SABR constant elasticity of variance (CEV) exponent

scalar numeric

SABR CEV exponent, specified as a scalar numeric.

---

**Note** Set the Beta parameter to 0 to allow a negative ForwardValue and Strike.

---

Data Types: double

### Rho — Correlation between forward value and volatility

scalar numeric

Correlation between forward value and volatility, specified as a scalar numeric.

Data Types: double

### Nu — Volatility of volatility

scalar numeric

Volatility of volatility, specified as a scalar numeric.

Data Types: double

### Settle — Settlement date

scalar for serial nonnegative date number | scalar for date character vector

Settlement date, specified as a scalar using a serial nonnegative date number or date character vector.

Data Types: double | char

**ExerciseDate — Option exercise date**

scalar for serial nonnegative date number | scalar for date character vector

Option exercise date, specified as a scalar using a serial nonnegative date number or date character vector.

Data Types: double | char

**ForwardValue — Current forward value of underlying asset**

scalar numeric | vector

Current forward value of the underlying asset, specified as a scalar numeric or vector of size `NumVols-by-1`.

Data Types: double

**Strike — Option strike price value**

scalar numeric | vector

Option strike price value, specified as a scalar numeric or a vector of size `NumVols-by-1`.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `outVol = normalvolbysabr(Alpha, Beta, Rho, Nu, Settle, ExerciseDate, ForwardValue, Strike, 'Basis', 2)`

**Basis — Day-count basis of instrument**

0 (actual/actual) (default) | positive integers of the set [1...13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer from the set [1...13].

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

## Output Arguments

### outVol — Normal (Bachelier) volatility computed by SABR model

scalar numeric | vector

Normal (Bachelier) volatility computed by the SABR model, returned as a scalar numeric or vector of size NumVols-by-1.

## Algorithms

The two general case algorithms for normalvolbysabr are not At-The-Money (ATM) and ATM.

For not ATM ( $F \neq K$ ):

$$\begin{aligned}\sigma_N(\alpha, \beta, \rho, v, F, K, T) &= \alpha \frac{(F - K)(1 - \beta)}{F^{(1 - \beta)} - K^{(1 - \beta)}} \left( \frac{z}{x(z)} \right) \left\{ 1 + \left[ \frac{\beta(\beta - 2)\alpha^2}{24F_{mid}^{2 - 2\beta}} + \frac{\rho\beta v\alpha}{4F_{mid}^{1 - \beta}} + \frac{2 - 3\rho^2}{24}v^2 \right] T \right\} \\ &= v \frac{(F - K)}{x(z)} \left\{ 1 + \left[ \frac{\beta(\beta - 2)\alpha^2}{24F_{mid}^{2 - 2\beta}} + \frac{\rho\beta v\alpha}{4F_{mid}^{1 - \beta}} + \frac{2 - 3\rho^2}{24}v^2 \right] T \right\} \\ F_{mid} &= \frac{F + K}{2} \\ z &= \frac{v}{\alpha} \left( \frac{F^{1 - \beta} - K^{1 - \beta}}{1 - \beta} \right) \quad x(z) = \ln \left( \frac{\sqrt{1 - 2\rho z + z^2} + z - \rho}{1 - \rho} \right)\end{aligned}$$

For ATM ( $F = K$ ):

$$\sigma_{N, ATM}(\alpha, \beta, \rho, v, F, T) = \alpha F^\beta \left\{ 1 + \left[ \frac{\beta(\beta - 2)\alpha^2}{24F^{2 - 2\beta}} + \frac{\rho\beta v\alpha}{4F^{1 - \beta}} + \frac{2 - 3\rho^2}{24}v^2 \right] T \right\}$$

The special case for normalvolbysabr where  $\beta = 0$  for not ATM ( $F \neq K$ ) is:

$$\begin{aligned}\sigma_N(\alpha, \rho, v, F, K, T) &= v \frac{(F - K)}{\lambda(\zeta)} \left( 1 + \frac{2 - 3\rho^2}{24}v^2 T \right) \\ \zeta &= \frac{v}{\alpha}(F - K) \\ \lambda(\zeta) &= \ln \left( \frac{\sqrt{1 - 2\rho\zeta + \zeta^2} + \zeta - \rho}{1 - \rho} \right)\end{aligned}$$

For ATM ( $F = K$ ):

$$\sigma_{N, ATM}(\alpha, \rho, v, T) = \alpha \left( 1 + \frac{2 - 3\rho^2}{24}v^2 T \right)$$

The special case for normal vol by sabr where  $\beta = 1$  for not ATM ( $F \neq K$ ) is:

$$\sigma_N(\alpha, \rho, v, F, K, T) = v \frac{(F - K)}{\hat{\lambda}(\zeta)} \left\{ 1 + \left[ \frac{-\alpha^2}{24} + \frac{\rho v \alpha}{4} + \frac{2 - 3\rho^2}{24} v^2 \right] T \right\}$$

$$\zeta = \frac{v}{\alpha} \ln \frac{F}{K}$$

$$\hat{\lambda}(\zeta) = \ln \left( \frac{\sqrt{1 - 2\rho\zeta + \zeta^2} + \zeta - \rho}{1 - \rho} \right)$$

For ATM ( $F = K$ ):

$$\sigma_{N, ATM}(\alpha, \rho, v, F, T) = \alpha F \left\{ 1 + \left[ \frac{-\alpha^2}{24} + \frac{\rho v \alpha}{4} + \frac{2 - 3\rho^2}{24} v^2 \right] T \right\}$$

## Introduced in R2018b

# numerix class

Create numerix object to set up Numerix CAIL environment

## Description

The `numerix` object makes the Numerix engine directly accessible from MATLAB. To use the capabilities of Numerix CAIL, you must have CAIL client software installed on your local desktop.

In addition, you must add the Numerix library file to MATLAB path to use the documentation examples:

- Add `<Numerix software package installation root>/lib` to `<matlabroot>/toolbox/local/librarypath.txt`
- or
- Place `<Numerix software package installation root>/lib/NxProjava.dll` in the folder `<matlabroot>/bin/win64`

## Construction

`N = numerix(DATADIRECTORYPATH)` constructs the `numerix` object and sets up the Numerix CrossAsset Integration Layer (CAIL) environment given the path, `DATADIRECTORYPATH`.

## Properties

The following properties are from the `numerix` class.

### Path

Defines the path for `DATADIRECTORYPATH`. This path is the location of the templates and is created by the client installation of CAIL. A template defines the interface; it encapsulates the instructions for performing calculations, the calculation's required and optional input parameters, and the calculation's outputs.

#### Attributes:

<code>SetAccess</code>	<code>public</code>
<code>GetAccess</code>	<code>public</code>

### RepositoryPath

`RepositoryPath` defines the path location for the repository folder in a file system.

#### Attributes:

<code>SetAccess</code>	<code>public</code>
<code>GetAccess</code>	<code>public</code>

**Repository**

Repositories are collections of templates and are defined as a folder in a file system.

**Attributes:**

SetAccess	public
GetAccess	public

**Context**

The calculation context manages all the CAIL information. `Context` contains the location of the template repository and is responsible for creating a CAIL application context in which to perform the calculations.

**Attributes:**

SetAccess	public
GetAccess	public

**LookupsPath**

Defines the path for the numeric instruments data types.

**Attributes:**

SetAccess	public
GetAccess	public

**MarketsPath**

Defines a path for the logical schema for naming all the market data. `MarketsPath` enables you to provide a data dictionary to map business market data to CAIL to reduce the task of inputting market data into CAIL objects directly.

**Attributes:**

SetAccess	public
GetAccess	public

**FixingsPath**

Defines the path for the schema for naming historical fixing data for rates and prices.

**Attributes:**

SetAccess	public
GetAccess	public

**TradesPath**

Defines the path to the trade instrument definitions.

**Attributes:**

SetAccess	public
GetAccess	public

**Parameters**

Defines the calculation parameters and market data, if available.

**Attributes:**

SetAccess	public
GetAccess	public

**Methods**

parseResults	Converts Numerix CAIL data to MATLAB data types
--------------	---

**Copy Semantics**

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

**Examples****Construct a Numerix Object**

Initialize Numerix CAIL environment.

```
import com.numerix.integration.*;
import com.numerix.integration.implementation.*;
```

Construct a numerix object.

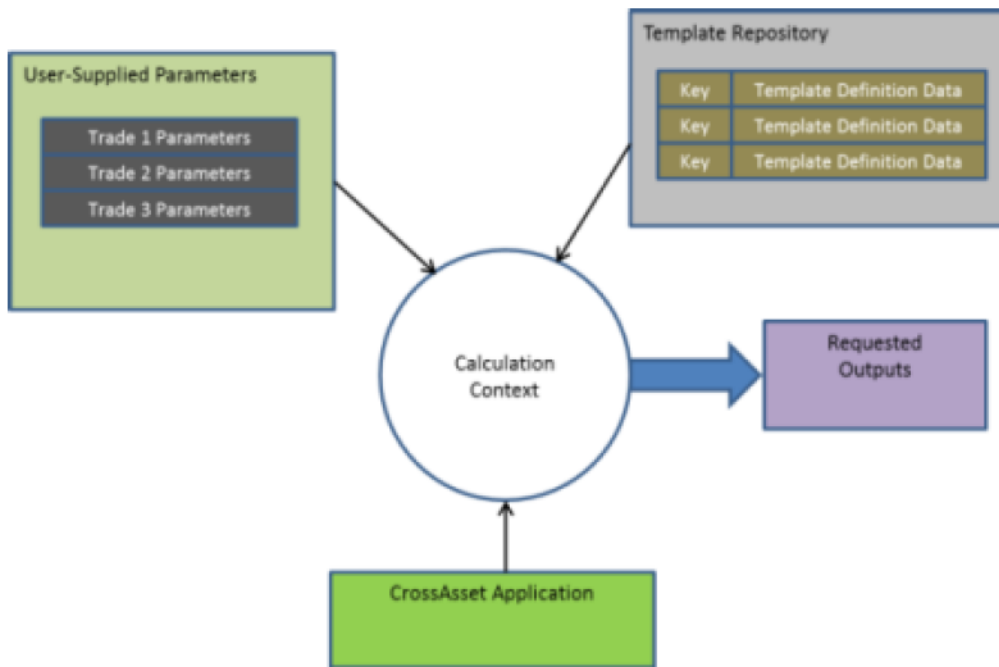

```
n = numerix('i:\NumeriX_java_10_3_0\data')
n =
    Path: 'i:\NumeriX_java_10_3_0\data'
    RepositoryPath: 'i:\NumeriX_java_10_3_0\data\Repository'
    Repository: [1x1 com.numerix.integration.implementation.FileSystemRepository]
    Context: [1x1 com.numerix.integration.implementation.LocalCalculationContext]
    LookupsPath: 'i:\NumeriX_java_10_3_0\data\Data\LookupRules'
    MarketsPath: 'i:\NumeriX_java_10_3_0\data\Data\Markets'
    FixingsPath: 'i:\NumeriX_java_10_3_0\data\Data\Fixings'
    TradesPath: 'i:\NumeriX_java_10_3_0\data\Data\Trades'
    Parameters: [1x1 com.numerix.integration.implementation.CalculationParameters]
```

**More About****CrossAsset Integration Layer (CAIL)**

The CrossAsset Integration Layer (CAIL) is an application programming interface (API), which extends the data-driven approach of Numerix.

The calculation workflow of CAIL is:

- 1 Select a trade template for a specified deal or trade from the repository. The trade template specifies a set of inputs, a set of outputs, and the dependencies on other information (model, market data, calendar, and so on).
- 2 Provide the input parameters to the trade template and call the calculation context. The calculation context follows the dependency path to collect the needed information and produces the output specified by the template.

## Introduced in R2013b

# numerixCrossAsset class

Create numerixCrossAsset object to set up Numerix CROSSASSET environment

## Description

Creating a numerixCrossAsset object initializes a Numerix CrossAsset object based on the Numerix data-driven CROSSASSET API. To use the Numerix engine directly from MATLAB, you must have the CROSSASSET client installed on your local desktop.

In addition, you must add the Numerix library file to MATLAB path to use the documentation examples:

- Add `<Numerix software package installation root>/lib` to `<matlabroot>/toolbox/local/librarypath.txt`
- or
- Place `<Numerix software package installation root>/lib/NxProjava.dll` in the folder `<matlabroot>/bin/win64`

## Construction

`c = numerixCrossAsset` constructs the numerixCrossAsset object and sets up the Numerix CROSSASSET environment.

## Properties

### Application — Application object

object

Application object, created when numerixCrossAsset object is initialized.

Example: `app = Application;`

#### Attributes:

SetAccess	private
GetAccess	public

### ApplicationWarning — ApplicationWarning object

object

ApplicationWarning object, created when numerixCrossAsset object is initialized.

Example: `appWarnings = ApplicationWarning;`

#### Attributes:

SetAccess	private
-----------	---------

GetAccess public

## Methods

applicationCall	Create and register Numerix CROSSASSET Call object
applicationData	Create and register data with Numerix CROSSASSET Application Data object
applicationMatrix	Create and register Numerix CROSSASSET Application Matrix object
close	Close numerixCrossAsset object
getdata	Convert Numerix CROSSASSET Application object to MATLAB structure

## Examples

### Construct a numerixCrossAsset Object

Construct a numerixCrossAsset object.

```
c = numerixCrossAsset
```

```
c =
```

```
numerixCrossAsset with properties:
```

```
Application: [1x1 com.numerix.pro.Application]
```

```
ApplicationWarning: [1x1 com.numerix.pro.ApplicationWarning]
```

## More About

### CROSSASSET

The CROSSASSET API is an application programming interface (API), which extends the data-driven approach of Numerix.

### Introduced in R2016b

# applicationCall

**Class:** numerixCrossAsset

Create and register Numerix CROSSASSET Call object

## Syntax

`applicationCall(C,Headers,Name,Value)`

## Description

`applicationCall(C,Headers,Name,Value)` creates and registers the Numerix CROSSASSET Call object with additional options specified by one or more `Name,Value` pair arguments. The name-value parameters conform to the Numerix Cross Asset Integration Layer interface and are defined by `N1, N2, ..., NN` to the values given in `V1, V2, ..., VN`.

Creating and registering the Call object calculates values in the Numerix Cross Asset Integration Layer and returns the data in MATLAB.

## Input Arguments

### **C — Connection object to Numerix CROSSASSET**

object

Connection object to Numerix CROSSASSET, specified using the `numerixCrossAsset` constructor.

### **Headers — Output names of the returned values from numerixCrossAsset connection object**

cell array of character vectors

Output names of the returned values from `numerixCrossAsset` connection object, specified as a cell array of character vectors.

Data Types: `cell`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **N1 — Numerix name-value parameter**

name-value parameter defined by Numerix

Numerix parameters, specified as a `Name,Value` argument pair.

```
Example: applicationCall(c,Headers,'ID','RATESPEC','OBJECT','MARKET
DATA','TYPE','YIELD','COMMENT','Comments
here','SKIP',false,'INTERPMETHOD','LogLinear','INTERPVARIABLE','DF','CURRENCY
','USD','DATA','USD_3MLIBOR_CURVE','BASIS','ACT/360');
```

Data Types: `char` | `double` | `logical`

**N2 — Numerix name-value parameters**

name-value parameter defined by Numerix

Numerix parameter, specified as a `Name, Value` argument pair.

```
Example: applicationCall(c,Headers,'ID','RATESPEC','OBJECT','MARKET
DATA','TYPE','YIELD','COMMENT','Comments
here','SKIP',false,'INTERPMETHOD','LogLinear','INTERPVARIABLE','DF','CURRENCY
','USD','DATA','USD_3MLIBOR_CURVE','BASIS','ACT/360');
```

Data Types: `char` | `double` | `logical`

**Attributes**

Access	public
Static	false
Hidden	false

To learn about attributes of methods, see [Method Attributes \(MATLAB\)](#).

**Examples****Create and Register a Numerix CROSSASSET Call Object**

Create a datetime object.

```
dates = datetime({'18-Feb-2014';'20-May-2014';'18-Jun-2014';'16-Jul-2014';
'20-Aug-2014';'17-Sep-2014';'15-Oct-2014';'19-Nov-2014';
'17-Dec-2014';'18-Mar-2015';'17-Jun-2015';'16-Sep-2015';
'16-Dec-2015';'16-Mar-2016';'15-Jun-2016';'21-Sep-2016';
'21-Dec-2016';'15-Mar-2017';'20-Feb-2018';'20-Feb-2019';
'20-Feb-2020';'22-Feb-2021';'22-Feb-2022';'21-Feb-2023';
'20-Feb-2024';'20-Feb-2025';'20-Feb-2026';'20-Feb-2029';
'21-Feb-2034';'22-Feb-2039';'22-Feb-2044';'20-Feb-2054';
'20-Feb-2064'});
```

Create the corresponding vector of discount factors for a 3-month LIBOR curve.

```
discountFactors = [1;0.99942;0.999231;0.999037;0.998797;0.998616;0.998385;...
0.998122;0.997941;0.997159;0.996157;0.994825;0.993065;...
0.99078;0.987889;0.984092;0.979913;0.975459;0.952707;...
0.922223;0.888128;0.852291;0.816462;0.781228;0.746677;...
0.712892;0.680462;0.592285;0.474003;0.383493;0.312617;...
0.213809;0.152345];
```

Create a Numerix CROSSASSET object.

```
c = numerixCrossAsset;
```

Add data to the Numerix Cross Asset Application Data object.

```
applicationData(c,'USD_3MLIBOR_CURVE','DATE',dates,'DISCOUNTFACTOR',discountFactors)
```

Define the `Headers` input and add the `RateSpec` Call object to the Numerix CROSSASSET Application object using name-value pairs, where `USD_3MLIBOR_CURVE` denotes the yield curve data object created previously.

```
headers = {'ID','LOCAL ID','TIMER','TIMER CPU','UPDATED'};
applicationCall(c,headers,'ID','RATESPEC','OBJECT','MARKET DATA','TYPE','YIELD','COMMENT','Comments here',...
```

```
'SKIP', false, 'INTERPMETHOD', 'LogLinear', 'INTERPVARIABLE', 'DF', ...  
'CURRENCY', 'USD', 'DATA', 'USD_3MLIBOR_CURVE', 'BASIS', 'ACT/360');
```

**Class:** numerixCrossAsset

Create and register data with Numerix CROSSASSET Application Data object

### Syntax

```
applicationData(C,Desc,Name,Value)
applicationData(C,Desc,T)
applicationData(C,Desc,S)
```

### Description

`applicationData(C,Desc,Name,Value)` `applicationData` creates and registers the data for Numerix CROSSASSET Application Data object with additional options specified by one or more `Name,Value` pair arguments. The name-value parameters conform to the Numerix Cross Asset Integration Layer interface and are defined by `N1, N2, ..., NN` to the values given in `V1, V2, ..., VN`.

`applicationData(C,Desc,T)` creates and registers the data for Numerix CROSSASSET Application Data object in table `T`.

`applicationData(C,Desc,S)` creates and registers the data in the structure, `S`. The structure `fieldnames` represents the property names for the values in each field.

### Input Arguments

#### **C — Connection object to Numerix CROSSASSET**

object

Connection object to Numerix CROSSASSET, specified using the `numerixCrossAsset` constructor.

#### **Desc — Description of data**

character vector or cell array of character vectors

Description of data, specified as a character vector or cell array of character vectors.

Data Types: `char` | `cell`

#### **T — Table input**

table `VariableNames` represents the property names for values in the corresponding column

Table input for data to register for the Numerix CROSSASSET Application Data object, specified using `VariableNames`.

Data Types: `table`

#### **S — Structure input**

structure `fieldnames` represents the property names for the values in each field

Structure input for data to register for the Numerix CROSSASSET Application Data object, specified using the `fieldnames`.

Data Types: `struct`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

#### N1 — Numerix name-value parameter

name-value parameter defined by Numerix

Numerix parameter, specified as `Name`, `Value` argument pair.

Example:

```
applicationData(c,'USD_3MLIBOR_CURVE','DATE',dates,'DISCOUNTFACTOR',discountF
actors)
```

Data Types: `char` | `double` | `logical`

#### N2 — Numerix name-value parameters

name-value parameter defined by Numerix

Numerix parameter, specified as `Name`, `Value` argument pair.

Example:

```
applicationData(c,'USD_3MLIBOR_CURVE','DATE',dates,'DISCOUNTFACTOR',discountF
actors)
```

Data Types: `char` | `double` | `logical`

## Attributes

Access	public
Static	false
Hidden	false

To learn about attributes of methods, see [Method Attributes \(MATLAB\)](#).

## Examples

### Create a Numerix CROSSASSET Application Data Object

Create a `datetime` object.

```
dates = datetime({'18-Feb-2014';'20-May-2014';'18-Jun-2014';'16-Jul-2014';
'20-Aug-2014';'17-Sep-2014';'15-Oct-2014';'19-Nov-2014';
'17-Dec-2014';'18-Mar-2015';'17-Jun-2015';'16-Sep-2015';
'16-Dec-2015';'16-Mar-2016';'15-Jun-2016';'21-Sep-2016';
'21-Dec-2016';'15-Mar-2017';'20-Feb-2018';'20-Feb-2019';
'20-Feb-2020';'22-Feb-2021';'22-Feb-2022';'21-Feb-2023';
'20-Feb-2024';'20-Feb-2025';'20-Feb-2026';'20-Feb-2029';
'21-Feb-2034';'22-Feb-2039';'22-Feb-2044';'20-Feb-2054';
'20-Feb-2064'});
```

Create the corresponding vector of discount factors for a 3-month LIBOR curve.

```
discountFactors = [1;0.99942;0.999231;0.999037;0.998797;0.998616;0.998385;...
0.998122;0.997941;0.997159;0.996157;0.994825;0.993065;...]
```

```
0.99078;0.987889;0.984092;0.979913;0.975459;0.952707;...  
0.922223;0.888128;0.852291;0.816462;0.781228;0.746677;...  
0.712892;0.680462;0.592285;0.474003;0.383493;0.312617;...  
0.213809;0.152345];
```

Create a Numerix CROSSASSET object.

```
c = numerixCrossAsset;
```

Create and register the data with the Numerix CROSSASSET Application Data object.

```
applicationData(c, 'USD_3MLIBOR_CURVE', 'DATE', dates, 'DISCOUNTFACTOR', discountFactors)
```

# applicationMatrix

**Class:** numerixCrossAsset

Create and register Numerix CROSSASSET Application Matrix object

## Syntax

```
applicationMatrix(C,Desc,Rdata,Cdata,Mdata)
```

## Description

`applicationMatrix(C,Desc,Rdata,Cdata,Mdata)` creates the CROSSASSET Application Matrix object from the row information (`Rdata`), column information (`Cdata`), and matrix (`Mdata`).

## Input Arguments

**C — Connection object to Numerix CROSSASSET**  
object

Connection object to Numerix CROSSASSET, specified using the `numerixCrossAsset` constructor.

**Desc — Description of data**  
character vector or cell array of character vectors

Description of data, specified as a character vector or cell array of character vectors.

Data Types: `char` | `cell`

**Rdata — Row information for Application Matrix object**  
numeric values

Row information for Application Matrix object, specified using numeric values.

Example: `Rdata = [41992,42020,42449,42905,43115];`

Data Types: `double`

**Cdata — Column information for Application Matrix object**  
numeric values

Column information for Application Matrix object, specified as numeric values.

Example: `Cdata = [390,395,400,405];`

Data Types: `double`

**Mdata — Volatility information for Application Matrix object**  
numeric values

Volatility information for Application Matrix object, specified as numeric values.

Example: `Mdata = [0.35778, 0.35132, 0.34394, 0.33582;...  
0.33405, 0.32819, 0.32669, 0.31904;...]`

```
0.31576, 0.31235, 0.30371, 0.30261;...  
0.29391, 0.29366, 0.28962, 0.28932;...  
0.28787, NaN, 0.28347, NaN ];
```

Data Types: double

## Attributes

Access	public
Static	false
Hidden	false

To learn about attributes of methods, see Method Attributes (MATLAB).

## Examples

### Create a Numerix CROSSASSET Application Matrix Object

Create a volatility matrix with dates describing the rows and strike prices describing the columns with the description `BYSTRIKEVOLDATA`. Missing values in the matrix input are denoted as `NaN`.

Create a Numerix CROSSASSET object.

```
c = numerixCrossAsset;
```

Define the matrix data.

```
rowData = [41992, 42020, 42449, 42905, 43115];  
colData = [390, 395, 400, 405];  
volData = [0.35778, 0.35132, 0.34394, 0.33582;...  
           0.33405, 0.32819, 0.32669, 0.31904;...  
           0.31576, 0.31235, 0.30371, 0.30261;...  
           0.29391, 0.29366, 0.28962, 0.28932;...  
           0.28787, NaN, 0.28347, NaN ];
```

Create and register a Numerix CROSSASSET Application Matrix object.

```
applicationMatrix(c, 'BYSTRIKEVOLDATA', rowData, colData, volData);
```

# close

**Class:** numerixCrossAsset

Close numerixCrossAsset object

## Syntax

```
AppData = close(C)
```

## Description

AppData = close(C) closes the numerixCrossAsset object (C).

## Input Arguments

**C** — Connection object to Numerix CROSSASSET

object

Connection object to Numerix CROSSASSET, specified using the numerixCrossAsset constructor.

## Attributes

Access	public
Static	false
Hidden	false

To learn about attributes of methods, see Method Attributes (MATLAB).

## Examples

### Close the Numerix CROSSASSET Object

Construct a numerixCrossAsset object.

```
c = numerixCrossAsset
```

```
c =
```

```
numerixCrossAsset with properties:
```

```
Application: [1x1 com.numerix.pro.Application]
ApplicationWarning: [1x1 com.numerix.pro.ApplicationWarning]
```

Close the numerixCrossAsset object.

```
close(c)
```

# getdata

**Class:** numerixCrossAsset

Convert Numerix CROSSASSET Application object to MATLAB structure

## Syntax

AppData = getdata(C)

## Description

AppData = getdata(C) converts a Numerix CROSSASSET Application object to a MATLAB structure.

## Input Arguments

**C — Connection object to Numerix CROSSASSET**  
object

Connection object to Numerix CROSSASSET, specified using the numerixCrossAsset constructor.

## Output Arguments

**AppData — Converted Numerix CROSSASSET Application object**  
structure

Converted Numerix CROSSASSET Application object, returned as a MATLAB structure

## Attributes

Access	public
Static	false
Hidden	false

To learn about attributes of methods, see Method Attributes (MATLAB).

## Examples

### Convert Numerix CROSSASSET Application Object to a MATLAB Structure

Create a datetime object.

```
dates = datetime({'18-Feb-2014'; '20-May-2014'; '18-Jun-2014'; '16-Jul-2014';
                 '20-Aug-2014'; '17-Sep-2014'; '15-Oct-2014'; '19-Nov-2014';
                 '17-Dec-2014'; '18-Mar-2015'; '17-Jun-2015'; '16-Sep-2015';
                 '16-Dec-2015'; '16-Mar-2016'; '15-Jun-2016'; '21-Sep-2016';
                 '21-Dec-2016'; '15-Mar-2017'; '20-Feb-2018'; '20-Feb-2019';
                 '20-Feb-2020'; '22-Feb-2021'; '22-Feb-2022'; '21-Feb-2023';
                 '20-Feb-2024'; '20-Feb-2025'; '20-Feb-2026'; '20-Feb-2029';
```

```
'21-Feb-2034'; '22-Feb-2039'; '22-Feb-2044'; '20-Feb-2054';
'20-Feb-2064'});
```

Create the corresponding vector of discount factors for a 3-month LIBOR curve.

```
discountFactors = [1;0.99942;0.999231;0.999037;0.998797;0.998616;0.998385;...
0.998122;0.997941;0.997159;0.996157;0.994825;0.993065;...
0.99078;0.987889;0.984092;0.979913;0.975459;0.952707;...
0.922223;0.888128;0.852291;0.816462;0.781228;0.746677;...
0.712892;0.680462;0.592285;0.474003;0.383493;0.312617;...
0.213809;0.152345];
```

Create a Numerix CROSSASSET object.

```
c = numerixCrossAsset;
```

Add data to the Numerix CROSSASSET Application Data object.

```
applicationData(c, 'USD_3MLIBOR_CURVE', 'DATE', dates, 'DISCOUNTFACTOR', discountFactors)
```

Add the RATESPEC Call object to the Numerix CROSSASSET Application object using name-value pairs, where USD\_3MLIBOR\_CURVE denotes yield curve data object created previously.

```
headers = {'ID', 'LOCAL ID', 'TIMER', 'TIMER CPU', 'UPDATED'};
applicationCall(c, headers, 'ID', 'RATESPEC', 'OBJECT', 'MARKET DATA', 'TYPE', 'YIELD', 'COMMENT', 'Comments here', ...
'SKIP', false, 'INTERPMETHOD', 'LogLinear', 'INTERPVARIABLE', 'DF', ...
'CURRENCY', 'USD', 'DATA', 'USD_3MLIBOR_CURVE', 'BASIS', 'ACT/360');
```

Use `getdata` to convert the Numerix CROSSASSET Application object to a MATLAB structure.

```
APPDATA = getdata(C)
```

## Introduced in R2016b

# parseResults

**Class:** numerix

Converts Numerix CAIL data to MATLAB data types

## Syntax

`R = parseResults(N,Results)`

## Description

`R = parseResults(N,Results)` returns Numerix CAIL data in native MATLAB data types.

## Input Arguments

**N**

Numerix object constructed using `numerix`.

**Results**

Result instances for each trade instance.

## Output Arguments

**R**

Results from Numerix table output represented as MATLAB data types.

## Attributes

Access	public
Static	false
Hidden	false

To learn about attributes of methods, see [Method Attributes \(MATLAB\)](#).

## Examples

### Return Results for Numerix CAIL API to Price a Callable Reverse Floater

Initialize Numerix environment.

```
import com.numerix.integration.*;
import com.numerix.integration.implementation.*;

n = numerix('i:\NumeriX_java_10_3_0\data')
```

```
n =
    Path: 'i:\NumeriX_java_10_3_0\data'
RepositoryPath: 'i:\NumeriX_java_10_3_0\data\Repository'
Repository: [1x1 com.numerix.integration.implementation.FileSystemRepository]
Context: [1x1 com.numerix.integration.implementation.LocalCalculationContext]
LookupsPath: 'i:\NumeriX_java_10_3_0\data\Data\LookupRules'
MarketsPath: 'i:\NumeriX_java_10_3_0\data\Data\Markets'
FixingsPath: 'i:\NumeriX_java_10_3_0\data\Data\Fixings'
TradesPath: 'i:\NumeriX_java_10_3_0\data\Data\Trades'
Parameters: [1x1 com.numerix.integration.implementation.CalculationParameters]
```

Create a market.

```
quotes = java.util.HashMap;
quotes.put('IR.USD-LIBOR-3M.SWAP-1Y.MID', 0.0066056);
quotes.put('IR.USD-LIBOR-3M.SWAP-10Y.MID', 0.022465005);
quotes.put('IR.USD-LIBOR-3M.SWAP-20Y.MID', 0.027544995);
market = Market('EOD_14-NOV-2011', DateExtensions.date('14-Nov-2011'), quotes.entrySet());
```

Define a trade instance based on instrument template found in the Repository.

```
tradeDescriptor = 'TRADE.IR.CALLBLEREVERSEFLOATER';
tradeParameters = java.util.HashMap;
tradeParameters.put('Trade ID', '1001');
tradeParameters.put('Quote Type', 'MID');
tradeParameters.put('Currency', 'USD');
tradeParameters.put('Notional', 1000000.0);
tradeParameters.put('Effective Date', DateExtensions.date('1-Dec-2011'));
tradeParameters.put('Termination Date', DateExtensions.date('1-Dec-2021'));
tradeParameters.put('IR Index', 'LIBOR');
tradeParameters.put('IR Index Tenor', '3M');
tradeParameters.put('Structured Freq', '3M');
tradeParameters.put('Structured Side', 'Receive');
tradeParameters.put('Structured Coupon Floor', 0.0);
tradeParameters.put('Structured Coupon UpBd', 0.08);
tradeParameters.put('Structured Coupon Multiplier', 1.4);
tradeParameters.put('Structured Coupon Cap', 0.05);
tradeParameters.put('Structured Basis', 'ACT/360');

tradeParameters.put('Funding Side', 'Pay');
tradeParameters.put('Funding Spread', 0.003);
tradeParameters.put('Funding Basis', 'ACT/360');
tradeParameters.put('Call Start Date', DateExtensions.date('1-Dec-2013'));
tradeParameters.put('Call End Date', DateExtensions.date('1-Dec-2020'));
tradeParameters.put('Option Side', 'Short');
tradeParameters.put('Option Type', 'Right to Terminate');
tradeParameters.put('Call Frequency', '3M');
tradeParameters.put('Model', 'IR.USD-LIBOR-3M.MID.DET');
tradeParameters.put('Method', 'BackwardAnalytic');
```

Create a trade instance.

```
trade = RepositoryExtensions.createTradeInstance(n.Repository, tradeDescriptor, tradeParameters);
```

Price the trades.

```
results = CalculationContextExtensions.calculate(n.Context, trade, market, Request.getAll());
```

Parse the results for MATLAB and display.

```
r = n.parseResults(results)
disp([r.Name r.Category r.Currency r.Data])
```

```
r =
    Category: {13x1 cell}
    Currency: {13x1 cell}
    Name: {13x1 cell}
    Data: {13x1 cell}

    'Reporting Currency'      'Price'      ''      'USD'
    'Structured Cashflow Log' 'Cashflow'   ''      {41x20 cell}
```

## oasbybdt

Determine option adjusted spread using Black-Derman-Toy model

### Syntax

```
[OAS,OAD,OAC] = oasbybdt(BDTree,Price,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[OAS,OAD,OAC] = oasbybdt( ___,Name,Value)
```

### Description

[OAS,OAD,OAC] = oasbybdt(BDTree,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates) calculates option adjusted spread using a Black-Derman-Toy model.

oasbybdt computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1290.

[OAS,OAD,OAC] = oasbybdt( \_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute OAS Using the Black-Derman-Toy (BDT) Model

This example shows how to compute OAS using the Black-Derman-Toy (BDT) model with the following data.

```
ValuationDate = 'Oct-1-2010';
Rates = [0.035; 0.042; 0.047; 0.052];
StartDates = ValuationDate;
EndDates = datemnth(ValuationDate, 12:12:48)';
Compounding = 1;
% define RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate,...
'StartDates', StartDates, 'EndDates', EndDates, ...
'Rates', Rates, 'Compounding', Compounding);

% specify VolSpec and TimeSpec
Sigma = 0.20;
VS = bdtvolspec(ValuationDate, EndDates, Sigma*ones(size(EndDates)));
TS = bdttimespec(ValuationDate, EndDates, Compounding);

% build the BDT tree
BDTree = bdttree(VS, RateSpec, TS);
BDTreerew = cvtree(BDTree);

% instrument information
CouponRate = 0.065;
Settle = ValuationDate;
Maturity = '01-Oct-2014';
```

```

OptSpec = 'call';
Strike = 100;
ExerciseDates = '01-Oct-2011';
Period = 1;
Price = 101.58;

% compute the OAS
OAS = oasbybdt(BDTTree, Price, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period)

OAS = 32.7688

```

### Compute OAS for an Amortizing Callable Bond Using a BDT Interest-Rate Tree Model

This example shows how to compute the OAS for an amortizing callable bond using a BDT lattice model.

Create a RateSpec.

```

Rates = [0.025;0.028;0.030;0.031];
ValuationDate = 'Jan-1-2018';
StartDates = ValuationDate;
EndDates = {'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'; 'Jan-1-2022'};
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

```

Build a BDT tree and assume a volatility of 5%.

```

Sigma = 0.05;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates)));
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);

```

Define the callable bond.

```

CouponRate = 0.05;
Settle = 'Jan-1-2018';
Maturity = 'Jan-1-2021';
Period = 1;

Face = {
    {'Jan-1-2019' 100;
     'Jan-1-2020' 70; ...
     'Jan-1-2021' 50};
};

OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates = {'Jan-1-2019' 'Jan-1-2020' 'Jan-1-2021'};

```

Compute the OAS for a callable amortizing bond using the BDT tree.

```

Price = 99;
BondType = 'amortizing';

```

```
OAS = oasbybdt(BDTree, Price, CouponRate, Settle, Maturity, ...  
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face, 'BondType', BondType)
```

```
OAS = 53.0303
```

## Input Arguments

### **BDTree — Interest-rate tree structure**

structure

Interest-rate tree structure, specified by using `bdtree`.

Data Types: `struct`

### **Price — Market prices of bonds with embedded options**

numeric

Market prices of bonds with embedded options, specified as an NINST-by-1 vector.

Data Types: `double`

### **CouponRate — Bond coupon rate**

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate.

Data Types: `double`

### **Settle — Settlement date**

serial date number | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

---

**Note** The `Settle` date for every bond with an embedded option is set to the `ValuationDate` of the BDT tree. The bond argument `Settle` is ignored.

---

Data Types: `double` | `char`

### **Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char`

### **OptSpec — Definition of option**

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: `char` | `cell`

**Strike — Option strike price values**

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

**ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES of serial date numbers or character vectors depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option is exercised between the underlying bond Settle date and the single listed exercise date.

Data Types: double | char

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: OAS =

```
oasbybdt(BDTree, Price, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'Period', 4)
```

**AmericanOpt — Option type**

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

**Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

### **IssueDate — Bond issue date**

serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | char

**FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char

**LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: char | double

**StartDate — Forward starting date of payments**

serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify StartDate, the effective start date is the Settle date.

Data Types: char | double

**Face — Face value**

100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

Data Types: double

**BondType — Type of underlying bond**

'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla', 'amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of 'BondType' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.

- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: `char` | `string`

### **Options — Derivatives pricing options**

structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with `derivset`.

Data Types: `struct`

## **Output Arguments**

### **OAS — Option adjusted spread**

vector

Option adjusted spread, returned as a NINST-by-1 vector.

### **OAD — Option adjusted duration**

vector

Option adjusted duration, returned as a NINST-by-1 vector.

### **OAC — Option adjusted convexity**

vector

Option adjusted convexity, returned as a NINST-by-1 vector.

## **More About**

### **Vanilla Bond with Embedded Option**

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

### **Stepped Coupon Bond with Callable and Puttable Features**

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

### **Sinking Fund Bond with Call Embedded Option**

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

### **Amortizing Callable or Puttable Bond**

Amortizing callable or puttable bonds work under a scheduled Face.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the Face amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

## oasbybk

Determine option adjusted spread using Black-Karasinski model

### Syntax

```
[OAS,OAD,OAC] = oasbybk(BKTree,Price,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[OAS,OAD,OAC] = oasbybk( ____,Name,Value)
```

### Description

[OAS,OAD,OAC] = oasbybk(BKTree,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates) calculates option adjusted spread using a Black-Karasinski model.

oasbybk computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1290.

[OAS,OAD,OAC] = oasbybk( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute OAS and OAD Using the Black-Karasinski (BK) Model

This example shows how to compute OAS and OAD using the Black-Karasinski (BK) model using the following data.

```
ValuationDate = 'Aug-2-2010';
Rates = [0.0355; 0.0382; 0.0427; 0.0489];
StartDates = ValuationDate;
EndDates = datemnth(ValuationDate, 12:12:48)';
Compounding = 1;

% define RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate,...
'StartDates', StartDates,'EndDates', EndDates, ...
'Rates', Rates,'Compounding', Compounding);

% specify VolSpec and TimeSpec
Sigma = 0.10;
Alpha = 0.01;
VS = bkvolspec(ValuationDate, EndDates, Sigma*ones(size(EndDates)),...
EndDates, Alpha*ones(size(EndDates)));
TS = bktimespec(ValuationDate, EndDates, Compounding);

% build the BK tree
BKTree = bktree(VS, RateSpec, TS);

% instrument information
CouponRate = 0.045;
```

```

Settle = ValuationDate;
Maturity = '02-Aug-2014';
OptSpec = 'put';
Strike = 100;
ExerciseDates = '02-Aug-2013';
Period = 1;
AmericanOpt = 1;
Price = 101;

% compute OAS and OAD
[OAS, OAD] = oasbybk(BKTree, Price, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'AmericanOpt', AmericanOpt)

OAS = 9.9999e+04
OAD = 0

```

### Compute OAS for an Amortizing Callable Bond Using a BK Interest-Rate Tree Model

This example shows how to compute the OAS for an amortizing callable bond using a BK lattice model.

Create a RateSpec.

```

Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

```

Build a BK tree.

```

VolDates = {'1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'};
VolCurve = 0.01;
AlphaDates = '01-01-2016';
AlphaCurve = 0.1;

```

```

BKVolSpec = bkvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RS.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RS, BKTimeSpec);

```

Define the callable bond.

```

CouponRate = 0.05;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2016';
Period = 1;

Face = {
    {'Jan-1-2014' 100;
     'Jan-1-2015' 70;
     'Jan-1-2016' 50};
};

```

```
OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates = {'Jan-1-2014' 'Jan-1-2015' 'Jan-1-2016'};
```

Compute OAS for a callable amortizing bond using the BK tree.

```
Price = 99;
BondType = 'amortizing';
OAS = oasbybk(BKT, Price, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face, 'BondType', BondType)

OAS = 0.6590
```

## Input Arguments

### **BKTree — Interest-rate tree structure**

structure

Interest-rate tree structure, specified by using bktree.

Data Types: struct

### **Price — Market prices of bonds with embedded options**

numeric

Market prices of bonds with embedded options, specified as an NINST-by-1 vector.

Data Types: double

### **CouponRate — Bond coupon rate**

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate.

Data Types: double

### **Settle — Settlement date**

serial date number | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

---

**Note** The Settle date for every bond with an embedded option is set to the ValuationDate of the BK tree. The bond argument Settle is ignored.

---

Data Types: double | char

### **Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char

**OptSpec — Definition of option**

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: char | cell

**Strike — Option strike price values**

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

**ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option is exercised between the underlying bond Settle date and the single listed exercise date.

Data Types: double | char

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: OAS =

```
oasbybk(BDTree, Price, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'Period', 4)
```

**AmericanOpt — Option type**

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

**Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

**IssueDate — Bond issue date**

serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | char

**FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using serial date numbers date or date character vectors.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char

**LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: char | double

**StartDate — Forward starting date of payments**

serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify StartDate, the effective start date is the Settle date.

Data Types: char | double

**Face — Face value**

100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

Data Types: double

**BondType — Type of underlying bond**

'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla', 'amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of 'BondType' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.
- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: char | string

**Options — Derivatives pricing options**

structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with `derivset`.

Data Types: struct

**Output Arguments****OAS — Option adjusted spread**

vector

Option adjusted spread, returned as a NINST-by-1 vector.

**OAD — Option adjusted duration**

vector

Option adjusted duration, returned as a NINST-by-1 vector.

**OAC — Option adjusted convexity**

vector

Option adjusted convexity, returned as a NINST-by-1 vector.

**More About****Vanilla Bond with Embedded Option**

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

## Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

## Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

## Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled Face.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the Face amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

## Introduced in R2011a

## oasbycir

Determine option adjusted spread using Cox-Ingersoll-Ross model

### Syntax

```
[OAS,OAD,OAC] = oasbycir(CIRTree,Price,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[OAS,OAD,OAC] = oasbycir( ___,Name,Value)
```

### Description

[OAS,OAD,OAC] = oasbycir(CIRTree,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates) calculates the option adjusted spread from a Cox-Ingersoll-Ross (CIR) interest-rate tree using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

oasbycir computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with embedded option. For more information, see “More About” on page 11-1290.

[OAS,OAD,OAC] = oasbycir( \_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute OAS Using a CIR Interest-Rate Tree

Create a RateSpec using the `intenvset` function.

```
ValuationDate = 'October-25-2018';
Rates = [0.0355; 0.0382; 0.0427; 0.0489];
StartDates = ValuationDate;
EndDates = datemnth(ValuationDate, 12:12:48)';
Compounding = 1;
```

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates', EndDates);
```

Create a CIR tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Maturity = '01-Jan-2023';
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolSpec(Sigma, Alpha, Theta);
```

```
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
    FinObj: 'CIRFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
```

```

RateSpec: [1x1 struct]
  tObs: [0 1.0462 2.0924 3.1386]
  dObs: [737358 737740 738122 738504]
  FwdTree: {[1.0373] [1.0750 1.0443 1.0229] [1x5 double] [1x7 double]}
  Connect: {[3x1 double] [3x3 double] [3x5 double]}
  Probs: {[3x1 double] [3x3 double] [3x5 double]}

```

Define the OAS instrument.

```

CouponRate = 0.045;
Settle = ValuationDate;
Maturity = '25-October-2019';
OptSpec = 'call';
Strike = 100;
ExerciseDates = {'25-October-2018', '25-October-2019'};
Period = 1;
AmericanOpt = 0;
Price = 97;

```

Compute the OAS.

```

[OAS,OAD] = oasbycir(CIRT,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'Period');
OAS = 416.9457
OAD = 0.9282

```

### Compute OAS for an Amortizing Callable Bond Using a CIR Interest-Rate Tree

This example shows how to compute the OAS for an amortizing callable bond using a CIR lattice model.

Create a RateSpec using the `intenvset` function.

```

Rates = [0.025; 0.032; 0.037; 0.042];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2016';
EndDates = Dates(2:end);
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates', EndDates);

```

Create a CIR tree.

```

NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Maturity = '01-Jan-2019';
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)

CIRT = struct with fields:
  FinObj: 'CIRFwdTree'
  VolSpec: [1x1 struct]

```

```

TimeSpec: [1x1 struct]
RateSpec: [1x1 struct]
    tObs: [0 0.7500 1.5000 2.2500]
    dObs: [736330 736604 736878 737152]
FwdTree: {[1.0187] [1.0338 1.0188 1.0083] [1x5 double] [1x7 double]}
Connect: {[3x1 double] [3x3 double] [3x5 double]}
Probs: {[3x1 double] [3x3 double] [3x5 double]}

```

Define the callable bond.

```

BondSettlement = 'Jan-1-2016';
BondMaturity   = 'Jan-1-2020';
CouponRate    = 0.035;
Period        = 1;
OptSpec       = 'call';
Strike        = 100;

Face = {
        {'Jan-1-2018' 100;
         'Jan-1-2019'  70;
         'Jan-1-2020'  50};
};

```

```
ExerciseDates = {'Jan-1-2018' '01-Jan-2019'};
```

Compute OAS for a callable amortizing bond using the CIR tree.

```

Price = 99;
BondType = 'amortizing';
OAS = oasbycir(CIRTree, Price, CouponRate, BondSettlement, Maturity, ...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face, 'BondType', BondType)

OAS = 80.4801

```

## Input Arguments

### CIRTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

### Price — Market prices of bonds with embedded options

numeric

Market prices of bonds with embedded options, specified as an NINST-by-1 vector.

Data Types: `double`

### CouponRate — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate.

Data Types: `double`

**Settle — Settlement date**

serial date number | date character vector | string array | datetime

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

---

**Note** The **Settle** date for every bond with an embedded option is set to the **ValuationDate** of the CIR tree. The bond argument **Settle** is ignored.

---

Data Types: double | char | string | datetime

**Maturity — Maturity date**

serial date number | date character vector | string array | datetime

Maturity date, specified as an NINST-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

**OptSpec — Definition of option**

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put' | string array with values "call" or "put"

Definition of option, specified as a NINST-by-1 cell array of character vectors or string arrays with values 'call' or 'put'.

Data Types: char | cell | string

**Strike — Option strike price values**

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

**ExerciseDates — Option exercise dates**

serial date number | date character vector | string array | datetime

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers, date character vectors, string arrays, or datetime arrays depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one **ExerciseDates** on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.

- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is a NINST-by-1 vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

Data Types: `double` | `char` | `string` | `datetime`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `OAS =`

```
oasbycir(CIRTree, Price, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'Period', 4)
```

### **AmericanOpt — Option type**

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: `double`

### **Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a NINST-by-1 vector.

Data Types: `double`

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

### **IssueDate — Bond issue date**

serial date number | date character vector | string array | datetime

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

### **FirstCouponDate — Irregular first coupon date**

serial date number | date character vector | string array | datetime

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using serial date numbers date, date character vectors, string arrays, or datetime arrays.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | string | datetime

### **LastCouponDate — Irregular last coupon date**

serial date number | date character vector | string array | datetime

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using serial date numbers, date character vectors, string arrays, or datetime arrays.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate,

regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `char` | `double` | `string` | `datetime`

### **StartDate — Forward starting date of payments**

serial date number | date character vector | string array | `datetime`

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a NINST-by-1 vector using serial date numbers, date character vectors, string arrays, or `datetime` array.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Data Types: `char` | `double` | `string` | `datetime`

### **Face — Face value**

100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

Data Types: `double`

### **BondType — Type of underlying bond**

`'vanilla'` for scalar Face values, `'callablesinking'` for scheduled Face values (default) | cell array of character vectors with values `'vanilla'`, `'amortizing'`, or `'callablesinking'` | string array with values `"vanilla"`, `"amortizing"`, or `"callablesinking"`

Type of underlying bond, specified as the comma-separated pair consisting of `'BondType'` and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- `'vanilla'` is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.
- `'callablesinking'` is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- `'amortizing'` is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: `char` | `string`

## **Output Arguments**

### **OAS — Option adjusted spread**

vector

Option adjusted spread, returned as a NINST-by-1 vector.

### **OAD — Option adjusted duration**

vector

Option adjusted duration, returned as a NINST-by-1 vector.

## **OAC — Option adjusted convexity**

vector

Option adjusted convexity, returned as a NINST-by-1 vector.

## **More About**

### **Vanilla Bond with Embedded Option**

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

### **Stepped Coupon Bond with Callable and Puttable Features**

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

### **Sinking Fund Bond with Call Embedded Option**

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

### **Amortizing Callable or Puttable Bond**

Amortizing callable or puttable bonds work under a scheduled Face.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the Face amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

## Introduced in R2018a

# oasbyhjm

Determine option adjusted spread using Heath-Jarrow-Morton model

## Syntax

```
[OAS,OAD,OAC] = oasbyhjm(HJMTree,Price,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[OAS,OAD,OAC] = oasbyhjm( ____,Name,Value)
```

## Description

[OAS,OAD,OAC] = oasbyhjm(HJMTree,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates) calculates option adjusted spread using a Heath-Jarrow-Morton model.

oasbyhjm computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1290.

[OAS,OAD,OAC] = oasbyhjm( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Compute OAS Using the Heath-Jarrow-Morton (HJM) Model

This example shows how to compute OAS using the Heath-Jarrow-Morton (HJM) model using the following data.

```
ValuationDate = 'Nov-1-2010';
Rates = [0.0356; 0.0427; 0.0478; 0.0529];
StartDates = ValuationDate;
EndDates = datemnth(ValuationDate, 12:12:48)';
Compounding = 1;

% define RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate,...
'StartDates', StartDates,'EndDates', EndDates, ...
'Rates', Rates,'Compounding', Compounding);

% specify VolSpec and TimeSpec
Sigma = 0.02;
VS = hjmvolspec('Constant', Sigma);
TS = hjmtimespec(ValuationDate, EndDates, Compounding);

% build the HJM tree
HJMTree = hjmtree(VS, RateSpec, TS);
HJMTreenew = cvtree(HJMTree);

% instrument information
CouponRate = 0.05;
Settle = ValuationDate;
```

```

Maturity = '01-Nov-2014';
OptSpec = 'call';
Strike = 100;
ExerciseDates = '01-Nov-2011';
Period = 1;
Price = 97.5;

% compute the OAS
OAS = oasbyhjm(HJMTree, Price, CouponRate, Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', Period)

OAS = 5.0057

```

### Compute OAS for an Amortizing Callable Bond Using an HJM Interest-Rate Tree Model

This example shows how to compute the OAS for amortizing callable bond using an HJM lattice model.

Create a RateSpec.

```

Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

```

Build a HJM tree.

```
VolSpec = hjmvolspec('Constant', 0.01)
```

```

VolSpec = struct with fields:
    FinObj: 'HJMVolSpec'
    FactorModels: {'Constant'}
    FactorArgs: {{1x1 cell}}
    SigmaShift: 0
    NumFactors: 1
    NumBranch: 2
    PBranch: [0.5000 0.5000]
    Fact2Branch: [-1 1]

```

```
TimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding)
```

```

TimeSpec = struct with fields:
    FinObj: 'HJMTimeSpec'
    ValuationDate: 734869
    Maturity: [4x1 double]
    Compounding: 1
    Basis: 0
    EndMonthRule: 1

```

```
HJMTree = hjmtree(VolSpec, RS, TimeSpec)
```

```
HJMTree = struct with fields:
    FinObj: 'HJMFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2 3]
    dObs: [734869 735235 735600 735965]
    TFwd: {[4x1 double] [3x1 double] [2x1 double] [3]}
    CFlowT: {[4x1 double] [3x1 double] [2x1 double] [4]}
    FwdTree: {[4x1 double] [3x1x2 double] [2x2x2 double] [1x4x2 double]}
```

Define the callable bond.

```
CouponRate = 0.05;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2016';
Period = 1;

Face = {
    {'Jan-1-2014' 100;
     'Jan-1-2015' 70;
     'Jan-1-2016' 50};
};

OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates = {'Jan-1-2014' 'Jan-1-2015' 'Jan-1-2016'};
```

Compute the OAS for a callable amortizing bond using the HJM tree.

```
Price = 99;
BondType = 'amortizing';
OAS = oasbyhjm(HJMTree, Price, CouponRate, Settle, Maturity, ...
    OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face, 'BondType', BondType)

OAS = -19.1325
```

## Input Arguments

**HJMTree — Interest-rate tree structure**  
structure

Interest-rate tree structure, specified by using `hjmTree`.

Data Types: `struct`

**Price — Market prices of bonds with embedded options**  
numeric

Market prices of bonds with embedded options, specified as an NINST-by-1 vector.

Data Types: `double`

**CouponRate — Bond coupon rate**  
positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate.

Data Types: double

### **Settle — Settlement date**

serial date number | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

---

**Note** The `Settle` date for every bond with an embedded option is set to the `ValuationDate` of the HJM tree. The bond argument `Settle` is ignored.

---

Data Types: double | char

### **Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char

### **OptSpec — Definition of option**

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: char | cell

### **Strike — Option strike price values**

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

### **ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.

- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is a NINST-by-1 vector, the option is exercised between the underlying bond `Settle` date and the single listed exercise date.

Data Types: `double` | `char`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `OAS =`

```
oasbybk(BDTree, Price, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'Period', 4)
```

### AmericanOpt — Option type

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: `double`

### Period — Coupons per year

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a NINST-by-1 vector.

Data Types: `double`

### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

### **IssueDate — Bond issue date**

serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | char

### **FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using serial date numbers date or date character vectors.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char

### **LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: char | double

**StartDate — Forward starting date of payments**

serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify StartDate, the effective start date is the Settle date.

Data Types: char | double

**Face — Face value**

100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

Data Types: double

**BondType — Type of underlying bond**

'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla', 'amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of 'BondType' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.
- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: char | string

**Options — Derivatives pricing options**

structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with derivset.

Data Types: struct

**Output Arguments****OAS — Option adjusted spread**

vector

Option adjusted spread, returned as a NINST-by-1 vector.

**OAD — Option adjusted duration**

vector

Option adjusted duration, returned as a NINST-by-1 vector.

**OAC — Option adjusted convexity**

vector

Option adjusted convexity, returned as a NINST-by-1 vector.

**More About****Vanilla Bond with Embedded Option**

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

**Stepped Coupon Bond with Callable and Puttable Features**

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

**Sinking Fund Bond with Call Embedded Option**

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

**Amortizing Callable or Puttable Bond**

Amortizing callable or puttable bonds work under a scheduled Face.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the Face amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

## Introduced in R2011a

## oasbyhw

Determine option adjusted spread using Hull-White model

### Syntax

```
[OAS,OAD,OAC] = oasbyhw(HWTree,Price,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[OAS,OAD,OAC] = oasbyhw( ____,Name,Value)
```

### Description

[OAS,OAD,OAC] = oasbyhw(HWTree,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates) calculates option adjusted spread using a Hull-White model.

oasbyhw computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1290.

[OAS,OAD,OAC] = oasbyhw( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute OAS and OAD Using the Hull-White (HW) Model

This example shows how to compute OAS and OAD using the Hull-White (HW) model using the following data.

```
ValuationDate = 'October-25-2010';
Rates = [0.0355; 0.0382; 0.0427; 0.0489];
StartDates = ValuationDate;
EndDates = datemnth(ValuationDate, 12:12:48)';
Compounding = 1;

% define RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate,...
'StartDates', StartDates, 'EndDates', EndDates, ...
'Rates', Rates, 'Compounding', Compounding);

% specify VolsSpec and TimeSpec
Sigma = 0.05;
Alpha = 0.01;
VS = hwtimespec(ValuationDate, EndDates, Sigma*ones(size(EndDates)),...
EndDates, Alpha*ones(size(EndDates)));
TS = hwtimespec(ValuationDate, EndDates, Compounding);

% build the HW tree
HWTree = hwtree(VS, RateSpec, TS);

% instrument information
CouponRate = 0.045;
```

```

Settle = ValuationDate;
Maturity = '25-October-2014';
OptSpec = 'call';
Strike = 100;
ExerciseDates = {'25-October-2010','25-October-2013'};
Period = 1;
AmericanOpt = 0;
Price = 97;

% compute the OAS
[OAS, OAD] = oasbyhw(HWTtree, Price, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'AmericanOpt', AmericanOpt)

OAS = -12.8538
OAD = 3.2910

```

### Compute the OAS to Measure Cost of an Embedded Option Relative to a Risk-Free Curve

This example shows how to compute the price of a callable bond using a Hull-White tree.

Use the following bond data:

```

Settle = datenum('20-Aug-2014');

% Bond Properties
Maturity = datenum('01-Apr-2034');
CouponRate = .0625;
CallDates = datemnth('01-Oct-2014',6*(0:19));
CallStrikes = [102.85 102.7 102.55 102.4 102.25 102.1 101.95 101.8 ...
101.65 101.5 101.35 101.2 101.05 100.9 100.75 100.6 100.45 100.3 ...
100.15 100];

```

Use the following zero-curve data:

```

CurveDates = datemnth(Settle,12*[1 2 3 5 7 10 20 30]');
ZeroRates = [.11 0.30 0.64 1.44 2.07 2.61 3.29 3.55]'/100;

```

Define the RateSpec and build the HW tree.

```

RateSpec = intenvset('StartDate',Settle,'EndDates',CurveDates,'Rates',ZeroRates);

```

```

% HW Model Properties

```

```

alpha = .1;
sigma = .01;

```

```

TimeSpec = hwtimespec(Settle,cfdates(Settle,Maturity,12),2);
VolSpec = hwvolspec(Settle,Maturity,sigma,Maturity,alpha);

```

```

HWTtree = hwtree(VolSpec,RateSpec,TimeSpec,'method','HW2000')

```

```

HWTtree = struct with fields:
    FinObj: 'HWFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]

```

```

tObs: [1x236 double]
dObs: [1x236 double]
CFlowT: {1x236 cell}
Probs: {1x235 cell}
Connect: {1x235 cell}
FwdTree: {1x236 cell}

```

Compute the OAS for the bond.

```

Price = 103.25;
OAS = oasbyhw(HWTree, Price, CouponRate, Settle, Maturity, 'call', CallStrikes, CallDates)
OAS = 234.8209

```

If you want to compute an OAS that only measures the option cost, you can pass in an issuer-specific curve instead of a risk-free curve (this would be done in the RateSpec argument).

### Compute OAS for an Amortizing Callable Bond Using an HW Interest-Rate Tree Model

This example shows how to compute the OAS for an amortizing callable bond using an HW lattice model.

Create a RateSpec.

```

Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

```

Build a HW tree.

```

VolDates = ['1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'];
VolCurve = 0.01;
AlphaDates = '01-01-2016';
AlphaCurve = 0.1;

```

```

HWVolSpec = hwvolspec(RS.ValuationDate, VolDates, VolCurve, ...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RS.ValuationDate, EndDates, Compounding);
HWT = hwtree(HWVolSpec, RS, HWTimeSpec);

```

Define the callable bond.

```

CouponRate = 0.05;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2016';
Period = 1;

Face = {
    {'Jan-1-2014' 100;
     'Jan-1-2015' 70;
     'Jan-1-2016' 50};

```

```

    };

    OptSpec = 'call';
    Strike = [97 95 93];
    ExerciseDates = {'Jan-1-2014' 'Jan-1-2015' 'Jan-1-2016'};

```

Compute the OAS for a callable amortizing bond using the HW tree.

```

Price = 55;
BondType = 'amortizing';
OAS = oasbyhw(HWT,Price, CouponRate, Settle, Maturity,...
    OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face, 'BondType', BondType)

OAS = 2.4023e+03

```

## Input Arguments

### **HWTtree — Interest-rate tree structure**

structure

Interest-rate tree structure, specified by using hwt tree.

Data Types: `struct`

### **Price — Market prices of bonds with embedded options**

numeric

Market prices of bonds with embedded options, specified as an NINST-by-1 vector.

Data Types: `double`

### **CouponRate — Bond coupon rate**

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate.

Data Types: `double`

### **Settle — Settlement date**

serial date number | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

---

**Note** The `Settle` date for every bond with an embedded option is set to the `ValuationDate` of the HW tree. The bond argument `Settle` is ignored.

---

Data Types: `double` | `char`

### **Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char`

**OptSpec — Definition of option**

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: char | cell

**Strike — Option strike price values**

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

**ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option is exercised between the underlying bond Settle date and the single listed exercise date.

Data Types: double | char

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: OAS =

```
oasbyk(BDTree, Price, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'Period', 4)
```

**AmericanOpt — Option type**

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

### **Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

**IssueDate — Bond issue date**

serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | char

**FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using serial date numbers date or date character vectors.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char

**LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: char | double

**StartDate — Forward starting date of payments**

serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify StartDate, the effective start date is the Settle date.

Data Types: char | double

**Face — Face value**

100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

Data Types: double

**BondType — Type of underlying bond**

'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla', 'amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of 'BondType' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.
- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: char | string

**Options — Derivatives pricing options**

structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with `derivset`.

Data Types: struct

**Output Arguments****OAS — Option adjusted spread**

vector

Option adjusted spread, returned as a NINST-by-1 vector.

**OAD — Option adjusted duration**

vector

Option adjusted duration, returned as a NINST-by-1 vector.

**OAC — Option adjusted convexity**

vector

Option adjusted convexity, returned as a NINST-by-1 vector.

**More About****Vanilla Bond with Embedded Option**

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

### **Stepped Coupon Bond with Callable and Puttable Features**

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

### **Sinking Fund Bond with Call Embedded Option**

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

### **Amortizing Callable or Puttable Bond**

Amortizing callable or puttable bonds work under a scheduled Face.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the Face amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

## **Introduced in R2011a**

## optbndbybdt

Price bond option from Black-Derman-Toy interest-rate tree

### Syntax

```
[Price,PriceTree] = optbndbybdt(BDTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,CouponRate,Settle,Maturity)
[Price,PriceTree] = optbndbybdt( ____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate,StartDate,Face,Options)
```

### Description

[Price,PriceTree] = optbndbybdt(BDTree,OptSpec,Strike,ExerciseDates, AmericanOpt, CouponRate, Settle, Maturity) calculates the price for a bond option from a Black-Derman-Toy interest-rate tree.

[Price,PriceTree] = optbndbybdt( \_\_\_\_, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face, Options) adds optional arguments.

### Examples

#### Price a European Call and Put Option on a Bond

Using the BDT interest-rate tree in the `deriv.mat` file, price a European call and put option on a 10% bond with a strike of 95. The exercise date for the option is Jan. 01, 2002. The settle date for the bond is Jan. 01, 2000, and the maturity date is Jan. 01, 2003.

Load the file `deriv.mat`, which provides `BDTree`. The `BDTree` structure contains the time and forward-rate information needed to price the bond.

```
load deriv.mat;
```

Use `optbndbybdt` to compute the price of the 'Call' option.

```
[Price,PriceTree] = optbndbybdt(BDTree,'Call',95,'01-Jan-2002',...
0,0.10,'01-Jan-2000','01-Jan-2003',1)
```

```
Price = 1.7657
```

```
PriceTree = struct with fields:
```

```
  FinObj: 'BDTPriceTree'
   tObs: [0 1 2 3 4]
   PTree: {1x5 cell}
  ExTree: {[0] [0 0] [1 1 0] [0 0 0 0] [0 0 0 0]}
```

Now use `optbndbybdt` to compute the price of a 'Put' option on the same bond.

```
[Price,PriceTree] = optbndbybdt(BDTree,'Put',95,'01-Jan-2002',...
0,0.10,'01-Jan-2000','01-Jan-2003',1)
```

```
Price = 0.5740

PriceTree = struct with fields:
  FinObj: 'BDTPriceTree'
  tObs: [0 1 2 3 4]
  PTree: {[0.5740] [0 1.2628] [0 0 2.8871] [0 0 0 0] [0 0 0 0]}
  ExTree: {[0] [0 0] [0 0 1] [0 0 0 0] [0 0 0 0]}
```

The `PriceTree.ExTree` output for the 'Call' and 'Put' option contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it is not.

## Input Arguments

### **BDTTree — Interest-rate tree structure**

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

### **OptSpec — Definition of option**

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: `char`

### **Strike — Option strike price values**

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: `double`

### **ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.

- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

Data Types: double | char

### AmericanOpt — Option type

0 European/Bermuda (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

### CouponRate — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

### Settle — Settlement date

serial date number | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

---

**Note** The Settle date for every bond is set to the ValuationDate of the BDT tree. The bond argument Settle is ignored.

---

Data Types: double | char

### Maturity — Maturity date

serial date number | date character vector

Maturity date, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char

### Period — Coupons per year

2 per year (default) | vector

(Optional) Coupons per year, specified as an NINST-by-1 vector.

Data Types: double

### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis, specified as a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

#### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

(Optional) End-of-month rule flag is specified as a nonnegative integer using a NINST-by-1 vector. This rule applies only when *Maturity* is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

#### **IssueDate — Bond issue date**

serial date number | date character vector

(Optional) Bond issue date, specified as an NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | char

#### **FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

(Optional) Irregular first coupon date, specified as an NINST-by-1 vector using serial date numbers date or date character vectors.

When *FirstCouponDate* and *LastCouponDate* are both specified, *FirstCouponDate* takes precedence in determining the coupon payment structure. If you do not specify a *FirstCouponDate*, the cash flow payment dates are determined from other inputs.

Data Types: double | char

### **LastCouponDate — Irregular last coupon date**

serial date number | date character vector

(Optional) Irregular last coupon date, specified as a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: char | double

### **StartDate — Forward starting date of payments**

serial date number | date character vector

(Optional) Forward starting date of payments (the date from which a bond cash flow is considered), specified as a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify StartDate, the effective start date is the Settle date.

Data Types: char | double

### **Face — Face value**

100 (default) | nonnegative value | cell array of nonnegative values

(Optional) Face or par value, specified as an NINST-by-1 vector.

Data Types: double

### **Options — Derivatives pricing options**

structure

(Optional) Derivatives pricing options, specified as structure that is created with derivset.

Data Types: struct

## **Output Arguments**

### **Price — Expected prices of bond option at time 0**

matrix

Expected price of the bond option at time 0, returned as a NINST-by-1 matrix.

### **PriceTree — Structure containing trees of vectors of instrument prices and accrued interest for each node**

structure

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- PriceTree.PTree contains the clean prices.
- PriceTree.tObs contains the observation times.

- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.

## More About

### Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.
- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

For more information, see “Bond Options” on page 2-5.

# optbndbybk

Price bond option from Black-Karasinski interest-rate tree

## Syntax

```
[Price,PriceTree] = optbndbybk(BKTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,CouponRate,Settle,Maturity)
[Price,PriceTree] = optbndbybk(____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate,StartDate,Face,Options)
```

## Description

[Price,PriceTree] = optbndbybk(BKTree,OptSpec,Strike,ExerciseDates, AmericanOpt,CouponRate,Settle,Maturity) calculates the price for a bond option from a Black-Karasinski interest-rate tree.

[Price,PriceTree] = optbndbybk(\_\_\_\_,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate,StartDate,Face,Options) adds optional arguments.

## Examples

### Price a European Call and Put Option on a Bond

Using the BK interest rate tree in the `deriv.mat` file, price a European call and put option on a 4% bond with a strike of 96. The exercise date for the option is Jan. 01, 2006. The settle date for the bond is Jan. 01, 2005, and the maturity date is Jan. 01, 2009.

Load the file `deriv.mat`, which provides `BKTree`. The `BKTree` structure contains the time and forward-rate information needed to price the bond.

```
load deriv.mat;
```

Use `optbndbybk` to compute the price of the 'call' option.

```
[Price,PriceTree] = optbndbybk(BKTree,'Call',96,'01-Jan-2006',...
0,0.04,'01-Jan-2005','01-Jan-2009')
```

```
Warning: OptBonds are valued at Tree ValuationDate rather than Settle.
```

```
> In optbndbytrintree (line 40)
```

```
  In optbndbybk (line 92)
```

```
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
```

```
> In optbndbytrintree (line 151)
```

```
  In optbndbybk (line 92)
```

```
Price =
```

```
    0.1512
```

```
PriceTree =
```

struct with fields:

```

FinObj: 'BKPriceTree'
PTree: {[0.1512] [0.0281 0.1481 0.3119] [0 0 0.1329 0.3886 0.3086] [0 0 0 0 0] [0 0 0 0 0]}
tObs: [0 1 2 3 4]
Connect: {[2] [2 3 4] [2 2 3 4 4]}
Probs: {[3×1 double] [3×3 double] [3×5 double]}
ExTree: {[0] [0 0 0] [0 0 1 1 1] [0 0 0 0 0] [0 0 0 0 0]}

```

Now use `optbndbybdt` to compute the price of a 'put' option on the same bond.

```
[Price,PriceTree] = optbndbybk(BKTree, 'Put', 96, '01-Jan-2006', ...
0,0.04, '01-Jan-2005', '01-Jan-2009')
```

Warning: OptBonds are valued at Tree ValuationDate rather than Settle.

> In `optbndbytrintree` (line 40)

In `optbndbybk` (line 92)

Warning: Not all cash flows are aligned with the tree. Result will be approximated.

> In `optbndbytrintree` (line 151)

In `optbndbybk` (line 92)

Price =

```
0.0272
```

PriceTree =

struct with fields:

```

FinObj: 'BKPriceTree'
PTree: {[0.0272] [0.0860 0.0204 0] [0.0474 0.1266 0 0 0] [0 0 0 0 0] [0 0 0 0 0]}
tObs: [0 1 2 3 4]
Connect: {[2] [2 3 4] [2 2 3 4 4]}
Probs: {[3×1 double] [3×3 double] [3×5 double]}
ExTree: {[0] [0 0 0] [1 1 0 0 0] [0 0 0 0 0] [0 0 0 0 0]}

```

The `PriceTree.ExTree` output for the 'call' and 'put' option contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it is not.

## Input Arguments

### BKTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: `char`

**Strike — Option strike price values**

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

**ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

Data Types: double | char

**AmericanOpt — Option type**

0 European/Bermuda (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

**CouponRate — Bond coupon rate**

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

**Settle — Settlement date**

serial date number | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

---

**Note** The `Settle` date for every bond is set to the `ValuationDate` of the BK tree. The bond argument `Settle` is ignored.

---

Data Types: `double` | `char`

**Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char`

**Period — Coupons per year**

2 per year (default) | vector

(Optional) Coupons per year, specified as an NINST-by-1 vector.

Data Types: `double`

**Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis, specified as a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

(Optional) End-of-month rule flag is specified as a nonnegative integer using a NINST-by-1 vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.

- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

### **IssueDate — Bond issue date**

serial date number | date character vector

(Optional) Bond issue date, specified as an NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | char

### **FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

(Optional) Irregular first coupon date, specified as an NINST-by-1 vector using serial date numbers or date character vectors.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char

### **LastCouponDate — Irregular last coupon date**

serial date number | date character vector

(Optional) Irregular last coupon date, specified as a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: char | double

### **StartDate — Forward starting date of payments**

serial date number | date character vector

(Optional) Forward starting date of payments (the date from which a bond cash flow is considered), specified as a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Data Types: char | double

### **Face — Face value**

100 (default) | nonnegative value | cell array of nonnegative values

(Optional) Face or par value, specified as an NINST-by-1 vector.

Data Types: double

### **Options — Derivatives pricing options**

structure

(Optional) Derivatives pricing options, specified as structure that is created with `derivset`.

Data Types: `struct`

## Output Arguments

### Price — Expected prices of bond option at time $\theta$

matrix

Expected price of the bond option at time  $\theta$ , returned as a NINST-by-1 matrix.

### PriceTree — Structure containing trees of vectors of instrument prices and accrued interest for each node

structure

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.

## More About

### Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.
- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

## optbndbycir

Price bond option from Cox-Ingersoll-Ross interest-rate tree

### Syntax

```
[Price,PriceTree] = optbndbycir(CIRTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,CouponRate,Settle,Maturity)
[Price,PriceTree] = optbndbycir( ____,Name,Value)
```

### Description

[Price,PriceTree] = optbndbycir(CIRTree,OptSpec,Strike,ExerciseDates, AmericanOpt,CouponRate,Settle,Maturity) calculates the price for a bond option from a Cox-Ingersoll-Ross (CIR) interest-rate tree using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

[Price,PriceTree] = optbndbycir( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price a European Call and Put Option on a Bond Using a CIR Interest-Rate Tree

Compute the price for a European call option on a 4% bond with a strike of 96. The exercise date for the option is Jan. 01, 2018. The settle date for the bond is Jan. 01, 2017, and the maturity date is Jan. 01, 2020.

Create a RateSpec using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a CIR tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = '01-Jan-2017';
Maturity = '01-Jan-2019';
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);
```

```
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
    FinObj: 'CIRFwdTree'
```

```

VolSpec: [1x1 struct]
TimeSpec: [1x1 struct]
RateSpec: [1x1 struct]
  tObs: [0 0.5000 1 1.5000]
  dObs: [736696 736878 737061 737243]
FwdTree: {[1.0173] [1.0276 1.0175 1.0097] [1x5 double] [1x7 double]}
Connect: {[3x1 double] [3x3 double] [3x5 double]}
Probs: {[3x1 double] [3x3 double] [3x5 double]}

```

Price the 'Call' option.

```
[Price,PriceTree] = optbndbycir(CIRT,'Call',96,'01-Jan-2018',...
0,0.04,'01-Jan-2017','01-Jan-2020')
```

Price = 2.6827

```
PriceTree = struct with fields:
  FinObj: 'CIRPriceTree'
  tObs: [0 0.5000 1 1.5000 2]
  PTree: {1x5 cell}
  Connect: {[3x1 double] [3x3 double] [3x5 double]}
  ExTree: {[0] [0 0 0] [0 0 1 1 1] [0 0 0 0 0 0 0] [0 0 0 0 0 0 0]}
```

Price the 'Put' option.

```
[Price,PriceTree] = optbndbycir(CIRT,'Put',96,'01-Jan-2018',...
0,0.04,'01-Jan-2017','01-Jan-2020')
```

Price = 0.6835

```
PriceTree = struct with fields:
  FinObj: 'CIRPriceTree'
  tObs: [0 0.5000 1 1.5000 2]
  PTree: {1x5 cell}
  Connect: {[3x1 double] [3x3 double] [3x5 double]}
  ExTree: {[0] [0 0 0] [1 1 0 0 0] [0 0 0 0 0 0 0] [0 0 0 0 0 0 0]}
```

The PriceTree.ExTree output for the 'Call' and 'Put' option contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it is not.

## Input Arguments

**CIRTree — Interest-rate tree structure**  
structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: struct

**OptSpec — Definition of option**

character vector with values 'call' or 'put' | cell array of character vectors with values 'call' or 'put' | string arrays with values "call" or "put"

Definition of option, specified as a NINST-by-1 cell array of character vectors or string arrays.

Data Types: `char` | `cell` | `string`

### Strike — Option strike price values

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: `double`

### ExerciseDates — Option exercise dates

serial date number | date character vector | string array | datetime

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers, data character vectors, string arrays, or datetime arrays depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is a NINST-by-1 vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

Data Types: `double` | `char` | `string` | `datetime`

### AmericanOpt — Option type

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: `double`

### CouponRate — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

**Settle – Settlement date**

serial date number | date character vector | string array | datetime

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

---

**Note** The `Settle` date for every bond is set to the `ValuationDate` of the CIR tree. The bond argument `Settle` is ignored.

---

Data Types: double | char | string

**Maturity – Maturity date**

serial date number | date character vector | string array | datetime

Maturity date, specified as an NINST-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

**Name-Value Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree] = optbndbycir(CIRTree, OptSpec, Strike, ExerciseDates, AmericanOpt, CouponRate, Settle, Maturity, 'Period'6, 'Basis', 7, 'Face', 1000)`

**Period – Coupons per year**

2 per year (default) | possible values include: 0, 1, 2, 3, 4, 6, 12.

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a NINST-by-1 vector.

Data Types: double

**Basis – Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)

- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

### **IssueDate — Bond issue date**

serial date number | date character vector | string array | datetime

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

### **FirstCouponDate — Irregular first coupon date**

serial date number | date character vector | string array | datetime

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using serial date numbers date, date character vectors, string arrays, or datetime arrays.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | string | datetime

### **LastCouponDate — Irregular last coupon date**

serial date number | date character vector | string array | datetime

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using serial date numbers, date character vectors, string arrays, or datetime arrays.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate,

regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `char` | `double` | `string` | `datetime`

### **StartDate — Forward starting date of payments**

serial date number | date character vector | string array | `datetime`

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using serial date numbers, date character vectors, string arrays, or `datetime` arrays.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Data Types: `char` | `double` | `string` | `datetime`

### **Face — Face value**

100 (default) | nonnegative value | cell array of nonnegative values

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector.

Data Types: `double`

## **Output Arguments**

### **Price — Expected prices of bond option at time 0**

matrix

Expected price of the bond option at time 0, returned as a NINST-by-1 matrix.

### **PriceTree — Structure containing trees of vectors of instrument prices and accrued interest for each node**

structure

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.PTree` contains the clean prices.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.

## **More About**

### **Bond Option**

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.

- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

For more information, see “Bond Options” on page 2-5.

## Introduced in R2018a

## optbndbyhjm

Price bond option from Heath-Jarrow-Morton interest-rate tree

### Syntax

```
[Price,PriceTree] = optbndbyhjm(HJMTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,CouponRate,Settle,Maturity)
[Price,PriceTree] = optbndbyhjm( ____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate,StartDate,Face,Options)
```

### Description

[Price,PriceTree] = optbndbyhjm(HJMTree,OptSpec,Strike,ExerciseDates, AmericanOpt,CouponRate,Settle,Maturity) calculates the price for a bond option from a Black-Karasinski interest-rate tree.

[Price,PriceTree] = optbndbyhjm( \_\_\_\_,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate,StartDate,Face,Options) adds optional arguments.

### Examples

#### Price a European Call and Put Option on a Bond

Using the HJM forward-rate tree in the `deriv.mat` file, price a European call and put option on a 4% bond with a strike of 96. The exercise date for the option is Jan. 01, 2003. The settle date for the bond is Jan. 01, 2000, and the maturity date is Jan. 01, 2004.

Load the file `deriv.mat`, which provides `HJMTree`. The `HJMTree` structure contains the time and forward-rate information needed to price the bond.

```
load deriv.mat;
```

Use `optbndbyhjm` to compute the price of the 'call' option.

```
[Price,PriceTree] = optbndbyhjm(HJMTree,'Call',96,'01-Jan-2003',...
0,0.04,'01-Jan-2000','01-Jan-2004')
```

```
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In optbndbyhjm (line 223)
```

```
Price =
```

```
    2.2410
```

```
PriceTree =
```

```
struct with fields:
```

```
    FinObj: 'HJMPriceTree'
```

```

tObs: [0 1 2 3 4]
PBush: {[2.2410] [1×1×2 double] [1×2×2 double] [1×4×2 double] [0 0 0 0 0 0 0 0]}
ExBush: {[0] [1×1×2 double] [1×2×2 double] [1×4×2 double] [0 0 0 0 0 0 0 0]}

```

Now use `optbndbyhjm` to compute the price of a 'put' option on the same bond.

```

[Price,PriceTree] = optbndbyhjm(HJMTree,'Put',96,'01-Jan-2003',...
0,0.04,'01-Jan-2000','01-Jan-2004')

```

```

Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In optbndbyhjm (line 223)

```

```

Price =

```

```

    0.0446

```

```

PriceTree =

```

```

struct with fields:

```

```

    FinObj: 'HJMPriceTree'
    tObs: [0 1 2 3 4]
    PBush: {[0.0446] [1×1×2 double] [1×2×2 double] [1×4×2 double] [0 0 0 0 0 0 0 0]}
    ExBush: {[0] [1×1×2 double] [1×2×2 double] [1×4×2 double] [0 0 0 0 0 0 0 0]}

```

The `PriceTree.ExBush` output for the 'call' and 'put' option contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it is not.

## Input Arguments

### HJMTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmTree`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: `char`

### Strike — Option strike price values

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.

- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

### **ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

Data Types: double | char

### **AmericanOpt — Option type**

0 European/Bermuda (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

### **CouponRate — Bond coupon rate**

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

### **Settle — Settlement date**

serial date number | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

---

**Note** The Settle date for every bond is set to the ValuationDate of the HJM tree. The bond argument Settle is ignored.

---

Data Types: double | char

### **Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char`

**Period — Coupons per year**

2 per year (default) | vector

(Optional) Coupons per year, specified as an NINST-by-1 vector.

Data Types: `double`

**Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis, specified as a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

(Optional) End-of-month rule flag is specified as a nonnegative integer using a NINST-by-1 vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

**IssueDate — Bond issue date**

serial date number | date character vector

(Optional) Bond issue date, specified as an NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: `double` | `char`

### **FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

(Optional) Irregular first coupon date, specified as an NINST-by-1 vector using serial date numbers or date character vectors.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char`

### **LastCouponDate — Irregular last coupon date**

serial date number | date character vector

(Optional) Irregular last coupon date, specified as a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `char` | `double`

### **StartDate — Forward starting date of payments**

serial date number | date character vector

(Optional) Forward starting date of payments (the date from which a bond cash flow is considered), specified as a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Data Types: `char` | `double`

### **Face — Face value**

100 (default) | nonnegative value | cell array of nonnegative values

(Optional) Face or par value, specified as an NINST-by-1 vector.

Data Types: `double`

### **Options — Derivatives pricing options**

structure

(Optional) Derivatives pricing options, specified as structure that is created with `derivset`.

Data Types: `struct`

## Output Arguments

### Price — Expected prices of bond option at time 0

matrix

Expected price of the bond option at time 0, returned as a NINST-by-1 matrix.

### PriceTree — Structure containing trees of vectors of instrument prices and accrued interest for each node

structure

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PBush` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.ExBush` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.

## More About

### Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.
- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

### Introduced before R2006a

# optbndbyhw

Price bond option from Hull-White interest-rate tree

## Syntax

```
[Price,PriceTree] = optbndbyhw(HWTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,CouponRate,Settle,Maturity)
[Price,PriceTree] = optbndbyhw(____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate,StartDate,Face,Options)
```

## Description

[Price,PriceTree] = optbndbyhw(HWTree,OptSpec,Strike,ExerciseDates, AmericanOpt,CouponRate,Settle,Maturity) calculates the price for a bond option from a Hull-White interest-rate tree.

[Price,PriceTree] = optbndbyhw(\_\_\_\_,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate,StartDate,Face,Options) adds optional arguments.

## Examples

### Price a European Call and Put Option on a Bond

Using the HW interest rate tree in the `deriv.mat` file, price a European call option on a 4% bond with a strike of 96. The exercise date for the option is Jan. 01, 2006. The settle date for the bond is Jan. 01, 2005, and the maturity date is Jan. 01, 2009.

Load the file `deriv.mat`, which provides `HWTtree`. The `HWTtree` structure contains the time and forward-rate information needed to price the bond.

```
load deriv.mat;
```

Use `optbndbyhw` to compute the price of the 'call' option.

```
[Price,PriceTree] = optbndbyhw(HWTtree,'Call',96,'01-Jan-2006',...
0,0.04,'01-Jan-2005','01-Jan-2009')
```

```
Warning: OptBonds are valued at Tree ValuationDate rather than Settle.
```

```
> In optbndbytrintree (line 40)
```

```
  In optbndbyhw (line 92)
```

```
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
```

```
> In optbndbytrintree (line 151)
```

```
  In optbndbyhw (line 92)
```

```
Price =
```

```
    1.1556
```

```
PriceTree =
```

```
struct with fields:
```

```
FinObj: 'HWPriceTree'
PTree: {[1.1556] [0.0150 0.8509 3.7085] [0 0 0.0722 4.9980 3.8429] [0 0 0 0 0] [0 0 0 0 0]}
tObs: [0 1 2 3 4]
Connect: {[2] [2 3 4] [2 2 3 4 4]}
Probs: {[3x1 double] [3x3 double] [3x5 double]}
ExTree: {[0] [0 0 0] [0 0 1 1 1] [0 0 0 0 0] [0 0 0 0 0]}
```

Now use `optbndbyhw` to compute the price of a 'put' option on the same bond.

```
[Price,PriceTree] = optbndbyhw(HWTree,'Put',96,'01-Jan-2006',...
0,0.04,'01-Jan-2005','01-Jan-2009')
```

```
Warning: OptBonds are valued at Tree ValuationDate rather than Settle.
```

```
> In optbndbytrintree (line 40)
```

```
In optbndbyhw (line 92)
```

```
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
```

```
> In optbndbytrintree (line 151)
```

```
In optbndbyhw (line 92)
```

```
Price =
```

```
1.0150
```

```
PriceTree =
```

```
struct with fields:
```

```
FinObj: 'HWPriceTree'
PTree: {[1.0150] [3.2945 0.7413 0] [3.5551 4.6060 0 0 0] [0 0 0 0 0] [0 0 0 0 0]}
tObs: [0 1 2 3 4]
Connect: {[2] [2 3 4] [2 2 3 4 4]}
Probs: {[3x1 double] [3x3 double] [3x5 double]}
ExTree: {[0] [0 0 0] [1 1 0 0 0] [0 0 0 0 0] [0 0 0 0 0]}
```

The `PriceTree.ExTree` output for the 'call' and 'put' option contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it is not.

## Input Arguments

### HWTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: `char`

**Strike — Option strike price values**

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

**ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or data character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

Data Types: double | char

**AmericanOpt — Option type**

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

**CouponRate — Bond coupon rate**

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

**Settle — Settlement date**

serial date number | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

---

**Note** The `Settle` date for every bond is set to the `ValuationDate` of the HW tree. The bond argument `Settle` is ignored.

---

Data Types: `double` | `char`

**Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char`

**Period — Coupons per year**

2 per year (default) | vector

(Optional) Coupons per year, specified as an NINST-by-1 vector.

Data Types: `double`

**Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis, specified as a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

(Optional) End-of-month rule flag is specified as a nonnegative integer using a NINST-by-1 vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.

- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

#### **IssueDate — Bond issue date**

serial date number | date character vector

(Optional) Bond issue date, specified as an NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | char

#### **FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

(Optional) Irregular first coupon date, specified as an NINST-by-1 vector using serial date numbers or date character vectors.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char

#### **LastCouponDate — Irregular last coupon date**

serial date number | date character vector

(Optional) Irregular last coupon date, specified as a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: char | double

#### **StartDate — Forward starting date of payments**

serial date number | date character vector

(Optional) Forward starting date of payments (the date from which a bond cash flow is considered), specified as a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Data Types: char | double

#### **Face — Face value**

100 (default) | nonnegative value | cell array of nonnegative values

(Optional) Face or par value, specified as an NINST-by-1 vector.

Data Types: double

#### **Options — Derivatives pricing options**

structure

(Optional) Derivatives pricing options, specified as structure that is created with `derivset`.

Data Types: `struct`

## Output Arguments

### Price — Expected prices of bond option at time $\theta$

`matrix`

Expected price of the bond option at time  $\theta$ , returned as a NINST-by-1 matrix.

### PriceTree — Structure containing trees of vectors of instrument prices and accrued interest for each node

`structure`

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.

## More About

### Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.
- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

For more information, see “Bond Options” on page 2-5.

## optByBatesFD

Option price by Bates model using finite differences

### Syntax

```
[Price,PriceGrid,AssetPrices,Variances,Times] = optByBatesFD(Rate,AssetPrice,
Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,
JumpVol,JumpFreq)
[Price,PriceGrid,AssetPrices,Variances,Times] = optByBatesFD( ____,Name,Value)
```

### Description

[Price,PriceGrid,AssetPrices,Variances,Times] = optByBatesFD(Rate,AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq) computes a vanilla European or American option price by the Bates model, using the alternating direction implicit (ADI) method.

[Price,PriceGrid,AssetPrices,Variances,Times] = optByBatesFD( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Price an American Option Using the Bates Model

Define the option variables and Bates model parameters.

```
AssetPrice = 90;
Strike = 100;
Rate = 0.03;
Settle = '01-Jan-2018';
ExerciseDates = '02-Jul-2018';

V0 = 0.04;
ThetaV = 0.04;
Kappa = 2;
SigmaV = 0.25;
RhoSV = -0.5;
JumpVol = 0.4;
MeanJ = exp(-0.5+JumpVol.^2/2)-1;
JumpFreq = 0.2;
```

Compute the American put option price using the finite differences method.

```
OptSpec = 'Put';
Price = optByBatesFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike, ...
V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'AmericanOpt', 1)

Price = 11.6116
```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

scalar decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal.

Data Types: double

### AssetPrice — Current underlying asset price

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: double

### Settle — Option settlement date

serial date number | date character vector | datetime | string array

Option settlement date, specified as a scalar using a serial date number, date character vector, datetime object, or string scalar.

Data Types: double | char | datetime | string

### ExerciseDates — Option exercise dates

serial date number | date character vector | datetime array | string array

Option exercise dates, specified as a serial date number, date character vector, datetime array, or string array:

- For a European option, use a scalar serial date number, date character vector, datetime object, or string scalar. For a European option, `ExerciseDates` contains only one value: the option expiry date.
- For an American option, use a 1-by-2 vector of serial date numbers, date character vectors, datetime arrays, or string arrays to specify the exercise date boundaries. An American option can be exercised on any date between or including the pair of dates. If only one non-NaN date is listed, then the option can be exercised between `Settle` date and the single listed value in `ExerciseDates`.

Data Types: double | char | datetime | string

### OptSpec — Definition of option

character vector with value of 'call' or 'put' | string with value of "call" or "put"

Definition of the option, specified as a scalar using a character vector or string with a value of 'call' or 'put'.

Data Types: cell | string

### Strike — Option strike price value

scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: double

**V0 — Initial variance of underlying asset**

scalar numeric

Initial variance of the underlying asset, specified as a scalar numeric.

Data Types: double

**ThetaV — Long-term variance of underlying asset**

scalar numeric

Long-term variance of the underlying asset, specified as a scalar numeric.

Data Types: double

**Kappa — Mean revision speed for the variance of underlying asset**

scalar numeric

Mean revision speed for the underlying asset, specified as a scalar numeric.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

scalar numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

scalar numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric.

Data Types: double

**MeanJ — Mean of random percentage jump size**

scalar decimal

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal where  $\log(1+J)$  is normally distributed with the mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$** 

scalar decimal

Standard deviation of  $\log(1+J)$  where  $J$  is the random percentage jump size, specified as a scalar decimal.

Data Types: double

**JumpFreq — Annual frequency of Poisson jump process**

scalar numeric

Annual frequency of the Poisson jump process, specified as a scalar numeric.

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1, Value1, . . . , NameN, ValueN**.

Example: `[Price, PriceGrid] = optByBatesFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'Basis', 7)`

### Basis — Day-count basis of instrument

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### DividendYield — Continuously compounded underlying asset yield

0 (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric.

---

**Note** If you enter a value for **DividendYield**, then set **DividendAmounts** and **ExDividendDates** = [ ] or do not enter them. If you enter values for **DividendAmounts** and **ExDividendDates**, then set **DividendYield** = 0.

---

Data Types: double

### DividendAmounts — Cash dividend amounts

[ ] (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of 'DividendAmounts' and an NDIV-by-1 vector.

---

**Note** Each dividend amount must have a corresponding ex-dividend date. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

---

Data Types: double

**ExDividendDates — Ex-dividend dates**

[ ] (default) | serial date number | date character vector | string array | datetime array

Ex-dividend dates, specified as the comma-separated pair consisting of 'ExDividendDates' and an NDIV-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

**AssetPriceMax — Maximum price for price grid boundary**

if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar numeric

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar numeric.

Data Types: double

**VarianceMax — Maximum variance for variance grid boundary**

1.0 (default) | scalar numeric

Maximum variance for the variance grid boundary, specified as the comma-separated pair consisting of 'VarianceMax' as a scalar numeric.

Data Types: double

**AssetGridSize — Size of asset grid for finite difference grid**

400 (default) | scalar numeric

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a scalar numeric.

Data Types: double

**VarianceGridSize — Number of nodes of variance grid for finite difference grid**

200 (default) | scalar numeric

Number of nodes of the variance grid for the finite difference grid, specified as the comma-separated pair consisting of 'VarianceGridSize' and a scalar numeric.

Data Types: double

**TimeGridSize — Number of nodes of time grid for finite difference grid**

100 (default) | positive numeric scalar

Number of nodes of the time grid for the finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive numeric scalar.

Data Types: double

**AmericanOpt — Option type**

0 (European) (default) | scalar with value of [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a scalar flag with one of these values:

- 0 — European
- 1 — American

Data Types: double

**Output Arguments****Price — Option price**

scalar numeric

Option price, returned as a scalar numeric.

**PriceGrid — Grid containing prices calculated by the finite difference method**

grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with size `AssetGridSize` × `TimeGridSize`. The number of columns is not necessarily equal to the `TimeGridSize` because exercise the function adds exercise and ex-dividend dates to the time grid. `PriceGrid(:, :, end)` contains the price for  $t = 0$ .

**AssetPrices — Prices of the asset**

vector

Prices of the asset corresponding to the first dimension of `PriceGrid`, returned as a vector.

**Variiances — Variiances**

vector

Variiances corresponding to the second dimension of `PriceGrid`, returned as a vector.

**Times — Times**

vector

Times corresponding to the third dimension of `PriceGrid`, returned as a vector.

**More About****Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$

- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Bates Stochastic Volatility Jump Diffusion Model

The Bates model [1] extends the Heston model by including stochastic volatility and (similar to Merton) jump diffusion parameters in the modeling of sudden asset price movements.

The stochastic differential equation is:

$$\begin{aligned} dS_t &= (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t \\ dv_t &= \kappa(\theta - v_t) dt + \sigma_v \sqrt{v_t} dW_t \\ E[dW_t dW_t^v] &= \rho dt \\ \text{prob}(dP_t = 1) &= \lambda_p dt \end{aligned}$$

where:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

where:

$v_0$  is the initial variance of the asset price at  $t = 0$  ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

## optSensByBatesFD

Option price and sensitivities by Bates model using finite differences

### Syntax

```
[PriceSens, PriceGrid, AssetPrices, Variances, Times] = optSensByBatesFD(Rate,
AssetPrice, Settle, ExerciseDates, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV,
MeanJ, JumpVol, JumpFreq)
[PriceSens, PriceGrid, AssetPrices, Variances, Times] = optSensByBatesFD( ____,
Name, Value)
```

### Description

[PriceSens, PriceGrid, AssetPrices, Variances, Times] = optSensByBatesFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq) computes a vanilla European or American option price and sensitivities by the Bates model, using the alternating direction implicit (ADI) method.

[PriceSens, PriceGrid, AssetPrices, Variances, Times] = optSensByBatesFD( \_\_\_\_, Name, Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute Price and Sensitivities for an American Option Using the Bates Model

Define the option variables and Bates model parameters.

```
AssetPrice = 90;
Strike = 100;
Rate = 0.03;
Settle = '01-Jan-2018';
ExerciseDates = '02-Jul-2018';

V0 = 0.04;
ThetaV = 0.04;
Kappa = 2;
SigmaV = 0.25;
RhoSV = -0.5;
JumpVol = 0.4;
MeanJ = exp(-0.5+JumpVol.^2/2)-1;
JumpFreq = 0.2;
```

Compute the American put option price and sensitivities using the finite differences method.

```
OptSpec = 'Put';
[Price, Delta, Gamma, Rho, Theta, Vega, VegaLT] = optSensByBatesFD(Rate, AssetPrice, Settle, Exe
OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'AmericanOpt', 1,..
'OutSpec', ["Price" "Delta" "Gamma" "Rho" "Theta" "Vega" "VegaLT"])

Price = 11.6116
```

Delta = -0.6578

Gamma = 0.0366

Rho = -20.1643

Theta = -4.8425

Vega = 14.3216

VegaLT = 8.1849

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

scalar decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal.

Data Types: double

### AssetPrice — Current underlying asset price

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: double

### Settle — Option settlement date

serial date number | date character vector | datetime | string scalar

Option settlement date, specified as a scalar using a serial date number, date character vector, datetime object, or string scalar.

Data Types: double | char | datetime | string

### ExerciseDates — Option exercise dates

serial date number | date character vector | datetime array | string array

Option exercise dates, specified as a serial date number, date character vector, datetime object or string scalar:

- For a European option, use a scalar serial date number, date character vector, datetime array, or string array. For a European option, `ExerciseDates` contains only one value: the option expiry date.
- For an American option, use a 1-by-2 vector of serial date numbers, date character vectors, datetime arrays, or string arrays to specify the exercise date boundaries. An American option can be exercised on any date between or including the pair of dates. If only one non-NaN date is listed, then the option can be exercised between `Settle` date and the single listed value in `ExerciseDates`.

Data Types: double | char | datetime | string

### OptSpec — Definition of option

character vector with value of 'call' or 'put' | string with value of "call" or "put"

Definition of the option, specified as a scalar using a character vector or string with a value of 'call' or 'put'.

Data Types: cell | string

**Strike — Option strike price value**

numeric

Option strike price value, specified as a scalar numeric.

Data Types: double

**V0 — Initial variance of underlying asset**

scalar numeric

Initial variance of the underlying asset, specified as a scalar numeric.

Data Types: double

**ThetaV — Long-term variance of underlying asset**

scalar numeric

Long-term variance of the underlying asset, specified as a scalar numeric.

Data Types: double

**Kappa — Mean revision speed for the variance of underlying asset**

scalar numeric

Mean revision speed for the underlying asset, specified as a scalar numeric.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

scalar numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

scalar numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric.

Data Types: double

**MeanJ — Mean of random percentage jump size**

scalar decimal

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal where  $\log(1+J)$  is normally distributed with the mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$**

scalar decimal

Standard deviation of  $\log(1+J)$  where  $J$  is the random percentage jump size, specified as a scalar decimal.

Data Types: double

### **JumpFreq — Annual frequency of Poisson jump process**

scalar numeric

Annual frequency of the Poisson jump process, specified as a scalar numeric.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[PriceSens, PriceGrid] =`

```
optSensByBatesFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike, V0, Theta
V, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'Basis', 7, 'OutSpec', 'delta')
```

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric.

---

**Note** If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates` = [ ] or do not enter them. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield` = 0.

---

Data Types: double

**DividendAmounts — Cash dividend amounts**

[ ] (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of 'DividendAmounts' and an NDIV-by-1 vector.

---

**Note** Each dividend amount must have a corresponding ex-dividend date. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield` = 0.

---

Data Types: double

**ExDividendDates — Ex-dividend dates**

[ ] (default) | serial date number | date character vector | string array | datetime array

Ex-dividend dates, specified as the comma-separated pair consisting of 'ExDividendDates' and an NDIV-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

**AssetPriceMax — Maximum price for price grid boundary**

if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar numeric

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar numeric.

Data Types: double

**VarianceMax — Maximum variance for variance grid boundary**

1.0 (default) | scalar numeric

Maximum variance for the variance grid boundary, specified as the comma-separated pair consisting of 'VarianceMax' as a scalar numeric.

Data Types: double

**AssetGridSize — Size of asset grid for finite difference grid**

400 (default) | scalar numeric

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a scalar numeric.

Data Types: double

**VarianceGridSize — Number of nodes of variance grid for finite difference grid**

200 (default) | scalar numeric

Number of nodes of the variance grid for the finite difference grid, specified as the comma-separated pair consisting of 'VarianceGridSize' and a scalar numeric.

Data Types: double

### **TimeGridSize — Number of nodes of time grid for finite difference grid**

100 (default) | positive numeric scalar

Number of nodes of the time grid for the finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive numeric scalar.

Data Types: double

### **AmericanOpt — Option type**

0 (European) (default) | scalar with value of [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a scalar flag with one of these values:

- 0 — European
- 1 — American

Data Types: double

### **OutSpec — Define outputs**

['price'] (default) | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', 'theta', and 'vegalt' | string array with values "price", "delta", "gamma", "vega", "rho", "theta", and "vegalt"

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT string array or cell array of character vectors with supported values.

---

**Note** 'vega' is the sensitivity with respect to the initial volatility  $\sqrt{V_0}$ . In contrast, 'vegalt' is the sensitivity with respect to the long-term volatility  $\sqrt{\Theta V}$ .

---

Example: OutSpec = ['price','delta','gamma','vega','rho','theta','vegalt']

Data Types: string | cell

## **Output Arguments**

### **PriceSens — Option price or sensitivities**

numeric

Option price or sensitivities, returned as a numeric. The name-value pair argument OutSpec determines the types and order of the outputs.

### **PriceGrid — Grid containing prices calculated by the finite difference method**

grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with size AssetGridSize  $\times$  TimeGridSize. The number of columns is not necessarily equal to the TimeGridSize because the function adds exercise and ex-dividend dates to the time grid. PriceGrid(:, :, end) contains the price for  $t = 0$ .

### **AssetPrices — Prices of the asset**

vector

Prices of the asset corresponding to the first dimension of PriceGrid, returned as a vector.

### **Variations — Variations**

vector

Variations corresponding to the second dimension of PriceGrid, returned as a vector.

### **Times — Times**

vector

Times corresponding to the third dimension of PriceGrid, returned as a vector.

## **More About**

### **Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### **Bates Stochastic Volatility Jump Diffusion Model**

The Bates model [1] extends the Heston model by including stochastic volatility and (similar to Merton) jump diffusion parameters in the modeling of sudden asset price movements.

The stochastic differential equation is

$$\begin{aligned} dS_t &= (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t \\ dv_t &= \kappa(\theta - v_t) dt + \sigma_v \sqrt{v_t} dW_t \\ E[dW_t dW_t^y] &= \rho dt \\ \text{prob}(dP_t = 1) &= \lambda_p dt \end{aligned}$$

where:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

where:

$v_0$  is the initial variance of the asset price at  $t = 0$  ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of variance for ( $\sigma_v > 0$ ).

$p$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq p \leq 1$ ).

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

## optByBatesFFT

Option price by Bates model using FFT and FRFT

### Syntax

```
[Price,StrikeOut] = optByBatesFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,
Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)
[Price,StrikeOut] = optByBatesFFT( ____,Name,Value)
```

### Description

[Price,StrikeOut] = optByBatesFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq) computes vanilla European option price by Bates model, using Carr-Madan FFT and Chourdakis FRFT methods.

[Price,StrikeOut] = optByBatesFFT( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Workflow for Plotting an Option Price Surface Using the Bates Model

Use optByBatesFFT to calibrate the FFT strike grid, compute option prices, and plot an option price surface.

#### Define Option Variables and Bates Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';
```

```
V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

#### Compute Option Prices for the Entire FFT (or FRFT) Strike Grid, Without Specifying Strike

Compute option prices and also output the corresponding strikes. If the Strike input is empty ([]), option prices will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid is determined as  $\exp(\log\text{-strike grid})$ , where each column of the log-strike grid has NumFFT points with LogStrikeStep spacing that are roughly centered around each element of  $\log(\text{AssetPrice})$ . The default value for NumFFT is  $2^{12}$ . In addition to the prices in the first output, the optional last output contains the corresponding strikes.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = []; % Strike is not specified (will use the entire FFT strike grid)

% Compute option prices for the entire FFT strike grid
[Call, Kout] = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield);

% Show the lowest and highest strike values on the FFT strike grid
format
MinStrike = Kout(1) % Lowest possible strike in the current FFT strike grid

MinStrike = 2.9205e-135

MaxStrike = Kout(end) % Highest possible strike in the current FFT strike grid

MaxStrike = 1.8798e+138

% Show a subset of the strikes and corresponding option prices
Range = (2046:2052);
[Kout(Range) Call(Range)]

ans = 7x2

    50.4929    29.4990
    58.8640    21.4545
    68.6231    12.8544
    80.0000     5.3484
    93.2631     1.2404
   108.7251     0.1648
   126.7505     0.0152

```

### Change the Number of FFT (or FRFT) Points and Compare with optByBatesNI

Try a different number of FFT (or FRFT) points, and compare the results with direct numerical integration. Unlike `optByBatesFFT`, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the `optByBatesNI` function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by `optByBatesNI` can serve as a benchmark for adjusting the settings for `optByBatesFFT`.

```

% Try a smaller number of FFT (or FRFT) points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Call, Kout] = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
Strike = Kout(Range);
CallFFT = Call(Range);
CallNI = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield);
Error = abs(CallFFT-CallNI);
table(Strike, CallFFT, CallNI, Error)

```

```
ans=7x4 table
  Strike      CallFFT      CallNI      Error
  -----
  12.696      66.237      66.696      0.45912
  23.449      55.86       56.103      0.24239
  43.312      36.418      36.541      0.12246
   80         5.4029      5.3484      0.054469
  147.76      0.044921    0.0010864   0.043835
  272.93      0.0094655  -7.8249e-08 0.0094656
  504.11      0.0024986  -3.3873e-07 0.0024989
```

### Make Further Adjustments to FFT (or FRFT)

If the values in the output CallFFT are significantly different from those in CallNI, try making adjustments to optByBatesFFT settings, such as CharacteristicFcnStep, LogStrikeStep, NumFFT, DampingFactor, and so on. Note that if (LogStrikeStep \* CharacteristicFcnStep) is  $2\pi / \text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

```
Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Call, Kout] = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001);

% Compare with numerical integration method
Strike = Kout(Range);
CallFFT = Call(Range);
CallNI = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield);
Error = abs(CallFFT-CallNI);
table(Strike, CallFFT, CallNI, Error)
```

```
ans=7x4 table
  Strike      CallFFT      CallNI      Error
  -----
  79.76      5.4682      5.4682      1.5355e-08
  79.84      5.4281      5.4281      1.4833e-08
  79.92      5.3882      5.3882      1.4244e-08
   80         5.3484      5.3484      1.359e-08
  80.08      5.3088      5.3088      1.2875e-08
  80.16      5.2693      5.2693      1.2101e-08
  80.24      5.23        5.23        1.1272e-08
```

```
% Save the final FFT (or FRFT) strike grid for future reference. For
% example, it provides information about the range of |Strike| inputs for
% which the FFT (or FRFT) operation is valid.
```

```
FFTStrikeGrid = Kout;
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike
```

```
MinStrike = 47.9437
```

```
MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike
```

```
MaxStrike = 133.3566
```

### Compute the Option Price for a Single Strike

Once the desired FFT (or FRFT) settings are determined, use the `Strike` input to specify the strikes (rather than providing an empty array). If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;

Call = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001)

Call = 5.3484
```

### Compute the Option Prices for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001)

Call = 5×1

    7.5765
    6.4020
    5.3484
    4.4173
    3.6073
```

### Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Call = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001) % Five values in vector output

Call = 5×1

    9.7516
```

```

10.3931
10.8865
11.2990
11.6491

```

### Expand the Outputs for a Surface

Set the `ExpandOutput` name-value pair argument to "true" to expand the outputs into `NStrikes-by-NMaturities` matrices. In this case, they are square matrices.

```

[Call, Kout] = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 5) matrix output

```

Call = 5×5

```

    9.7516    11.4387    12.8395    14.0588    15.1361
    8.6554    10.3931    11.8344    13.0890    14.1980
    7.6432     9.4149    10.8865    12.1693    13.3046
    6.7153     8.5035     9.9952    11.2990    12.4553
    5.8705     7.6581     9.1594    10.4771    11.6491

```

Kout = 5×5

```

    76     76     76     76     76
    78     78     78     78     78
    80     80     80     80     80
    82     82     82     82     82
    84     84     84     84     84

```

### Compute Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is "true", `NStrikes` do not have to match `NMaturities` (that is, the output `NStrikes-by-NMaturities` matrix can be rectangular).

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84)'; % Five strikes

Call = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 6) matrix output

```

Call = 5×6

```

    7.5765     9.7516    11.4387    12.8395    14.0588    15.1361
    6.4020     8.6554    10.3931    11.8344    13.0890    14.1980
    5.3484     7.6432     9.4149    10.8865    12.1693    13.3046
    4.4173     6.7153     8.5035     9.9952    11.2990    12.4553
    3.6073     5.8705     7.6581     9.1594    10.4771    11.6491

```

## Compute the Option Prices for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is "true", the output can also be a `NStrikes-by-NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call = optByBatesFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 4) matrix output

Call = 5x4

    4.2033    6.6918    9.7516   13.2808
    3.5558    5.8112    8.6554   11.9993
    2.9906    5.0181    7.6432   10.7934
    2.5018    4.3096    6.7153    9.6652
    2.0825    3.6818    5.8705    8.6158
```

## Plot an Option Price Surface

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to "true" to output the surface as a `NStrikes-by-NMaturities` matrix.

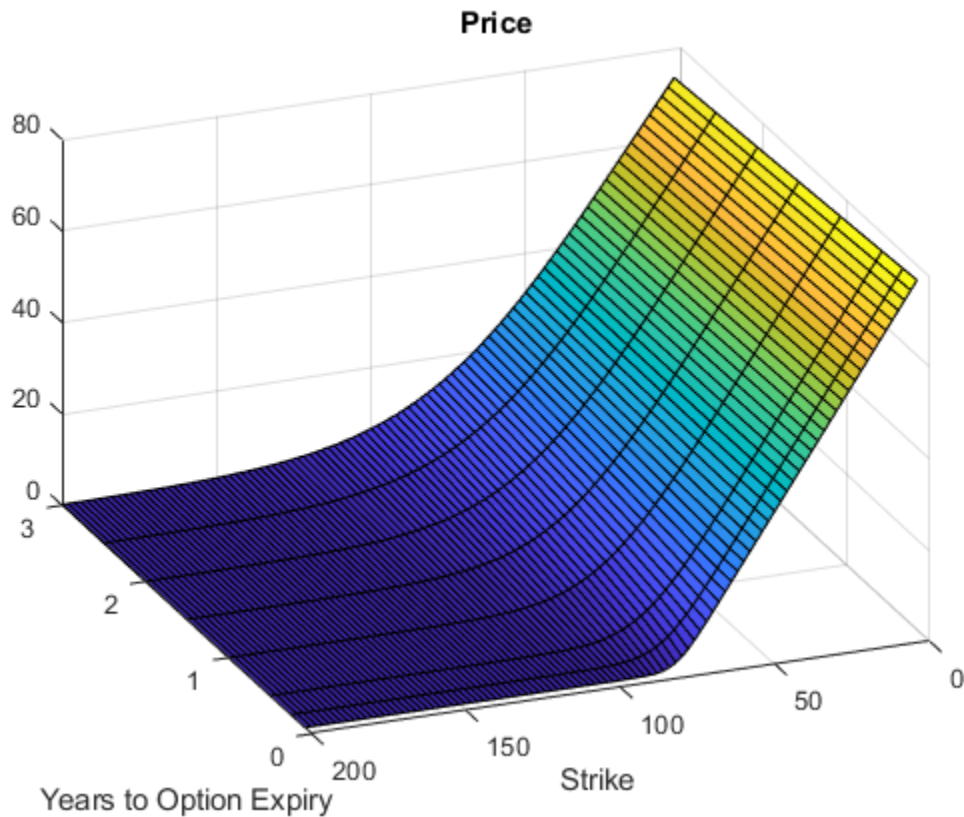

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

% Increase |NumFFT| to support a wider range of strikes
NumFFT = 2^13;

Call = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Call);
title('Price');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
zlim([0 80]);
```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

### AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST-by-1` or `NColumns-by-1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### Settle — Option settlement date

serial date number | date character vector | datetime | string array

Option settlement date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The `Settle` date must be before the `Maturity` date.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **Maturity — Option maturity date**

serial date number | date character vector | `datetime` | string array

Option maturity date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, `datetime` arrays, or string arrays.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **OptSpec — Definition of option**

cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a `NINST-by-1` or `NColumns-by-1` vector using a cell array of character vectors or string arrays with values 'call' or 'put'.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

### **Strike — Option strike price value**

numeric

Option strike price value, specified as a `NINST-by-1`, `NRows-by-1`, `NRows-by-NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has 'NumFFT' points with 'LogStrikeStep' spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **V0 — Initial variance of underlying asset**

numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

### **ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

**Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, specified as a scalar numeric value.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric value.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: double

**MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal value where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$** 

decimal

Standard deviation of  $\log(1+J)$  where  $J$  is the random percentage jump size, specified as a scalar decimal value.

Data Types: double

**JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1, Value1, . . . , NameN, ValueN**.

Example: `[Price, StrikeOut] =`

```
optByBatesFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,  
SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq,'Basis',7)
```

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

#### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

#### **VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

#### **LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with values true or false

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- `true` — Use the Albrecher *et al* formulation.
- `false` — Use the original Heston formation.

Data Types: logical

#### **NumFFT — Number of grid points in the characteristic function variable**

4096 (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of 'NumFFT' and a scalar numeric value.

Data Types: double

### **CharacteristicFcnStep — Characteristic function variable grid spacing**

0.01 (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of 'CharacteristicFcnStep' and a scalar numeric value.

Data Types: double

### **LogStrikeStep — Log-strike grid spacing**

$2\pi/\text{NumFFT}/\text{CharacteristicFcnStep}$  (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of 'LogStrikeStep' and a scalar numeric value.

---

**Note** If  $(\text{LogStrikeStep} \times \text{CharacteristicFcnStep})$  is  $2\pi/\text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

---

Data Types: double

### **DampingFactor — Damping factor for Carr-Madan formulation**

1.5 (default) | numeric

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of 'DampingFactor' and a scalar numeric value.

Data Types: double

### **Quadrature — Type of quadrature**

"simpson" (default) | character vector with values: 'simpson' or 'trapezoidal' | string array with values: "simpson" or "trapezoidal"

Type of quadrature, specified as the comma-separated pair consisting of 'Quadrature' and a single character vector or string array with a value of 'simpson' or 'trapezoidal'.

Data Types: char | string

### **ExpandOutput — Flag to expand the outputs**

false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- **true** — If true, the outputs are NRows-by- NColumns matrices. NRows is the number of strikes for each column and it is determined by the Strike input. For example, Strike can be a NRows-by-1 vector, or a NRows-by-NColumns matrix. If Strike is empty, NRows is equal to NumFFT. NColumns is determined by the sizes of AssetPrice, Settle, Maturity, and OptSpec, which must all be either scalar or NColumns-by-1 vectors.
- **false** — If false, the outputs are NINST-by-1 vectors. Also, the inputs Strike, AssetPrice, Settle, Maturity, and OptSpec must all be either scalar or NINST-by-1 vectors.

Data Types: logical

## Output Arguments

### Price — Option prices

numeric

Option prices, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput.

### StrikeOut — Strikes corresponding to Price

numeric

Strikes corresponding to Price, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates (1996)) is an extension of the Heston model, where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) were also added to model sudden asset price movements.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t$$

$$dv_t = \kappa(\theta - v_t) dt + \sigma_v \sqrt{v_t} dW_t$$

$$E[dW_t dW_t^y] = \rho dt$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

$v_0$  is the initial variance of the asset price at  $t = 0$  ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

The characteristic function  $f_{Bates_j(\phi)}$  for  $j = 1$  (asset price mean measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t) \exp(\lambda_p \tau (1 + \mu_j)^{m_j + \frac{1}{2}} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 (m_j i\phi + \frac{(i\phi)^2}{2})} - 1 \right] - \lambda_p \tau \mu_j i\phi)$$

$$m_j = \begin{cases} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{cases}$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi + d_j)\tau - 2\ln \left( \frac{1 - g_j e^{d_j \tau}}{1 - g_j} \right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j \tau}}{1 - g_j e^{d_j \tau}} \right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - p\sigma_v i\phi)^2 - \sigma_v^2 (2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity for ( $\tau = T - t$ ).

$i$  is the unit imaginary number for ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  under “The Little Heston Trap” by Albrecher et al. (2007) are:

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln \left( \frac{1 - \varepsilon_j e^{-d_j \tau}}{1 - \varepsilon_j} \right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j \tau}}{1 - \varepsilon_j e^{-d_j \tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities  $P_1$  and  $P_2$  as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi} \int_{-\infty}^{\infty} \text{Re}[e^{-iuk} \psi(u)] du$$

$$\psi(u) = \frac{e^{-r\tau} f_2(\phi = (u - (\alpha + 1)i))}{\alpha^2 + \alpha - u^2 + iu(2\alpha + 1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$

$i$  is a unit imaginary number ( $i^2 = -1$ )

$\phi$  is the characteristic function variable.

$\alpha$  is the damping factor.

$u$  is the characteristic function variable for integration, where  $\phi = (u - (\alpha+1)i)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration,  $u$ , is discretized into NumFFT( $N$ ) points with the step size CharacteristicFcnStep ( $\Delta u$ ), and the log-strike  $k$  is discretized into  $N$  points with the step size LogStrikeStep( $\Delta k$ ).

The discretized characteristic function variable for integration,  $u_j$  (for  $j = 1, 2, 3, \dots, N$ ), has a minimum value of 0 and a maximum value of  $(N-1) (\Delta u)$ , and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid,  $k_n$  (for  $n = 1, 2, 3, N$ ) is approximately centered around  $\ln(S_t)$ , with a minimum value of

$$\ln(S_t) - \frac{N}{2} \Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right) \Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2} \Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^N \operatorname{Re}\left[e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iu_j \left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j)\right] w_j$$

where

$\Delta u$  is the step size of discretized characteristic function variable for integration.

$\Delta k$  is the step size of discretized log-strike.

$N$  is the number of FFT/FRFT points

$w_j$  is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if  $\Delta k$  and  $\Delta u$  are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

# optSensByBatesFFT

Option price and sensitivities by Bates model using FFT and FRFT

## Syntax

```
[PriceSens,StrikeOut] = optSensByBatesFFT(Rate,AssetPrice,Settle,Maturity,
OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)
[PriceSens,StrikeOut] = optSensByBatesFFT( ____,Name,Value)
```

## Description

[PriceSens,StrikeOut] = optSensByBatesFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq) computes vanilla European option price and sensitivities by Bates model, using Carr-Madan FFT and Chourdakis FRFT methods.

[PriceSens,StrikeOut] = optSensByBatesFFT( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Workflow for Plotting an Option Sensitivity Surface Using the Bates Model

Use optSensByBatesFFT to calibrate the FFT strike grid for sensitivities, compute option sensitivities, and plot option sensitivity surfaces.

#### Define Option Variables and Bates Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

#### Compute the Option Sensitivities for the Entire FFT (or FRFT) Strike Grid, Without Specifying "Strike"

Compute option sensitivities and also output the corresponding strikes. If the Strike input is empty ( [] ), option sensitivities will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid is determined as  $\exp(\log\text{-strike grid})$ , where each column of the log-strike grid has NumFFT points with LogStrikeStep spacing that are roughly centered around each

element of  $\log(\text{AssetPrice})$ . The default value for NumFFT is  $2^{12}$ . In addition to the sensitivities in the first output, the optional last output contains the corresponding strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = []; % Strike is not specified (will use the entire FFT strike grid)

% Compute option sensitivities for the entire FFT strike grid
[Delta, Kout] = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta");

% Show the lowest and highest strike values on the FFT strike grid
format
MinStrike = Kout(1) % Lowest possible strike in the current FFT strike grid
MinStrike = 2.9205e-135

MaxStrike = Kout(end) % Highest possible strike in the current FFT strike grid
MaxStrike = 1.8798e+138

% Show a subset of the strikes and corresponding option sensitivities
Range = (2046:2052);
[Kout(Range) Delta(Range)]

ans = 7x2

    50.4929    0.9846
    58.8640    0.9585
    68.6231    0.8498
    80.0000    0.5630
    93.2631    0.1955
   108.7251    0.0319
   126.7505    0.0033
```

### Change the Number of FFT (or FRFT) Points and Compare with optSensByBatesNI

Try a different number of FFT (or FRFT) points, and compare the results with numerical integration. Unlike `optSensByBatesFFT`, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the `optSensByBatesNI` function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by `optSensByBatesNI` can serve as a benchmark for adjusting the settings for `optSensByBatesFFT`.

```
% Try a smaller number of FFT points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Delta, Kout] = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
Strike = Kout(Range);
DeltaFFT = Delta(Range);
DeltaNI = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
```

```

ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)

```

ans=7×4 table

Strike	DeltaFFT	DeltaNI	Error
12.696	0.9265	0.99002	0.063524
23.449	0.95153	0.99002	0.038497
43.312	0.95928	0.98928	0.029994
80	0.5355	0.56303	0.027531
147.76	0.0016267	0.00025691	0.0013698
272.93	0.00058267	1.8942e-09	0.00058267
504.11	0.00017752	8.7099e-10	0.00017752

### Make Further Adjustments to FFT (or FRFT)

If the values in the output DeltaFFT are significantly different from those in DeltaNI, try making adjustments to optSensByBatesFFT settings, such as CharacteristicFcnStep, LogStrikeStep, NumFFT, DampingFactor, and so on. Note that if (LogStrikeStep \* CharacteristicFcnStep) is  $2\pi / \text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

```

Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Delta, Kout] = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001);

```

% Compare with numerical integration method

```

Strike = Kout(Range);
DeltaFFT = Delta(Range);
DeltaNI = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)

```

ans=7×4 table

Strike	DeltaFFT	DeltaNI	Error
79.76	0.57037	0.57037	6.3042e-09
79.84	0.56793	0.56793	7.156e-09
79.92	0.56548	0.56548	7.975e-09
80	0.56303	0.56303	8.7573e-09
80.08	0.56057	0.56057	9.4992e-09
80.16	0.55811	0.55811	1.0197e-08
80.24	0.55564	0.55564	1.0847e-08

% Save the final FFT (or FRFT) strike grid for future reference. For % example, it provides information about the range of Strike inputs for % which the FFT (or FRFT) operation is valid.

```

FFTStrikeGrid = Kout;
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike

```

```

MinStrike = 47.9437
MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike
MaxStrike = 133.3566

```

### Compute the Option Sensitivity for a Single Strike

Once the desired FFT (or FRFT) settings are determined, use the `Strike` input to specify the strikes rather than providing an empty array. If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;

Delta = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)

Delta = 0.5630

```

### Compute the Option Sensitivities for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Delta = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)

Delta = 5x1

    0.6807
    0.6234
    0.5630
    0.5011
    0.4392

```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Delta = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...

```

```

'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001) % Five values in vector output
Delta = 5×1

    0.6625
    0.6232
    0.5958
    0.5748
    0.5577

```

### Expand the Outputs for a Surface

Set the ExpandOutput name-value pair argument to "true" to expand the outputs into NStrikes-by-NMaturities matrices. In this case, they are square matrices.

```

[Delta, Kout] = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 5) matrix output
Delta = 5×5

    0.6625    0.6556    0.6515    0.6483    0.6455
    0.6222    0.6232    0.6239    0.6241    0.6238
    0.5805    0.5900    0.5958    0.5996    0.6019
    0.5381    0.5564    0.5674    0.5748    0.5798
    0.4954    0.5225    0.5389    0.5499    0.5577

```

```

Kout = 5×5

    76    76    76    76    76
    78    78    78    78    78
    80    80    80    80    80
    82    82    82    82    82
    84    84    84    84    84

```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When ExpandOutput is "true", NStrikes do not have to match NMaturities. That is, the output NStrikes-by-NMaturities matrix can be rectangular.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84)'; % Five strikes

Delta = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 6) matrix output
Delta = 5×6

```

```

0.6807    0.6625    0.6556    0.6515    0.6483    0.6455
0.6234    0.6222    0.6232    0.6239    0.6241    0.6238
0.5630    0.5805    0.5900    0.5958    0.5996    0.6019
0.5011    0.5381    0.5564    0.5674    0.5748    0.5798
0.4392    0.4954    0.5225    0.5389    0.5499    0.5577

```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is "true", the output can also be a `NStrikes-by-NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta = optSensByBatesFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, ...
    Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 4) matrix output

```

Delta = 5x4

```

0.4350    0.5579    0.6625    0.7457
0.3881    0.5124    0.6222    0.7120
0.3432    0.4670    0.5805    0.6763
0.3010    0.4223    0.5381    0.6390
0.2619    0.3789    0.4954    0.6002

```

### Plot Option Sensitivity Surfaces

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to "true" to output the surfaces as `NStrikes-by-NMaturities` matrices.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

% Increase 'NumFFT' to support a wider range of strikes
NumFFT = 2^13;

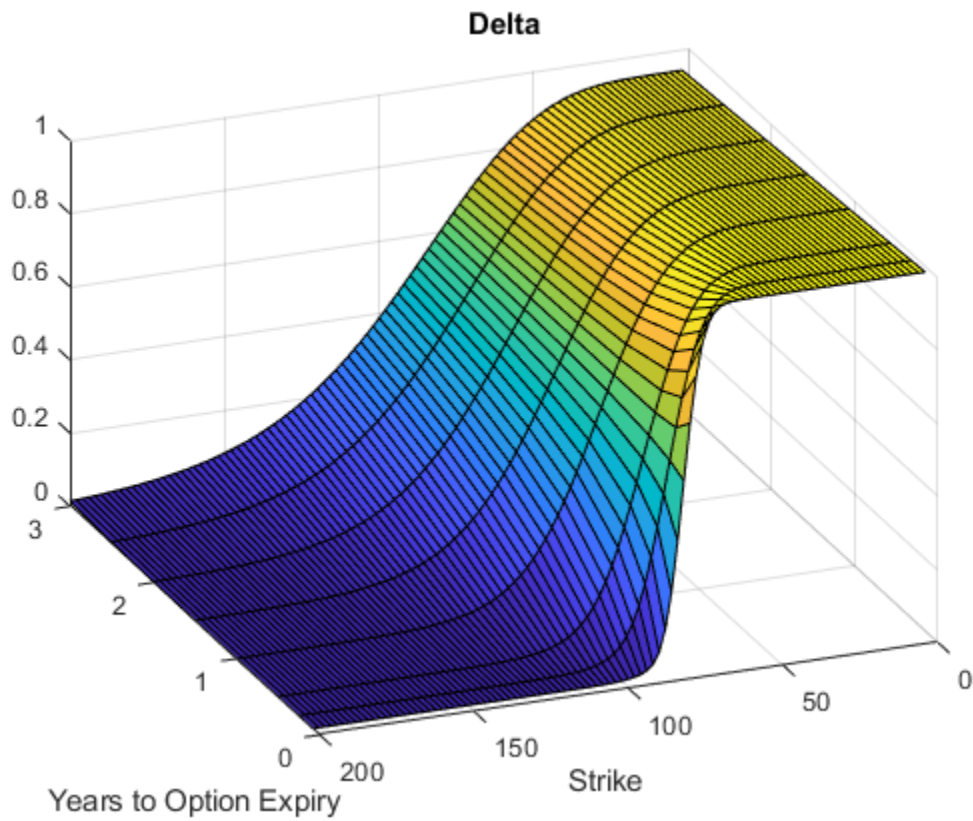

[Delta, Gamma, Rho, Theta, Vega, VegaLT] = optSensByBatesFFT(...

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

### AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST-by-1` or `NColumns-by-1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### Settle — Option settlement date

serial date number | date character vector | datetime | string array

Option settlement date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The `Settle` date must be before the `Maturity` date.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **Maturity — Option maturity date**

serial date number | date character vector | `datetime` | string array

Option maturity date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, `datetime` arrays, or string arrays.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **OptSpec — Definition of option**

cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a `NINST-by-1` or `NColumns-by-1` vector using a cell array of character vectors or string arrays with values 'call' or 'put'.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

### **Strike — Option strike price value**

numeric

Option strike price value, specified as a `NINST-by-1`, `NRows-by-1`, `NRows-by-NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has 'NumFFT' points with 'LogStrikeStep' spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **V0 — Initial variance of underlying asset**

numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

### **ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

**Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, specified as a scalar numeric value.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric value.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: double

**MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal value where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$** 

decimal

Standard deviation of  $\log(1+J)$  where  $J$  is the random percentage jump size, specified as a scalar decimal value.

Data Types: double

**JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[PriceSens, StrikeOut] = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'Basis', 7)`

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

### **VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

### **LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with values true or false

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- **true** — Use the Albrecher *et al* formulation.
- **false** — Use the original Heston formation.

Data Types: logical

**OutSpec — Define outputs**

["price"] (default) | string array with values "price", "delta", "gamma", "vega", "rho", "theta", and "vegalt" | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', 'theta', and 'vegalt'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT string array or cell array of character vectors with supported values.

---

**Note** "vega" is the sensitivity with respect the initial volatility  $\sqrt{V_0}$ . In contrast, "vegalt" is the sensitivity with respect to the long-term volatility  $\sqrt{\text{Theta}V}$ .

---

Example: OutSpec = ["price","delta","gamma","vega","rho","theta","vegalt"]

Data Types: string | cell

**NumFFT — Number of grid points in the characteristic function variable**

4096 (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of 'NumFFT' and a scalar numeric value.

Data Types: double

**CharacteristicFcnStep — Characteristic function variable grid spacing**

0.01 (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of 'CharacteristicFcnStep' and a scalar numeric value.

Data Types: double

**LogStrikeStep — Log-strike grid spacing**

$2\pi/\text{NumFFT}/\text{CharacteristicFcnStep}$  (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of 'LogStrikeStep' and a scalar numeric value.

---

**Note** If  $(\text{LogStrikeStep} \times \text{CharacteristicFcnStep})$  is  $2\pi/\text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

---

Data Types: double

**DampingFactor — Damping factor for Carr-Madan formulation**

1.5 (default) | numeric

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of 'DampingFactor' and a scalar numeric value.

Data Types: double

**Quadrature — Type of quadrature**

"simpson" (default) | character vector with values: 'simpson' or 'trapezoidal' | string array with values: "simpson" or "trapezoidal"

Type of quadrature, specified as the comma-separated pair consisting of 'Quadrature' and a single character vector or string array with a value of 'simpson' or 'trapezoidal'.

Data Types: char | string

### **ExpandOutput — Flag to expand the outputs**

false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- **true** — If true, the outputs are NRows-by- NColumns matrices. NRows is the number of strikes for each column and it is determined by the Strike input. For example, Strike can be a NRows-by-1 vector, or a NRows-by-NColumns matrix. If Strike is empty, NRows is equal to NumFFT. NColumns is determined by the sizes of AssetPrice, Settle, Maturity, and OptSpec, which must all be either scalar or NColumns-by-1 vectors.
- **false** — If false, the outputs are NINST-by-1 vectors. Also, the inputs Strike, AssetPrice, Settle, Maturity, and OptSpec must all be either scalar or NINST-by-1 vectors.

Data Types: logical

## **Output Arguments**

### **PriceSens — Option prices or sensitivities**

numeric

Option prices or sensitivities, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput. The name-value pair argument OutSpec determines the types and order of the outputs.

### **StrikeOut — Strikes corresponding to Price**

numeric

Strikes corresponding to Price, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput.

## **More About**

### **Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates (1996)) is an extension of the Heston model, where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) were also added to model sudden asset price movements.

The stochastic differential equation is:

$$\begin{aligned} dS_t &= (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t \\ dv_t &= \kappa(\theta - v_t) dt + \sigma_v \sqrt{v_t} dW_t \\ E[dW_t dW_t^v] &= \rho dt \\ \text{prob}(dP_t = 1) &= \lambda_p dt \end{aligned}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

$v_0$  is the initial variance of the asset price at  $t = 0$  ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

The characteristic function  $f_{Bates_j(\phi)}$  for  $j = 1$  (asset price mean measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t) \exp(\lambda_p \tau (1 + \mu_j)^{m_j + \frac{1}{2}} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 (m_j i\phi + \frac{(i\phi)^2}{2})} - 1 \right] - \lambda_p \tau \mu_j i\phi)$$

$$m_j = \begin{cases} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{cases}$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j \tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j \tau}}{1 - g_j e^{d_j \tau}} \right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - p\sigma_v i\phi)^2 - \sigma_v^2 (2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity for ( $\tau = T - t$ ).

$i$  is the unit imaginary number for ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  under “The Little Heston Trap” by Albrecher et al. (2007) are:

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j \tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j \tau}}{1 - \varepsilon_j e^{-d_j \tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities  $P_1$  and  $P_2$  as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi} \int_0^{\infty} \text{Re}[e^{-iuk}\psi(u)]du$$

$$\psi(u) = \frac{e^{-r\tau}f_2(\phi = (u - (\alpha + 1)i))}{\alpha^2 + \alpha - u^2 + iu(2\alpha + 1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$\alpha$  is the damping factor.

$u$  is the characteristic function variable for integration, where  $\phi = (u - (\alpha+1)i)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration,  $u$ , is discretized into NumFFT( $N$ ) points with the step size CharacteristicFcnStep ( $\Delta u$ ), and the log-strike  $k$  is discretized into  $N$  points with the step size LogStrikeStep( $\Delta k$ ).

The discretized characteristic function variable for integration,  $u_j$ (for  $j = 1, 2, 3, \dots, N$ ), has a minimum value of 0 and a maximum value of  $(N-1) (\Delta u)$ , and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid,  $k_n$ (for  $n = 1, 2, 3, N$ ) is approximately centered around  $\ln(S_t)$ , with a minimum value of

$$\ln(S_t) - \frac{N}{2}\Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^N \operatorname{Re}\left[e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iu_j \left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j)\right] w_j$$

where

$\Delta u$  is the step size of discretized characteristic function variable for integration.

$\Delta k$  is the step size of discretized log-strike.

$N$  is the number of FFT/FRFT points

$w_j$  is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if  $\Delta k$  and  $\Delta u$  are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

**Introduced in R2018a**

# optByBatesNI

Option price by Bates model using numerical integration

## Syntax

```
Price = optByBatesNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,
ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)
Price = optByBatesNI( ____,Name,Value)
```

## Description

Price = optByBatesNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq) computes vanilla European option price by Bates model, using numerical integration methods.

Price = optByBatesNI( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Workflow for Plotting an Option Price Surface Using the Bates Model

optByBatesNI uses numerical integration to compute option prices and then plot an option price surface.

#### Define Option Variables and Bates Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';
```

```
V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

#### Compute the Option Price for a Single Strike

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;
```

```
Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield)
```

```
Call = 5.3484
```

### Compute the Option Prices for a Vector of Strikes

The Strike input can be a vector.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield)

Call = 5×1

    7.5765
    6.4020
    5.3484
    4.4173
    3.6073
```

### Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the Strike input to specify the strikes. Also, the Maturity input can be a vector, but it must match the length of the Strike vector if the ExpandOutput name-value pair argument is not set to "true".

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield) % Five values in vector output

Call = 5×1

    9.7516
   10.3931
   10.8865
   11.2990
   11.6491
```

### Expand the Output for a Surface

Set the ExpandOutput name-value pair argument to "true" to expand the output into a NStrikes-by-NMaturities matrix. In this case, it is a square matrix.

```
Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'ExpandOutput', true) % (5 x 5) matrix output

Call = 5×5

    9.7516    11.4387    12.8395    14.0588    15.1361
    8.6554    10.3931    11.8344    13.0890    14.1980
```

```

7.6432    9.4149    10.8865    12.1693    13.3046
6.7153    8.5035     9.9951    11.2990    12.4553
5.8705    7.6581     9.1594    10.4771    11.6491

```

### Compute the Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When ExpandOutput is "true", NStrikes do not have to match NMaturities (that is, the output NStrikes-by-NMaturities matrix can be rectangular).

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84)'; % Five strikes

Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'ExpandOutput', true) % (5 x 6) matrix output

```

Call = 5x6

```

7.5765    9.7516    11.4387    12.8395    14.0588    15.1361
6.4020    8.6554    10.3931    11.8344    13.0890    14.1980
5.3484    7.6432     9.4149    10.8865    12.1693    13.3046
4.4173    6.7153     8.5035     9.9951    11.2990    12.4553
3.6073    5.8705     7.6581     9.1594    10.4771    11.6491

```

### Compute Option Prices for a Vector of Strikes and a Vector of Asset Prices

When ExpandOutput is "true", the output can also be a NStrikes-by-NAssetPrices rectangular matrix by accepting a vector of asset prices.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call = optByBatesNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'ExpandOutput', true) % (5 x 4) matrix output

```

Call = 5x4

```

4.2033    6.6918    9.7516    13.2808
3.5558    5.8111    8.6554    11.9993
2.9906    5.0181    7.6432    10.7934
2.5018    4.3096    6.7153     9.6651
2.0825    3.6818    5.8705     8.6158

```

### Plot an Option Price Surface

The Strike and Maturity inputs can be vectors. Set ExpandOutput to "true" to output the surface as a NStrikes-by-NMaturities matrix.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]);

```

```

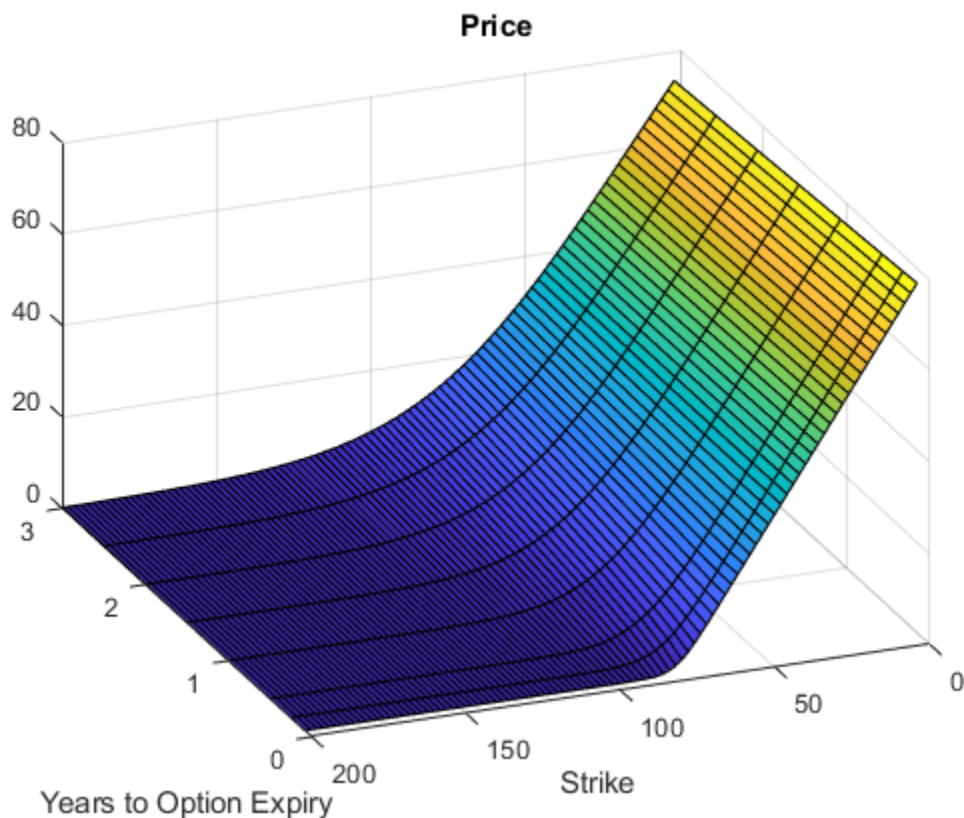

Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Call);
title('Price');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
zlim([0 80]);

```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: double

**AssetPrice — Current underlying asset price**

numeric

Current underlying asset price, specified as numeric value using a scalar or a NINST-by-1 or NColumns-by-1 vector.

For more information on the proper dimensions for AssetPrice, see the name-value pair argument ExpandOutput.

Data Types: double

**Settle — Option settlement date**

serial date number | date character vector | datetime | string array

Option settlement date, specified as a NINST-by-1 or NColumns-by-1 vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The Settle date must be before the Maturity date.

For more information on the proper dimensions for Settle, see the name-value pair argument ExpandOutput.

Data Types: double | char | datetime | string

**Maturity — Option maturity date**

serial date number | date character vector | datetime | string array

Option maturity date, specified as a NINST-by-1 or NColumns-by-1 vector using serial date numbers, date character vectors, datetime arrays, or string arrays.

For more information on the proper dimensions for Maturity, see the name-value pair argument ExpandOutput.

Data Types: double | char | datetime | string

**OptSpec — Definition of option**

cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a NINST-by-1 or NColumns-by-1 vector using a cell array of character vectors or string arrays with values 'call' or 'put'.

For more information on the proper dimensions for OptSpec, see the name-value pair argument ExpandOutput.

Data Types: cell | string

**Strike — Option strike price value**

numeric

Option strike price value, specified as a NINST-by-1, NRows-by-1, NRows-by-NColumns vector of strike prices.

For more information on the proper dimensions for Strike, see the name-value pair argument ExpandOutput.

Data Types: double

**V0 — Initial variance of underlying asset**

numeric

Initial variance of the underlying asset, specified as a scalar numeric value.

Data Types: double

**ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underlying asset, specified as a scalar numeric value.

Data Types: double

**Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, specified as a scalar numeric value.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric value.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: double

**MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal value where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$** 

decimal

Standard deviation of  $\log(1+J)$  where  $J$  is the random percentage jump size, specified as a scalar decimal value.

Data Types: double

**JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside quotes. You can specify several name and value pair arguments in any order as *Name1*, *Value1*, . . . , *NameN*, *ValueN*.

Example: `Price = optByBatesNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq,'Basis',7)`

## Basis — Day-count basis of instrument

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

## DividendYield — Continuously compounded underlying asset yield

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

## VolRiskPremium — Volatility risk premium

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

**LittleTrap — Flag indicating "Little Heston Trap" formulation**

true (default) | logical with values true or false

Flag indicating "Little Heston Trap" formulation by Albrecher *et al*, specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- true — Use the Albrecher *et al* formulation.
- false — Use the original Heston formation.

Data Types: logical

**AbsTol — Absolute error tolerance for numerical integration**

1e-10 (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of 'AbsTol' and a scalar numeric value.

Data Types: double

**RelTol — Relative error tolerance for numerical integration**

1e-6 (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of 'RelTol' and a scalar numeric value.

Data Types: double

**IntegrationRange — Numerical integration range used to approximate continuous integral over [0 Inf]**

[1e-9 Inf] (default) | vector

Numerical integration range used to approximate the continuous integral over [0 Inf], specified as the comma-separated pair consisting of 'IntegrationRange' and a 1-by-2 vector representing [LowerLimit UpperLimit].

Data Types: double

**Framework — Framework for computing option prices and sensitivities using numerical integration of models**

"heston1993" (default) | string with values "heston1993" or "lewis2001" | character vector with values 'heston1993' or 'lewis2001'

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of 'Framework' and a scalar string or character vector with the following values:

- "heston1993" or 'heston1993' — Method used in Heston (1993)
- "lewis2001" or 'lewis2001' — Method used in Lewis (2001)

Data Types: char | string

**ExpandOutput — Flag to expand the outputs**

false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- `true` — If `true`, the outputs are `NRows`-by-`NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

## Output Arguments

### Price — Option prices

`numeric`

Option prices, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates (1996)) is an extension of the Heston model, where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) were also added to model sudden asset price movements.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t$$

$$dv_t = \kappa(\theta - v_t) dt + \sigma_v \sqrt{v_t} dW_t$$

$$E[dW_t dW_t^y] = \rho dt$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

$v_0$  is the initial variance of the asset price at  $t = 0$  ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of variance for ( $\sigma_v > 0$ ).

$p$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq p \leq 1$ ).

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

The characteristic function  $f_{Bates_j(\phi)}$  for  $j = 1$  (asset price mean measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t) \exp(\lambda_p \tau (1 + \mu_j)^{m_j + \frac{1}{2}} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 (m_j i\phi + \frac{(i\phi)^2}{2})} - 1 \right] - \lambda_p \tau \mu_j i\phi)$$

$$m_j = \begin{cases} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{cases}$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi + d_j)\tau - 2\ln \left( \frac{1 - g_j e^{d_j \tau}}{1 - g_j} \right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j \tau}}{1 - g_j e^{d_j \tau}} \right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - p\sigma_v i\phi)^2 - \sigma_v^2 (2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity for ( $\tau = T - t$ ).

$i$  is the unit imaginary number for ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  under “The Little Heston Trap” by Albrecher et al. (2007) are:

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln \left( \frac{1 - \varepsilon_j e^{-d_j \tau}}{1 - \varepsilon_j} \right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j \tau}}{1 - \varepsilon_j e^{-d_j \tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \operatorname{Re} \left[ \frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$

$i$  is a unit imaginary number ( $i^2 = -1$ )

$\phi$  is the characteristic function variable.

$f_j(\phi)$  is the characteristic function for  $P_j$  ( $j = 1, 2$ ).

$P_1$  is the probability of  $S_t > K$  under the asset price measure for the model.

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

Where  $j = 1, 2$  so that  $f_1(\phi)$  and  $f_2(\phi)$  are the characteristic functions for probabilities  $P_1$  and  $P_2$ , respectively.

This framework is chosen with the default value "Heston1993" for the Framework name-value pair argument.

### Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K} e^{-r\tau}}{\pi} \int_0^{\infty} \operatorname{Re} \left[ K^{-iu} f_2 \left( \phi = \left( u - \frac{i}{2} \right) \frac{1}{u^2 + \frac{1}{4}} \right) \right] du$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$

$i$  is a unit imaginary number ( $i^2 = -1$ )

$\phi$  is the characteristic function variable.

$u$  is the characteristic function variable for integration, where  $\phi = \left(u - \frac{i}{2}\right)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

This framework is chosen with the value "Lewis2001" for the Framework name-value pair argument.

## Introduced in R2018a

## optSensByBatesNI

Option price or sensitivities by Bates model using numerical integration

### Syntax

```
PriceSens = optSensByBatesNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,
V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)
PriceSens = optSensByBatesNI( ____,Name,Value)
```

### Description

PriceSens = optSensByBatesNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike, V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq) computes vanilla European option price and sensitivities by Bates model, using numerical integration methods.

PriceSens = optSensByBatesNI( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Workflow for Plotting an Option Sensitivity Surface Using the Bates Model

optSensByBatesNI uses numerical integration to compute option sensitivities and then to plot option sensitivity surfaces.

#### Define Option Variables and Bates Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';
```

```
V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

#### Compute the Option Sensitivity for a Single Strike

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;
```

```
Delta = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta")
```

```
Delta = 0.5630
```

## Compute the Option Sensitivities for a Vector of Strikes

The Strike input can be a vector.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Delta = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta")
```

```
Delta = 5x1

    0.6807
    0.6234
    0.5630
    0.5011
    0.4392
```

## Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the Strike input to specify the strikes. Also, the Maturity input can be a vector, but it must match the length of the Strike vector if the ExpandOutput name-value pair argument is not set to "true".

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Delta = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta") % Five values in vector output
```

```
Delta = 5x1

    0.6625
    0.6232
    0.5958
    0.5748
    0.5577
```

## Expand the Output for a Surface

Set the ExpandOutput name-value pair argument to "true" to expand the output into a NStrikes-by-NMaturities matrix. In this case, it is a square matrix.

```
Delta = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'ExpandOutput', true) % (5 x 5) matrix output
```

```
Delta = 5x5

    0.6625    0.6556    0.6515    0.6483    0.6455
```

```

0.6222    0.6232    0.6239    0.6241    0.6238
0.5805    0.5900    0.5958    0.5996    0.6019
0.5381    0.5564    0.5674    0.5748    0.5798
0.4954    0.5225    0.5389    0.5499    0.5577

```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is "true", `NStrikes` do not have to match `NMaturities`. That is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84)'; % Five strikes

Delta = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'ExpandOutput', true) % (5 x 6) matrix output

```

Delta = 5x6

```

0.6807    0.6625    0.6556    0.6515    0.6483    0.6455
0.6234    0.6222    0.6232    0.6239    0.6241    0.6238
0.5630    0.5805    0.5900    0.5958    0.5996    0.6019
0.5011    0.5381    0.5564    0.5674    0.5748    0.5798

```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is "true", the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta = optSensByBatesNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'ExpandOutput', true) % (5 x 4) matrix output

```

Delta = 5x4

```

0.4350    0.5579    0.6625    0.7457
0.3881    0.5124    0.6222    0.7120
0.3432    0.4670    0.5805    0.6763
0.3010    0.4223    0.5381    0.6390
0.2619    0.3789    0.4954    0.6002

```

### Plot Option Sensitivity Surfaces

The `Strike` and `Maturity` inputs can be vectors. Set `ExpandOutput` to "true" to output the surfaces as `NStrikes`-by-`NMaturities` matrices.

```

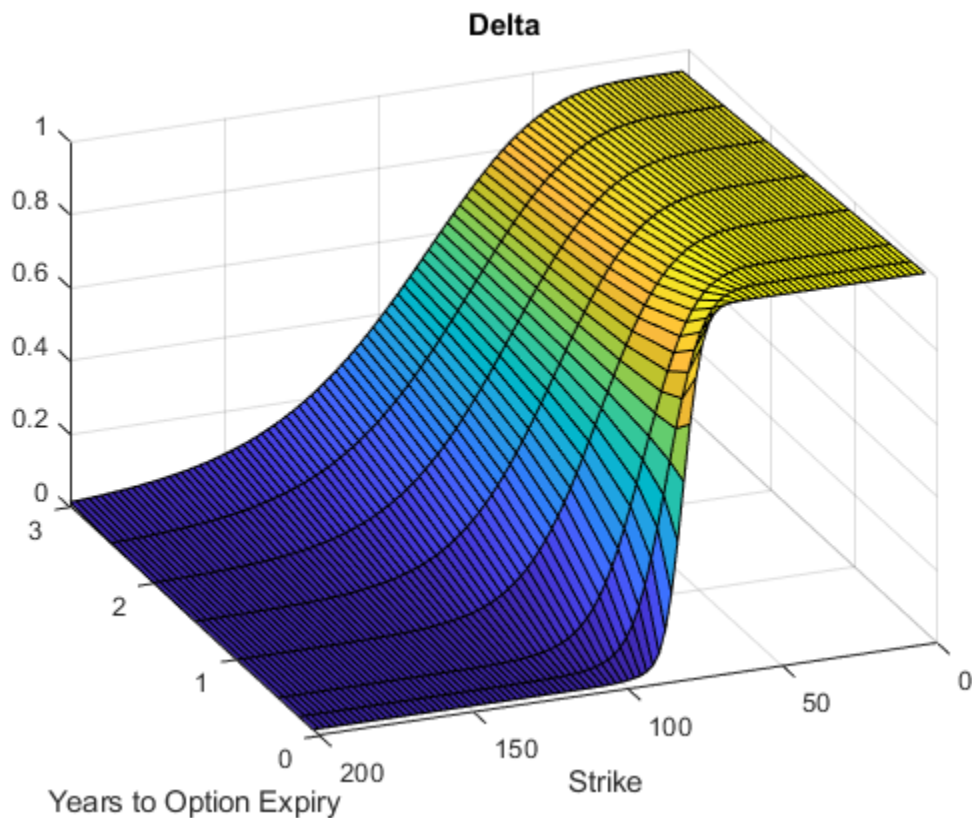

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

[Delta, Gamma, Rho, Theta, Vega, VegaLT] = optSensByBatesNI(...
    Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ThetaV, Kappa, ...
    SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', ["delta", "gamma", "rho", "theta", "vega", "vegalt"], ...
    'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Delta);
title('Delta');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);

```

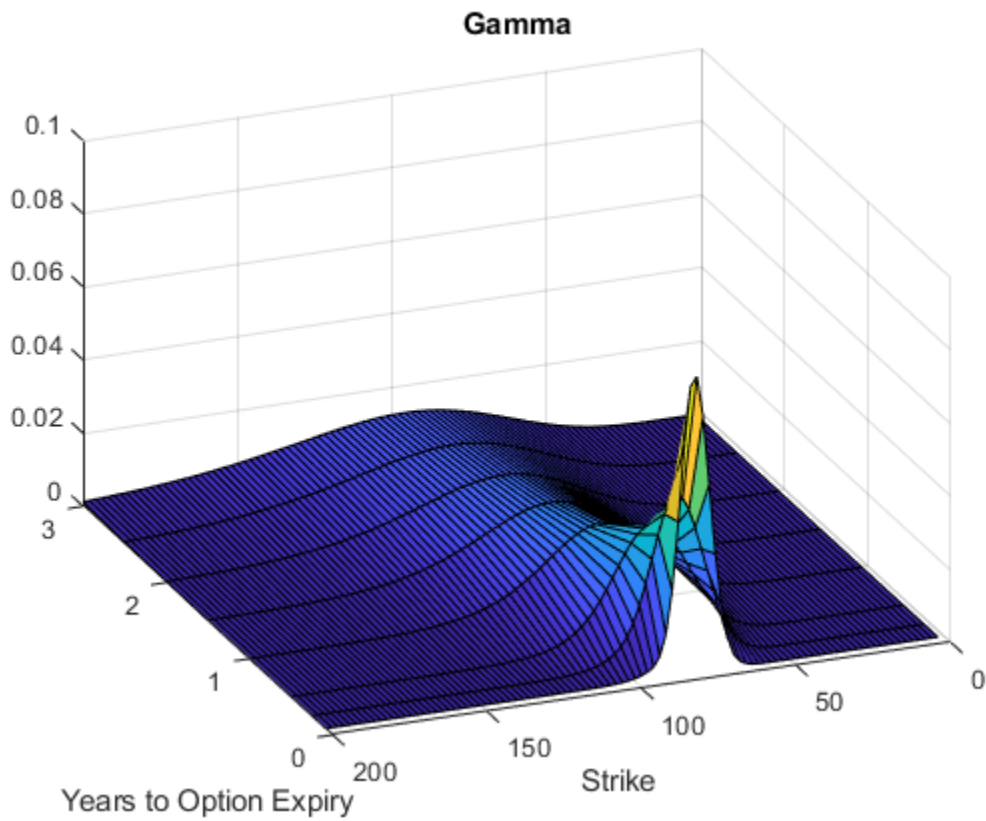

```

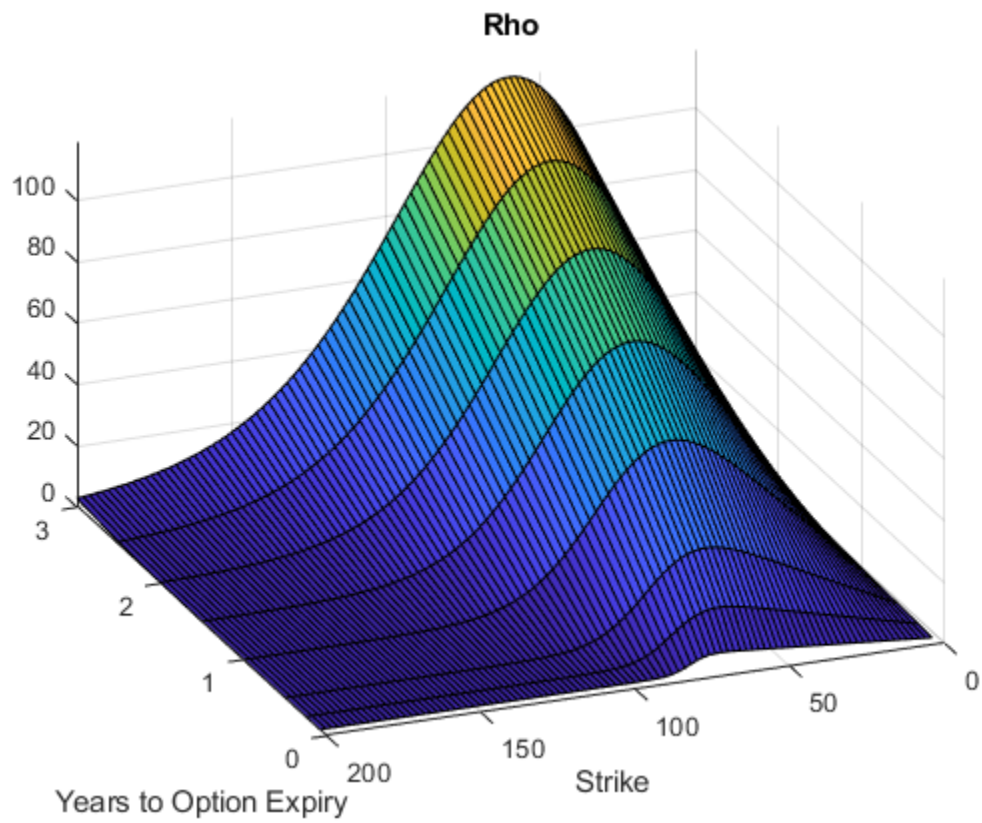

figure;
surf(X,Y,Gamma)
title('Gamma')
xlabel('Years to Option Expiry')
ylabel('Strike')

```

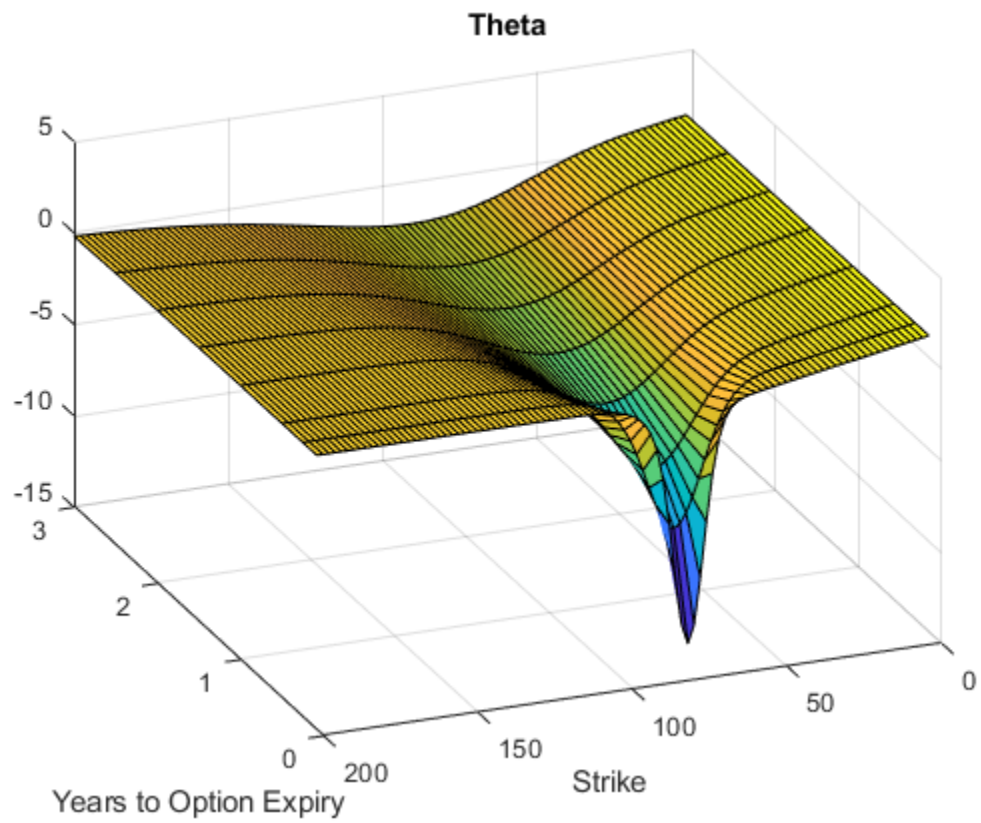

```
view(-112,34);  
xlim([0 Times(end)]);
```

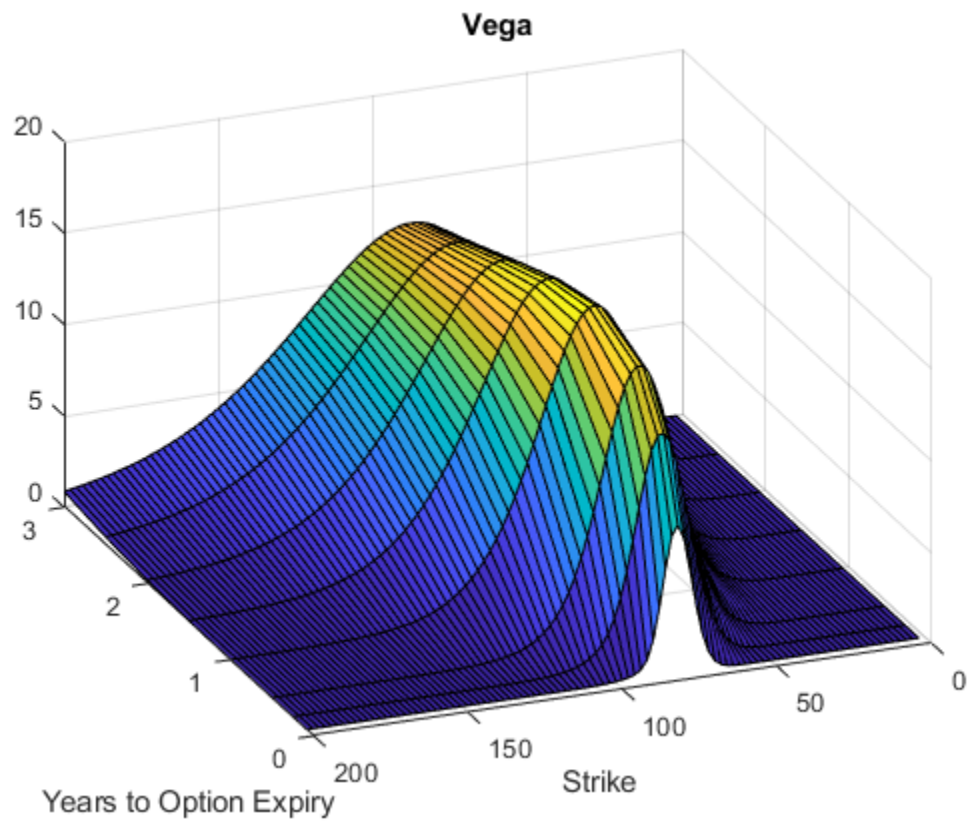

```
figure;  
surf(X,Y,Rho)  
title('Rho')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

```
figure;  
surf(X,Y,Theta)  
title('Theta')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

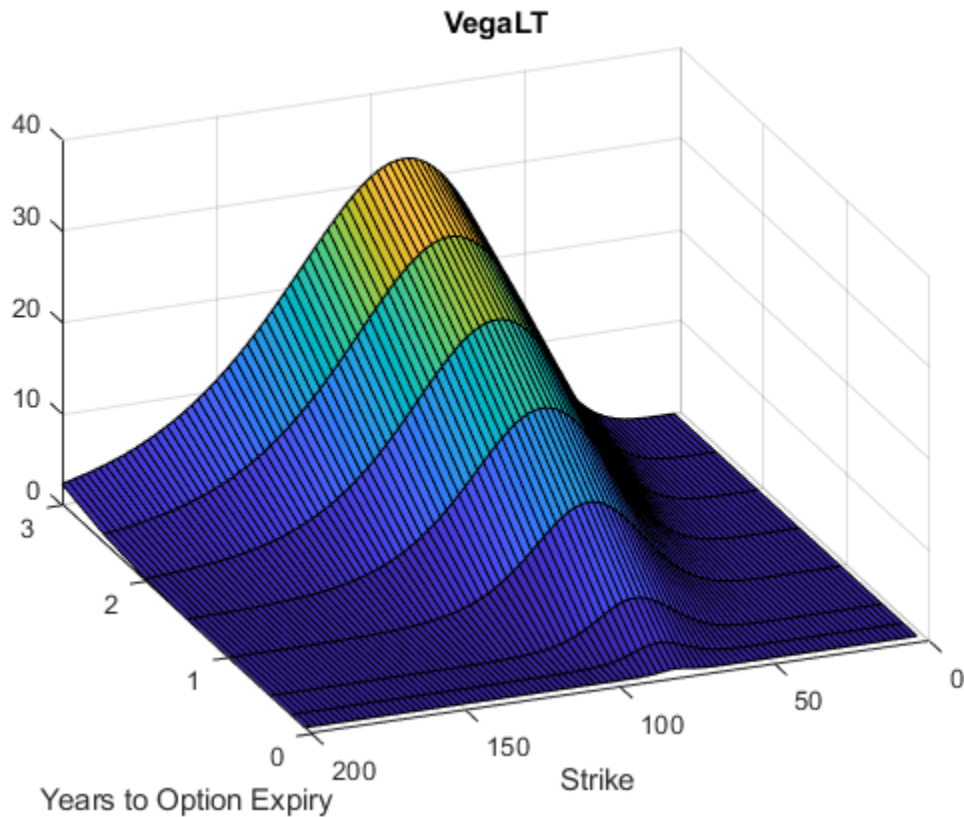

```
figure;  
surf(X,Y,Vega)  
title('Vega')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

```
figure;  
surf(X,Y,VegaLT)  
title('VegaLT')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

### AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST-by-1` or `NColumns-by-1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### Settle — Option settlement date

serial date number | date character vector | datetime | string array

Option settlement date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The `Settle` date must be before the `Maturity` date.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **Maturity — Option maturity date**

serial date number | date character vector | `datetime` | string array

Option maturity date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, `datetime` arrays, or string arrays.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **OptSpec — Definition of option**

cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a `NINST-by-1` or `NColumns-by-1` vector using a cell array of character vectors or string arrays with values 'call' or 'put'.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

### **Strike — Option strike price value**

numeric

Option strike price value, specified as a `NINST-by-1`, `NRows-by-1`, `NRows-by-NColumns` vector of strike prices.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **V0 — Initial variance of underlying asset**

numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

### **ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

### **Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underling asset, specified as a scalar numeric value.

Data Types: double

### **SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric value.

Data Types: double

### **RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: double

### **MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal value where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

### **JumpVol — Standard deviation of $\log(1+J)$**

decimal

Standard deviation of  $\log(1+J)$  where  $J$  is the random percentage jump size, specified as a scalar decimal value.

Data Types: double

### **JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `PriceSens = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'Basis', 7)`

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual

- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: `double`

### **VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: `double`

### **LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with values true or false

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- `true` — Use the Albrecher *et al* formulation.
- `false` — Use the original Heston formation.

Data Types: `logical`

### **OutSpec — Define outputs**

["price"] (default) | string array with values "price", "delta", "gamma", "vega", "rho", "theta", and "vegalt" | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', 'theta', and 'vegalt'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT string array or cell array of character vectors with supported values.

---

**Note** "vega" is the sensitivity with respect the initial volatility  $\sqrt{V_0}$ . In contrast, "vegal<sub>t</sub>" is the sensitivity with respect to the long-term volatility  $\sqrt{\text{Theta}V}$ .

---

Example: OutSpec = ["price", "delta", "gamma", "vega", "rho", "theta", "vegal<sub>t</sub>"]

Data Types: string | cell

### **AbsTol — Absolute error tolerance for numerical integration**

1e-10 (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of 'AbsTol' and a scalar numeric value.

Data Types: double

### **RelTol — Relative error tolerance for numerical integration**

1e-6 (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of 'RelTol' and a scalar numeric value.

Data Types: double

### **IntegrationRange — Numerical integration range used to approximate continuous integral over [0 Inf]**

[1e-9 Inf] (default) | vector

Numerical integration range used to approximate the continuous integral over [0 Inf], specified as the comma-separated pair consisting of 'IntegrationRange' and a 1-by-2 vector representing [LowerLimit UpperLimit].

Data Types: double

### **Framework — Framework for computing option prices and sensitivities using numerical integration of models**

"heston1993" (default) | string with values "heston1993" or "lewis2001" | character vector with values 'heston1993' or 'lewis2001'

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of 'Framework' and a scalar string or character vector with the following values:

- "heston1993" or 'heston1993' — Method used in Heston (1993)
- "lewis2001" or 'lewis2001' — Method used in Lewis (2001)

Data Types: char | string

### **ExpandOutput — Flag to expand the outputs**

false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- true — If true, the outputs are NRows-by- NColumns matrices. NRows is the number of strikes for each column and it is determined by the Strike input. For example, Strike can be a NRows-by-1 vector, or a NRows-by-NColumns matrix. NColumns is determined by the sizes of

AssetPrice, Settle, Maturity, and OptSpec, which must all be either scalar or NColumns-by-1 vectors.

- `false` — If `false`, the outputs are NINST-by-1 vectors. Also, the inputs Strike, AssetPrice, Settle, Maturity, and OptSpec must all be either scalar or NINST-by-1 vectors.

Data Types: `logical`

## Output Arguments

### PriceSens — Option prices

numeric

Option prices or sensitivities, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput. The name-value pair argument OutSpec determines the types and order of the outputs.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates (1996)) is an extension of the Heston model, where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) were also added to model sudden asset price movements.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t$$

$$dv_t = \kappa(\theta - v_t) dt + \sigma_v \sqrt{v_t} dW_t$$

$$E[dW_t dW_t^y] = \rho dt$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

$v_0$  is the initial variance of the asset price at  $t = 0$  ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

The characteristic function  $f_{Bates_j(\phi)}$  for  $j = 1$  (asset price mean measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t) \exp(\lambda_p \tau (1 + \mu_j)^{m_j + \frac{1}{2}} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 (m_j i\phi + \frac{(i\phi)^2}{2})} - 1 \right] - \lambda_p \tau \mu_j i\phi)$$

$$m_j = \begin{cases} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{cases}$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi + d_j)\tau - 2\ln \left( \frac{1 - g_j e^{d_j \tau}}{1 - g_j} \right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j \tau}}{1 - g_j e^{d_j \tau}} \right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - p\sigma_v i\phi)^2 - \sigma_v^2 (2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity for ( $\tau = T - t$ ).

$i$  is the unit imaginary number for ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  under “The Little Heston Trap” by Albrecher et al. (2007) are:

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln \left( \frac{1 - \varepsilon_j e^{-d_j \tau}}{1 - \varepsilon_j} \right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j \tau}}{1 - \varepsilon_j e^{-d_j \tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Numerical Integration method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \operatorname{Re} \left[ \frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$f_j(\phi)$  is the characteristic function for  $P_j$  ( $j = 1, 2$ ).

$P_1$  is the probability of  $S_t > K$  under the asset price measure for the model.

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

Where  $j = 1, 2$  so that  $f_1(\phi)$  and  $f_2(\phi)$  are the characteristic functions for probabilities  $P_1$  and  $P_2$ , respectively.

This framework is chosen with the default value "Heston1993" for the Framework name-value pair argument.

### Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K} e^{-r\tau}}{\pi} \int_0^{\infty} \operatorname{Re} \left[ K^{-iu} f_2 \left( \phi = \left( u - \frac{i}{2} \right) \frac{1}{u^2 + \frac{1}{4}} \right) \right] du$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$u$  is the characteristic function variable for integration, where  $\phi = \left(u - \frac{i}{2}\right)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

This framework is chosen with the value "Lewis2001" for the Framework name-value pair argument.

## Introduced in R2018a

## optByHestonFD

Option price by Heston model using finite differences

### Syntax

```
[Price,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD(Rate,
AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV)
[Price,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD( ____,Name,Value)
```

### Description

[Price,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD(Rate, AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV) computes a vanilla European or American option price by the Heston model, using the alternating direction implicit (ADI) method.

[Price,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Price an American Option Using the Heston Model

Define the option variables and Heston model parameters.

```
AssetPrice = 10;
Strike = 10;
Rate = 0.1;
Settle = '01-Jan-2017';
ExerciseDates = '02-Apr-2017';
```

```
V0 = 0.0625;
ThetaV = 0.16;
Kappa = 5.0;
SigmaV = 0.9;
RhoSV = 0.1;
```

Compute the American put option price.

```
OptSpec = 'Put';
Price = optByHestonFD(Rate, AssetPrice, Settle, ...
ExerciseDates, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, 'AmericanOpt', 1)

Price = 0.5188
```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

scalar decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal.

Data Types: double

### AssetPrice — Current underlying asset price

scalar numeric

Current underlying asset price, specified as numeric value using a scalar numeric.

Data Types: double

### Settle — Option settlement date

serial date number | date character vector | datetime array | string array

Option settlement date, specified as a scalar using serial date numbers, date character vectors, datetime arrays, or string arrays.

Data Types: double | char | datetime | string

### ExerciseDates — Option exercise dates

serial date number | date character vector | string array | datetime array

Option exercise dates, specified as a serial date number, date character vector, string array, or datetime array:

- For a European option, there is only one ExerciseDates value and this is the option expiry date.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, the option can be exercised between the Settle date and the single listed ExerciseDate.

Data Types: double | char | string | datetime

### OptSpec — Definition of option

cell array of character vectors with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a scalar using a cell array of character vectors or string arrays with values 'call' or 'put'.

Data Types: cell | string

### Strike — Option strike price value

scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: double

### V0 — Initial variance of underlying asset

scalar numeric

Initial variance of the underlying asset, specified as a scalar numeric.

Data Types: double

**ThetaV — Long-term variance of underlying asset**

scalar numeric

Long-term variance of the underlying asset, specified as a scalar numeric.

Data Types: double

**Kappa — Mean revision speed for variance of underlying asset**

scalar numeric

Mean revision speed for the variance of the underlying asset, specified as a scalar numeric.

Data Types: double

**SigmaV — Volatility of variance of underlying asset**

scalar numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

scalar numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceGrid, AssetPrices, Variances, Times] = optByHestonD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, 'Basis', 7)`

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric.

---

**Note** If you enter a value for DividendYield, then set DividendAmounts and ExDividendDates = [ ] or do not enter them. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

---

Data Types: double

### **DividendAmounts — Cash dividend amounts**

[ ] (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of 'DividendAmounts' and a NDIV-by-1 vector.

---

**Note** Each dividend amount must have a corresponding ex-dividend date. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

---

Data Types: double

### **ExDividendDates — Ex-dividend dates**

[ ] (default) | serial date number | date character vector | string array | datetime array

Ex-dividend dates, specified as the comma-separated pair consisting of 'ExDividendDates' and an NDIV-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

### **AssetPriceMax — Maximum price for price grid boundary**

if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar.

Data Types: `single` | `double`

**VarianceMax — Maximum variance to use for variance grid boundary**

1.0 (default) | scalar numeric

Maximum variance to use for the variance grid boundary, specified as the comma-separated pair consisting of 'VarianceMax' as a scalar numeric.

Data Types: `double`

**AssetGridSize — Size of asset grid for finite difference grid**

400 (default) | scalar numeric

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a scalar numeric.

Data Types: `double`

**VarianceGridSize — Number of nodes for variance grid for finite difference grid**

200 (default) | scalar numeric

Number of nodes for the variance grid for finite difference grid, specified as the comma-separated pair consisting of 'VarianceGridSize' and a scalar numeric.

Data Types: `double`

**TimeGridSize — Number of nodes of time grid for finite difference grid**

100 (default) | positive numeric scalar

Number of nodes of the time grid for finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive numeric scalar.

Data Types: `double`

**AmericanOpt — Option type**

0 (European) (default) | scalar with value of [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a scalar flag with one of these values:

- 0 — European
- 1 — American

Data Types: `double`

## Output Arguments

**Price — Option price**

numeric

Option price, returned as a scalar numeric.

**PriceGrid — Grid containing prices calculated by the finite difference method**

numeric

Grid containing prices calculated by the finite difference method, returned as a three-dimensional grid with size `AssetGridSize` × `VarianceGridSize` × `TimeGridSize`. The depth is not necessarily

equal to the `TimeGridSize`, because exercise and ex-dividend dates are added to the time grid. `PriceGrid(:, :, end)` contains the price for  $t = 0$ .

### AssetPrices – Prices of the asset

vector

Prices of the asset corresponding to the first dimension of `PriceGrid`, returned as a vector.

### Variances – Variances

vector

Variances corresponding to the second dimension of `PriceGrid`, returned as a vector.

### Times – Times

vector

Times corresponding to the third dimension of `PriceGrid`, returned as a vector.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is:

$$dS_t = (r - q)S_t dt + \sqrt{v_t}S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v\sqrt{v_t}dW_t^v$$

$$E[dW_t dW_t^v] = \rho dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$

$v_0$  is the initial variance of the asset price at  $t = 0$  for ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for the variance for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of the variance for ( $\sigma_v > 0$ ).

$p$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq p \leq 1$ ).

## Introduced in R2018b

# optSensByHestonFD

Option price and sensitivities by Heston model using finite differences

## Syntax

```
[PriceSens, PriceGrid, AssetPrices, Variances, Times] = optByHestonFD(Rate,
AssetPrice, Settle, ExerciseDates, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV)
[PriceSens, PriceGrid, AssetPrices, Variances, Times] = optByHestonFD( ____,
Name, Value)
```

## Description

[PriceSens, PriceGrid, AssetPrices, Variances, Times] = optByHestonFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV) computes a vanilla European or American option price and sensitivities by the Heston model, using the alternating direction implicit (ADI) method.

[PriceSens, PriceGrid, AssetPrices, Variances, Times] = optByHestonFD( \_\_\_\_, Name, Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute an American Option Price and Sensitivities Using the Heston Model

Define the option variables and Heston model parameters.

```
AssetPrice = 10;
Strike = 10;
Rate = 0.1;
Settle = '01-Jan-2017';
ExerciseDates = '02-Apr-2017';
```

```
V0 = 0.0625;
ThetaV = 0.16;
Kappa = 5.0;
SigmaV = 0.9;
RhoSV = 0.1;
```

Compute the American put option price and sensitivities.

```
OptSpec = 'Put';
[Price, Delta, Gamma, Rho, Theta, Vega, VegaLT] = optSensByHestonFD(Rate, AssetPrice, Settle, ExerciseDates,
OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, 'AmericanOpt', 1, ...
'OutSpec', ["Price" "Delta" "Gamma" "Rho" "Theta" "Vega" "VegaLT"])
```

```
Price = 0.5188
```

```
Delta = -0.4472
```

```
Gamma = 0.2822
```

Rho = -0.9234  
Theta = -1.1614  
Vega = 0.8998  
VegaLT = 1.0921

## Input Arguments

### **Rate — Continuously compounded risk-free interest rate**

scalar decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal.

Data Types: double

### **AssetPrice — Current underlying asset price**

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: double

### **Settle — Option settlement date**

serial date number | date character vector | datetime array | string array

Option settlement date, specified as a scalar using serial date numbers, date character vectors, datetime arrays, or string arrays.

Data Types: double | char | datetime | string

### **ExerciseDates — Option exercise dates**

serial date number | date character vector | string array | datetime array

Option exercise dates, specified as a serial date number, date character vector, string array, or datetime array:

- For a European option, there is only one ExerciseDates value and this is the option expiry date.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, the option can be exercised between the Settle date and the single listed ExerciseDate.

Data Types: double | char | string | datetime

### **OptSpec — Definition of option**

cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a scalar using a cell array of character vectors or string arrays with values 'call' or 'put'.

Data Types: cell | string

### **Strike — Option strike price value**

scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: double

### **V0 — Initial variance of underlying asset**

scalar numeric

Initial variance of the underlying asset, specified as a scalar numeric.

Data Types: double

### **ThetaV — Long-term variance of underlying asset**

scalar numeric

Long-term variance of the underlying asset, specified as a scalar numeric.

Data Types: double

### **Kappa — Mean revision speed for the variance of underlying asset**

scalar numeric

Mean revision speed for the variance of the underlying asset, specified as a scalar numeric.

Data Types: double

### **SigmaV — Volatility of the variance of underlying asset**

scalar numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric.

Data Types: double

### **RhoSV — Correlation between Weiner processes for underlying asset and its variance**

scalar numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[PriceSens, PriceGrid, AssetPrices, Variances, Times] = optSensByHestonFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, 'Basis', 7)`

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual

- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric.

---

**Note** If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates` = [ ] or do not enter them. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield` = 0.

---

Data Types: double

### **DividendAmounts — Cash dividend amounts**

[ ] (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of 'DividendAmounts' and a `NDIV-by-1` vector.

---

**Note** Each dividend amount must have a corresponding ex-dividend date. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield` = 0.

---

Data Types: double

### **ExDividendDates — Ex-dividend dates**

[ ] (default) | serial date number | date character vector | string array | datetime array

Ex-dividend dates, specified as the comma-separated pair consisting of 'ExDividendDates' and a `NDIV-by-1` vector of serial date numbers, character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

**AssetPriceMax — Maximum price for price grid boundary**

if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar

Maximum price for price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar.

Data Types: single | double

**VarianceMax — Maximum variance to use for variance grid boundary**

1.0 (default) | scalar numeric

Maximum variance to use for variance grid boundary, specified as the comma-separated pair consisting of 'VarianceMax' as a scalar numeric.

Data Types: double

**AssetGridSize — Size of asset grid for finite difference grid**

400 (default) | scalar numeric

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a scalar numeric.

Data Types: double

**VarianceGridSize — Number of nodes for variance grid for finite difference grid**

200 (default) | scalar numeric

Number of nodes for the variance grid for finite difference grid, specified as the comma-separated pair consisting of 'VarianceGridSize' and a scalar numeric.

Data Types: double

**TimeGridSize — Number of nodes of time grid for finite difference grid**

100 (default) | positive numeric scalar

Number of nodes of the time grid for finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive numeric scalar.

Data Types: double

**AmericanOpt — Option type**

0 (European) (default) | scalar with values [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a scalar flag with one of these values:

- 0 — European
- 1 — American

Data Types: double

**OutSpec — Define outputs**

["price"] (default) | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', 'theta', and 'vegalt' | string array with values "price", "delta", "gamma", "vega", "rho", "theta", and "vegalt"

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and an NOUT-by-1 or a 1-by-NOUT string array or cell array of character vectors with the supported values.

---

**Note** 'vega' is the sensitivity with respect to the initial volatility  $\sqrt{V_0}$ . In contrast, 'vegal't' is the sensitivity with respect to the long-term volatility  $\sqrt{\text{Theta}V}$ .

---

Example: OutSpec = {'price','delta','gamma','vega','rho','theta','vegal't'}

Data Types: string | cell

## Output Arguments

### PriceSens — Option price and sensitivities

scalar numeric

Option price and sensitivities, returned as a scalar numeric. OutSpec determines the types and order of the outputs.

### PriceGrid — Grid containing prices calculated by the finite difference method

numeric

Grid containing prices calculated by the finite difference method, returned as a three-dimensional grid with size AssetGridSize  $\times$  VarianceGridSize  $\times$  TimeGridSize. The depth is not necessarily equal to the TimeGridSize, because exercise and ex-dividend dates are added to the time grid. PriceGrid(:, :, end) contains the price for  $t = 0$ .

### AssetPrices — Prices of the asset

vector

Prices of the asset corresponding to the first dimension of PriceGrid, returned as a vector.

### Variances — Variances

vector

Variances corresponding to the second dimension of PriceGrid, returned as a vector.

### Times — Times

vector

Times corresponding to the third dimension of PriceGrid, returned as a vector.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is:

$$dS_t = (r - q)S_t dt + \sqrt{v_t}S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$E[dW_t dW_t^v] = \rho dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$

$v_0$  is the initial variance of the asset price at  $t = 0$  for ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for the variance for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of the variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

**Introduced in R2018b**

# optByHestonFFT

Option price by Heston model using FFT and FRFT

## Syntax

```
[Price,StrikeOut] = optByHestonFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,
Strike,V0,ThetaV,Kappa,SigmaV,RhoSV)
[Price,StrikeOut] = optByHestonFFT( ____,Name,Value)
```

## Description

[Price,StrikeOut] = optByHestonFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV) computes vanilla European option price by Heston model, using Carr-Madan FFT and Chourdakis FRFT methods.

[Price,StrikeOut] = optByHestonFFT( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Workflow for Plotting an Option Price Surface Using the Heston Model

Use optByHestonFFT to calibrate a FFT strike grid and then compute option prices and plot an option price surface.

#### Define Option Variables and Heston Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';
```

```
V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
```

#### Compute the Option Prices for the Entire FFT (or FRFT) Strike Grid, Without Specifying "Strike"

Compute option prices and also output the corresponding strikes. If the Strike input is empty ( [] ), option prices will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid is determined as  $\exp(\log\text{-strike grid})$ , where each column of the log-strike grid has NumFFT points with LogStrikeStep spacing that are roughly centered around each element of  $\log(\text{AssetPrice})$ . The default value for NumFFT is  $2^{12}$ . In addition to the prices in the first output, the optional last output contains the corresponding strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
```

```

Strike = []; % Strike is not specified (will use the entire FFT strike grid)

% Compute option prices for the entire FFT strike grid
[Call, Kout] = optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield);

% Show the lowest and highest strike values on the FFT strike grid
format
MinStrike = Kout(1) % Lowest possible strike in the current FFT strike grid

MinStrike = 2.9205e-135

MaxStrike = Kout(end) % Highest possible strike in the current FFT strike grid

MaxStrike = 1.8798e+138

% Show a subset of the strikes and corresponding option prices
Range = (2046:2052);
[Kout(Range) Call(Range)]

ans = 7×2

    50.4929    29.4843
    58.8640    21.3767
    68.6231    12.5614
    80.0000     4.7008
    93.2631     0.6496
   108.7251     0.0144
   126.7505     0.0001

```

### Change the Number of FFT (or FRFT) Points, and Compare with optByHestonNI

Try a different number of FFT (or FRFT) points, and compare the results with direct numerical integration. Unlike `optByHestonFFT`, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the `optByHestonNI` function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by `optByHestonNI` can serve as a benchmark for adjusting the settings for `optByHestonFFT`.

```

% Try a smaller number of FFT (or FRFT) points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Call, Kout] = optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
Strike = Kout(Range);
CallFFT = Call(Range);
CallNI = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield);
Error = abs(CallFFT-CallNI);
table(Strike, CallFFT, CallNI, Error)

```

```

ans=7×4 table
    Strike    CallFFT    CallNI    Error
    _____    _____    _____    _____

```

12.696	66.066	66.696	0.62964
23.449	55.766	56.103	0.33672
43.312	36.359	36.539	0.17974
80	4.7727	4.7007	0.071928
147.76	0.066156	2.3472e-08	0.066156
272.93	0.013271	-2.5036e-09	0.013271
504.11	0.0034504	-3.0876e-07	0.0034508

### Make Further Adjustments to FFT (or FRFT)

If the values in the output CallFFT are significantly different from those in CallNI, try making adjustments to optByHestonFFT settings, such as CharacteristicFcnStep, LogStrikeStep, NumFFT, DampingFactor, and so on. Note that if  $(\text{LogStrikeStep} * \text{CharacteristicFcnStep})$  is  $2 * \pi / \text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

```
Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Call, Kout] = optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001);
```

```
% Compare with numerical integration method
```

```
Strike = Kout(Range);
```

```
CallFFT = Call(Range);
```

```
CallNI = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield);
```

```
Error = abs(CallFFT-CallNI);
```

```
table(Strike, CallFFT, CallNI, Error)
```

```
ans=7x4 table
```

Strike	CallFFT	CallNI	Error
79.76	4.826	4.826	2.7708e-08
79.84	4.7841	4.7841	3.0111e-08
79.92	4.7423	4.7423	3.2376e-08
80	4.7007	4.7007	3.4496e-08
80.08	4.6593	4.6593	3.6457e-08
80.16	4.6181	4.6181	3.8253e-08
80.24	4.577	4.577	3.9872e-08

```
% Save the final FFT (or FRFT) strike grid for future reference. For
% example, it provides information about the range of Strike inputs for
% which the FFT (or FRFT) operation is valid.
```

```
FFTStrikeGrid = Kout;
```

```
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike
```

```
MinStrike = 47.9437
```

```
MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike
```

```
MaxStrike = 133.3566
```

### Compute the Option Price for a Single Strike

Once the desired FFT (or FRFT) settings are determined, use the `Strike` input to specify the strikes rather than providing an empty array. If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;

Call = optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)

Call = 4.7007
```

### Compute the Option Prices for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call = optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)

Call = 5×1

    7.0401
    5.8053
    4.7007
    3.7316
    2.8991
```

### Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Call = optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001) % Five values in vector output

Call = 5×1

    8.9560
    9.3419
    9.6240
    9.8560
```

10.0500

### Expand the Outputs for a Surface

Set the ExpandOutput name-value pair argument to "true" to expand the outputs into NStrikes-by-NMaturities matrices. In this case, they are square matrices.

```
[Call, Kout] = optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 5) matrix outputs
```

Call = 5×5

8.9560	10.4543	11.7058	12.8009	13.7728
7.7946	9.3419	10.6337	11.7644	12.7685
6.7244	8.3028	9.6240	10.7828	11.8134
5.7475	7.3379	8.6771	9.8560	10.9074
4.8645	6.4474	7.7930	8.9840	10.0500

Kout = 5×5

76	76	76	76	76
78	78	78	78	78
80	80	80	80	80
82	82	82	82	82
84	84	84	84	84

### Compute the Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When ExpandOutput is "true", NStrikes do not have to match NMaturities (that is, the output NStrikes-by-NMaturities matrix can be rectangular).

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84)'; % Five strikes
```

```
Call = optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 6) matrix output
```

Call = 5×6

7.0401	8.9560	10.4543	11.7058	12.8009	13.7728
5.8053	7.7946	9.3419	10.6337	11.7644	12.7685
4.7007	6.7244	8.3028	9.6240	10.7828	11.8134
3.7316	5.7475	7.3379	8.6771	9.8560	10.9074
2.8991	4.8645	6.4474	7.7930	8.9840	10.0500

### Compute the Option Prices for a Vector of Strikes and a Vector of Asset Prices

When ExpandOutput is "true", the output can also be a NStrikes-by-NAssetPrices rectangular matrix by accepting a vector of asset prices.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call = optByHestonFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 4) matrix output

Call = 5x4

    3.2944    5.8047    8.9560   12.6052
    2.6413    4.8810    7.7946   11.2507
    2.0864    4.0575    6.7244    9.9738
    1.6230    3.3325    5.7475    8.7783
    1.2429    2.7028    4.8645    7.6676

```

### Plot an Option Price Surface

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to "true" to output the surface as a `NStrikes-by-NMaturities` matrix.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

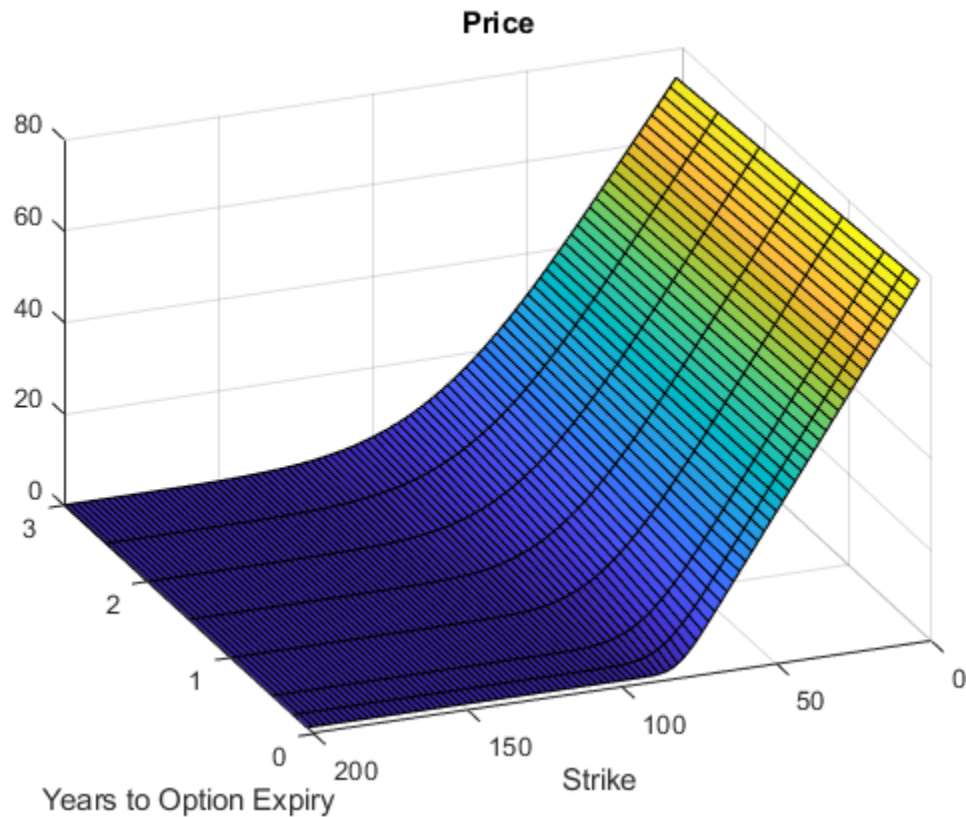

% Increase 'NumFFT' to support a wider range of strikes
NumFFT = 2^13;

Call = optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, 'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Call);
title('Price');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
zlim([0 80]);

```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

### AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST-by-1` or `NColumns-by-1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### Settle — Option settlement date

serial date number | date character vector | datetime | string array

Option settlement date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The `Settle` date must be before the `Maturity` date.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **Maturity – Option maturity date**

serial date number | date character vector | `datetime` | string array

Option maturity date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, `datetime` arrays, or string arrays.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **OptSpec – Definition of option**

cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option as 'call' or 'put', specified as a `NINST-by-1` or `NColumns-by-1` vector using a cell array of character vectors or string arrays with values "call" or "put".

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

### **Strike – Option strike price value**

numeric

Option strike price value, specified as a `NINST-by-1`, `NRows-by-1`, `NRows-by-NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has 'NumFFT' points with 'LogStrikeStep' spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **V0 – Initial variance of underlying asset**

numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

### **ThetaV – Long-term variance of underlying asset**

numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

**Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, specified as a scalar numeric value.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric value.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, StrikeOut] =`

```
optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, 'Basis', 7)
```

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

### **VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

### **LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with values true or false

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- true — Use the Albrecher *et al* formulation.
- false — Use the original Heston formation.

Data Types: logical

### **NumFFT — Number of grid points in the characteristic function variable**

4096 (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of 'NumFFT' and a scalar numeric value.

Data Types: double

### **CharacteristicFcnStep — Characteristic function variable grid spacing**

0.01 (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of 'CharacteristicFcnStep' and a scalar numeric value.

Data Types: double

### **LogStrikeStep — Log-strike grid spacing**

$2\pi/\text{NumFFT}/\text{CharacteristicFcnStep}$  (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of 'LogStrikeStep' and a scalar numeric value.

---

**Note** If  $(\text{LogStrikeStep} \times \text{CharacteristicFcnStep})$  is  $2\pi/\text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

---

Data Types: `double`

### **DampingFactor — Damping factor for Carr-Madan formulation**

1.5 (default) | `numeric`

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of 'DampingFactor' and a scalar numeric value.

Data Types: `double`

### **Quadrature — Type of quadrature**

"simpson" (default) | character vector with values: 'simpson' or 'trapezoidal' | string array with values: "simpson" or "trapezoidal"

Type of quadrature, specified as the comma-separated pair consisting of 'Quadrature' and a single character vector or string array with a value of 'simpson' or 'trapezoidal'.

Data Types: `char` | `string`

### **ExpandOutput — Flag to expand the outputs**

false (outputs are NINST-by-1 vectors) (default) | `logical` with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- `true` — If `true`, the outputs are `NRows`-by-`NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. If `Strike` is empty, `NRows` is equal to `NumFFT`. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

## **Output Arguments**

### **Price — Option prices**

`numeric`

Option prices, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

### **StrikeOut — Strikes corresponding to Price**

`numeric`

Strikes corresponding to `Price`, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

## **More About**

### **Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This process allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is:

$$\begin{aligned} dS_t &= (r - q)S_t dt + \sqrt{v_t}S_t dW_t \\ dv_t &= \kappa(\theta - v_t)dt + \sigma_v\sqrt{v_t}dW_t^\nu \\ E[dW_t dW_t^\nu] &= \rho dt \end{aligned}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$

$v_0$  is the initial variance of the asset price at  $t = 0$  for ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for the variance for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of the variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^\nu$  for ( $-1 \leq \rho \leq 1$ ).

The characteristic function  $f_{Heston_j}(\phi)$  for  $j = 1$  (asset price measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}} \right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - p\sigma_v i\phi)^2 - \sigma_v^2(2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  under “The Little Heston Trap” by Albrecher et al. (2007) are:

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities  $P_1$  and  $P_2$  as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi} \int_0^\infty \text{Re}[e^{-iuk} \psi(u)] du$$

$$\psi(u) = \frac{e^{-r\tau} f_2(\phi = (u - (\alpha + 1)i))}{\alpha^2 + \alpha - u^2 + iu(2\alpha + 1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

$\tau$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$

$i$  is a unit imaginary number ( $i^2 = -1$ )

$\phi$  is the characteristic function variable.

$\alpha$  is the damping factor.

$u$  is the characteristic function variable for integration, where  $\phi = (u - (\alpha+1)i)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration,  $u$ , is discretized into NumFFT( $N$ ) points with the step size CharacteristicFcnStep ( $\Delta u$ ), and the log-strike  $k$  is discretized into  $N$  points with the step size LogStrikeStep( $\Delta k$ ).

The discretized characteristic function variable for integration,  $u_j$  (for  $j = 1, 2, 3, \dots, N$ ), has a minimum value of 0 and a maximum value of  $(N-1) (\Delta u)$ , and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid,  $k_n$  (for  $n = 1, 2, 3, N$ ) is approximately centered around  $\ln(S_t)$ , with a minimum value of

$$\ln(S_t) - \frac{N}{2} \Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right) \Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2} \Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right) \Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^N \operatorname{Re} \left[ e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iu_j \left[ \frac{N\Delta k}{2} - \ln(S_t) \right]} \psi(u_j) \right] w_j$$

where

$\Delta u$  is the step size of discretized characteristic function variable for integration.

$\Delta k$  is the step size of discretized log-strike.

$N$  is the number of FFT or FRFT points.

$w_j$  is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if  $\Delta k$  and  $\Delta u$  are subject to the following constraint:

$$\Delta k \Delta u = \left( \frac{2\pi}{N} \right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

## optSensByHestonFFT

Option price and sensitivities by Heston model using FFT and FRFT

### Syntax

```
[PriceSens,StrikeOut] = optSensByHestonFFT(Rate,AssetPrice,Settle,Maturity,
OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV)
[PriceSens,StrikeOut] = optSensByHestonFFT( ____,Name,Value)
```

### Description

[PriceSens,StrikeOut] = optSensByHestonFFT(Rate,AssetPrice,Settle,Maturity, OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV) computes vanilla European option price and sensitivities by Heston model, using Carr-Madan FFT and Chourdakis FRFT methods.

[PriceSens,StrikeOut] = optSensByHestonFFT( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Workflow for Plotting an Option Sensitivity Surface Using the Heston Model

Use optSensByHestonFFT to calibrate the FFT strike grid for sensitivities, compute option sensitivities, and plot option sensitivity surfaces.

#### Define Option Variables and Heston Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';
```

```
V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
```

#### Compute the Option Sensitivities for the Entire FFT (or FRFT) Strike Grid, Without Specifying "Strike"

Compute option sensitivities and also output the corresponding strikes. If the `Strike` input is empty ( `[]` ), option sensitivities will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid is determined as `exp(log-strike grid)`, where each column of the log-strike grid has `NumFFT` points with `LogStrikeStep` spacing that are roughly centered around each element of `log(AssetPrice)`. The default value for `NumFFT` is  $2^{12}$ . In addition to the sensitivities in the first output, the optional last output contains the corresponding strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
```

```

Strike = []; % Strike is not specified (will use the entire FFT strike grid)

% Compute option sensitivities for the entire FFT strike grid
[Delta, Kout] = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'OutSpec', "delta");

% Show the lowest and highest strike values on the FFT strike grid
format
MinStrike = Kout(1) % Lowest possible strike in the current FFT strike grid
MinStrike = 2.9205e-135

MaxStrike = Kout(end) % Highest possible strike in the current FFT strike grid
MaxStrike = 1.8798e+138

% Show a subset of the strikes and corresponding option sensitivities
Range = (2046:2052);

### Change the Number of FFT (or FRFT) Points, and Compare With optSensByHestonNI

Try a different number of FFT (or FRFT) points, and compare the results with numerical integration. Unlike `optSensByHestonFFT`, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the `optSensByHestonNI` function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by `optSensByHestonNI` can serve as a benchmark for adjusting the settings for `optSensByHestonFFT`.

```

% Try a smaller number of FFT points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Delta, Kout] = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
Strike = Kout(Range);
DeltaFFT = Delta(Range);
DeltaNI = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)

ans=7x4 table
    Strike    DeltaFFT    DeltaNI    Error

```

12.696	0.90066	0.99002	0.08936
23.449	0.93635	0.99002	0.053677
43.312	0.94796	0.9896	0.041645
80	0.53274	0.57747	0.044733
147.76	0.0032769	2.45e-08	0.0032769
272.93	0.00098029	-1.399e-10	0.00098029
504.11	0.00028151	5.2868e-10	0.00028151

### Make Further Adjustments to FFT (or FRFT)

If the values in the output `DeltaFFT` are significantly different from those in `DeltaNI`, try making adjustments to `optSensByHestonFFT` settings, such as `CharacteristicFcnStep`, `LogStrikeStep`, `NumFFT`, `DampingFactor`, and so on. Note that if (`LogStrikeStep` \* `CharacteristicFcnStep`) is  $2\pi/\text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

```
Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Delta, Kout] = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001
```

```
% Compare with numerical integration method
```

```
Strike = Kout(Range);
DeltaFFT = Delta(Range);
DeltaNI = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)
```

```
ans=7x4 table
```

Strike	DeltaFFT	DeltaNI	Error
79.76	0.58558	0.58558	3.0538e-08
79.84	0.58289	0.58289	2.8865e-08
79.92	0.58018	0.58018	2.7053e-08
80	0.57747	0.57747	2.5111e-08
80.08	0.57476	0.57476	2.3049e-08
80.16	0.57203	0.57203	2.0875e-08
80.24	0.5693	0.5693	1.8601e-08

```
% Save the final FFT (or FRFT) strike grid for future reference. For
% example, it provides information about the range of Strike inputs for
% which the FFT (or FRFT) operation is valid.
```

```
FFTStrikeGrid = Kout;
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike
```

```
MinStrike = 47.9437
```

```
MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike
```

```
MaxStrike = 133.3566
```

### Compute the Option Sensitivity for a Single Strike

Once you determine FFT (or FRFT) settings, use the `Strike` input to specify the strikes rather than providing an empty array. If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;

Delta = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001)

Delta = 0.5775
```

### Compute the Option Sensitivities for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Delta = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001)

Delta = 5×1

    0.7043
    0.6433
    0.5775
    0.5083
    0.4377
```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Delta = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001) % Five values in vector output

Delta = 5×1

    0.6848
```

```

0.6413
0.6095
0.5841
0.5631

```

### Expand the Outputs for a Surface

Set the `ExpandOutput` name-value pair argument to "true" to expand the outputs into `NStrikes-by-NMaturities` matrices. In this case, they are square matrices.

```

[Delta, Kout] = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 5) matrix output

```

Delta = 5x5

```

    0.6848    0.6762    0.6703    0.6654    0.6609
    0.6416    0.6413    0.6404    0.6390    0.6372
    0.5960    0.6048    0.6095    0.6119    0.6129
    0.5485    0.5671    0.5776    0.5841    0.5882
    0.4997    0.5286    0.5452    0.5559    0.5631

```

Kout = 5x5

```

    76    76    76    76    76
    78    78    78    78    78
    80    80    80    80    80
    82    82    82    82    82
    84    84    84    84    84

```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is "true", `NStrikes` do not have to match `NMaturities` (that is, the output `NStrikes-by-NMaturities` matrix can be rectangular).

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84)'; % Five strikes

```

```

Delta = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 6) matrix output

```

Delta = 5x6

```

    0.7043    0.6848    0.6762    0.6703    0.6654    0.6609
    0.6433    0.6416    0.6413    0.6404    0.6390    0.6372
    0.5775    0.5960    0.6048    0.6095    0.6119    0.6129
    0.5083    0.5485    0.5671    0.5776    0.5841    0.5882
    0.4377    0.4997    0.5286    0.5452    0.5559    0.5631

```

## Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is "true", the output can also be a `NStrikes-by-NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta = optSensByHestonFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 4) matrix output

Delta = 5x4

    0.4293    0.5708    0.6848    0.7705
    0.3737    0.5193    0.6416    0.7364
    0.3200    0.4668    0.5960    0.6994
    0.2693    0.4143    0.5485    0.6597
    0.2226    0.3628    0.4997    0.6177
```

## Plot Option Sensitivity Surfaces

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to "true" to output the surfaces as `NStrikes-by-NMaturities` matrices.

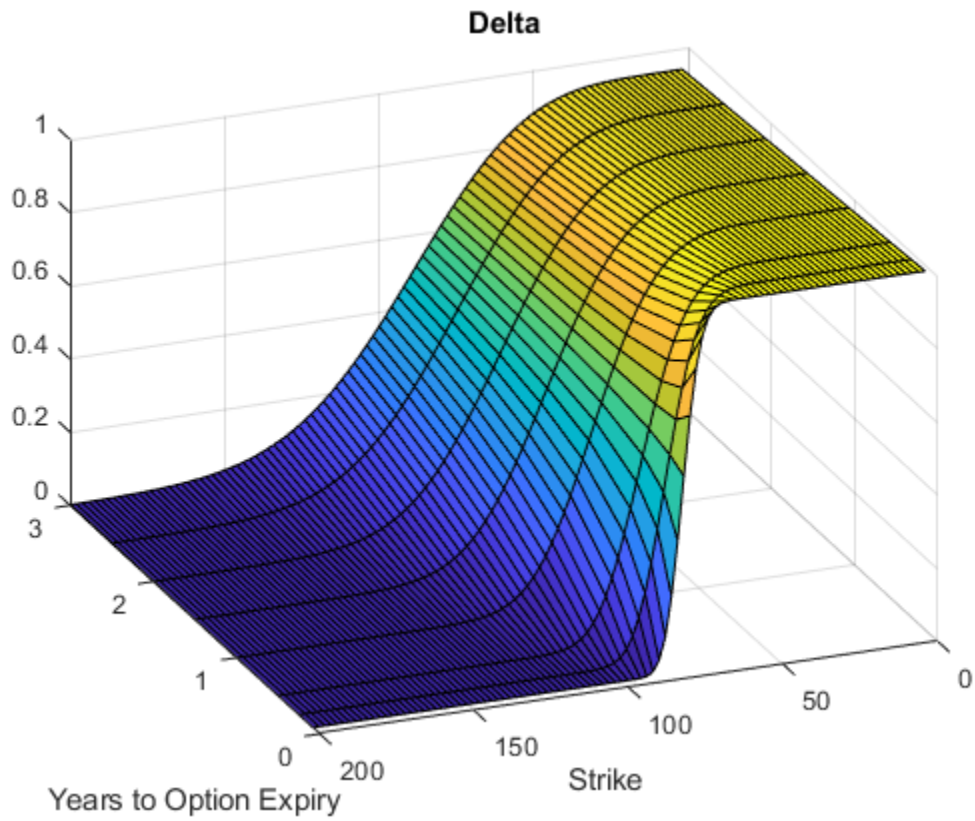

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

% Increase 'NumFFT' to support a wider range of strikes
NumFFT = 2^13;

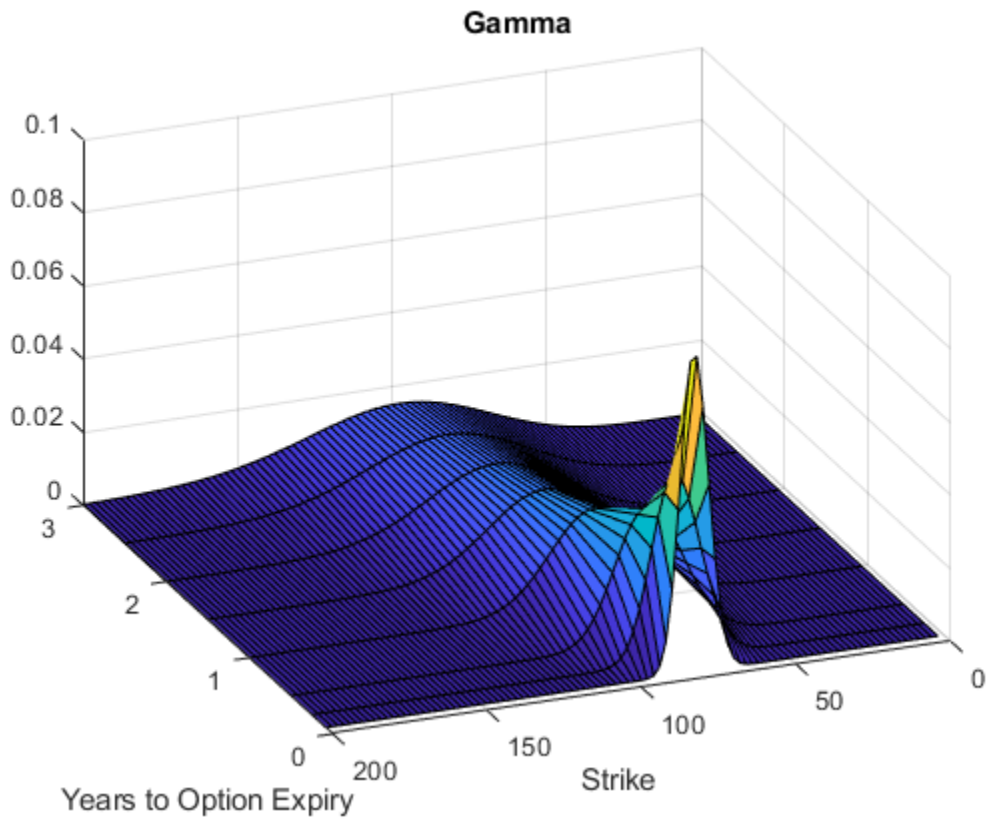

[Delta, Gamma, Rho, Theta, Vega, VegaLT] = ...
    optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, 'ExpandOutput', true, ...
    'OutSpec', ["delta", "gamma", "rho", "theta", "vega", "vegalt"]);

[X,Y] = meshgrid(Times,Strike);

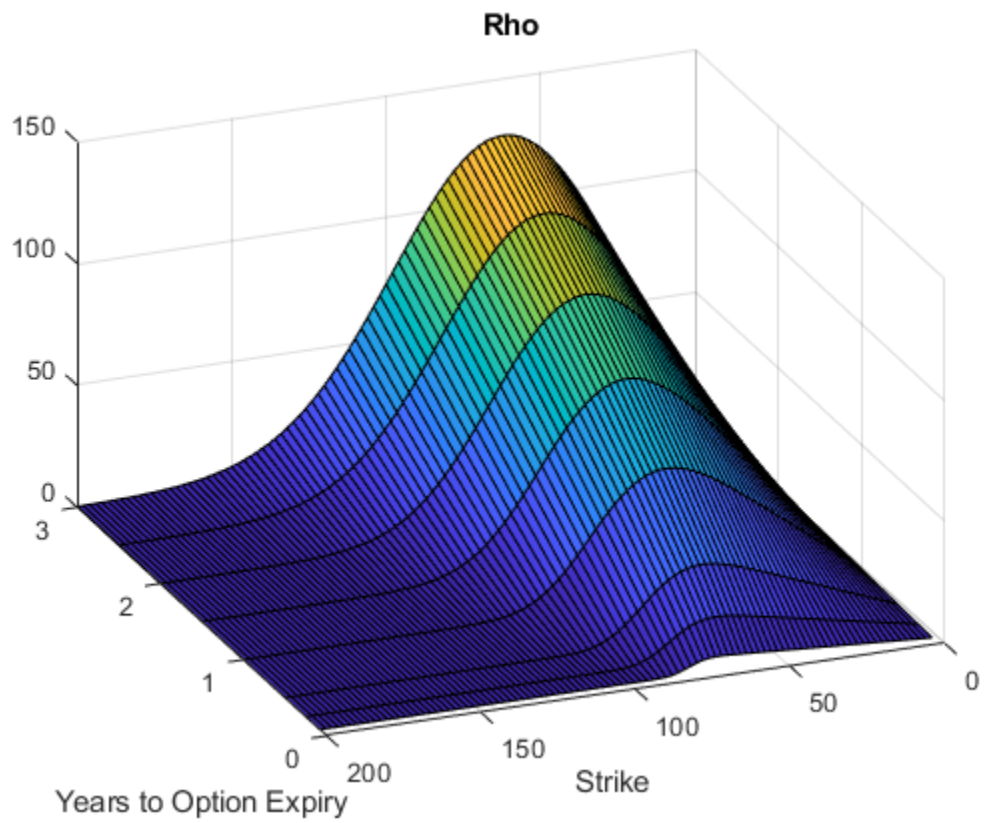

figure;
surf(X,Y,Delta);
title('Delta');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
```

```
figure;  
surf(X,Y,Gamma)  
title('Gamma')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

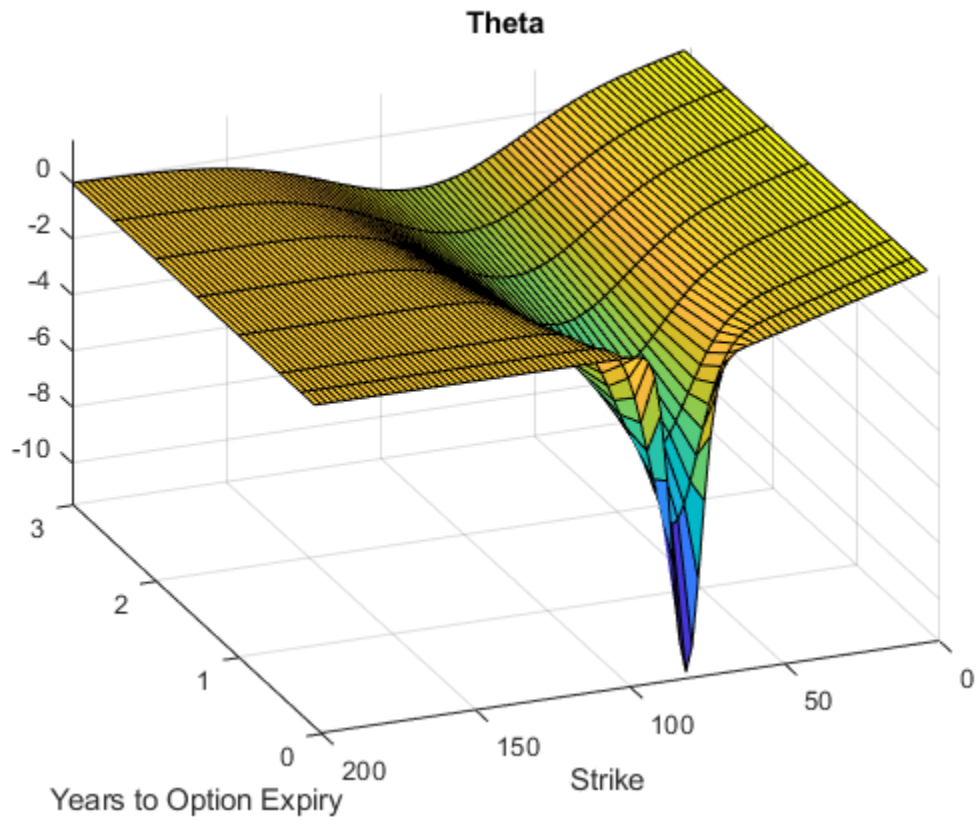

```

xlim([0 Times(end)]);
```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

### AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST-by-1` or `NColumns-by-1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### Settle — Option settlement date

serial date number | date character vector | datetime | string array

Option settlement date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The `Settle` date must be before the `Maturity` date.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **Maturity – Option maturity date**

serial date number | date character vector | `datetime` | string array

Option maturity date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, `datetime` arrays, or string arrays.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **OptSpec – Definition of option**

cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a `NINST-by-1` or `NColumns-by-1` vector using a cell array of character vectors or string arrays with values 'call' or 'put'.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

### **Strike – Option strike price value**

numeric

Option strike price value, specified as a `NINST-by-1`, `NRows-by-1`, `NRows-by-NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has 'NumFFT' points with 'LogStrikeStep' spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **V0 – Initial variance of underlying asset**

numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

### **ThetaV – Long-term variance of underlying asset**

numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

**Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, specified as a scalar numeric value.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric value.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[PriceSens, StrikeOut] = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, 'Basis', 7, 'OptSpec', "vega")`

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

### **VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

### **LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with values true or false

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- true — Use the Albrecher *et al* formulation.
- false — Use the original Heston formation.

Data Types: logical

### **OutSpec — Define outputs**

["price"] (default) | string array with values "price", "delta", "gamma", "vega", "rho", "theta", and "vegalt" | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', 'theta', and 'vegalt'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT string array or cell array of character vectors with supported values.

---

**Note** "vega" is the sensitivity with respect the initial volatility  $\sqrt{V_0}$ . In contrast, "vegalt" is the sensitivity with respect to the long-term volatility  $\sqrt{\Theta V}$ .

---

Example: OutSpec = ["price","delta","gamma","vega","rho","theta","vegalt"]

Data Types: string | cell

### **NumFFT — Number of grid points in the characteristic function variable**

4096 (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of 'NumFFT' and a scalar numeric value.

Data Types: double

**CharacteristicFcnStep — Characteristic function variable grid spacing**

0.01 (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of 'CharacteristicFcnStep' and a scalar numeric value.

Data Types: double

**LogStrikeStep — Log-strike grid spacing** $2\pi/\text{NumFFT}/\text{CharacteristicFcnStep}$  (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of 'LogStrikeStep' and a scalar numeric value.

---

**Note** If  $(\text{LogStrikeStep} \times \text{CharacteristicFcnStep})$  is  $2\pi/\text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

---

Data Types: double

**DampingFactor — Damping factor for Carr-Madan formulation**

1.5 (default) | numeric

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of 'DampingFactor' and a scalar numeric value.

Data Types: double

**Quadrature — Type of quadrature**

simpson (default) | character vector with values: simpson or trapezoidal | string array with values: simpson or trapezoidal

Type of quadrature, specified as the comma-separated pair consisting of 'Quadrature' and a single character vector or string array with a value of simpson or trapezoidal.

Data Types: char | string

**ExpandOutput — Flag to expand the outputs**

false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- **true** — If true, the outputs are NRows-by- NColumns matrices. NRows is the number of strikes for each column and it is determined by the Strike input. For example, Strike can be a NRows-by-1 vector, or a NRows-by-NColumns matrix. If Strike is empty, NRows is equal to NumFFT. NColumns is determined by the sizes of AssetPrice, Settle, Maturity, and OptSpec, which must all be either scalar or NColumns-by-1 vectors.
- **false** — If false, the outputs are NINST-by-1 vectors. Also, the inputs Strike, AssetPrice, Settle, Maturity, and OptSpec must all be either scalar or NINST-by-1 vectors.

Data Types: logical

## Output Arguments

### PriceSens — Option prices or sensitivities

numeric

Option prices or sensitivities, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput. The name-value pair argument OutSpec determines the types and order of the outputs.

### StrikeOut — Strikes corresponding to Price

numeric

Strikes corresponding to Price, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This process allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is:

$$dS_t = (r - q)S_t dt + \sqrt{v_t}S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$E[dW_t dW_t^v] = \rho dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$

$v_0$  is the initial variance of the asset price at  $t = 0$  for ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for the variance for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of the variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

The characteristic function  $f_{Heston_j}(\phi)$  for  $j = 1$  (asset price measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - \rho\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - \rho\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}} \right)$$

$$g_j = \frac{b_j - \rho\sigma_v i\phi + d_j}{b_j - \rho\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - \rho\sigma_v i\phi)^2 - \sigma_v^2(2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - \rho\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  under ‘‘The Little Heston Trap’’ by Albrecher et al. (2007) are:

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - \rho\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - \rho\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}} \right)$$

$$\varepsilon_j = \frac{b_j - \rho\sigma_v i\phi - d_j}{b_j - \rho\sigma_v i\phi + d_j}$$

### Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities  $P_1$  and  $P_2$  as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi} \int_0^{\infty} \text{Re}[e^{-iuk} \psi(u)] du$$

$$\psi(u) = \frac{e^{-r\tau} f_2(\phi = (u - (\alpha + 1)i))}{\alpha^2 + \alpha - u^2 + iu(2\alpha + 1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$\alpha$  is the damping factor.

$u$  is the characteristic function variable for integration, where  $\phi = (u - (\alpha + 1)i)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration,  $u$ , is discretized into NumFFT( $N$ ) points with the step size CharacteristicFcnStep ( $\Delta u$ ), and the log-strike  $k$  is discretized into  $N$  points with the step size LogStrikeStep( $\Delta k$ ).

The discretized characteristic function variable for integration,  $u_j$  (for  $j = 1, 2, 3, \dots, N$ ), has a minimum value of 0 and a maximum value of  $(N-1) (\Delta u)$ , and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid,  $k_n$  (for  $n = 1, 2, 3, N$ ) is approximately centered around  $\ln(S_t)$ , with a minimum value of

$$\ln(S_t) - \frac{N}{2} \Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^N \operatorname{Re} \left[ e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iu_j \left[ \frac{N\Delta k}{2} - \ln(S_t) \right]} \psi(u_j) \right] w_j$$

where

$\Delta u$  is the step size of discretized characteristic function variable for integration.

$\Delta k$  is the step size of discretized log-strike.

$N$  is the number of FFT or FRFT points.

$w_j$  is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if  $\Delta k$  and  $\Delta u$  are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

# optByHestonNI

Option price by Heston model using numerical integration

## Syntax

```
Price = optByHestonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,
ThetaV,Kappa,SigmaV,RhoSV)
Price = optByHestonNI( ____,Name,Value)
```

## Description

Price = optByHestonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV) computes vanilla European option price by Heston model, using numerical integration methods.

Price = optByHestonNI( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Workflow for Plotting an Option Price Surface Using the Heston Model

optByHestonNI uses numerical integration to compute option prices and then to plot an option price surface.

#### Define Option Variables and Heston Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';
```

```
V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
```

#### Compute the Option Price for a Single Strike

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;
```

```
Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield)
```

```
Call = 4.7007
```

#### Compute the Option Prices for a Vector of Strikes

The Strike input can be a vector.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield)

Call = 5×1

    7.0401
    5.8053
    4.7007
    3.7316
    2.8991

```

### Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield)

Call = 5×1

    8.9560
    9.3419
    9.6240
    9.8560
   10.0500

% Five values in vector output

```

### Expand the Output for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the output into a `NStrikes-by-NMaturities` matrix. In this case, it is a square matrix.

```

Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 5) matrix output

Call = 5×5

    8.9560    10.4543    11.7058    12.8009    13.7728
    7.7946     9.3419    10.6337    11.7644    12.7685
    6.7244     8.3028     9.6240    10.7828    11.8134
    5.7474     7.3378     8.6771     9.8560    10.9074
    4.8645     6.4474     7.7930     8.9840    10.0500

```

### Compute the Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When ExpandOutput is "true", NStrikes do not have to match NMaturities (that is, the output NStrikes-by-NMaturities matrix can be rectangular).

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84)'; % Five strikes

Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 6) matrix output

Call = 5x6

    7.0401    8.9560    10.4543    11.7058    12.8009    13.7728
    5.8053    7.7946    9.3419    10.6337    11.7644    12.7685
    4.7007    6.7244    8.3028    9.6240    10.7828    11.8134
    3.7316    5.7474    7.3378    8.6771    9.8560    10.9074
    2.8991    4.8645    6.4474    7.7930    8.9840    10.0500
```

### Compute the Option Prices for a Vector of Strikes and a Vector of Asset Prices

When ExpandOutput is "true", the output can also be a NStrikes-by-NAssetPrices rectangular matrix by accepting a vector of asset prices.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call = optByHestonNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 4) matrix output

Call = 5x4

    3.2944    5.8047    8.9560    12.6052
    2.6413    4.8810    7.7946    11.2507
    2.0864    4.0575    6.7244    9.9738
    1.6230    3.3325    5.7474    8.7783
    1.2429    2.7028    4.8645    7.6676
```

### Plot an Option Price Surface

The Strike and Maturity inputs can be vectors. Set ExpandOutput to "true" to output the surface as a NStrikes-by-NMaturities matrix.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
```

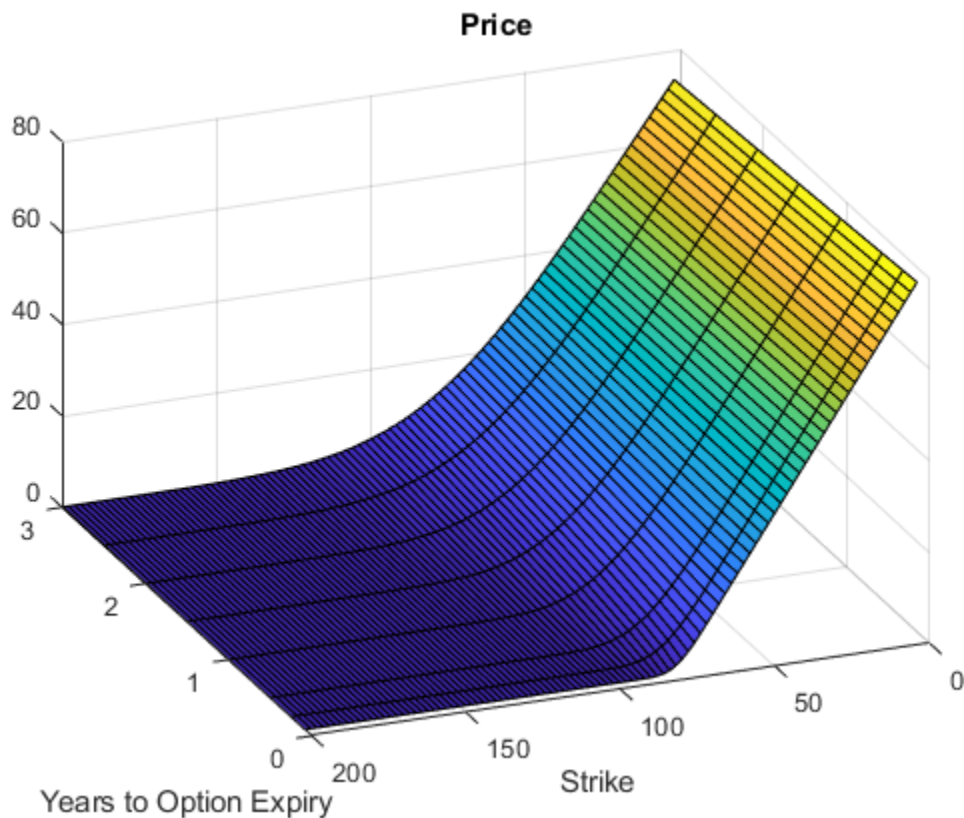

```

    'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Call);
title('Price');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
zlim([0 80]);

```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: double

### AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a NINST-by-1 or NColumns-by-1 vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **Settle — Option settlement date**

serial date number | date character vector | datetime | string array

Option settlement date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The `Settle` date must be before the `Maturity` date.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **Maturity — Option maturity date**

serial date number | date character vector | datetime | string array

Option maturity date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **OptSpec — Definition of option**

cell array of character vector with values `'call'` or `'put'` | string array with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST-by-1` or `NColumns-by-1` vector using a cell array of character vectors or string arrays with values `"call"` or `"put"`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

### **Strike — Option strike price value**

numeric

Option strike price value, specified as a `NINST-by-1`, `NRows-by-1`, `NRows-by-NColumns` vector of strike prices.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **V0 — Initial variance of underlying asset**

numeric

Initial variance of the underlying asset, specified as a scalar numeric value.

Data Types: `double`

**ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underlying asset, specified as a scalar numeric value.

Data Types: double

**Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, specified as a scalar numeric value.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric value.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Price =`

```
optByHestonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,  
SigmaV,RhoSV,'Basis',7,'Framework',"lewis2001")
```

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

### **VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

### **LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with values true or false

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- true — Use the Albrecher *et al* formulation.
- false — Use the original Heston formation.

Data Types: logical

### **AbsTol — Absolute error tolerance for numerical integration**

1e-10 (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of 'AbsTol' and a scalar numeric value.

Data Types: double

### **RelTol — Relative error tolerance for numerical integration**

1e-6 (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of 'RelTol' and a scalar numeric value.

Data Types: double

### **IntegrationRange — Numerical integration range used to approximate continuous integral over [0 Inf]**

[1e-9 Inf] (default) | vector

Numerical integration range used to approximate the continuous integral over  $[0 \text{ } \text{Inf}]$ , specified as the comma-separated pair consisting of 'IntegrationRange' and a 1-by-2 vector representing [LowerLimit UpperLimit].

Data Types: double

### Framework — Framework for computing option prices and sensitivities using numerical integration of models

"heston1993" (default) | string with values "heston1993" or "lewis2001" | character vector with values 'heston1993' or 'lewis2001'

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of 'Framework' and a scalar string or character vector with the following values:

- "heston1993" or 'heston1993' — Method used in Heston (1993)
- "lewis2001" or 'lewis2001' — Method used in Lewis (2001)

Data Types: char | string

### ExpandOutput — Flag to expand the outputs

false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- true — If true, the outputs are NRows-by-NColumns matrices. NRows is the number of strikes for each column and it is determined by the Strike input. For example, Strike can be a NRows-by-1 vector, or a NRows-by-NColumns matrix. NColumns is determined by the sizes of AssetPrice, Settle, Maturity, and OptSpec, which must all be either scalar or NColumns-by-1 vectors.
- false — If false, the outputs are NINST-by-1 vectors. Also, the inputs Strike, AssetPrice, Settle, Maturity, and OptSpec must all be either scalar or NINST-by-1 vectors.

Data Types: logical

## Output Arguments

### Price — Option prices

numeric

Option prices, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is:

$$dS_t = (r - q)S_t dt + \sqrt{v_t} S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$E[dW_t dW_t^v] = \rho dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$

$v_0$  is the initial variance of the asset price at  $t = 0$  for ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for the variance for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of the variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

The characteristic function  $f_{Heston_j}(\phi)$  for  $j = 1$  (asset price measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi + d_j)\tau - 2\ln \left( \frac{1 - g_j e^{d_j\tau}}{1 - g_j} \right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}} \right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - p\sigma_v i\phi)^2 - \sigma_v^2 (2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  under “The Little Heston Trap” by Albrecher et al. (2007) are:

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln \left( \frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j} \right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \operatorname{Re} \left[ \frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$f_j(\phi)$  is the characteristic function for  $P_j$  ( $j = 1, 2$ ).

$P_1$  is the probability of  $S_t > K$  under the asset price measure for the model.

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

Where  $j = 1, 2$  so that  $f_1(\phi)$  and  $f_2(\phi)$  are the characteristic functions for probabilities  $P_1$  and  $P_2$ , respectively.

This framework is chosen with the default value "Heston1993" for the Framework name-value pair argument.

### Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K} e^{-\tau t}}{\pi} \int_0^{\infty} \operatorname{Re} \left[ K^{-iu} f_2 \left( \phi = \left( u - \frac{i}{2} \right) \right) \frac{1}{u^2 + \frac{1}{4}} \right] du$$

$$Put(K) = Call(K) = Ke^{-\tau t} - S_t e^{-q\tau}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$u$  is the characteristic function variable for integration, where  $\phi = \left(u - \frac{i}{2}\right)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

This framework is chosen with the value "Lewis2001" for the Framework name-value pair argument.

# optSensByHestonNI

Option price and sensitivities by Heston model using numerical integration

## Syntax

```
PriceSens = optSensByHestonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,
V0,ThetaV,Kappa,SigmaV,RhoSV)
PriceSens = optSensByHestonNI( ____,Name,Value)
```

## Description

`PriceSens = optSensByHestonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike, V0,ThetaV,Kappa,SigmaV,RhoSV)` computes vanilla European option price and sensitivities by Heston model, using numerical integration methods.

`PriceSens = optSensByHestonNI( ____,Name,Value)` adds optional name-value pair arguments.

## Examples

### Workflow for Plotting an Option Sensitivity Surface Using the Heston Model

`optSensByHestonNI` uses numerical integration to compute option sensitivities and then to plot option sensitivity surfaces.

#### Define Option Variables and Heston Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';
```

```
V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
```

#### Compute the Option Sensitivity for a Single Strike

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;
```

```
Delta = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'OutSpec', "delta")
```

```
Delta = 0.5775
```

### Compute the Option Sensitivities for a Vector of Strikes

The Strike input can be a vector.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';
```

```
Delta = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'OutSpec', "delta")
```

```
Delta = 5×1
```

```
0.7043
0.6433
0.5775
0.5083
0.4377
```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the Strike input to specify the strikes. Also, the Maturity input can be a vector, but it must match the length of the Strike vector if the ExpandOutput name-value pair argument is not set to "true".

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes
```

```
Delta = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta") % Five values in vector output
```

```
Delta = 5×1
```

```
0.6848
0.6413
0.6095
0.5841
0.5631
```

### Expand the Output for a Surface

Set the ExpandOutput name-value pair argument to "true" to expand the output into a NStrikes-by-NMaturities matrix. In this case, it is a square matrix.

```
Delta = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true) % (5 x 5) matrix output
```

```
Delta = 5×5
```

```
0.6848    0.6762    0.6703    0.6654    0.6609
0.6416    0.6413    0.6404    0.6390    0.6372
0.5960    0.6048    0.6095    0.6119    0.6129
```

```

0.5485    0.5671    0.5776    0.5841    0.5882
0.4997    0.5286    0.5452    0.5559    0.5631

```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When ExpandOutput is "true", NStrikes do not have to match NMaturities (that is, the output NStrikes-by-NMaturities matrix can be rectangular).

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84)'; % Five strikes

Delta = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true) % (5 x 6) matrix output

```

Delta = 5x6

```

0.7043    0.6848    0.6762    0.6703    0.6654    0.6609
0.6433    0.6416    0.6413    0.6404    0.6390    0.6372
0.5775    0.5960    0.6048    0.6095    0.6119    0.6129
0.5083    0.5485    0.5671    0.5776    0.5841    0.5882
0.4377    0.4997    0.5286    0.5452    0.5559    0.5631

```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When ExpandOutput is "true", the output can also be a NStrikes-by-NAssetPrices rectangular matrix by accepting a vector of asset prices.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta = optSensByHestonNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true) % (5 x 4) matrix output

```

Delta = 5x4

```

0.4293    0.5708    0.6848    0.7705
0.3737    0.5193    0.6416    0.7364
0.3200    0.4668    0.5960    0.6994
0.2693    0.4143    0.5485    0.6597
0.2226    0.3628    0.4997    0.6177

```

### Plot Option Sensitivity Surfaces

The Strike and Maturity inputs can be vectors. Set ExpandOutput to "true" to output the surfaces as NStrikes-by-NMaturities matrices.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]);
Times = yearfrac(Settle, Maturity);

```

```

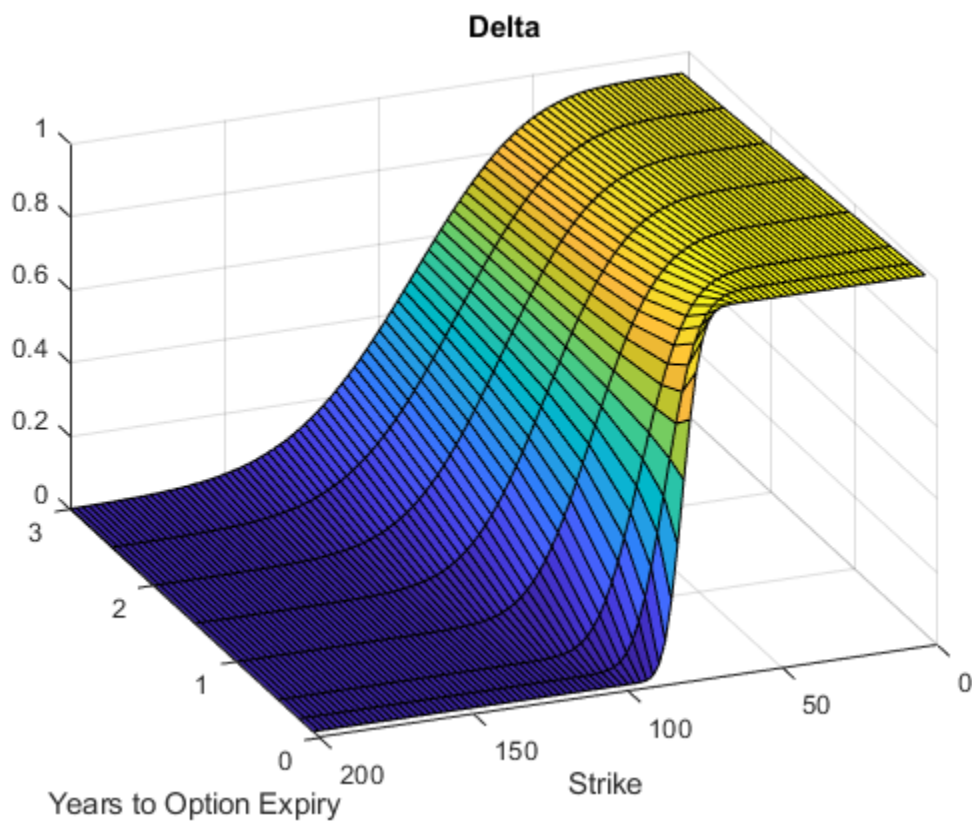

Strike = (2:2:200)';

[Delta, Gamma, Rho, Theta, Vega, VegaLT] = ...
    optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', ["delta", "gamma", "rho", "theta", "vega", "vegalt"], ...
    'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Delta);
title('Delta');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);

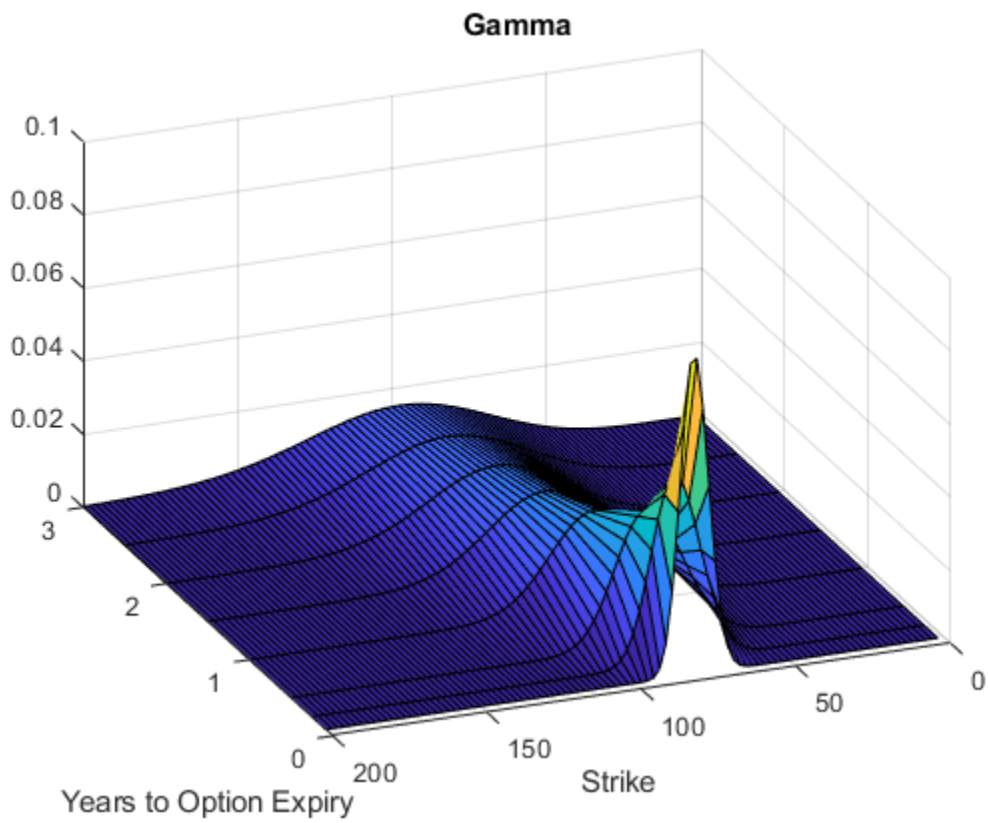

```

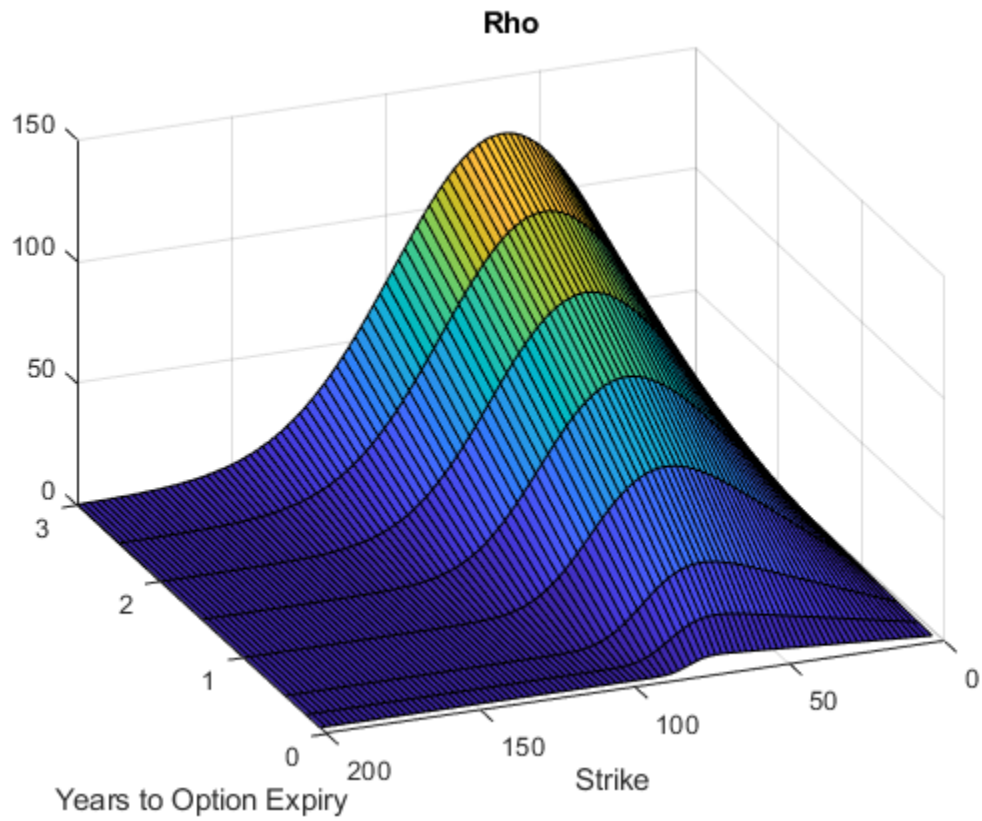

```

figure;
surf(X,Y,Gamma)
title('Gamma')
xlabel('Years to Option Expiry')
ylabel('Strike')
view(-112,34);
xlim([0 Times(end)]);

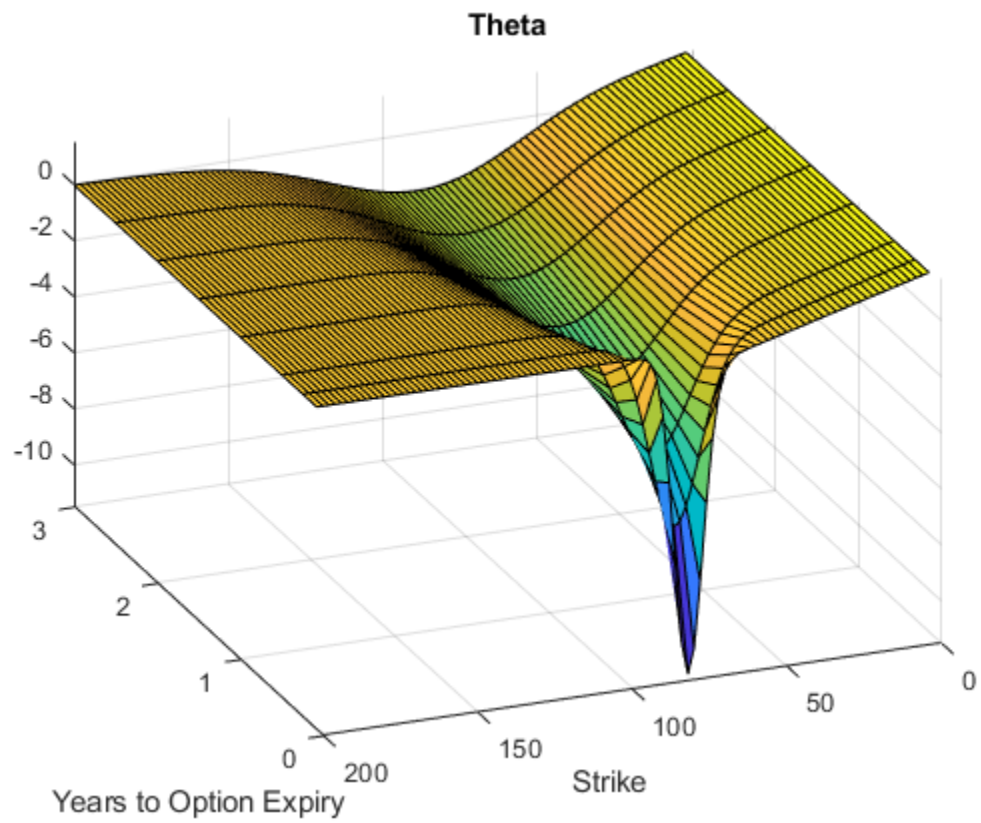

```

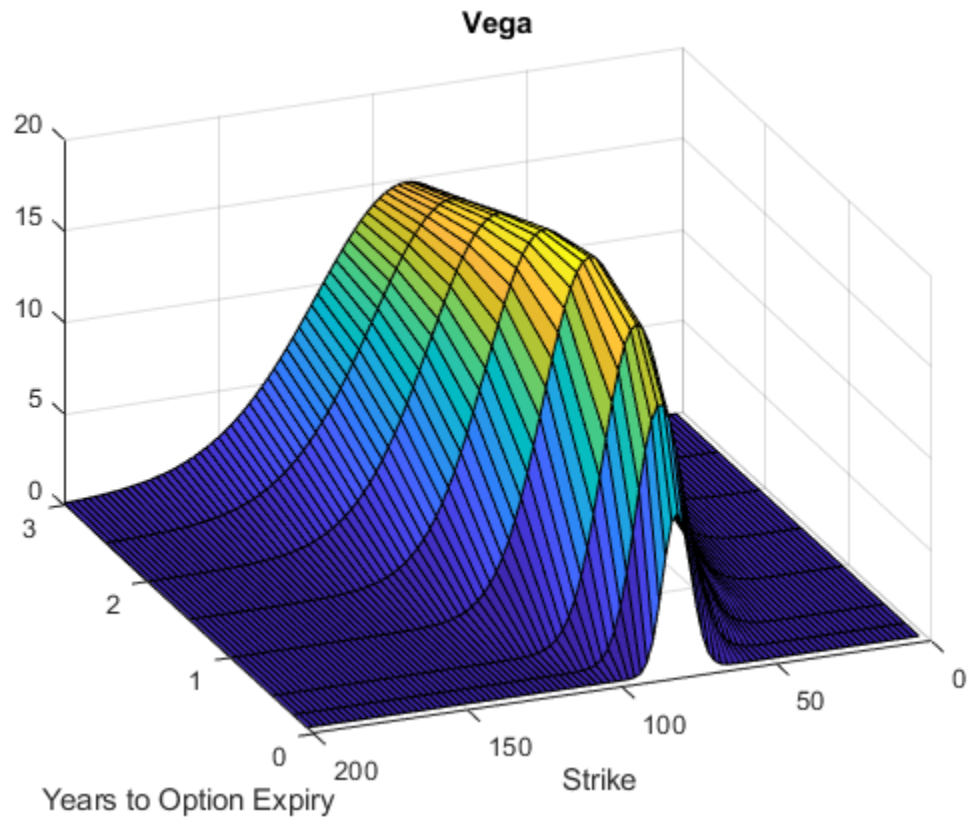

```
figure;  
surf(X,Y,Rho)  
title('Rho')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

```
figure;  
surf(X,Y,Theta)  
title('Theta')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

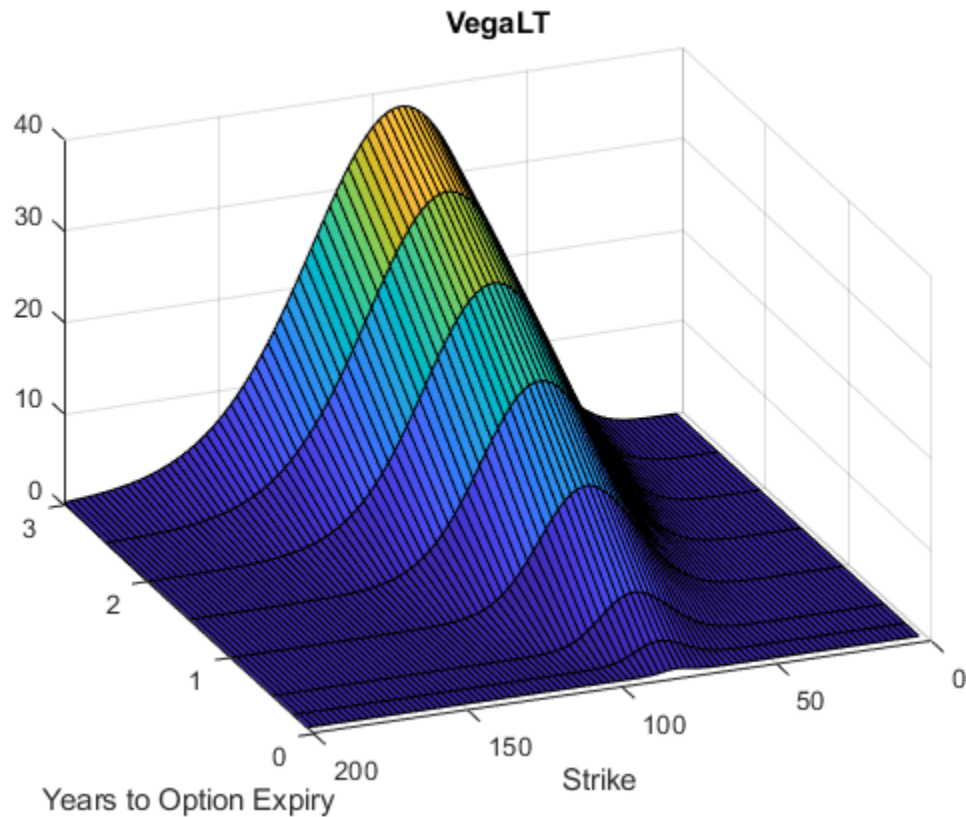

```
figure;  
surf(X,Y,Vega)  
title('Vega')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

```
figure;  
surf(X,Y,VegaLT)  
title('VegaLT')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

### AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST-by-1` or `NColumns-by-1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### Settle — Option settlement date

serial date number | date character vector | datetime | string array

Option settlement date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The `Settle` date must be before the `Maturity` date.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **Maturity — Option maturity date**

serial date number | date character vector | `datetime` | string array

Option maturity date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, `datetime` arrays, or string arrays.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **OptSpec — Definition of option**

cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a `NINST-by-1` or `NColumns-by-1` vector using a cell array of character vectors or string arrays with values 'call' or 'put'.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

### **Strike — Option strike price value**

numeric

Option strike price value, specified as a `NINST-by-1`, `NRows-by-1`, `NRows-by-NColumns` vector of strike prices.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **V0 — Initial variance of underlying asset**

numeric

Initial variance of the underlying asset, specified as a scalar numeric value.

Data Types: `double`

### **ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underlying asset, specified as a scalar numeric value.

Data Types: `double`

### **Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, specified as a scalar numeric value.

Data Types: double

### **SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric value.

Data Types: double

### **RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `PriceSens = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, 'Basis', 7)`

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

**VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

**LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with values true or false

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- `true` — Use the Albrecher *et al* formulation.
- `false` — Use the original Heston formation.

Data Types: logical

**OutSpec — Define outputs**

["price"] (default) | string array with values "price", "delta", "gamma", "vega", "rho", "theta", and "vegalt" | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', 'theta', and 'vegalt'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT string array or cell array of character vectors with supported values.

---

**Note** "vega" is the sensitivity with respect the initial volatility  $\sqrt{V_0}$ . In contrast, "vegalt" is the sensitivity with respect to the long-term volatility  $\sqrt{\text{Theta}V}$ .

---

Example: OutSpec = ["price","delta","gamma","vega","rho","theta","vegalt"]

Data Types: string | cell

**AbsTol — Absolute error tolerance for numerical integration**

1e-10 (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of 'AbsTol' and a scalar numeric value.

Data Types: double

**RelTol — Relative error tolerance for numerical integration**

1e-6 (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of 'RelTol' and a scalar numeric value.

Data Types: double

**IntegrationRange — Numerical integration range used to approximate continuous integral over [0 Inf]**

[1e-9 Inf] (default) | vector

Numerical integration range used to approximate the continuous integral over [0 Inf], specified as the comma-separated pair consisting of 'IntegrationRange' and a 1-by-2 vector representing [LowerLimit UpperLimit].

Data Types: double

**Framework — Framework for computing option prices and sensitivities using numerical integration of models**

"heston1993" (default) | string with values "heston1993" or "lewis2001" | character vector with values 'heston1993' or 'lewis2001'

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of 'Framework' and a scalar string or character vector with the following values:

- "heston1993" or 'heston1993' — Method used in Heston (1993)
- "lewis2001" or 'lewis2001' — Method used in Lewis (2001)

Data Types: char | string

**ExpandOutput — Flag to expand the outputs**

false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- true — If true, the outputs are NRows-by- NColumns matrices. NRows is the number of strikes for each column and it is determined by the Strike input. For example, Strike can be a NRows-by-1 vector, or a NRows-by-NColumns matrix. NColumns is determined by the sizes of AssetPrice, Settle, Maturity, and OptSpec, which must all be either scalar or NColumns-by-1 vectors.
- false — If false, the outputs are NINST-by-1 vectors. Also, the inputs Strike, AssetPrice, Settle, Maturity, and OptSpec must all be either scalar or NINST-by-1 vectors.

Data Types: logical

## Output Arguments

**PriceSens — Option prices or sensitivities**

numeric

Option prices or sensitivities, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput. The name-value pair argument OutSpec determines the types and order of the outputs.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is:

$$dS_t = (r - q)S_t dt + \sqrt{v_t}S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$E[dW_t dW_t^v] = \rho dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$v_0$  is the initial variance of the asset price at  $t = 0$  for ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for the variance for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of the variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

The characteristic function  $f_{Heston_j}(\phi)$  for  $j = 1$  (asset price measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}} \right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - p\sigma_v i\phi)^2 - \sigma_v^2(2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  under “The Little Heston Trap” by Albrecher et al. (2007) are:

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \text{Re} \left[ \frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$f_j(\phi)$  is the characteristic function for  $P_j$  ( $j = 1, 2$ ).

$P_1$  is the probability of  $S_t > K$  under the asset price measure for the model.

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

Where  $j = 1, 2$  so that  $f_1(\phi)$  and  $f_2(\phi)$  are the characteristic functions for probabilities  $P_1$  and  $P_2$ , respectively.

This framework is chosen with the default value "Heston1993" for the Framework name-value pair argument.

### Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K} e^{-\tau t}}{\pi} \int_0^{\infty} \text{Re} \left[ K^{-iu} f_2 \left( \phi = \left( u - \frac{i}{2} \right) \frac{1}{u^2 + \frac{1}{4}} \right) \right] du$$

$$Put(K) = Call(K) = K e^{-\tau t} - S_t e^{-q\tau}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$u$  is the characteristic function variable for integration, where  $\phi = \left(u - \frac{i}{2}\right)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

This framework is chosen with the value "Lewis2001" for the Framework name-value pair argument.

## Introduced in R2018a

## optByLocalVolFD

Option price by local volatility model, using finite differences

### Syntax

```
[Price,PriceGrid,AssetPrices,Times] = optByLocalVolFD(Rate,AssetPrice,Settle,
ExerciseDates,OptSpec,Strike,ImpliedVolData)
[Price,PriceGrid,AssetPrices,Times] = optByLocalVolFD( ____,Name,Value)
```

### Description

[Price,PriceGrid,AssetPrices,Times] = optByLocalVolFD(Rate,AssetPrice,Settle,ExerciseDates,OptSpec,Strike,ImpliedVolData) compute a Vanilla European or American option price by the local volatility model, using the Crank-Nicolson method.

[Price,PriceGrid,AssetPrices,Times] = optByLocalVolFD( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Price a European Option Using the Local Volatility Model

Define the option variables.

```
AssetPrice = 590;
Strike = 590;
Rate = 0.06;
DividendYield = 0.0262;
Settle = '01-Jan-2018';
ExerciseDates = '01-Jan-2020';
```

Define the implied volatility surface data.

```
Maturity = ["06-Mar-2018" "05-Jun-2018" "12-Sep-2018" "10-Dec-2018" "01-Jan-2019" ...
"02-Jul-2019" "01-Jan-2020" "01-Jan-2021" "01-Jan-2022" "01-Jan-2023"];
Maturity = repmat(Maturity,10,1);
Maturity = Maturity(:);
```

```
ExercisePrice = AssetPrice.*[0.85 0.90 0.95 1.00 1.05 1.10 1.15 1.20 1.30 1.40];
ExercisePrice = repmat(ExercisePrice,1,10)';
```

```
ImpliedVol = [...
0.190; 0.168; 0.133; 0.113; 0.102; 0.097; 0.120; 0.142; 0.169; 0.200; ...
0.177; 0.155; 0.138; 0.125; 0.109; 0.103; 0.100; 0.114; 0.130; 0.150; ...
0.172; 0.157; 0.144; 0.133; 0.118; 0.104; 0.100; 0.101; 0.108; 0.124; ...
0.171; 0.159; 0.149; 0.137; 0.127; 0.113; 0.106; 0.103; 0.100; 0.110; ...
0.171; 0.159; 0.150; 0.138; 0.128; 0.115; 0.107; 0.103; 0.099; 0.108; ...
0.169; 0.160; 0.151; 0.142; 0.133; 0.124; 0.119; 0.113; 0.107; 0.102; ...
0.169; 0.161; 0.153; 0.145; 0.137; 0.130; 0.126; 0.119; 0.115; 0.111; ...
0.168; 0.161; 0.155; 0.149; 0.143; 0.137; 0.133; 0.128; 0.124; 0.123; ...
```

```
0.168; 0.162; 0.157; 0.152; 0.148; 0.143; 0.139; 0.135; 0.130; 0.128; ...
0.168; 0.164; 0.159; 0.154; 0.151; 0.147; 0.144; 0.140; 0.136; 0.132];
```

```
ImpliedVolData = table(Maturity, ExercisePrice, ImpliedVol);
```

Compute the European call option price.

```
OptSpec = 'Call';
Price = optByLocalVolFD(Rate, AssetPrice, ...
Settle, ExerciseDates, OptSpec, Strike, ImpliedVolData, 'DividendYield',DividendYield)

Price = 65.1319
```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

scalar numeric

Continuously compounded risk-free interest rate, specified by a scalar numeric.

Data Types: double

### AssetPrice — Current underlying asset price

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: double

### Settle — Settlement date

serial date number | date character vector | datetime array | string array

Settlement date, specified as a scalar serial date number, date character vector, datetime array, or string array.

Data Types: double | char | datetime | string

### ExerciseDates — Option exercise dates

serial date number | date character vector | datetime array | string array

Option exercise dates, specified as a serial date number, a date character vector, a datetime array, or a string array:

- For a European option, there is only one ExerciseDates value and this is the option expiry date.
- For an American option, use a 1-by-2 vector of serial date numbers, date character vectors, datetime arrays, or string arrays. The American option can be exercised on any date between or including the pair of dates. If only one non-NaN date is listed, the option can be exercised between Settle and the single listed date in ExerciseDates.

Data Types: double | char | cell | datetime | string

### OptSpec — Definition of option

character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a character vector or string array with values 'call' or 'put'.

Data Types: char | string

**Strike — Option strike price value**

nonnegative scalar

Option strike price value, specified as a nonnegative scalar.

Data Types: double

**ImpliedVolData — Table of maturity dates, strike or exercise prices, and corresponding implied volatilities**

table

Table of maturity dates, strike or exercise prices, and their corresponding implied volatilities, specified as a NVOL-by-3 table.

Data Types: table

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside quotes. You can specify several name and value pair arguments in any order as *Name*<sub>1</sub>, *Value*<sub>1</sub>, . . . , *Name*<sub>N</sub>, *Value*<sub>N</sub>.

Example: `Price = optByLocalVolFD(Rate,AssetPrice,Settle,ExerciseDates,OptSpec,Strike,ImpliedVolData,'AssetGridSize',1000)`

**Basis — Day-count basis**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar using one of the supported values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric.

---

**Note** If you enter a value for DividendYield, then set DividendAmounts and ExDividendDates = [ ] or do not enter them. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

---

Data Types: double

**DividendAmounts — Cash dividend amounts**

[ ] (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of 'DividendAmounts' and a NDIV-by-1 vector.

For each dividend amount, there must be a corresponding ExDividendDates date. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

---

**Note** If you enter a value for DividendYield, then set DividendAmounts and ExDividendDates = [ ] or do not enter them.

---

Data Types: double

**ExDividendDates — Ex-dividend dates**

[ ] (default) | serial date number | date character vector | datetime array | string array

Ex-dividend dates, specified as the comma-separated pair consisting of 'ExDividendDates' and a NDIV-by-1 vector.

Data Types: double | char | string | datetime

**AssetPriceMax — Maximum price for price grid boundary**

if unspecified, AssetPriceMax values are calculated using asset distributions at maturity (default) | positive scalar

Maximum price for price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar.

Data Types: double

**AssetGridSize — Size of asset grid for finite difference grid**

400 (default) | positive scalar

Size of the asset grid for a finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a positive scalar.

Data Types: double

**TimeGridSize — Size of time grid for finite difference grid**

100 (default) | positive scalar

Size of the time grid for a finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive scalar.

Data Types: double

### **AmericanOpt — Option type**

0 (European) (default) | scalar with values [0,1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a positive integer scalar flag with one of these values:

- 0 — European
- 1 — American

Data Types: double

### **InterpMethod — Method of interpolation for estimating the implied volatility surface from ImpliedVolData**

'linear' (default) | character vector with values 'linear', 'makima', 'spline', or 'tpaps' | string with values "linear", "makima", "spline", or "tpaps"

Method of interpolation for estimating the implied volatility surface from ImpliedVolData, specified as the comma-separated pair consisting of 'InterpMethod' and a character vector or string array with one of the following values:

- 'linear' — Linear interpolation
- 'makima' — Modified Akima cubic Hermite interpolation
- 'spline' — Cubic spline interpolation
- 'tpaps' — Thin-plate smoothing spline interpolation

---

**Note** The 'tpaps' method uses the thin-plate smoothing spline functionality from Curve Fitting Toolbox.

The 'makima' and 'spline' methods work only for gridded data. For scattered data, use the 'linear' or 'tpaps' methods.

---

For more information on gridded or scattered data and details on interpolation methods, see “Gridded and Scattered Sample Data” (MATLAB) and “Interpolating Gridded Data” (MATLAB).

Data Types: char | string

## **Output Arguments**

### **Price — Option price**

scalar numeric

Option price, returned as a scalar numeric.

### **PriceGrid — Grid containing prices calculated by finite difference method**

grid

Grid containing prices calculated by the finite difference method, returned as a grid that is two-dimensional with size AssetGridSize × TimeGridSize. The number of columns does not have to

be equal to the TimeGridSize, because ExerciseDates and ExDividendDates are added to the time grid. PriceGrid(:, :, end) contains the price for  $t = 0$ .

### AssetPrices – Prices of asset

vector

Prices of the asset corresponding to the first dimension of PriceGrid, returned as a vector.

### Times – Times

vector

Times corresponding to second dimension of the PriceGrid, returned as a vector.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Local Volatility Model

A local volatility model treats volatility as a function both of the current asset level and of time.

The local volatility can be estimated by using the Dupire formula [2]:

$$\sigma_{loc}^2(K, \tau) = \frac{\sigma_{imp}^2 + 2\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial\tau} + 2(\tau - d)K\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial K}}{\left(1 + Kd_1\sqrt{\tau}\frac{\partial\sigma_{imp}}{\partial K}\right)^2 + K^2\tau\sigma_{imp}\left(\frac{\partial^2\sigma_{imp}}{\partial K^2} - d_1\sqrt{\tau}\left(\frac{\partial\sigma_{imp}}{\partial K}\right)^2\right)}$$

$$d_1 = \frac{\ln(S_0/K) + ((\tau - d) + \sigma_{imp}^2/2)\tau}{\sigma_{imp}\sqrt{\tau}}$$

# optSensByLocalVolFD

Option price and sensitivities by local volatility model, using finite differences

## Syntax

```
[PriceSens,PriceGrid,AssetPrices,Times] = optSensByLocalVolFD(Rate,
AssetPrice,Settle,ExerciseDates,OptSpec,Strike,ImpliedVolData)
[PriceSens,PriceGrid,AssetPrices,Times] = optSensByLocalVolFD( ____,Name,Value)
```

## Description

[PriceSens,PriceGrid,AssetPrices,Times] = optSensByLocalVolFD(Rate,AssetPrice,Settle,ExerciseDates,OptSpec,Strike,ImpliedVolData) compute option price and sensitivities by the local volatility model, using the Crank-Nicolson method.

[PriceSens,PriceGrid,AssetPrices,Times] = optSensByLocalVolFD( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute European Option Price and Sensitivities Using the Local Volatility Model

Define the option variables.

```
AssetPrice = 590;
Strike = 590;
Rate = 0.06;
DividendYield = 0.0262;
Settle = '01-Jan-2018';
ExerciseDates = '01-Jan-2020';
```

Define the implied volatility surface data.

```
Maturity = ["06-Mar-2018" "05-Jun-2018" "12-Sep-2018" "10-Dec-2018" "01-Jan-2019" ...
"02-Jul-2019" "01-Jan-2020" "01-Jan-2021" "01-Jan-2022" "01-Jan-2023"];
```

```
Maturity = repmat(Maturity,10,1);
```

```
Maturity = Maturity(:);
```

```
ExercisePrice = AssetPrice.*[0.85 0.90 0.95 1.00 1.05 1.10 1.15 1.20 1.30 1.40];
```

```
ExercisePrice = repmat(ExercisePrice,1,10)';
```

```
ImpliedVol = [...

```

```
0.168; 0.162; 0.157; 0.152; 0.148; 0.143; 0.139; 0.135; 0.130; 0.128; ...
0.168; 0.164; 0.159; 0.154; 0.151; 0.147; 0.144; 0.140; 0.136; 0.132];
```

```
ImpliedVolData = table(Maturity, ExercisePrice, ImpliedVol);
```

Compute the European call option price and sensitivities.

```
OptSpec = 'Call';
[Delta,Gamma,Lambda,Theta,Price] = optSensByLocalVolFD(Rate, AssetPrice, ...
Settle, ExerciseDates, OptSpec, Strike, ImpliedVolData, 'DividendYield',DividendYield, ...
'OutSpec',["Delta" "Gamma" "Lambda" "Theta" "Price"])
```

```
Delta = 0.5519
```

```
Gamma = 0.0091
```

```
Lambda = 4.9994
```

```
Theta = -20.9529
```

```
Price = 65.1319
```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

scalar numeric

Continuously compounded risk-free interest rate, specified by a scalar numeric.

Data Types: double

### AssetPrice — Current underlying asset price

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: double

### Settle — Settlement date

serial date number | date character vector | datetime array | string

Settlement date, specified as a scalar serial date number, date character vector, datetime object, or string array

Data Types: double | char | datetime | string

### ExerciseDates — Option exercise dates

serial date number | date character vector | datetime array | string array

Option exercise dates, specified as a serial date number, a date character vector, a datetime array, or a string array:

- For a European option, there is only one ExerciseDates value and this is the option expiry date.
- For an American option, use a 1-by-2 vector of serial date numbers, date character vectors, datetimes, or strings. The American option can be exercised on any date between or including the pair of dates. If only one non-NaN date is listed, the option can be exercised between Settle and the single listed date in ExerciseDates.

Data Types: double | char | cell | datetime | string

### **OptSpec — Definition of option**

character vector with value of 'call' or 'put' | string array with value of "call" or "put"

Definition of the option, specified as a character vector or string array with a value of 'call' or 'put'.

Data Types: char | string

### **Strike — Option strike price value**

nonnegative scalar

Option strike price value, specified as a nonnegative scalar.

Data Types: double

### **ImpliedVolData — Table of maturity dates, strike or exercise prices, and corresponding implied volatilities**

table

A table of maturity dates, strike or exercise prices, and their corresponding implied volatilities, specified as a NVOL-by-3 table.

Data Types: table

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: PriceSens = Price = optByLocalVolFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike, ImpliedVolData, 'AssetGridSize', 1000, 'OutSpec', {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'})

### **Basis — Day-count basis**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar using one of these supported values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric.

---

**Note** If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates` = [ ] or do not enter them. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield` = 0.

---

Data Types: double

### **DividendAmounts — Cash dividend amounts**

[ ] (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of 'DividendAmounts' and a `NDIV-by-1` vector.

For each dividend amount, there must be a corresponding `ExDividendDates` date. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield` = 0.

---

**Note** If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates` = [ ] or do not enter them.

---

Data Types: double

### **ExDividendDates — Ex-dividend dates**

[ ] (default) | serial date number | date character vector | datetime array | string array

Ex-dividend dates, specified as the comma-separated pair consisting of 'ExDividendDates' and a `NDIV-by-1` vector.

Data Types: double | char | string | datetime

### **AssetPriceMax — Maximum price for price grid boundary**

if unspecified, `AssetPriceMax` values are calculated using asset distributions at maturity (default) | positive scalar

Maximum price for price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar.

Data Types: double

**AssetGridSize — Size of asset grid for finite difference grid**

400 (default) | positive scalar

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a positive scalar.

Data Types: double

**TimeGridSize — Size of time grid for finite difference grid**

100 (default) | positive scalar

Size of the time grid for finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive scalar.

Data Types: double

**AmericanOpt — Option type**

0 (European) (default) | scalar with values [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a positive integer scalar flag with one of these values:

- 0 — European
- 1 — American

Data Types: double

**InterpMethod — Method of interpolation for estimating the implied volatility surface from ImpliedVolData**

'linear' (default) | character vector with values 'linear', 'makima', 'spline', or 'tpaps' | string with values "linear", "makima", "spline", or "tpaps"

Method of interpolation for estimating the implied volatility surface from ImpliedVolData, specified as the comma-separated pair consisting of 'InterpMethod' and a character vector or string with one of the following values:

- 'linear' — Linear interpolation
- 'makima' — Modified Akima cubic Hermite interpolation
- 'spline' — Cubic spline interpolation
- 'tpaps' — Thin-plate smoothing spline interpolation

---

**Note** The 'tpaps' method uses the thin-plate smoothing spline functionality from Curve Fitting Toolbox.

The 'makima' and 'spline' methods work only for gridded data. For scattered data, use the 'linear' or 'tpaps' methods.

---

For more information on gridded or scattered data and details on interpolation methods, see “Gridded and Scattered Sample Data” (MATLAB) and “Interpolating Gridded Data” (MATLAB).

Data Types: char | string

**OutSpec — Define outputs**

{'price'} (default) | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta' | string array with values "price", "delta", "gamma", "vega", "rho", "theta"

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and an NOUT-by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'price', 'delta', 'gamma', 'vega', 'lambda', 'rho', and 'theta'.

Example: OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}

Data Types: cell | string

**Output Arguments****PriceSens — Option price and sensitivities**

scalar numeric

Option price and sensitivities, returned as a scalar numeric. OutSpec determines the types and order of the output.

**PriceGrid — Grid containing prices calculated by finite difference method**

grid

Grid containing prices calculated by the finite difference method, returned as a grid that is two-dimensional with size AssetGridSize × TimeGridSize. The number of columns does not have to be equal to the TimeGridSize, because ExerciseDates and ExDividendDates are added to the time grid. PriceGrid(:, :, end) contains the price for  $t = 0$ .

**AssetPrices — Prices of asset**

vector

Prices of the asset corresponding to the first dimension of PriceGrid, returned as a vector.

**Times — Times**

vector

Times corresponding to second dimension of the PriceGrid, returned as a vector.

**More About****Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Local Volatility Model

A local volatility model treats volatility as a function both of the current asset level and of time.

The local volatility can be estimated by using the Dupire formula [2]:

$$\sigma_{loc}^2(K, \tau) = \frac{\sigma_{imp}^2 + 2\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial\tau} + 2(\tau - d)K\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial K}}{\left(1 + Kd_1\sqrt{\tau}\frac{\partial\sigma_{imp}}{\partial K}\right)^2 + K^2\tau\sigma_{imp}\left(\frac{\partial^2\sigma_{imp}}{\partial K^2} - d_1\sqrt{\tau}\left(\frac{\partial\sigma_{imp}}{\partial K}\right)^2\right)}$$

$$d_1 = \frac{\ln(S_0/K) + ((\tau - d) + \sigma_{imp}^2/2)\tau}{\sigma_{imp}\sqrt{\tau}}$$

## optByMertonFD

Option price by Merton76 model using finite differences

### Syntax

```
[Price,PriceGrid,AssetPrices,Times] = optByMertonFD(Rate,AssetPrice,Settle,
ExerciseDates,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq)
[Price,PriceGrid,AssetPrices,Times] = optByMertonFD( ____,Name,Value)
```

### Description

[Price,PriceGrid,AssetPrices,Times] = optByMertonFD(Rate,AssetPrice,Settle, ExerciseDates,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq) computes a vanilla European or American option price by the Merton76 model, using the Crank-Nicolson Adams-Bashforth (CNAB) IMEX method.

[Price,PriceGrid,AssetPrices,Times] = optByMertonFD( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute Price for an American Option Using the Merton Model

Define the option variables and Merton model parameters.

```
AssetPrice = 90;
Strike = 100;
Rate = 0.06;
DividendYield = 0.1;
Settle = '01-Jan-2018';
ExerciseDates = '02-Apr-2018';
```

```
Sigma = 0.40;
MeanJ = -0.10;
JumpVol = 0.01;
JumpFreq = 1.00;
```

Compute the American call option price using the finite differences method.

```
OptSpec = 'Call';
```

```
Price = optSensByMertonFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike,...
Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'AmericanOpt', 1)
```

```
Price = 3.4551
```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

scalar decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: double

### AssetPrice — Current underlying asset price

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: double

### Settle — Option settlement date

serial date number | date character vector | datetime | string scalar

Option settlement date, specified as a scalar using a serial date number, date character vector, datetime object, or string scalar.

Data Types: double | char | datetime | string

### ExerciseDates — Option exercise dates

serial date number | date character vector | datetime array | string array

Option exercise dates, specified as a serial date number, date character vector, datetime array, or string array:

- For a European option, use a scalar serial date number, date character vector, datetime object, or string scalar. For a European option, `ExerciseDates` contains only one value: the option expiry date.
- For an American option, use a 1-by-2 vector of serial date numbers, date character vectors, datetime arrays, or string arrays to specify the exercise date boundaries. An American option can be exercised on any date between or including the pair of dates. If only one non-NaN date is listed, then the option can be exercised between `Settle` date and the single listed value in `ExerciseDates`.

Data Types: double | char | datetime | string

### OptSpec — Definition of option

character vector with value of 'call' or 'put' | string array with value of "call" or "put"

Definition of the option, specified as a scalar using a character vector or string array with a value of 'call' or 'put'.

Data Types: cell | string

### Strike — Option strike price value

scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: double

**Sigma – Volatility of underlying asset**

scalar numeric

Volatility of the underlying asset, specified as a scalar numeric.

Data Types: double

**MeanJ – Mean of the random percentage jump size**

scalar decimal

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal value where  $\log(1+J)$  is normally distributed with the mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

**JumpVol – Standard deviation of  $\log(1+J)$** 

scalar decimal

Standard deviation of  $\log(1+J)$  where  $J$  is the random percentage jump size, specified as a scalar decimal.

Data Types: double

**JumpFreq – Annual frequency of Poisson jump process**

numeric

Annual frequency of the Poisson jump process, specified as a scalar numeric.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Price, PriceGrid] =``optByMertonFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike, MeanJ, JumpVol, JumpFreq, 'Basis', 7)`**Basis – Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric.

---

**Note** If you enter a value for DividendYield, then set DividendAmounts and ExDividendDates = [ ] or do not enter them. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

---

Data Types: double

### **DividendAmounts — Cash dividend amounts**

[ ] (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of 'DividendAmounts' and an NDIV-by-1 vector.

---

**Note** Each dividend amount must have a corresponding ex-dividend date. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

---

Data Types: double

### **ExDividendDates — Ex-dividend dates**

[ ] (default) | serial date number | date character vector | string array | datetime array

Ex-dividend dates, specified as the comma-separated pair consisting of 'ExDividendDates' and an NDIV-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

### **AssetPriceMax — Maximum price for price grid boundary**

if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar numeric

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar numeric.

Data Types: double

**AssetGridSize — Size of asset grid for finite difference grid**

400 (default) | scalar numeric

Size of the asset grid for the finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a scalar numeric.

Data Types: double

**TimeGridSize — Number of nodes of time grid for finite difference grid**

100 (default) | positive numeric scalar

Number of nodes of the time grid for the finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive numeric scalar.

Data Types: double

**AmericanOpt — Option type**

0 (European) (default) | scalar with value of [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a scalar flag with one of these values:

- 0 — European
- 1 — American

Data Types: double

**Output Arguments****Price — Option price**

scalar numeric

Option price, returned as a scalar numeric.

**PriceGrid — Grid containing prices calculated by the finite difference method**

grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with size AssetGridSize × TimeGridSize. The number of columns is not necessarily equal to the TimeGridSize because exercise and ex-dividend dates are added to the time grid.

PriceGrid(:, :, end) contains the price for  $t = 0$ .

**AssetPrices — Prices of the asset**

vector

Prices of the asset corresponding to the first dimension of PriceGrid, returned as a vector.

**Times — Times**

vector

Times corresponding to the second dimension of PriceGrid, returned as a vector.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Merton Jump Diffusion Model

The Merton jump diffusion model [2] extends the Black-Scholes model by using the Poisson process to include jump diffusion parameters in the modeling of sudden asset price movements (both up and down).

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + JS_t dP_t$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$W_t$  is the Weiner process.

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

where:

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

$\sigma$  is the volatility of the asset price for ( $\sigma > 0$ ).

## optSensByMertonFD

Option price and sensitivities by Merton76 model using finite differences

### Syntax

```
[PriceSens,PriceGrid,AssetPrices,Times] = optSensByMertonFD(Rate,AssetPrice,
Settle,ExerciseDates,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq)
[PriceSens,PriceGrid,AssetPrices,Times] = optSensByMertonFD( ____,Name,Value)
```

### Description

[PriceSens,PriceGrid,AssetPrices,Times] = optSensByMertonFD(Rate,AssetPrice,Settle,ExerciseDates,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq) computes a vanilla European or American option price and sensitivities by the Merton76 model, using the Crank-Nicolson Adams-Bashforth (CNAB) IMEX method.

[PriceSens,PriceGrid,AssetPrices,Times] = optSensByMertonFD( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute Price and Sensitivities for an American Option Using the Merton Model

Define the option variables and Merton model parameters.

```
AssetPrice = 90;
Strike = 100;
Rate = 0.06;
DividendYield = 0.1;
Settle = '01-Jan-2018';
ExerciseDates = '02-Apr-2018';
```

```
Sigma = 0.40;
MeanJ = -0.10;
JumpVol = 0.01;
JumpFreq = 1.00;
```

Compute the American call option price and sensitivities using the finite differences method.

```
OptSpec = 'Call';
```

```
[Price, Delta, Gamma, Rho, Theta, Vega] = optSensByMertonFD(Rate, AssetPrice, Settle, ExerciseDates,
Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'AmericanOpt', 1,...
'OutSpec', ["Price" "Delta" "Gamma" "Rho" "Theta" "Vega"])
```

```
Price = 3.4551
```

```
Delta = 0.3211
```

```
Gamma = 0.0195
```

Rho = 5.6610

Theta = -11.9877

Vega = 15.5156

## Input Arguments

### **Rate — Continuously compounded risk-free interest rate**

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: double

### **AssetPrice — Current underlying asset price**

numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: double

### **Settle — Option settlement date**

serial date number | date character vector | datetime | string array

Option settlement date, specified as a scalar using a serial date number, date character vector, datetime array, or string array.

Data Types: double | char | datetime | string

### **ExerciseDates — Option exercise dates**

serial date number | date character vector | datetime array | string array

Option exercise dates, specified as a serial date number, date character vector, datetime array, or string array:

- For a European option, use a scalar serial date number, date character vector, datetime array, or string array. For a European option, `ExerciseDates` contains only one value: the option expiry date.
- For an American option, use a 1-by-2 vector of serial date numbers, date character vectors, datetime arrays, or string arrays to specify the exercise date boundaries. An American option can be exercised on any date between or including the pair of dates. If only one non-`NaN` date is listed, then the option can be exercised between `Settle` date and the single listed value in `ExerciseDates`.

Data Types: double | char | datetime | string

### **OptSpec — Definition of option**

character vector with value of 'call' or 'put' | string array with value of "call" or "put"

Definition of the option, specified as a scalar using a character vector or string array with a value of 'call' or 'put'.

Data Types: cell | string

**Strike — Option strike price value**

scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: double

**Sigma — Volatility of underlying asset**

scalar numeric

Volatility of the underlying asset, specified as a scalar numeric.

Data Types: double

**MeanJ — Mean of the random percentage jump size**

scalar decimal

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal value where  $\log(1+J)$  is normally distributed with the mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$** 

scalar decimal

Standard deviation of  $\log(1+J)$  where  $J$  is the random percentage jump size, specified as a scalar decimal.

Data Types: double

**JumpFreq — Annual frequency of Poisson jump process**

scalar numeric

Annual frequency of the Poisson jump process, specified as a scalar numeric.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: [Price, PriceGrid] =

```
optByMertonFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike, MeanJ, JumpVol, JumpFreq, 'Basis', 7, 'OutSpec', 'delta')
```

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)

- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric.

---

**Note** If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates` = [ ] or do not enter them. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield` = 0.

---

Data Types: double

### **DividendAmounts — Cash dividend amounts**

[ ] (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of 'DividendAmounts' and an NDIV-by-1 vector.

---

**Note** Each dividend amount must have a corresponding ex-dividend date. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield` = 0.

---

Data Types: double

### **ExDividendDates — Ex-dividend dates**

[ ] (default) | serial date number | date character vector | string array | datetime array

Ex-dividend dates, specified as the comma-separated pair consisting of 'ExDividendDates' and an NDIV-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

**AssetPriceMax — Maximum price for price grid boundary**

if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar numeric

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar numeric.

Data Types: double

**AssetGridSize — Size of asset grid for the finite difference grid**

400 (default) | scalar numeric

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a scalar numeric.

Data Types: double

**TimeGridSize — Number of nodes of time grid for the finite difference grid**

100 (default) | positive numeric scalar

Number of nodes of the time grid for finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive numeric scalar.

Data Types: double

**AmericanOpt — Option type**

0 (European) (default) | scalar with value of [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a scalar flag with one of these values:

- 0 — European
- 1 — American

Data Types: double

**OutSpec — Define outputs**

['price'] (default) | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', and 'theta' | string array with values "price", "delta", "gamma", "vega", "rho", and "theta"

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT string array or cell array of character vectors with supported values.

Example: OutSpec = ['price', 'delta', 'gamma', 'vega', 'rho', 'theta']

Data Types: string | cell

**Output Arguments****PriceSens — Option price or sensitivities**

numeric

Option price or sensitivities, returned as a numeric. The name-value pair argument OutSpec determines the types and order of the outputs.

**PriceGrid — Grid containing prices calculated by the finite difference method**

grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with size `AssetGridSize`  $\times$  `TimeGridSize`. The number of columns is not necessarily equal to the `TimeGridSize` because exercise and ex-dividend dates are added to the time grid. `PriceGrid(:, :, end)` contains the price for  $t = 0$ .

**AssetPrices — Prices of the asset**

vector

Prices of the asset corresponding to the first dimension of `PriceGrid`, returned as a vector.

**Times — Times**

vector

Times corresponding to the second dimension of `PriceGrid`, returned as a vector.

**More About****Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

**Merton Jump Diffusion Model**

The Merton jump diffusion model [2] extends the Black-Scholes model by using the Poisson process to include jump diffusion parameters in the modeling of sudden asset price movements (both up and down).

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + JS_t dP_t$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$W_t$  is the Weiner process.

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

where:

$\mu_J$  is the mean of  $J$  for  $(\mu_J > -1)$ .

$\delta$  is the standard deviation of  $\ln(1+J)$  for  $(\delta \geq 0)$ .

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for  $(\lambda_p \geq 0)$ .

$\sigma$  is the volatility of the asset price for  $(\sigma > 0)$ .

## optByMertonFFT

Option price by Merton76 model using FFT and FRFT

### Syntax

```
[Price,StrikeOut] = optByMertonFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,
Strike,Sigma,MeanJ,JumpVol,JumpFreq)
[Price,StrikeOut] = optByMertonFFT( ____,Name,Value)
```

### Description

[Price,StrikeOut] = optByMertonFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq) computes vanilla European option price by Merton76 model, using Carr-Madan FFT and Chourdakis FRFT methods.

[Price,StrikeOut] = optByMertonFFT( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Workflow for Plotting an Option Price Surface Using the Merton76 Model

Use optByMertonFFT to calibrate the FFT strike grid, compute option prices, and plot an option price surface.

#### Define Option Variables and Merton76 Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';
```

```
Sigma = 0.16;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

#### Compute the Option Prices for the Entire FFT (or FRFT) Strike Grid, Without Specifying "Strike"

Compute option prices and also output the corresponding strikes. If the Strike input is empty ( [] ), option prices will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid is determined as  $\exp(\log\text{-strike grid})$ , where each column of the log-strike grid has NumFFT points with LogStrikeStep spacing that are roughly centered around each element of  $\log(\text{AssetPrice})$ . The default value for NumFFT is  $2^{12}$ . In addition to the prices in the first output, the optional last output contains the corresponding strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
```

```

% Compute option prices for the entire FFT strike grid
[Call, Kout] = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield);

% Show the lowest and highest strike values on the FFT strike grid
format
MinStrike = Kout(1) % Lowest possible strike in the current FFT strike grid

MinStrike = 2.9205e-135

MaxStrike = Kout(end) % Highest possible strike in the current FFT strike grid

MaxStrike = 1.8798e+138

% Show a subset of the strikes and corresponding option prices
Range = (2046:2052);
[Kout(Range) Call(Range)]

ans = 7x2

    50.4929    29.4645
    58.8640    21.2601
    68.6231    12.2218
    80.0000     4.5600
    93.2631     0.9579
   108.7251     0.1236
   126.7505     0.0113

```

### Change the Number of FFT (or FRFT) Points and Compare with optByMertonNI

Try a different number of FFT(or FRFT) points, and compare the results with direct numerical integration. Unlike `optByMertonFFT`, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the `optByMertonNI` function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by `optByMertonNI` can serve as a benchmark for adjusting the settings for `optByMertonFFT`.

```

% Try a smaller number of FFT (or FRFT) points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Call, Kout] = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
Strike = Kout(Range);
CallFFT = Call(Range);
CallNI = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield);
Error = abs(CallFFT-CallNI);
table(Strike, CallFFT, CallNI, Error)

```

```

ans=7x4 table
    Strike    CallFFT    CallNI    Error
    _____    _____    _____    _____

```

12.696	66.328	66.696	0.36786
23.449	55.922	56.103	0.18071
43.312	36.481	36.536	0.055233
80	4.7387	4.56	0.17867
147.76	0.046602	0.0008089	0.045793
272.93	0.0092842	-7.0709e-08	0.0092842
504.11	0.0024041	-2.4515e-07	0.0024044

### Make Further Adjustments to FFT (or FRFT)

If the values in the output CallFFT are significantly different from those in CallNI, try making adjustments to optByMertonFFT settings, such as CharacteristicFcnStep, LogStrikeStep, NumFFT, DampingFactor, and so on. Note that if  $(\text{LogStrikeStep} * \text{CharacteristicFcnStep})$  is  $2*\pi / \text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

```
Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Call, Kout] = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001);
```

```
% Compare with numerical integration method
```

```
Strike = Kout(Range);
CallFFT = Call(Range);
CallNI = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield);
Error = abs(CallFFT-CallNI);
table(Strike, CallFFT, CallNI, Error)
```

```
ans=7x4 table
```

Strike	CallFFT	CallNI	Error
79.76	4.674	4.674	4.9664e-10
79.84	4.6358	4.6358	4.9651e-10
79.92	4.5978	4.5978	4.9642e-10
80	4.56	4.56	4.9641e-10
80.08	4.5224	4.5224	4.9642e-10
80.16	4.485	4.485	4.965e-10
80.24	4.4478	4.4478	4.966e-10

```
% Save the final FFT (or FRFT) strike grid for future reference. For
% example, it provides information about the range of Strike inputs for
% which the FFT (or FRFT) operation is valid.
```

```
FFTStrikeGrid = Kout;
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike
```

```
MinStrike = 47.9437
```

```
MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike
```

```
MaxStrike = 133.3566
```

### Compute Option Price for a Single Strike

Once the desired FFT (or FRFT) settings are determined, use the `Strike` input to specify the strikes rather than providing an empty array. If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;

Call = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)

Call = 4.5600
```

### Compute the Option Prices for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)

Call = 5×1

    6.7411
    5.5762
    4.5600
    3.6891
    2.9551
```

### Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Call = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001) % Five values in vector output

Call = 5×1

    8.5589
    8.9439
    9.2316
    9.4653
```

9.6565

### Expand the Outputs for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the outputs into `NStrikes-by-NMaturities` matrices. In this case, they are square matrices.

```
[Call, Kout] = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 5) matrix output
```

Call = 5×5

8.5589	9.9675	11.1343	12.1492	13.0464
7.4844	8.9439	10.1481	11.1939	12.1181
6.5125	8.0023	9.2316	10.2999	11.2449
5.6401	7.1402	8.3827	9.4653	10.4249
4.8630	6.3545	7.5990	8.6881	9.6565

Kout = 5×5

76	76	76	76	76
78	78	78	78	78
80	80	80	80	80
82	82	82	82	82
84	84	84	84	84

### Compute the Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities`. That is, the output `NStrikes-by-NMaturities` matrix can be rectangular.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84)'; % Five strikes
```

```
Call = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 6) matrix output
```

Call = 5×6

6.7411	8.5589	9.9675	11.1343	12.1492	13.0464
5.5762	7.4844	8.9439	10.1481	11.1939	12.1181
4.5600	6.5125	8.0023	9.2316	10.2999	11.2449
3.6891	5.6401	7.1402	8.3827	9.4653	10.4249
2.9551	4.8630	6.3545	7.5990	8.6881	9.6565

### Compute the Option Prices for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes-by-NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call = optByMertonFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 4) matrix output

Call = 5x4

    3.4187    5.6579    8.5589   12.0417
    2.8538    4.8401    7.4844   10.7343
    2.3718    4.1205    6.5125    9.5230
    1.9635    3.4922    5.6401    8.4090
    1.6198    2.9476    4.8630    7.3921

```

### Plot an Option Price Surface

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to "true" to output the surface as a `NStrikes-by-NMaturities` matrix.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

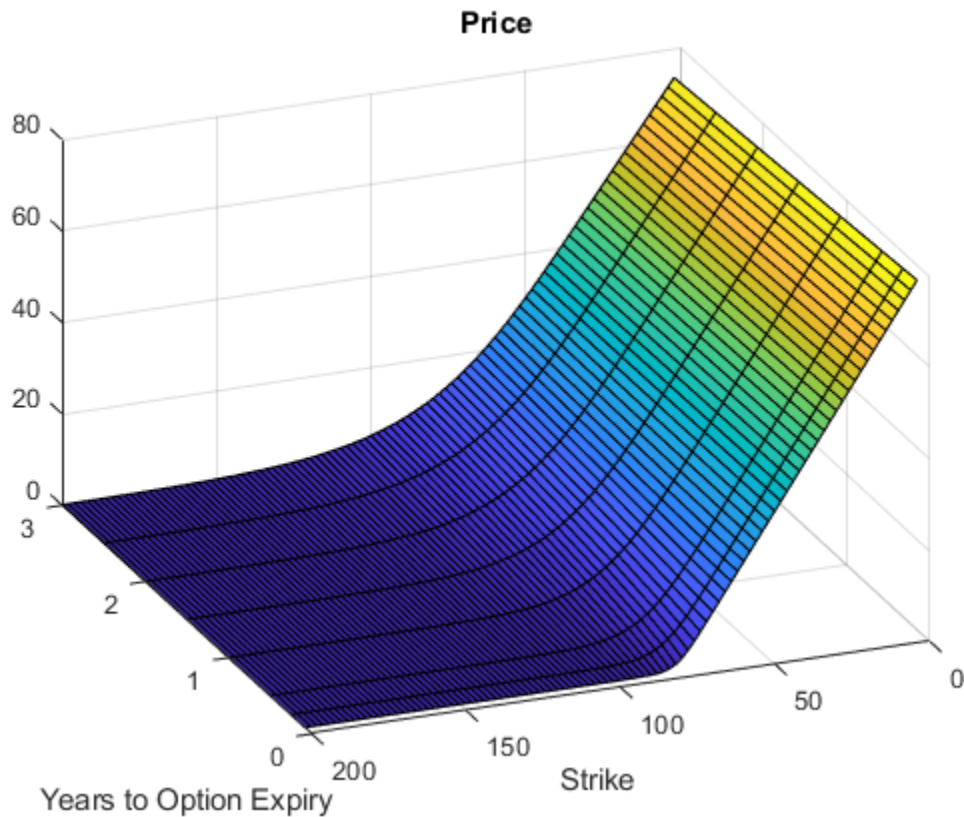

% Increase 'NumFFT' to support a wider range of strikes
NumFFT = 2^13;

Call = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, 'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Call);
title('Price');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
zlim([0 80]);

```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

### AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST-by-1` or `NColumns-by-1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### Settle — Option settlement date

serial date number | date character vector | datetime | string array

Option settlement date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The `Settle` date must be before the `Maturity` date.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **Maturity – Option maturity date**

serial date number | date character vector | `datetime` | string array

Option maturity date, specified as a `NINST`-by-1 or `NColumns`-by-1 vector using serial date numbers, date character vectors, `datetime` arrays, or string arrays.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **OptSpec – Definition of option**

cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a `NINST`-by-1 or `NColumns`-by-1 vector using a cell array of character vectors or string arrays with values 'call' or 'put'.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

### **Strike – Option strike price value**

numeric

Option strike price value, specified as a `NINST`-by-1, `NRows`-by-1, `NRows`-by-`NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has 'NumFFT' points with 'LogStrikeStep' spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **Sigma – Volatility of underlying asset**

numeric

Volatility of the underlying asset, specified as a scalar numeric value.

Data Types: `double`

### **MeanJ – Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal value where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation `JumpVol`.

Data Types: double

### **JumpVol — Standard deviation of $\log(1+J)$**

decimal

Standard deviation of  $\log(1+J)$  where J is the random percentage jump size, specified as a scalar decimal value.

Data Types: double

### **JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, StrikeOut] = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, Sigma, MeanJ, JumpVol, JumpFreq, 'Basis', 7)`

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-129.

Data Types: double

**DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

**NumFFT — Number of grid points in the characteristic function variable**

4096 (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of 'NumFFT' and a scalar numeric value.

Data Types: double

**CharacteristicFcnStep — Characteristic function variable grid spacing**

0.01 (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of 'CharacteristicFcnStep' and a scalar numeric value.

Data Types: double

**LogStrikeStep — Log-strike grid spacing** $2\pi/\text{NumFFT}/\text{CharacteristicFcnStep}$  (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of 'LogStrikeStep' and a scalar numeric value.

---

**Note** If  $(\text{LogStrikeStep} \times \text{CharacteristicFcnStep})$  is  $2\pi/\text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

---

Data Types: double

**DampingFactor — Damping factor for Carr-Madan formulation**

1.5 (default) | numeric

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of 'DampingFactor' and a scalar numeric value.

Data Types: double

**Quadrature — Type of quadrature**

"simpson" (default) | character vector with values: 'simpson' or 'trapezoidal' | string array with values: "simpson" or "trapezoidal"

Type of quadrature, specified as the comma-separated pair consisting of 'Quadrature' and a single character vector or string array with a value of 'simpson' or 'trapezoidal'.

Data Types: char | string

**ExpandOutput — Flag to expand the outputs**

false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- `true` — If `true`, the outputs are `NRows`-by-`NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. If `Strike` is empty, `NRows` is equal to `NumFFT`. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

## Output Arguments

### Price — Option prices

`numeric`

Option prices, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

### StrikeOut — Strikes corresponding to Price

`numeric`

Strikes corresponding to `Price`, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Merton Jump Diffusion Model

The Merton jump diffusion model (Merton (1976)) is a different extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + JS_t dP_t$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$W_t$  is the Weiner process.

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

$\sigma$  is the volatility of the asset price for ( $\sigma > 0$ ).

The characteristic function  $f_{Merton76_j}(\phi)$  for  $j = 1$  (asset prices measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Merton76_j} = f_{BS_j} \exp\left(\lambda_p \tau (1 + \mu_j)^{m_j} + \frac{1}{2} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 \left(m_j i\phi + \frac{(i\phi)^2}{2}\right)} - 1 \right] - \lambda_p \tau \mu_j i\phi\right)$$

where for  $j = 1, 2$ :

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS_2}(\phi) = \exp\left(i\phi \left[ \ln S_t + \left(r - q - \frac{\sigma^2}{2}\right)\tau \right] - \frac{\phi^2 \sigma^2}{2} \tau\right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

where

$\phi$  is the characteristic function variable.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

### Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities  $P_1$  and  $P_2$  as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi} \int_0^{\infty} \text{Re}[e^{-iuk} \psi(u)] du$$

$$\psi(u) = \frac{e^{-r\tau} f_2(\phi = (u - (\alpha + 1)i))}{\alpha^2 + \alpha - u^2 + iu(2\alpha + 1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$

$i$  is a unit imaginary number ( $i^2 = -1$ )

$\phi$  is the characteristic function variable.

$\alpha$  is the damping factor.

$u$  is the characteristic function variable for integration, where  $\phi = (u - (\alpha + 1)i)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration,  $u$ , is discretized into NumFFT( $N$ ) points with the step size CharacteristicFcnStep ( $\Delta u$ ), and the log-strike  $k$  is discretized into  $N$  points with the step size LogStrikeStep( $\Delta k$ ).

The discretized characteristic function variable for integration,  $u_j$  (for  $j = 1, 2, 3, \dots, N$ ), has a minimum value of 0 and a maximum value of  $(N-1) (\Delta u)$ , and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid,  $k_n$  (for  $n = 1, 2, 3, N$ ) is approximately centered around  $\ln(S_t)$ , with a minimum value of

$$\ln(S_t) - \frac{N}{2} \Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^N \operatorname{Re} \left[ e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iu_j \left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j) \right] w_j$$

where

$\Delta u$  is the step size of discretized characteristic function variable for integration.

$\Delta k$  is the step size of discretized log-strike.

$N$  is the number of FFT or FRFT points.

$w_j$  is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if  $\Delta k$  and  $\Delta u$  are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

# optSensByMertonFFT

Option price and sensitivities by Merton76 model using FFT and FRFT

## Syntax

```
[PriceSens,StrikeOut] = optSensByMertonFFT(Rate,AssetPrice,Settle,Maturity,
OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq)
[PriceSens,StrikeOut] = optSensByMertonFFT( ____,Name,Value)
```

## Description

[PriceSens,StrikeOut] = optSensByMertonFFT(Rate,AssetPrice,Settle,Maturity, OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq) computes vanilla European option price and sensitivities by Merton76 model, using Carr-Madan FFT and Chourdakis FRFT methods.

[PriceSens,StrikeOut] = optSensByMertonFFT( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Workflow for Plotting an Option Sensitivity Surface Using the Merton76 Model

Use optSensByMertonFFT to calibrate the FFT strike grid for sensitivities, compute option sensitivities, and plot option sensitivity surfaces.

#### Define Option Variables and Merton76 Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';
```

```
Sigma = 0.16;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

#### Compute the Option Prices for the Entire FFT (or FRFT) Strike Grid, Without Specifying "Strike"

Compute option sensitivities and also output the corresponding strikes. If the Strike input is empty ( [] ), option sensitivities will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid is determined as  $\exp(\log\text{-strike grid})$ , where each column of the log-strike grid has NumFFT points with LogStrikeStep spacing that are roughly centered around each element of  $\log(\text{AssetPrice})$ . The default value for NumFFT is  $2^{12}$ . In addition to the sensitivities in the first output, the optional last output contains the corresponding strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = []; % Strike is not specified
```

```

[Delta, Kout] = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta");

% Show the lowest and highest strike values on the FFT strike grid
format
[Kout(1) Kout(end)]

ans = 1×2
10138 ×

    0.0000    1.8798

% Show a subset of the strikes and corresponding option sensitivities
Range = (2046:2052);
[Kout(Range) Delta(Range)]

ans = 7×2

    50.4929    0.9895
    58.8640    0.9801
    68.6231    0.8816
    80.0000    0.5283
    93.2631    0.1551
   108.7251    0.0241
   126.7505    0.0025

```

### Change the Number of FFT (or FRFT) Points and Compare with optSensByMertonNI

Try a different number of FFT (or FRFT) points, and compare the results with numerical integration. Unlike `optSensByMertonFFT`, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the `optSensByMertonNI` function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by `optSensByMertonNI` can serve as a benchmark for adjusting the settings for `optSensByMertonFFT`.

```

% Try a smaller number of FFT points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Delta, Kout] = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
Strike = Kout(Range);
DeltaFFT = Delta(Range);
DeltaNI = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)

ans=7×4 table
    Strike    DeltaFFT    DeltaNI    Error

```

12.696	0.89726	0.99002	0.092766
23.449	0.93421	0.99002	0.05581
43.312	0.94691	0.99001	0.043093
80	0.50983	0.52827	0.018446
147.76	0.004147	0.00019101	0.003956
272.93	0.001071	1.547e-09	0.001071
504.11	0.00030521	5.7578e-10	0.00030521

### Make Further Adjustments to FFT (or FRFT)

If the values in the output DeltaFFT are significantly different from those in DeltaNI, try making adjustments to optSensByMertonFFT settings, such as CharacteristicFcnStep, LogStrikeStep, NumFFT, DampingFactor, and so on. Note that if (LogStrikeStep \* CharacteristicFcnStep) is  $2\pi$ / NumFFT, FFT is used. Otherwise, FRFT is used.

```
Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Delta, Kout] = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001);
```

```
% Compare with numerical integration method
```

```
Strike = Kout(Range);
DeltaFFT = Delta(Range);
DeltaNI = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)
```

```
ans=7x4 table
```

Strike	DeltaFFT	DeltaNI	Error
79.76	0.53701	0.53701	5.6407e-12
79.84	0.5341	0.5341	5.3257e-12
79.92	0.53119	0.53119	5.0099e-12
80	0.52827	0.52827	4.6956e-12

80.16	0.52245	0.52245	4.0653e-12
80.24	0.51953	0.51953	3.7503e-12

```
% Save the final FFT (or FRFT) strike grid for future reference. For
% example, it provides information about the range of Strike inputs for
% which the FFT (or FRFT) operation is valid.
```

```
FFTStrikeGrid = Kout;
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike
```

```
MinStrike = 47.9437
```

```
MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike
```

```
MaxStrike = 133.3566
```

### Compute the Option Sensitivity for a Single Strike

Once the desired FFT (or FRFT) settings are determined, use the `Strike` input to specify the strikes rather than providing an empty array. If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;

Delta = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)

Delta = 0.5283
```

### Compute the Option Sensitivities for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Delta = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)

Delta = 5×1

    0.6727
    0.6013
    0.5283
    0.4565
    0.3883
```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Delta = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001) % Five values in vector output

Delta = 5×1

    0.6419
    0.5907
    0.5565
```

```
0.5311
0.5110
```

### Expand the Outputs for a Surface

Set the ExpandOutput name-value pair argument to "true" to expand the outputs into NStrikes-by-NMaturities matrices. In this case, they are square matrices.

```
[Delta, Kout] = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 5) matrix output
```

Delta = 5x5

```
0.6419    0.6305    0.6245    0.6204    0.6173
0.5922    0.5907    0.5905    0.5905    0.5905
0.5422    0.5507    0.5565    0.5607    0.5637
0.4927    0.5112    0.5229    0.5311    0.5372
0.4447    0.4725    0.4898    0.5020    0.5110
```

Kout = 5x5

```
76    76    76    76    76
78    78    78    78    78
80    80    80    80    80
82    82    82    82    82
84    84    84    84    84
```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When ExpandOutput is "true", NStrikes do not have to match NMaturities. That is, the output NStrikes-by-NMaturities matrix can be rectangular.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84); % Five strikes
```

```
Delta = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 6) matrix output
```

Delta = 5x6

```
0.6727    0.6419    0.6305    0.6245    0.6204    0.6173
0.6013    0.5922    0.5907    0.5905    0.5905    0.5905
0.5283    0.5422    0.5507    0.5565    0.5607    0.5637
0.4565    0.4927    0.5112    0.5229    0.5311    0.5372
0.3883    0.4447    0.4725    0.4898    0.5020    0.5110
```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is "true", the output can also be a `NStrikes-by-NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta = optSensByMertonFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 4) matrix output

Delta = 5x4

    0.3796    0.5157    0.6419    0.7472
    0.3315    0.4637    0.5922    0.7043
    0.2874    0.4137    0.5422    0.6592
    0.2474    0.3664    0.4927    0.6128
    0.2117    0.3224    0.4447    0.5657
```

### Plot Option Sensitivity Surfaces

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to "true" to output the surfaces as `NStrikes-by-NMaturities` matrices.

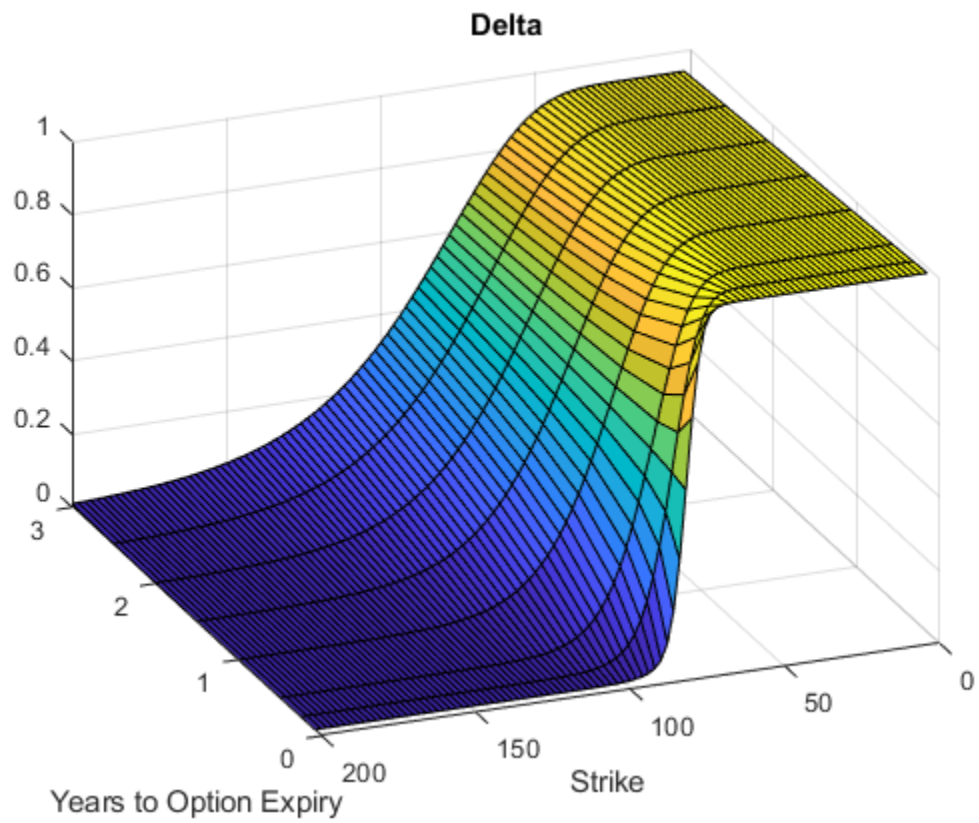

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

% Increase 'NumFFT' to support a wider range of strikes
NumFFT = 2^13;

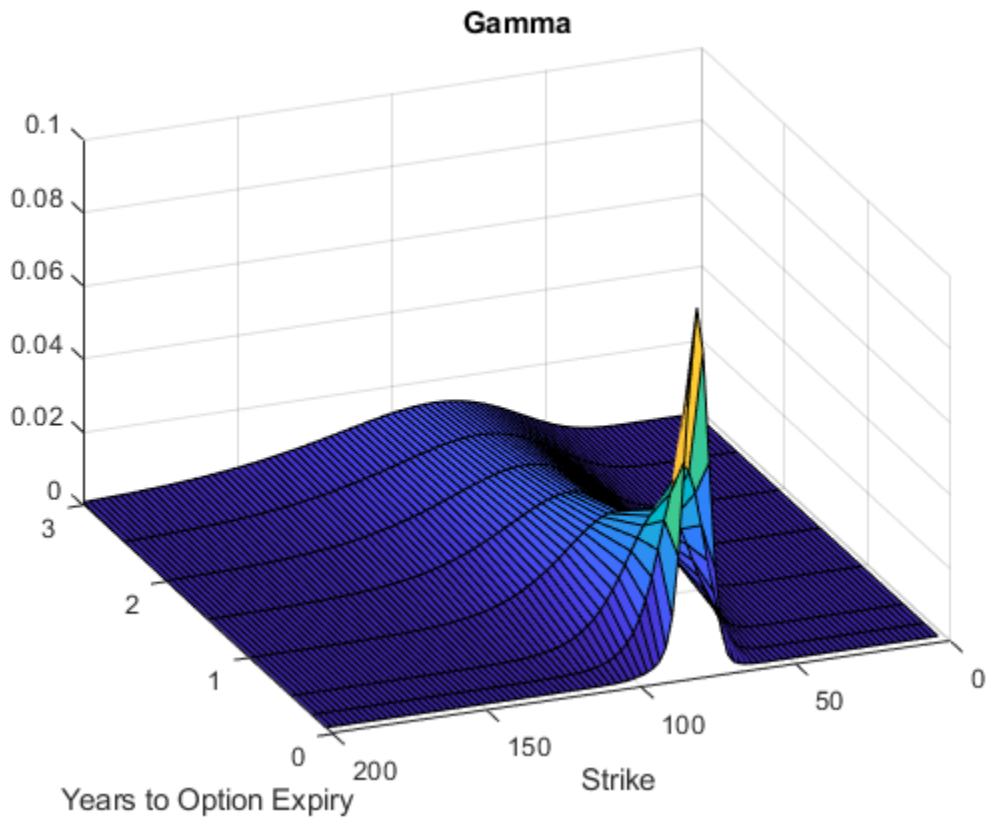

[Delta, Gamma, Rho, Theta, Vega] = optSensByMertonFFT(...
    Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'OutSpec', ["delta", "gamma", "rho", "theta", "vega"], ...
    'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

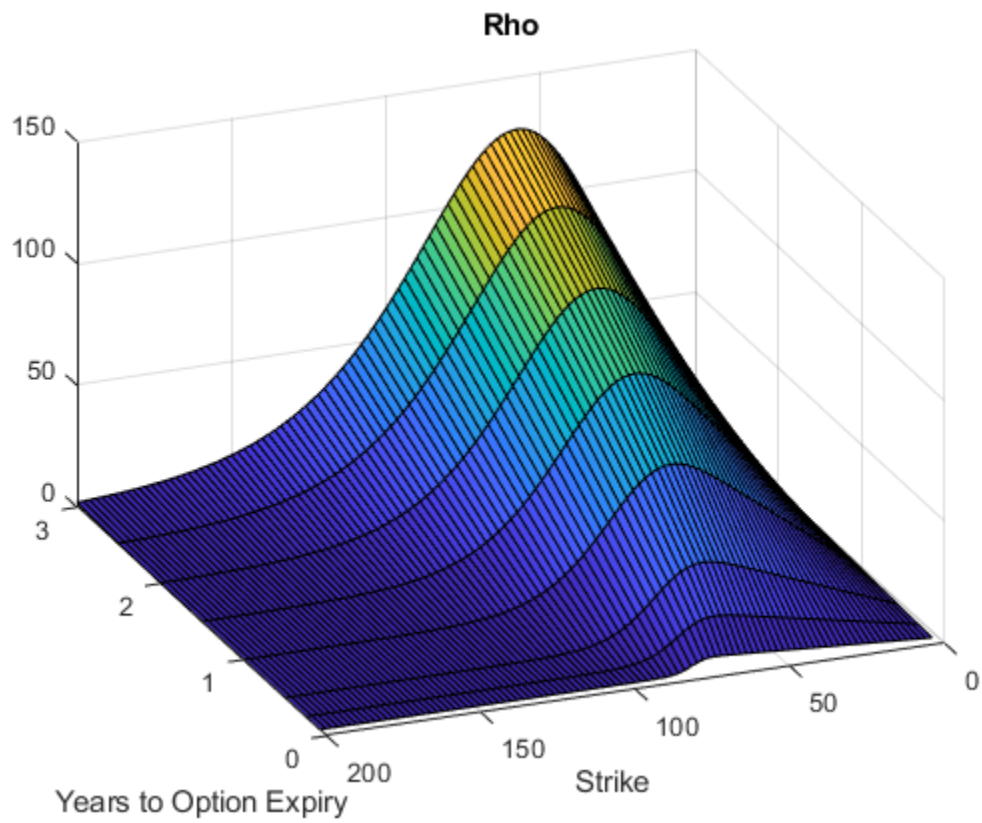

figure;
surf(X,Y,Delta);
title('Delta');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
```

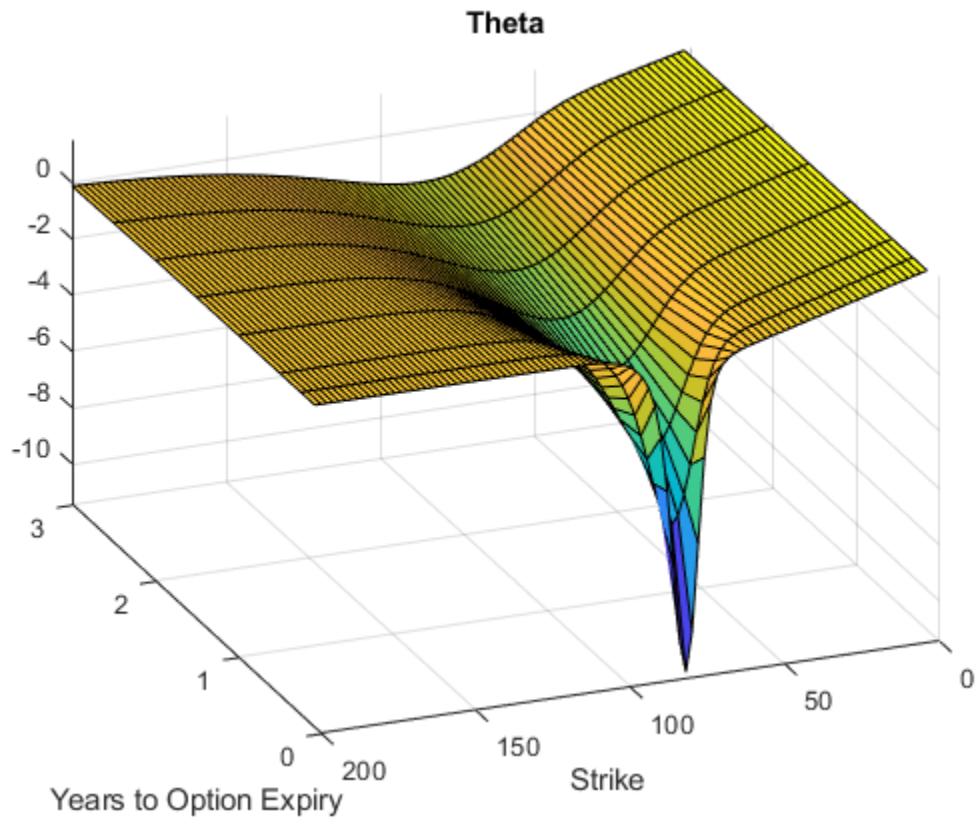

```
figure;  
surf(X,Y,Gamma)  
title('Gamma')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

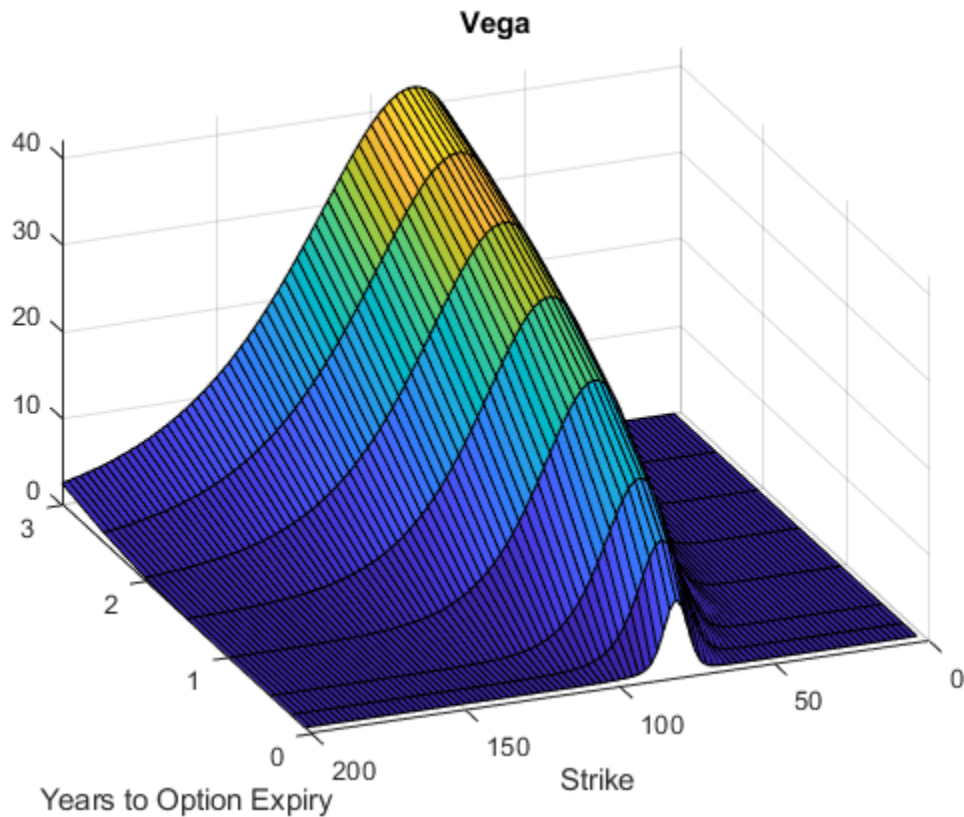

```
figure;  
surf(X,Y,Rho)  
title('Rho')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

```
figure;  
surf(X,Y,Theta)  
title('Theta')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

```
figure;  
surf(X,Y,Vega)  
title('Vega')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

### AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST-by-1` or `NColumns-by-1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### Settle — Option settlement date

serial date number | date character vector | datetime | string array

Option settlement date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The `Settle` date must be before the `Maturity` date.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **Maturity – Option maturity date**

`serial date number` | `date character vector` | `datetime` | `string array`

Option maturity date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **OptSpec – Definition of option**

`cell array of character vector with values 'call' or 'put'` | `string array with values "call" or "put"`

Definition of the option, specified as a `NINST-by-1` or `NColumns-by-1` vector using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

### **Strike – Option strike price value**

`numeric`

Option strike price value, specified as a `NINST-by-1`, `NRows-by-1`, `NRows-by-NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has `'NumFFT'` points with `'LogStrikeStep'` spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **Sigma – Volatility of underlying asset**

`numeric`

Volatility of the underlying asset, specified as a scalar numeric value.

Data Types: `double`

### **MeanJ – Mean of the random percentage jump size**

`decimal`

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal value where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation `JumpVol`.

Data Types: double

### **JumpVol — Standard deviation of $\log(1+J)$**

decimal

Standard deviation of  $\log(1+J)$  where J is the random percentage jump size, specified as a scalar decimal value.

Data Types: double

### **JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[PriceSens, StrikeOut] = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, Sigma, MeanJ, JumpVol, JumpFreq, 'Basis', 7)`

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-129.

Data Types: double

**DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

**OutSpec — Define outputs**

["price"] (default) | string array with values "price", "delta", "gamma", "vega", "rho", and "theta" | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', and 'theta'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT string array or cell array of character vectors with supported values.

---

**Note** "vega" is the sensitivity with respect the initial volatility  $\sqrt{V_0}$ .

---

Example: OutSpec = ["price", "delta", "gamma", "vega", "rho", "theta"]

Data Types: string | cell

**NumFFT — Number of grid points in the characteristic function variable**

4096 (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of 'NumFFT' and a scalar numeric value.

Data Types: double

**CharacteristicFcnStep — Characteristic function variable grid spacing**

0.01 (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of 'CharacteristicFcnStep' and a scalar numeric value.

Data Types: double

**LogStrikeStep — Log-strike grid spacing** $2\pi/\text{NumFFT}/\text{CharacteristicFcnStep}$  (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of 'LogStrikeStep' and a scalar numeric value.

---

**Note** If  $(\text{LogStrikeStep} \times \text{CharacteristicFcnStep})$  is  $2\pi/\text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

---

Data Types: double

**DampingFactor — Damping factor for Carr-Madan formulation**

1.5 (default) | numeric

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of 'DampingFactor' and a scalar numeric value.

Data Types: double

### Quadrature — Type of quadrature

"simpson" (default) | character vector with values: 'simpson' or 'trapezoidal' | string array with values: "simpson" or "trapezoidal"

Type of quadrature, specified as the comma-separated pair consisting of 'Quadrature' and a single character vector or string array with a value of 'simpson' or 'trapezoidal'.

Data Types: char | string

### ExpandOutput — Flag to expand the outputs

false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- **true** — If true, the outputs are NRows-by- NColumns matrices. NRows is the number of strikes for each column and it is determined by the Strike input. For example, Strike can be a NRows-by-1 vector, or a NRows-by-NColumns matrix. If Strike is empty, NRows is equal to NumFFT. NColumns is determined by the sizes of AssetPrice, Settle, Maturity, and OptSpec, which must all be either scalar or NColumns-by-1 vectors.
- **false** — If false, the outputs are NINST-by-1 vectors. Also, the inputs Strike, AssetPrice, Settle, Maturity, and OptSpec must all be either scalar or NINST-by-1 vectors.

Data Types: logical

## Output Arguments

### PriceSens — Option prices or sensitivities

numeric

Option prices or sensitivities, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput. The name-value pair argument OutSpec determines the types and order of the outputs.

### StrikeOut — Strikes corresponding to Price

numeric

Strikes corresponding to Price, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Merton Jump Diffusion Model

The Merton jump diffusion model (Merton (1976)) is a different extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + JS_t dP_t$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$W_t$  is the Weiner process.

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ -\frac{\left[ \ln(1 + J) - \left( \ln(1 + \mu_J) - \frac{\delta^2}{2} \right) \right]^2}{2\delta^2} \right\}$$

$\mu_J$  is the mean of  $J$  for  $(\mu_J > -1)$ .

$\delta$  is the standard deviation of  $\ln(1+J)$  for  $(\delta \geq 0)$ .

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for  $(\lambda_p \geq 0)$ .

$\sigma$  is the volatility of the asset price for  $(\sigma > 0)$ .

The characteristic function  $f_{Merton76,j}(\phi)$  for  $j = 1$  (asset prices measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Merton76_j} = f_{BS_j} \exp \left( \lambda_p \tau (1 + \mu_j)^{m_j + \frac{1}{2}} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 \left( m_j i\phi + \frac{(i\phi)^2}{2} \right)} - 1 \right] - \lambda_p \tau \mu_j i\phi \right)$$

where for  $j = 1, 2$ :

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS_2}(\phi) = \exp \left( i\phi \left[ \ln S_t + \left( r - q - \frac{\sigma^2}{2} \right) \tau \right] - \frac{\phi^2 \sigma^2}{2} \tau \right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

where

$\phi$  is the characteristic function variable.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

### Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities  $P_1$  and  $P_2$  as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi} \int_0^{\infty} \text{Re} \left[ e^{-iuk} \psi(u) \right] du$$

$$\psi(u) = \frac{e^{-r\tau} f_2(\phi = (u - (\alpha + 1)i))}{\alpha^2 + \alpha - u^2 + iu(2\alpha + 1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$\tau$  is time to maturity ( $\tau = T - t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$\alpha$  is the damping factor.

$u$  is the characteristic function variable for integration, where  $\phi = (u - (\alpha+1)i)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration,  $u$ , is discretized into NumFFT( $N$ ) point with the step size CharacteristicFcnStep ( $\Delta u$ ), and the log-strike  $k$  is discretized into  $N$  points with the step size LogStrikeStep( $\Delta k$ ).

The discretized characteristic function variable for integration,  $u_j$ (for  $j = 1, 2, 3, \dots, N$ ), has a minimum value of 0 and a maximum value of  $(N-1) (\Delta u)$ , and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid,  $k_n$ (for  $n = 1, 2, 3, N$ ) is approximately centered around  $\ln(S_t)$ , with a minimum value of

$$\ln(S_t) - \frac{N}{2}\Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^N \operatorname{Re}\left[e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iu_j \left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j)\right] w_j$$

where

$\Delta u$  is the step size of discretized characteristic function variable for integration.

$\Delta k$  is the step size of discretized log-strike.

$N$  is the number of FFT or FRFT points.

$w_j$  is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if  $\Delta k$  and  $\Delta u$  are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

## Topics

"Vanilla Option" on page 3-26

"Supported Equity Derivative Functions" on page 3-18

## Introduced in R2018a

## optByMertonNI

Option price by Merton76 model using numerical integration

### Syntax

```
Price = optByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,Sigma,
MeanJ,JumpVol,JumpFreq)
Price = optByMertonNI( ____,Name,Value)
```

### Description

Price = optByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,Sigma, MeanJ,JumpVol,JumpFreq) computes vanilla European option price by the Merton76 model, using numerical integration.

Price = optByMertonNI( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Workflow for Plotting an Option Price Surface Using the Merton76 Model

optByMertonNI uses numerical integration to compute option prices and then plot an option price surface.

#### Define Option Variables and Merton76 Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';
```

```
Sigma = 0.16;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

#### Compute the Option Price for a Single Strike

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;
```

```
Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield)
```

```
Call = 4.5600
```

#### Compute the Option Prices for a Vector of Strikes

The Strike input can be a vector.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield)

Call = 5×1

    6.7410
    5.5762
    4.5600
    3.6891
    2.9551

```

### Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to "true".

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield)

Call = 5×1

    8.5589
    8.9439
    9.2316
    9.4653
    9.6565

% Five values in vector output

```

### Expand the Output for a Surface

Set the `ExpandOutput` name-value pair argument to "true" to expand the output into a `NStrikes-by-NMaturities` matrix. In this case, it is a square matrix.

```

Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 5) matrix output

Call = 5×5

    8.5589    9.9675   11.1343   12.1492   13.0464
    7.4844    8.9439   10.1481   11.1939   12.1181
    6.5125    8.0023    9.2316   10.2999   11.2449
    5.6401    7.1402    8.3827    9.4653   10.4249
    4.8630    6.3545    7.5990    8.6881    9.6565

```

### Compute the Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is "true", `NStrikes` do not have to match `NMaturities`. That is, the output `NStrikes-by-NMaturities` matrix can be rectangular.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84)'; % Five strikes

Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 6) matrix output

Call = 5x6

    6.7410    8.5589    9.9675    11.1343    12.1492    13.0464
    5.5762    7.4844    8.9439    10.1481    11.1939    12.1181
    4.5600    6.5125    8.0023    9.2316    10.2999    11.2449
    3.6891    5.6401    7.1402    8.3827    9.4653    10.4249
    2.9551    4.8630    6.3545    7.5990    8.6881    9.6565
```

### Compute the Option Prices for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is "true", the output can also be a `NStrikes-by-NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call = optByMertonNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 4) matrix output

Call = 5x4

    3.4186    5.6579    8.5589    12.0417
    2.8538    4.8401    7.4844    10.7343
    2.3718    4.1205    6.5125    9.5230
    1.9635    3.4922    5.6401    8.4090
    1.6198    2.9476    4.8630    7.3921
```

### Plot an Option Price Surface

The `Strike` and `Maturity` inputs can be vectors. Set `ExpandOutput` to "true" to output the surface as a `NStrikes-by-NMaturities` matrix.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
```

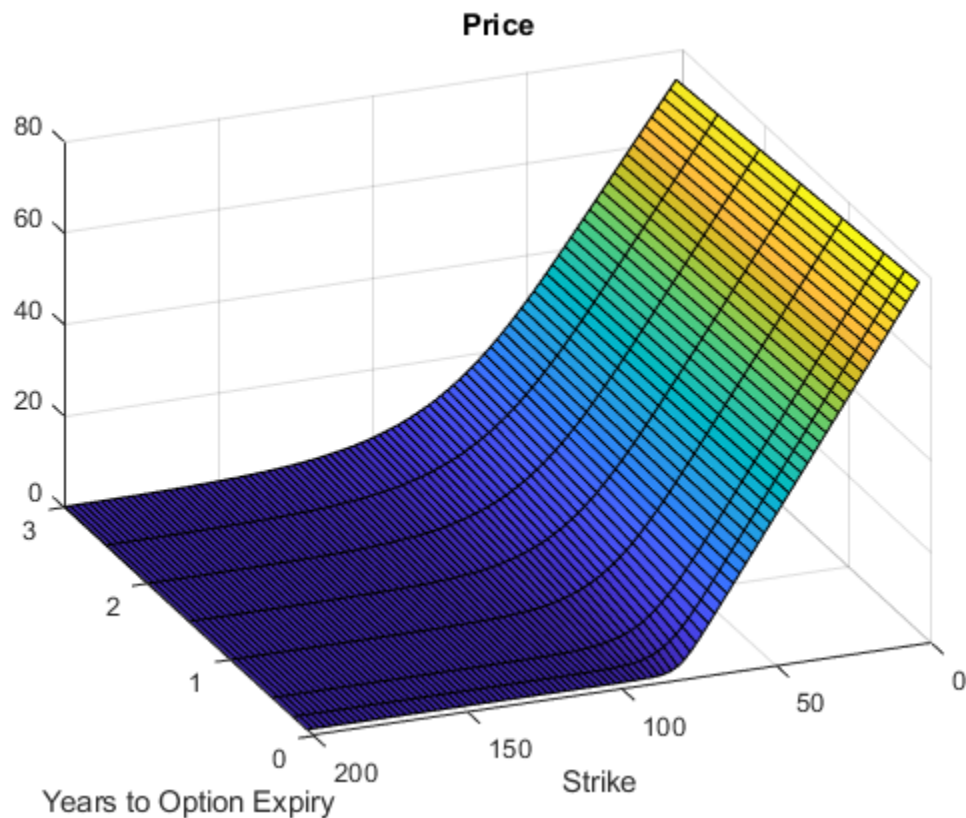

```

    'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Call);
title('Price');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
zlim([0 80]);

```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: double

### AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a NINST-by-1 or NColumns-by-1 vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **Settle — Option settlement date**

serial date number | date character vector | datetime | string array

Option settlement date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The `Settle` date must be before the `Maturity` date.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **Maturity — Option maturity date**

serial date number | date character vector | datetime | string array

Option maturity date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **OptSpec — Definition of option**

cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a `NINST-by-1` or `NColumns-by-1` vector using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

### **Strike — Option strike price value**

numeric

Option strike price value, specified as a `NINST-by-1`, `NRows-by-1`, `NRows-by-NColumns` vector of strike prices.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **Sigma — Volatility of underlying asset**

numeric

Volatility of the underling asset, specified as a scalar numeric value.

Data Types: `double`

**MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal value where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$** 

decimal

Standard deviation of  $\log(1+J)$  where  $J$  is the random percentage jump size, specified as a scalar decimal value.

Data Types: double

**JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `Price =`

```
optByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq,'Basis',7)
```

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

### **AbsTol — Absolute error tolerance for numerical integration**

1e-10 (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of 'AbsTol' and a scalar numeric value.

Data Types: double

### **RelTol — Relative error tolerance for numerical integration**

1e-6 (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of 'RelTol' and a scalar numeric value.

Data Types: double

### **IntegrationRange — Numerical integration range used to approximate continuous integral over [0 Inf]**

[1e-9 Inf] (default) | vector

Numerical integration range used to approximate the continuous integral over [0 Inf], specified as the comma-separated pair consisting of 'IntegrationRange' and a 1-by-2 vector representing [LowerLimit UpperLimit].

Data Types: double

### **Framework — Framework for computing option prices and sensitivities using numerical integration of models**

"heston1993" (default) | string with values "heston1993" or "lewis2001" | character vector with values 'heston1993' or 'lewis2001'

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of 'Framework' and a scalar string or character vector with the following values:

- "heston1993" or 'heston1993' — Method used in Heston (1993)
- "lewis2001" or 'lewis2001' — Method used in Lewis (2001)

Data Types: char | string

### **ExpandOutput — Flag to expand the outputs**

false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- `true` — If `true`, the outputs are `NRows`-by-`NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

## Output Arguments

### Price — Option prices

`numeric`

Option prices, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Merton Jump Diffusion Model

The Merton jump diffusion model (Merton (1976)) is a different extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + JS_t dP_t$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$W_t$  is the Weiner process.

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

$\sigma$  is the volatility of the asset price for ( $\sigma > 0$ ).

The characteristic function  $f_{Merton76_j}(\phi)$  for  $j = 1$  (asset prices measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Merton76_j} = f_{BS_j} \exp\left(\lambda_p \tau (1 + \mu_j)^{mj} + \frac{1}{2} \left[ (1 + \mu_j)^i \phi e^{\delta^2 \left( m_j i \phi + \frac{(i\phi)^2}{2} \right)} - 1 \right] - \lambda_p \tau \mu_j i \phi \right)$$

where for  $j = 1, 2$ :

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS_2}(\phi) = \exp\left(i\phi \left[ \ln S_t + \left( r - q - \frac{\sigma^2}{2} \right) \tau \right] - \frac{\phi^2 \sigma^2}{2} \tau \right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

where

$\phi$  is the characteristic function variable

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

### Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \operatorname{Re} \left[ \frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$

$i$  is a unit imaginary number ( $i^2 = -1$ )

$\phi$  is the characteristic function variable.

$f_j(\phi)$  is the characteristic function for  $P_j$  ( $j = 1, 2$ ).

$P_1$  is the probability of  $S_t > K$  under the asset price measure for the model.

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

Where  $j = 1, 2$  so that  $f_1(\phi)$  and  $f_2(\phi)$  are the characteristic functions for probabilities  $P_1$  and  $P_2$ , respectively.

This framework is chosen with the default value "Heston1993" for the Framework name-value pair argument.

### Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K} e^{-r\tau}}{\pi} \int_0^{\infty} \operatorname{Re} \left[ K^{-iu} f_2 \left( \phi = \left( u - \frac{i}{2} \right) \frac{1}{u^2 + \frac{1}{4}} \right) \right] du$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$

$i$  is a unit imaginary number ( $i^2 = -1$ )

$\phi$  is the characteristic function variable.

$u$  is the characteristic function variable for integration, where  $\phi = \left(u - \frac{i}{2}\right)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

This framework is chosen with the value "Lewis2001" for the Framework name-value pair argument.

## optSensByMertonNI

Option price and sensitivities by Merton76 model using numerical integration

### Syntax

```
PriceSens = optSensByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,
Sigma,MeanJ,JumpVol,JumpFreq)
PriceSens = optSensByMertonNI( ____,Name,Value)
```

### Description

`PriceSens = optSensByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike, Sigma,MeanJ,JumpVol,JumpFreq)` computes vanilla European option price and sensitivities by the Merton76 model, using numerical integration.

`PriceSens = optSensByMertonNI( ____,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Workflow for Plotting an Option Sensitivity Surface Using the Merton76 Model

`optSensByMertonNI` uses numerical integration to compute option sensitivities and then plot option sensitivity surfaces.

#### Define Option Variables and Merton76 Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';
```

```
Sigma = 0.16;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

#### Compute the Option Sensitivity for a Single Strike

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = 80;
```

```
Delta = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta")
```

```
Delta = 0.5283
```

## Compute the Option Sensitivities for a Vector of Strikes

The Strike input can be a vector.

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';
```

```
Delta = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta")
```

```
Delta = 5×1
```

```
0.6727
0.6013
0.5283
0.4565
0.3883
```

## Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the Strike input to specify the strikes. Also, the Maturity input can be a vector, but it must match the length of the Strike vector if the ExpandOutput name-value pair argument is not set to "true".

```
Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes
```

```
Delta = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta")
```

```
Delta = 5×1
```

```
0.6419
0.5907
0.5565
0.5311
0.5110
```

```
% Five values in vector output
```

## Expand the Output for a Surface

Set the ExpandOutput name-value pair argument to "true" to expand the output into a NStrikes-by-NMaturities matrix. In this case, it is a square matrix.

```
Delta = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true) % (5 x 5) matrix output
```

```
Delta = 5×5
```

```
0.6419    0.6305    0.6245    0.6204    0.6173
```

```

0.5922    0.5907    0.5905    0.5905    0.5905
0.5422    0.5507    0.5565    0.5607    0.5637
0.4927    0.5112    0.5229    0.5311    0.5372
0.4447    0.4725    0.4898    0.5020    0.5110

```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is "true", `NStrikes` do not have to match `NMaturities`. That is, the output `NStrikes-by-NMaturities` matrix can be rectangular.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*(0.5:0.5:3)); % Six maturities
Strike = (76:2:84)'; % Five strikes

Delta = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true) % (5 x 6) matrix output

```

Delta = 5x6

```

0.6727    0.6419    0.6305    0.6245    0.6204    0.6173
0.6013    0.5922    0.5907    0.5905    0.5905    0.5905
0.5283    0.5422    0.5507    0.5565    0.5607    0.5637
0.4565    0.4927    0.5112    0.5229    0.5311    0.5372
0.3883    0.4447    0.4725    0.4898    0.5020    0.5110

```

### Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is "true", the output can also be a `NStrikes-by-NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta = optSensByMertonNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true) % (5 x 4) matrix output

```

Delta = 5x4

```

0.3796    0.5157    0.6419    0.7472
0.3315    0.4637    0.5922    0.7043
0.2874    0.4137    0.5422    0.6592
0.2474    0.3664    0.4927    0.6128
0.2117    0.3224    0.4447    0.5657

```

### Plot Option Sensitivity Surfaces

The `Strike` and `Maturity` inputs can be vectors. Set `ExpandOutput` to "true" to output the surfaces as `NStrikes-by-NMaturities` matrices.

```

Settle = datenum('29-Jun-2017');
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]);

```

```

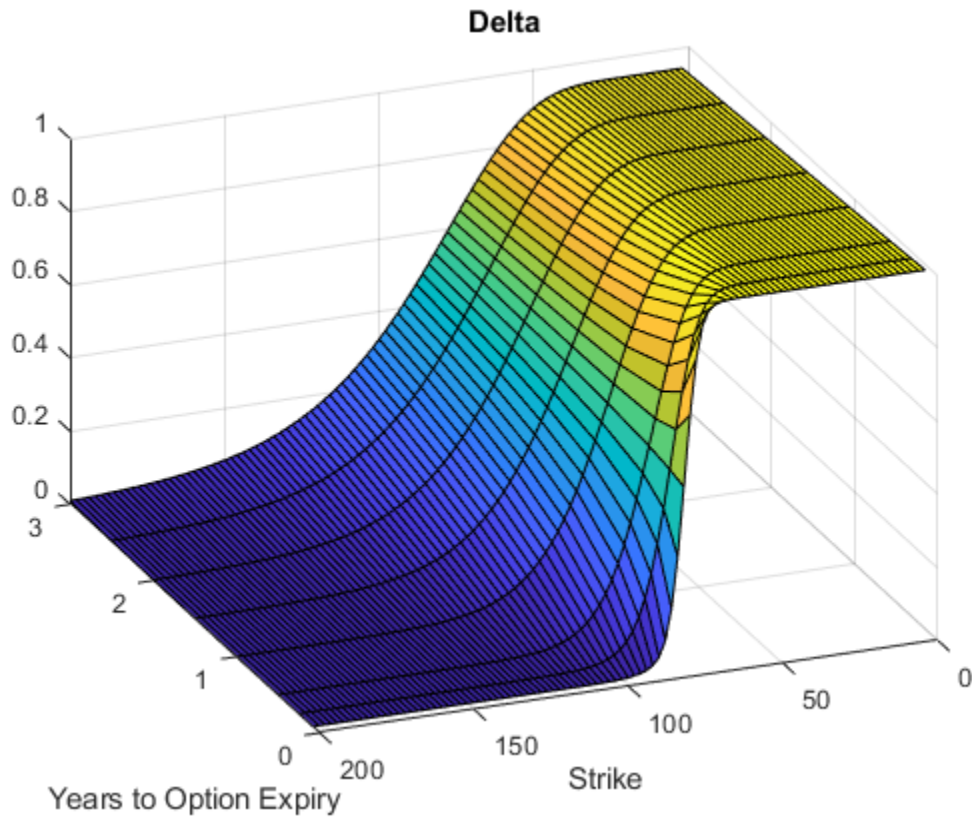

Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

[Delta, Gamma, Rho, Theta, Vega] = optSensByMertonNI(...
    Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', ['delta', 'gamma', 'rho', 'theta', 'vega'], ...
    'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Delta);
title('Delta');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);

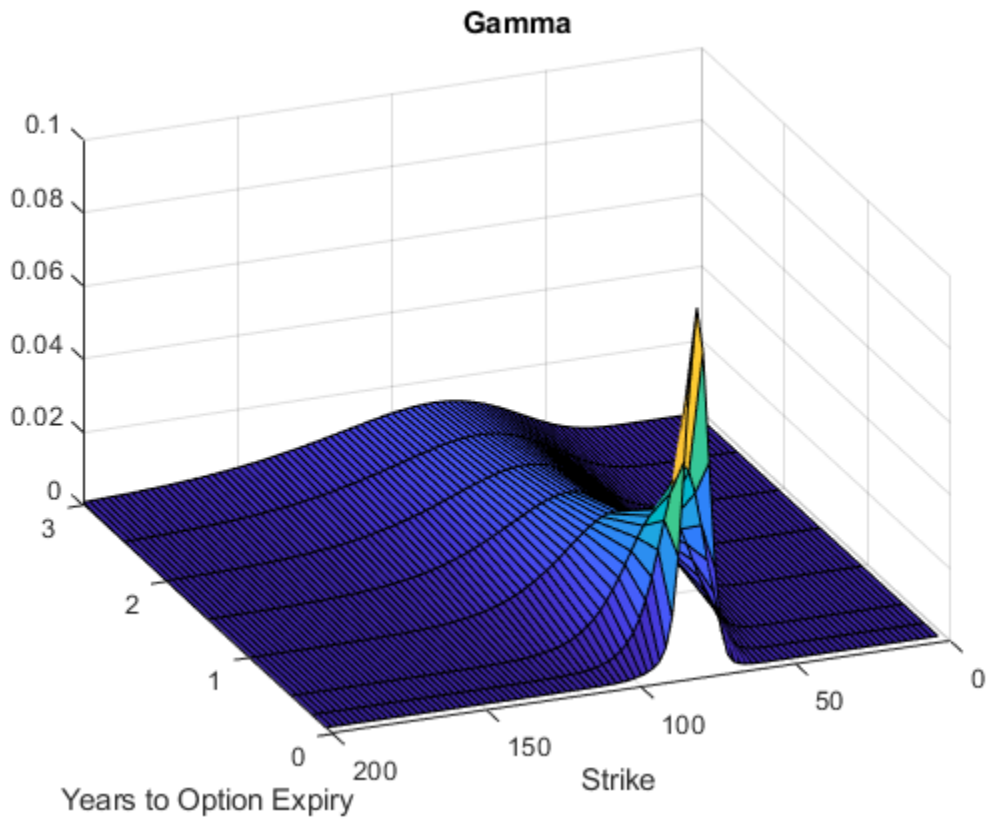

```

```

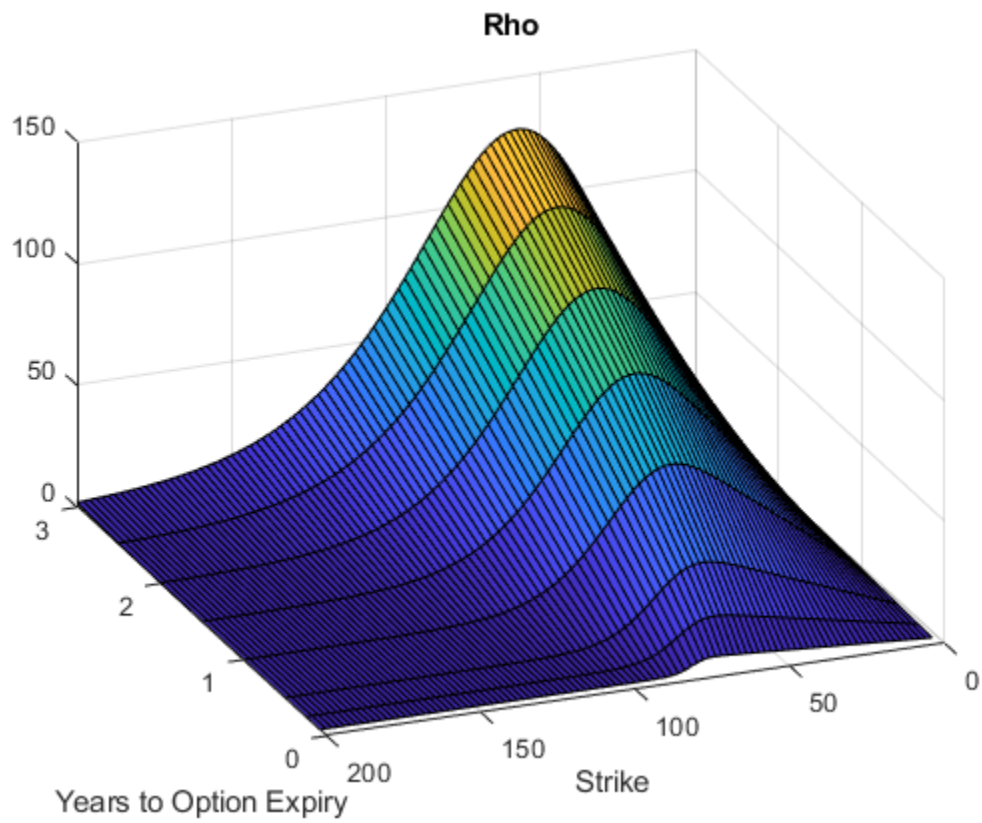

figure;
surf(X,Y,Gamma)
title('Gamma')
xlabel('Years to Option Expiry')
ylabel('Strike')
view(-112,34);
xlim([0 Times(end)]);

```

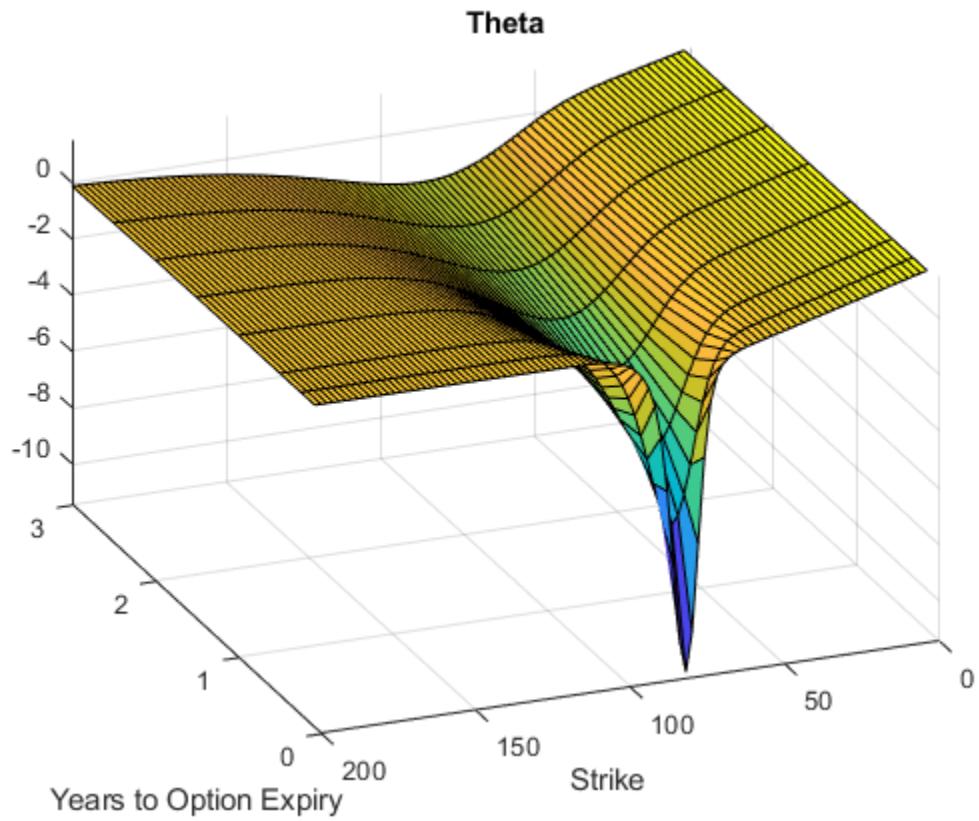

```
figure;  
surf(X,Y,Rho)  
title('Rho')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

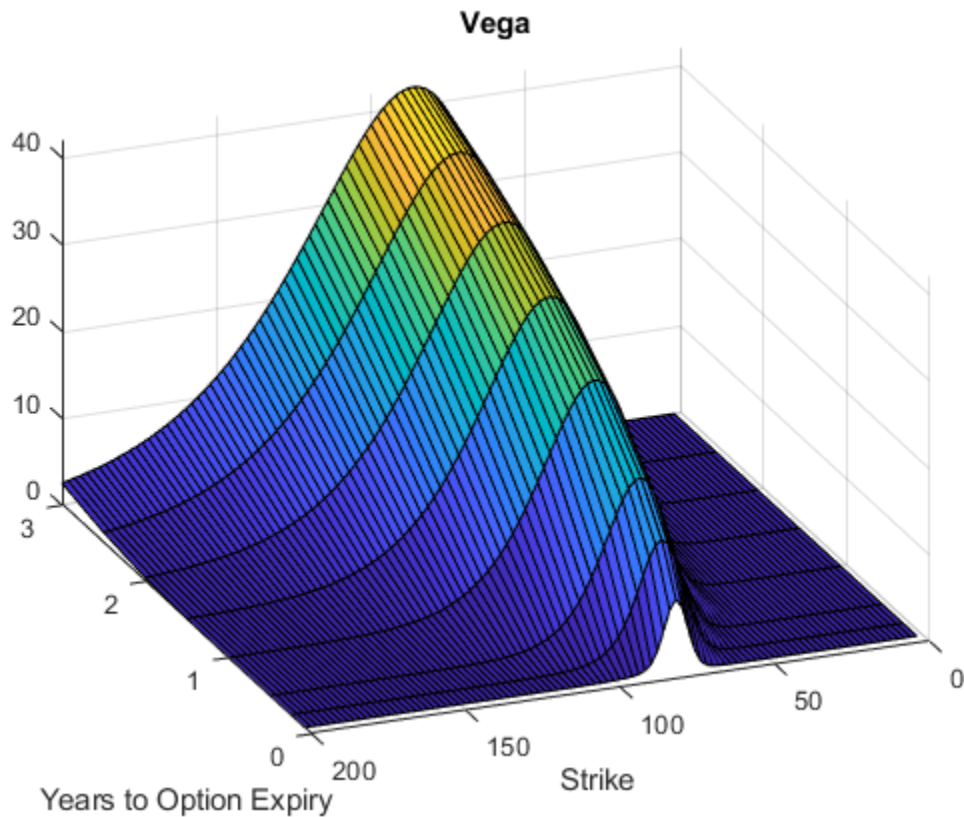

```
figure;  
surf(X,Y,Theta)  
title('Theta')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

```
figure;  
surf(X,Y,Vega)  
title('Vega')  
xlabel('Years to Option Expiry')  
ylabel('Strike')  
view(-112,34);  
xlim([0 Times(end)]);
```

## Input Arguments

### Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

### AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST-by-1` or `NColumns-by-1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### Settle — Option settlement date

serial date number | date character vector | datetime | string array

Option settlement date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, datetime arrays, or string arrays. The `Settle` date must be before the `Maturity` date.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **Maturity — Option maturity date**

serial date number | date character vector | `datetime` | string array

Option maturity date, specified as a `NINST-by-1` or `NColumns-by-1` vector using serial date numbers, date character vectors, `datetime` arrays, or string arrays.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

Data Types: `double` | `char` | `datetime` | `string`

### **OptSpec — Definition of option**

cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a `NINST-by-1` or `NColumns-by-1` vector using a cell array of character vectors or string arrays with values 'call' or 'put'.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

### **Strike — Option strike price value**

numeric

Option strike price value, specified as a `NINST-by-1`, `NRows-by-1`, `NRows-by-NColumns` vector of strike prices.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

### **Sigma — Volatility of underlying asset**

numeric

Volatility of the underling asset, specified as a scalar numeric value.

Data Types: `double`

### **MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), specified as a scalar decimal value where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation `JumpVol`.

Data Types: `double`

### **JumpVol — Standard deviation of $\log(1+J)$**

decimal

Standard deviation of  $\log(1+J)$  where  $J$  is the random percentage jump size, specified as a scalar decimal value.

Data Types: double

### **JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: `Price =`

```
optSensByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,Sigma,MeanJ,
JumpVol,JumpFreq,'Basis',7)
```

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **DividendYield — Continuously compounded underlying asset yield**

0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

### OutSpec — Define outputs

["price"] (default) | string array with values "price", "delta", "gamma", "vega", "rho", and "theta" | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', and 'theta'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT string array or cell array of character vectors with supported values.

---

**Note** "vega" is the sensitivity with respect the initial volatility  $\sqrt{V_0}$ .

---

Example: OutSpec = ["price","delta","gamma","vega","rho","theta"]

Data Types: string | cell

### AbsTol — Absolute error tolerance for numerical integration

1e-10 (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of 'AbsTol' and a scalar numeric value.

Data Types: double

### RelTol — Relative error tolerance for numerical integration

1e-6 (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of 'RelTol' and a scalar numeric value.

Data Types: double

### IntegrationRange — Numerical integration range used to approximate continuous integral over [0 Inf]

[1e-9 Inf] (default) | vector

Numerical integration range used to approximate the continuous integral over [0 Inf], specified as the comma-separated pair consisting of 'IntegrationRange' and a 1-by-2 vector representing [LowerLimit UpperLimit].

Data Types: double

### Framework — Framework for computing option prices and sensitivities using numerical integration of models

"heston1993" (default) | string with values "heston1993" or "lewis2001" | character vector with values 'heston1993' or 'lewis2001'

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of 'Framework' and a scalar string or character vector with the following values:

- "heston1993" or 'heston1993' — Method used in Heston (1993)
- "lewis2001" or 'lewis2001' — Method used in Lewis (2001)

Data Types: char | string

**ExpandOutput — Flag to expand the outputs**

false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- **true** — If true, the outputs are NRows-by- NColumns matrices. NRows is the number of strikes for each column and it is determined by the Strike input. For example, Strike can be a NRows-by-1 vector, or a NRows-by-NColumns matrix. NColumns is determined by the sizes of AssetPrice, Settle, Maturity, and OptSpec, which must all be either scalar or NColumns-by-1 vectors.
- **false** — If false, the outputs are NINST-by-1 vectors. Also, the inputs Strike, AssetPrice, Settle, Maturity, and OptSpec must all be either scalar or NINST-by-1 vectors.

Data Types: logical

**Output Arguments****PriceSens — Option prices or sensitivities**

numeric

Option prices or sensitivities, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput. The name-value pair argument OutSpec determines the types and order of the outputs.

**More About****Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

**Merton Jump Diffusion Model**

The Merton jump diffusion model (Merton (1976)) is a different extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + JS_t dP_t$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$W_t$  is the Weiner process.

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

$\sigma$  is the volatility of the asset price for ( $\sigma > 0$ ).

The characteristic function  $f_{Merton76_j}(\phi)$  for  $j = 1$  (asset prices measure) and  $j = 2$  (risk-neutral measure) is:

$$f_{Merton76_j} = f_{BS_j} \exp\left(\lambda_p \tau (1 + \mu_j)^{m_j} + \frac{1}{2} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 \left(m_j i\phi + \frac{(i\phi)^2}{2}\right)} - 1 \right] - \lambda_p \tau \mu_j i\phi\right)$$

where for  $j = 1, 2$ :

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS_2}(\phi) = \exp\left(i\phi \left[\ln S_t + \left(r - q - \frac{\sigma^2}{2}\right)\tau\right] - \frac{\phi^2 \sigma^2}{2} \tau\right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

where

$\phi$  is the characteristic function variable.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

### Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$\begin{aligned} Call(K) &= S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2 \\ Put(K) &= Call(K) + K e^{-r\tau} - S_t e^{-q\tau} \\ P_j &= \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \operatorname{Re} \left[ \frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi \end{aligned}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$f_j(\phi)$  is the characteristic function for  $P_j$  ( $j = 1, 2$ ).

$P_1$  is the probability of  $S_t > K$  under the asset price measure for the model.

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

Where  $j = 1, 2$  so that  $f_1(\phi)$  and  $f_2(\phi)$  are the characteristic functions for probabilities  $P_1$  and  $P_2$ , respectively.

This framework is chosen with the default value "Heston1993" for the Framework name-value pair argument.

### Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$\begin{aligned} Call(k) &= S_t e^{-q\tau} - \frac{\sqrt{K} e^{-r\tau}}{\pi} \int_0^{\infty} \operatorname{Re} \left[ K^{-iu} f_2 \left( \phi = \left( u - \frac{i}{2} \right) \frac{1}{u^2 + \frac{1}{4}} \right) \right] du \\ Put(K) &= Call(K) + K e^{-r\tau} - S_t e^{-q\tau} \end{aligned}$$

where

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$u$  is the characteristic function variable for integration, where  $\phi = \left(u - \frac{i}{2}\right)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

This framework is chosen with the value "Lewis2001" for the Framework name-value pair argument.

## optembndbybdt

Price bonds with embedded options by Black-Derman-Toy interest-rate tree

### Syntax

```
[Price,PriceTree] = optembndbybdt(BDTree,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optembndbybdt( ____,Name,Value)
```

### Description

[Price,PriceTree] = optembndbybdt(BDTree,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates) calculates price for bonds with embedded options from a Black-Derman-Toy interest-rate tree and returns exercise probabilities in PriceTree.

optembndbybdt computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1290.

[Price,PriceTree] = optembndbybdt( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price a Callable Bond Using a BDT Interest-Rate Tree Model

Create a BDTree with the following data:

```
ZeroRates = [ 0.035;0.04;0.045];
Compounding = 1;
StartDates = ['jan-1-2007';'jan-1-2008';'jan-1-2009'];
EndDates = ['jan-1-2008';'jan-1-2009';'jan-1-2010'];
ValuationDate = 'jan-1-2007';
```

Create a RateSpec.

```
RateSpec = intenvset('Rates', ZeroRates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [3x1 double]
    Rates: [3x1 double]
    EndTimes: [3x1 double]
    StartTimes: [3x1 double]
    EndDates: [3x1 double]
    StartDates: 733043
    ValuationDate: 733043
    Basis: 0
```

```
EndMonthRule: 1
```

Create a VolSpec.

```
Volatility = 0.10 * ones (3,1);
VolSpec = bdtvolspec(ValuationDate, EndDates, Volatility)
```

```
VolSpec = struct with fields:
    FinObj: 'BDTVolSpec'
    ValuationDate: 733043
    VolDates: [3x1 double]
    VolCurve: [3x1 double]
    VolInterpMethod: 'linear'
```

Create a TimeSpec.

```
TimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
```

Build the BDTTree.

```
BDTTree = bdttree(VolSpec, RateSpec, TimeSpec)
```

```
BDTTree = struct with fields:
    FinObj: 'BDTFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2]
    dObs: [733043 733408 733774]
    TFwd: {[3x1 double] [2x1 double] [2]}
    CFwdT: {[3x1 double] [2x1 double] [3]}
    FwdTree: {[1.0350] [1.0406 1.0495] [1.0447 1.0546 1.0667]}
```

To compute the price of an American callable bond that pays a 5.25% annual coupon, matures in Jan-1-2010, and is callable on Jan-1-2008 and 01-Jan-2010.

```
BondSettlement = 'jan-1-2007';
BondMaturity = 'jan-1-2010';
CouponRate = 0.0525;
Period = 1;
OptSpec = 'call';
Strike = [100];
ExerciseDates = {'jan-1-2008' '01-Jan-2010'};
AmericanOpt = 1;
```

```
PriceCallBond = optembndbybdt(BDTTree, CouponRate, BondSettlement, BondMaturity,...
    OptSpec, Strike, ExerciseDates, 'Period', 1, 'AmericanOp', 1)
```

```
PriceCallBond = 101.4750
```

### Obtain Callable Bond Exercise Information Using a BDT Interest-Rate Tree Model

Create a BDTTree with the following data:

```
ZeroRates = [ 0.025;0.03;0.045];
Compounding = 1;
StartDates = ['jan-1-2007';'jan-1-2008';'jan-1-2009'];
EndDates = ['jan-1-2008';'jan-1-2009';'jan-1-2010'];
ValuationDate = 'jan-1-2007';
```

Create a RateSpec.

```
RateSpec = intenvset('Rates', ZeroRates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate);
```

Build the BDT tree with the following data.

```
Volatility = 0.10 * ones (3,1);
VolSpec = bdtvolspec(ValuationDate, EndDates, Volatility)
```

```
VolSpec = struct with fields:
    FinObj: 'BDTVolSpec'
    ValuationDate: 733043
    VolDates: [3x1 double]
    VolCurve: [3x1 double]
    VolInterpMethod: 'linear'
```

```
TimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
BDTTree = bdttree(VolSpec, RateSpec, TimeSpec)
```

```
BDTTree = struct with fields:
    FinObj: 'BDTFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2]
    dObs: [733043 733408 733774]
    TFwd: {[3x1 double] [2x1 double] [2]}
    CFLOWT: {[3x1 double] [2x1 double] [3]}
    FwdTree: {[1.0250] [1.0315 1.0385] [1.0614 1.0750 1.0917]}
```

Define the callable bond instruments.

```
Settle = '01-Jan-2007';
Maturity = {'01-Jan-2008';'01-Jan-2010'};
CouponRate = {'01-Jan-2008' .0425;'01-Jan-2010' .0450};
OptSpec='call';
Strike= [86;90];
ExerciseDates= {'01-Jan-2008';'01-Jan-2010'};
```

Price the instruments.

```
[Price, PriceTree]= optembndbybdt(BDTTree, CouponRate, Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', 1,'AmericanOp', 1)
```

```
Price = 2x1
```

```
86
90
```

```

PriceTree = struct with fields:
    FinObj: 'BDTPriceTree'
    tObs: [0 1 2 3]
    PTree: {1x4 cell}
    ProbTree: {1x4 cell}
    ExTree: {1x4 cell}
    ExProbTree: {1x4 cell}
    ExProbsByTreeLevel: [2x4 double]

```

Examine the output `PriceTree.ExTree`. `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it is not.

```
PriceTree.ExTree{4}
```

```
ans = 2x3
```

```

0     0     0
1     1     1

```

There is no exercise for instrument 1 and instrument 2 is exercised at all nodes.

```
PriceTree.ExTree{3}
```

```
ans = 2x3
```

```

0     0     0
0     0     0

```

There is no exercise for instrument 1 or instrument 2.

```
PriceTree.ExTree{2}
```

```
ans = 2x2
```

```

1     1
1     0

```

There is exercise for instrument 1 at all nodes and instrument 2 is exercised at some nodes.

Next view the probability of reaching each node from the root node using `PriceTree.ProbTree`.

```
PriceTree.ProbTree{2}
```

```
ans = 1x2
```

```
0.5000    0.5000
```

```
PriceTree.ProbTree{3}
```

```
ans = 1x3
```

```
0.2500    0.5000    0.2500
```

```
PriceTree.ProbTree{4}
```

```
ans = 1×3
```

```
0.2500    0.5000    0.2500
```

Then view the exercise probabilities using `PriceTree.ExProbTree`. `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceTree.ExProbTree{4}
```

```
ans = 2×3
```

```
      0      0      0
0.2500  0.5000  0.2500
```

```
PriceTree.ExProbTree{3}
```

```
ans = 2×3
```

```
      0      0      0
      0      0      0
```

```
PriceTree.ExProbTree{2}
```

```
ans = 2×2
```

```
0.5000    0.5000
0.5000         0
```

View the exercise probabilities at each tree level using `PriceTree.ExProbsByTreeLevel`. `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

```
PriceTree.ExProbsByTreeLevel
```

```
ans = 2×4
```

```
1.0000    1.0000         0         0
1.0000    0.5000         0    1.0000
```

### Price Single Stepped Callable Bonds Using a BDT Interest-Rate Tree Model

Price the following single stepped callable bonds using the following data: The data for the interest rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2010';
StartDates = ValuationDate;
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'};
```

```

Compounding = 1;

% Create RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% Instrument
Settle = '01-Jan-2010';
Maturity = {'01-Jan-2013'; '01-Jan-2014'};
CouponRate = {'01-Jan-2012' .0425; '01-Jan-2014' .0750};
OptSpec='call';
Strike=100;
ExerciseDates='01-Jan-2012'; %Callable in two years

% Build the tree
% Assume the volatility to be 10%
Sigma = 0.1;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates)));
BDTT = bdttree(BDTVolSpec, RS, BDTTimeSpec);

% The first row corresponds to the price of the callable bond with maturity
% of three years. The second row corresponds to the price of the callable bond
% with maturity of four years.
PBDT= optembndbybdt(BDTT, CouponRate, Settle, Maturity ,OptSpec, Strike,...
ExerciseDates, 'Period', 1)

PBDT = 2×1

    100.0945
    100.0297

```

### Price a Sinking Fund Bond Using a BDT Interest-Rate Tree Model

A corporation issues a three year bond with a sinking fund obligation requiring the company to sink 1/3 of face value after the first year and 1/3 after the second year. The company has the option to buy the bonds in the market or call them at \$98. The following data describes the details needed for pricing the sinking fund bond:

```

Rates = [0.1;0.1;0.1;0.1];
ValuationDate = 'Jan-1-2011';
StartDates = ValuationDate;
EndDates = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
Compounding = 1;

% Create RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% Build the BDT tree
% Assume the volatility to be 10%
Sigma = 0.1;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates)));

```

```

BDTT = bdttree(BDTVolspec, RateSpec, BDTTimeSpec);

% Instrument
% The bond has a coupon rate of 9%, a period of one year and matures in
% 1-Jan-2014. Face decreases 1/3 after the first year and 1/3 after the
% second year.
CouponRate = 0.09;
Settle = 'Jan-1-2011';
Maturity = 'Jan-1-2014';
Period = 1;
Face = { ...
        {'Jan-1-2012' 100; ...
         'Jan-1-2013' 66.6666; ...
         'Jan-1-2014' 33.3333};
};

% Option provision
OptSpec = 'call';
Strike = [98 98];
ExerciseDates = {'Jan-1-2012', 'Jan-1-2013'};

% Price of non-sinking fund bond.
PNSF = bondbybdt(BDTT, CouponRate, Settle, Maturity, Period)

PNSF = 97.5131

Price of the bond with the option sinking provision.

PriceSF = optembndbybdt(BDTT, CouponRate, Settle, Maturity, ...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face)

PriceSF = 96.8364

```

### Price an Amortizing Callable Bond Using a BDT Interest-Rate Tree Model

This example shows how to price an amortizing callable bond and a vanilla callable bond using a BDT lattice model.

Create a RateSpec.

```

Rates = [0.025;0.028;0.030;0.031];
ValuationDate = 'Jan-1-2018';
StartDates = ValuationDate;
EndDates = {'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'; 'Jan-1-2022'};
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

```

Build a BDT tree and assume a volatility of 5%.

```

Sigma = 0.05;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
BDTVolspec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates)));
BDTT = bdttree(BDTVolspec, RateSpec, BDTTimeSpec);

```

Define the callable bond.

```

CouponRate = 0.05;
Settle = 'Jan-1-2018';
Maturity = 'Jan-1-2021';
Period = 1;

    Face = {
        {'Jan-1-2019' 100;
         'Jan-1-2020' 70; ...
         'Jan-1-2021' 50};
    };

OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates = {'Jan-1-2019' 'Jan-1-2020' 'Jan-1-2021'};

```

Price a callable amortizing bond using the BDT tree.

```

BondType = 'amortizing';
Pcallbonds = optembndbybdt(BDTree, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, ' ');

Pcallbonds = 99.5122

```

## Input Arguments

### BDTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bdtree`.

Data Types: struct

### CouponRate — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

### Settle — Settlement date

serial date number | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

---

**Note** The `Settle` date for every bond is set to the `ValuationDate` of the BDT tree. The bond argument `Settle` is ignored.

---

Data Types: double | char

### Maturity — Maturity date

serial date number | date character vector

Maturity date, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char

#### **OptSpec — Definition of option**

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: char

#### **Strike — Option strike price values**

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

#### **ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

Data Types: double | char

#### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: Price =  
optembndbybdt(BDTree, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'Period', 1, 'AmericanOp', 1)

#### **AmericanOpt — Option type**

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

### **Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.

- **1** = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

**IssueDate — Bond issue date**

serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | char

**FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using serial date numbers date or date character vectors.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char

**LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: char | double

**StartDate — Forward starting date of payments**

serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify StartDate, the effective start date is the Settle date.

Data Types: char | double

**Face — Face value**

100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

---

**Note** Instruments without a Face schedule are treated as either vanilla bonds or stepped coupon bonds with embedded options.

---

Data Types: double

### **BondType — Type of underlying bond**

'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla', 'amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of 'BondType' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.
- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: char | string

### **Options — Derivatives pricing options**

structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with derivset.

Data Types: struct

## **Output Arguments**

### **Price — Expected prices of embedded option at time 0**

matrix

Expected price of the embedded option at time 0, returned as a NINST-by-1 matrix.

### **PriceTree — Structure containing trees of vectors of instrument prices and exercise probabilities for each node**

structure

Structure containing trees of vectors of instrument prices, a vector of observation times for each node, and exercise probabilities. Values are:

- PriceTree.PTree contains the clean prices.
- PriceTree.tObs contains the observation times.
- PriceTree.EXTree contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.
- PriceTree.ProbTree contains the probability of reaching each node from root node.

- `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.
- `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

## More About

### Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

### Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

### Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

### Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

## optembndbybk

Price bonds with embedded options by Black-Karasinski interest-rate tree

### Syntax

```
[Price,PriceTree] = optembndbybk(BKTree,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optembndbybk( ____,Name,Value)
```

### Description

[Price,PriceTree] = optembndbybk(BKTree,CouponRate,Settle,Maturity,OptSpec, Strike,ExerciseDates) calculates price for bonds with embedded options from a Black-Karasinski interest-rate tree and returns exercise probabilities in PriceTree.

optembndbybk computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1303.

[Price,PriceTree] = optembndbybk( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price a Callable Bond Using a BK Interest-Rate Tree Model

Create a BKTREE with the following data:

```
ZeroRates = [ 0.035;0.04;0.045];
Compounding = 1;
StartDates = ['jan-1-2007';'jan-1-2008';'jan-1-2009'];
EndDates = ['jan-1-2008';'jan-1-2009';'jan-1-2010'];
ValuationDate = 'jan-1-2007';
```

Create a RateSpec.

```
RateSpec = intenvset('Rates', ZeroRates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [3x1 double]
    Rates: [3x1 double]
    EndTimes: [3x1 double]
    StartTimes: [3x1 double]
    EndDates: [3x1 double]
    StartDates: 733043
    ValuationDate: 733043
    Basis: 0
```

```
EndMonthRule: 1
```

Create a VolSpec.

```
VolDates = ['jan-1-2008'; 'jan-1-2009'; 'jan-1-2010'];
VolCurve = 0.01;
AlphaDates = 'jan-1-2010';
AlphaCurve = 0.1;
BKVolSpec = bkvolspec(ValuationDate, VolDates, VolCurve, AlphaDates, AlphaCurve)
```

```
BKVolSpec = struct with fields:
    FinObj: 'BKVolSpec'
    ValuationDate: 733043
    VolDates: [3x1 double]
    VolCurve: [3x1 double]
    AlphaCurve: 0.1000
    AlphaDates: 734139
    VolInterpMethod: 'linear'
```

Create a TimeSpec.

```
BKTimeSpec = bktimespec(ValuationDate, EndDates, Compounding);
```

Build the BKTree.

```
BKTree = bktree(BKVolSpec, RateSpec, BKTimeSpec)
```

```
BKTree = struct with fields:
    FinObj: 'BKFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2]
    dObs: [733043 733408 733774]
    CFlowT: {[3x1 double] [2x1 double] [3]}
    Probs: {[3x1 double] [3x3 double]}
    Connect: {[2] [2 3 4]}
    FwdTree: {[1.0350] [1.0458 1.0450 1.0442] [1x5 double]}
```

To compute the price of an American puttable bond that pays an annual coupon of 5.25% , matures on January 1, 2010, and is callable on January 1, 2008 and January 1, 2010.

```
BondSettlement = 'jan-1-2007';
BondMaturity = 'jan-1-2010';
CouponRate = 0.0525;
Period = 1;
OptSpec = 'put';
Strike = [100];
ExerciseDates = {'jan-1-2008' '01-Jan-2010'};
AmericanOpt = 1;
```

```
PricePutBondBK = optembndbybk(BKTree, CouponRate, BondSettlement, BondMaturity,...
    OptSpec, Strike, ExerciseDates, 'Period', 1, 'AmericanOpt', 1)
```

```
PricePutBondBK = 102.3820
```

### Obtain Callable Bond Exercise Information Using a BK Interest-Rate Tree Model

Create a BKTREE with the following data:

```
ZeroRates = [ 0.025;0.03;0.045];
Compounding = 1;
StartDates = ['jan-1-2007';'jan-1-2008';'jan-1-2009'];
EndDates = ['jan-1-2008';'jan-1-2009';'jan-1-2010'];
ValuationDate = 'jan-1-2007';
```

Create a RateSpec.

```
RateSpec = intenvset('Rates', ZeroRates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate);
```

Build the BK tree with the following data.

```
VolDates = ['jan-1-2008';'jan-1-2009';'jan-1-2010'];
VolCurve = 0.01;
AlphaDates = 'jan-1-2010';
AlphaCurve = 0.1;
BKVolspec = bkvolSpec(ValuationDate, VolDates, VolCurve, AlphaDates, AlphaCurve);
```

```
BKTimeSpec = bktimespec(ValuationDate, EndDates, Compounding);
BKTree = bktree(BKVolspec, RateSpec, BKTimeSpec);
```

Define the callable bond instruments.

```
Settle = '01-Jan-2007';
Maturity = {'01-Jan-2008';'01-Jan-2010'};
CouponRate = {'01-Jan-2008' .0315;'01-Jan-2010' .0350};
OptSpec='call';
Strike= [86;90];
ExerciseDates= {'01-Jan-2008';'01-Jan-2010'};
```

Price the instruments.

```
[Price, PriceTree]= optembndbybk(BKTree, CouponRate, Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', 1,'AmericanOp', 1)
```

```
Price = 2x1
```

```
86.0000
88.3060
```

```
PriceTree = struct with fields:
    FinObj: 'BKPriceTree'
    tObs: [0 1 2 3]
    PTree: {1x4 cell}
    ProbTree: {1x4 cell}
    ExTree: {1x4 cell}
    ExProbTree: {1x4 cell}
    ExProbsByTreeLevel: [2x4 double]
    Connect: {[2] [2 3 4]}
```

Examine the output `PriceTree.ExTree`. `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it is not.

```
PriceTree.ExTree{4}
```

```
ans = 2×5
```

```
    0    0    0    0    0
    1    1    1    1    1
```

There is no exercise for instrument 1 and instrument 2 is exercised at all nodes.

```
PriceTree.ExTree{3}
```

```
ans = 2×5
```

```
    0    0    0    0    0
    0    0    0    0    0
```

There is no exercise for instrument 1 or instrument 2.

```
PriceTree.ExTree{2}
```

```
ans = 2×3
```

```
    1    1    1
    0    0    0
```

There is exercise for instrument 1 at all nodes and instrument 2 is not exercised.

Next view the probability of reaching each node from the root node using `PriceTree.ProbTree`.

```
PriceTree.ProbTree{2}
```

```
ans = 1×3
```

```
    0.1667    0.6667    0.1667
```

```
PriceTree.ProbTree{3}
```

```
ans = 1×5
```

```
    0.0203    0.2206    0.5183    0.2206    0.0203
```

```
PriceTree.ProbTree{4}
```

```
ans = 1×5
```

```
    0.0203    0.2206    0.5183    0.2206    0.0203
```

Then view the exercise probabilities using `PriceTree.ExProbTree`. `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceTree.ExProbTree{4}
```

```
ans = 2x5
```

```
      0      0      0      0      0
0.0203  0.2206  0.5183  0.2206  0.0203
```

```
PriceTree.ExProbTree{3}
```

```
ans = 2x5
```

```
      0      0      0      0      0
      0      0      0      0      0
```

```
PriceTree.ExProbTree{2}
```

```
ans = 2x3
```

```
      0.1667  0.6667  0.1667
      0      0      0
```

View the exercise probabilities at each tree level using `PriceTree.ExProbsByTreeLevel`.

`PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

```
PriceTree.ExProbsByTreeLevel
```

```
ans = 2x4
```

```
      1.0000  1.0000      0      0
      0      0      0      1.0000
```

### Price Single Stepped Callable Bonds Using a BK Interest-Rate Tree Model

Price the following single stepped callable bonds using the following data: The data for the interest rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2010';
StartDates = ValuationDate;
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'};
Compounding = 1;

% Create RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% Instrument
Settle = '01-Jan-2010';
Maturity = {'01-Jan-2013'; '01-Jan-2014'};
CouponRate = {'01-Jan-2012' .0425; '01-Jan-2014' .0750};
OptSpec='call';
```

```

Strike=100;
ExerciseDates='01-Jan-2012'; %Callable in two years

% Build the tree with the following data
VolDates = ['1-Jan-2011'; '1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'];
VolCurve = 0.01;
AlphaDates = '01-01-2014';
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RS.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RS, BKTimeSpec);

% The first row corresponds to the price of the callable bond with maturity
% of three years. The second row corresponds to the price of the callable bond
% with maturity of four years.
PBK= optembndbybk(BKT, CouponRate, Settle, Maturity ,OptSpec, Strike,...
ExerciseDates, 'Period', 1)

PBK = 2×1

    100.0945
    100.0945

```

### Price an Amortizing Callable Bond Using a BK Interest-Rate Tree Model

This example shows how to price an amortizing callable bond and a vanilla callable bond using a BK lattice model.

Create a RateSpec.

```

Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

```

Build a BK tree.

```

VolDates = ['1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'];
VolCurve = 0.01;
AlphaDates = '01-01-2016';
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RS.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RS, BKTimeSpec);

```

Define the callable bond.

```

CouponRate = 0.05;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2016';
Period = 1;

    Face = {
        {'Jan-1-2014' 100;
         'Jan-1-2015' 70;
         'Jan-1-2016' 50};
    };

OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates = {'Jan-1-2014' 'Jan-1-2015' 'Jan-1-2016'};

```

Price a callable amortizing bond using the BDT tree.

```

BondType = 'amortizing';
Pcallbonds = optembndbybk(BKT, CouponRate, Settle, Maturity, OptSpec, Strike, ...
ExerciseDates, 'Period', 1, 'Face', Face, 'BondType', BondType)

Pcallbonds = 98.7475

```

## Input Arguments

### BKTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using bktree.

Data Types: struct

### CouponRate — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

### Settle — Settlement date

serial date number | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

---

**Note** The Settle date for every bond is set to the ValuationDate of the BK tree. The bond argument Settle is ignored.

---

Data Types: double | char

### Maturity — Maturity date

serial date number | date character vector

Maturity date, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char

### OptSpec — Definition of option

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: char

### Strike — Option strike price values

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

### ExerciseDates — Option exercise dates

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

Data Types: double | char

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: Price =

```
optembndbybk(BKTree, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'Period', 1, 'AmericanOp', 1)
```

### AmericanOpt — Option type

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

### **Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.

- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

### **IssueDate — Bond issue date**

serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | char

### **FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char

### **LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: char | double

### **StartDate — Forward starting date of payments**

serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify StartDate, the effective start date is the Settle date.

Data Types: char | double

### **Face — Face value**

100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

---

**Note** Instruments without a Face schedule are treated as either vanilla bonds or stepped coupon bonds with embedded options.

---

Data Types: double

### **BondType — Type of underlying bond**

'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla', 'amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of 'BondType' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.
- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: char | string

### **Options — Derivatives pricing options**

structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with derivset.

Data Types: struct

## **Output Arguments**

### **Price — Expected prices of embedded option at time 0**

matrix

Expected price of the embedded option at time 0, returned as a NINST-by-1 matrix.

### **PriceTree — Structure containing trees of vectors of instrument prices and exercise probabilities for each node**

structure

Structure containing trees of vectors of instrument prices, a vector of observation times for each node, and exercise probabilities. Values are:

- PriceTree.PTree contains the clean prices.
- PriceTree.tObs contains the observation times.
- PriceTree.EXTree contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.
- PriceTree.ProbTree contains the probability of reaching each node from root node.

- `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.
- `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

## More About

### Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

### Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

### Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

### Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled Face.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the Face amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

## **Introduced in R2008a**

# optembndbycir

Price bonds with embedded options by Cox-Ingersoll-Ross interest-rate tree

## Syntax

```
[Price,PriceTree] = optembndbycir(CIRTree,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optembndbycir( ____,Name,Value)
```

## Description

[Price,PriceTree] = optembndbycir(CIRTree,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates) calculates price for bonds with embedded options from a Cox-Ingersoll-Ross (CIR) interest-rate tree and returns exercise probabilities in PriceTree.

optembndbycir computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option using a CIR++ model with the Nawalka-Beliaeva (NB) approach. For more information, see “More About” on page 11-1315.

[Price,PriceTree] = optembndbycir( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Price a Callable Bond Using a CIR Interest-Rate Tree

Create a RateSpec using the intenvset function.

```
Rates = [0.025; 0.032; 0.037; 0.042];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a CIR tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Maturity = '01-Jan-2018';
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolSpec(Sigma, Alpha, Theta);
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
    FinObj: 'CIRFwdTree'
    VolSpec: [1x1 struct]
```

```

TimeSpec: [1x1 struct]
RateSpec: [1x1 struct]
    tObs: [0 0.2500 0.5000 0.7500]
    dObs: [736696 736787 736878 736969]
FwdTree: {[1.0062] [1.0090 1.0062 1.0039] [1x5 double] [1x7 double]}
Connect: {[3x1 double] [3x3 double] [3x5 double]}
Probs: {[3x1 double] [3x3 double] [3x5 double]}

```

Define the bond with embedded option instrument.

```

BondSettlement = 'Jan-1-2017';
BondMaturity   = 'Jan-1-2020';
CouponRate    = 0.035;
Period        = 1;
OptSpec       = 'put';
Strike        = 100;
ExerciseDates = {'Jan-1-2018' '01-Jan-2019'};

```

Price the bond.

```

[Price,PriceTree] = optembndbycir(CIRT,CouponRate,BondSettlement,BondMaturity,OptSpec,...
Strike,ExerciseDates,'AmericanOpt',1,'Period',1)

```

```
Price = 103.3099
```

```

PriceTree = struct with fields:
    FinObj: 'CIRPriceTree'
    tObs: [0 0.2500 0.5000 0.7500 1]
    PTree: {1x5 cell}
    ProbTree: {1x5 cell}
    ExTree: {1x5 cell}
    ExProbTree: {1x5 cell}
    ExProbsByTreeLevel: [0 0 0 0 0.3089]
    Connect: {[3x1 double] [3x3 double] [3x5 double]}

```

### Obtain Callable Bond Exercise Information Using a CIR Interest-Rate Tree Model

Create a CIRTree with the following data:

```

Rates = [0.025; 0.027; 0.028; 0.03];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;

```

Create a RateSpec.

```

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

```

Build the CIR tree with the following data.

```

NumPeriods = length(EndDates);
Alpha = 0.03;

```

```

Theta = 0.02;
Sigma = 0.1;
Maturity = '01-Jan-2018';
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec);

```

Define the callable bond instruments.

```

Settle = '01-Jan-2017';
Maturity = {'01-Jan-2018'; '01-Jan-2020'};
CouponRate = {'01-Jan-2019' .0325; '01-Jan-2020' .0375};
OptSpec='call';
Strike= [100;110];
ExerciseDates= {'01-Jan-2018'; '01-Jan-2020'};

```

Price the instruments.

```

[Price, PriceTree]= optembndbycir(CIRT, CouponRate, Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', 1, 'AmericanOpt', 1)

```

```
Price = 2x1
```

```

    98.1718
   102.6458

```

```
PriceTree = struct with fields:
```

```

    FinObj: 'CIRPriceTree'
      tObs: [0 0.2500 0.5000 0.7500 1]
      PTree: {1x5 cell}
    ProbTree: {1x5 cell}
      ExTree: {1x5 cell}
    ExProbTree: {1x5 cell}
  ExProbsByTreeLevel: [2x5 double]
      Connect: {[3x1 double] [3x3 double] [3x5 double]}

```

Examine the output `PriceTree.ExTree`. `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it is not.

```
PriceTree.ExTree{4}
```

```
ans = 2x7
```

```

    0    0    0    0    0    0    0
    0    0    0    0    0    0    0

```

There is no exercise for instrument 1 or instrument 2.

```
PriceTree.ExTree{3}
```

```
ans = 2x5
```

```

    0    0    0    0    0
    0    0    0    0    0

```

There is no exercise for instrument 1 or instrument 2.

```
PriceTree.ExTree{2}
```

```
ans = 2×3
```

```
  0    0    0
  0    0    0
```

There is exercise for instrument 1 or instrument 2.

Next view the probability of reaching each node from the root node using `PriceTree.ProbTree`.

```
PriceTree.ProbTree{2}
```

```
ans = 1×3
```

```
 0.2794  0.3750  0.3456
```

```
PriceTree.ProbTree{3}
```

```
ans = 1×5
```

```
 0.0786  0.2095  0.3318  0.2592  0.1209
```

```
PriceTree.ProbTree{4}
```

```
ans = 1×7
```

```
 0.0222  0.0885  0.1982  0.2678  0.2442  0.1360  0.0432
```

Then view the exercise probabilities using `PriceTree.ExProbTree`. `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceTree.ExProbTree{4}
```

```
ans = 2×7
```

```
  0    0    0    0    0    0    0
  0    0    0    0    0    0    0
```

```
PriceTree.ExProbTree{3}
```

```
ans = 2×5
```

```
  0    0    0    0    0
  0    0    0    0    0
```

```
PriceTree.ExProbTree{2}
```

```
ans = 2×3
```

```
  0    0    0
```

```
0 0 0
```

View the exercise probabilities at each tree level using `PriceTree.ExProbsByTreeLevel`. `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

```
PriceTree.ExProbsByTreeLevel
```

```
ans = 2x5
```

```
0 0 0 0 0
0 0 0 0 0
```

### Price a Callable Bond Using a CIR Interest-Rate Tree

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.025; 0.032; 0.037; 0.042];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates', EndDates);
```

Create a CIR tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Maturity = '01-Jan-2018';
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolSpec(Sigma, Alpha, Theta);
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)

CIRT = struct with fields:
    FinObj: 'CIRFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 0.2500 0.5000 0.7500]
    dObs: [736696 736787 736878 736969]
    FwdTree: {[1.0062] [1.0090 1.0062 1.0039] [1x5 double] [1x7 double]}
    Connect: {[3x1 double] [3x3 double] [3x5 double]}
    Probs: {[3x1 double] [3x3 double] [3x5 double]}
```

Define the bond with embedded option instrument.

```
BondSettlement = 'Jan-1-2017';
BondMaturity = 'Jan-1-2020';
CouponRate = 0.035;
Period = 1;
```

```
OptSpec = 'put';
Strike = 100;
ExerciseDates = {'Jan-1-2018' '01-Jan-2019'};
```

Price the bond.

```
[Price,PriceTree] = optembndbycir(CIRT,CouponRate,BondSettlement,BondMaturity,OptSpec,...
Strike,ExerciseDates,'AmericanOpt',1,'Period',1)
```

```
Price = 103.3099
```

```
PriceTree = struct with fields:
    FinObj: 'CIRPriceTree'
    tObs: [0 0.2500 0.5000 0.7500 1]
    PTree: {1x5 cell}
    ProbTree: {1x5 cell}
    ExTree: {1x5 cell}
    ExProbTree: {1x5 cell}
    ExProbsByTreeLevel: [0 0 0 0 0.3089]
    Connect: {[3x1 double] [3x3 double] [3x5 double]}
```

## Input Arguments

### CIRTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: struct

### CouponRate — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

### Settle — Settlement date

serial date number | date character vector | string array | datetime

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

---

**Note** The `Settle` date for every bond is set to the `ValuationDate` of the CIR tree. The bond argument `Settle` is ignored.

---

Data Types: double | char | string | datetime

### Maturity — Maturity date

serial date number | date character vector | string array | datetime

Maturity date, specified as a NINST-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

### OptSpec — Definition of option

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put' | string array with value "call" or "put"

Definition of option, specified as a NINST-by-1 cell array of character vectors or string arrays with a value of 'call' or 'put'.

Data Types: char | cell | string

### Strike — Option strike price values

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

### ExerciseDates — Option exercise dates

serial date number | date character vector | string array | datetime

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers, date character vectors, string arrays, or datetime arrays depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

Data Types: double | char | string | datetime

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: [Price, PriceTree] =  
optembndbycir(BDTree, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'Period', 1, 'AmericanOpt', 1)

**AmericanOpt — Option type**

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and an NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

**Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

### **IssueDate — Bond issue date**

serial date number | date character vector | string array | datetime

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: double | char | string | datetime

### **FirstCouponDate — Irregular first coupon date**

serial date number | date character vector | string array | datetime

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using serial date numbers, date character vectors, string arrays, or datetime arrays.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | string | datetime

### **LastCouponDate — Irregular last coupon date**

serial date number | date character vector | string array | datetime

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using serial date numbers, date character vectors, string arrays, or datetime arrays.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: char | double | string | datetime

### **StartDate — Forward starting date of payments**

serial date number | date character vector | string array | datetime

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using serial date numbers, date character vectors, string arrays, or datetime arrays.

If you do not specify StartDate, the effective start date is the Settle date.

Data Types: char | double | string | datetime

### **Face — Face value**

100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

---

**Note** Instruments without a Face schedule are treated as either vanilla bonds or stepped coupon bonds with embedded options.

---

Data Types: double

### BondType — Type of underlying bond

'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla', 'amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of 'BondType' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.
- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: char | string

## Output Arguments

### Price — Expected prices of embedded option at time 0

matrix

Expected price of the embedded option at time 0, returned as a NINST-by-1 matrix.

### PriceTree — Structure containing trees of vectors of instrument prices and exercise probabilities for each node

structure

Structure containing trees of vectors of instrument prices, a vector of observation times for each node, and exercise probabilities. Values are:

- PriceTree.tObs contains the observation times.
- PriceTree.PTree contains the clean prices.
- PriceTree.Connect contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are NumNodes elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- PriceTree.ExTree contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.

- `PriceTree.ProbTree` contains the probability of reaching each node from root node.
- `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.
- `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

## More About

### Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

### Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (calls and puts).

### Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

### Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled Face.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the Face amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

## Introduced in R2018a

# optembndbyhjm

Price bonds with embedded options by Heath-Jarrow-Morton interest-rate tree

## Syntax

```
[Price,PriceTree] = optembndbyhjm(HJMTTree,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optembndbyhjm( ____,Name,Value)
```

## Description

[Price,PriceTree] = optembndbyhjm(HJMTTree,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates) calculates price for bonds with embedded options from a Heath-Jarrow-Morton interest-rate tree and returns exercise probabilities in PriceTree.

optembndbyhjm computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1330.

[Price,PriceTree] = optembndbyhjm( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Price a Callable Bond Using an HJM Interest-Rate Tree Model

Create a HJMTTree with the following data:

```
Rates = [0.05;0.06;0.07];
Compounding = 1;
StartDates = ['jan-1-2007';'jan-1-2008';'jan-1-2009'];
EndDates = ['jan-1-2008';'jan-1-2009';'jan-1-2010'];
ValuationDate = 'jan-1-2007';
```

Create a RateSpec.

```
RateSpec = intenvset('Rates', Rates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [3x1 double]
    Rates: [3x1 double]
    EndTimes: [3x1 double]
    StartTimes: [3x1 double]
    EndDates: [3x1 double]
    StartDates: 733043
    ValuationDate: 733043
    Basis: 0
```

```
EndMonthRule: 1
```

Create a VolSpec.

```
VolSpec = hjmvolspec('Constant', 0.01)
```

```
VolSpec = struct with fields:
    FinObj: 'HJMVolSpec'
    FactorModels: {'Constant'}
    FactorArgs: {{1x1 cell}}
    SigmaShift: 0
    NumFactors: 1
    NumBranch: 2
    PBranch: [0.5000 0.5000]
    Fact2Branch: [-1 1]
```

Create a TimeSpec.

```
TimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding)
```

```
TimeSpec = struct with fields:
    FinObj: 'HJMTimeSpec'
    ValuationDate: 733043
    Maturity: [3x1 double]
    Compounding: 1
    Basis: 0
    EndMonthRule: 1
```

Build the HJMTree.

```
HJMTree = hjmtree(VolSpec, RateSpec, TimeSpec)
```

```
HJMTree = struct with fields:
    FinObj: 'HJMTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    t0bs: [0 1 2]
    d0bs: [733043 733408 733774]
    TFwd: {[3x1 double] [2x1 double] [2]}
    CFlowT: {[3x1 double] [2x1 double] [3]}
    FwdTree: {[3x1 double] [2x1x2 double] [1x2x2 double]}
```

To compute the price of an American callable bond that pays a 6% annual coupon and matures and is callable on January 1, 2010.

```
BondSettlement = 'jan-1-2007';
BondMaturity = 'jan-1-2010';
CouponRate = 0.06;
Period = 1;
OptSpec = 'call';
Strike = [98];
ExerciseDates = '01-Jan-2010';
AmericanOpt = 1;
```

```
[PriceCallBond,PT] = optembndbyhjm(HJMTree, CouponRate, BondSettlement, BondMaturity,...
OptSpec, Strike, ExerciseDates, 'Period', 1, 'AmericanOp',1)
```

```
PriceCallBond = 95.9492
```

```
PT = struct with fields:
```

```
    FinObj: 'HJMPriceTree'
      tObs: [0 1 2 3]
      PBush: {1x4 cell}
      ProbBush: {[1] [1x1x2 double] [1x2x2 double] [1x4 double]}
      ExBush: {[0] [1x1x2 double] [1x2x2 double] [1 1 1 1]}
      ExProbBush: {[0] [1x1x2 double] [1x2x2 double] [1x4 double]}
      ExProbsByBushLevel: [0 0 0 1]
```

### Obtain Callable Bond Exercise Information Using a HJM Interest-Rate Tree Model

Create a `HJMTree` with the following data:

```
Rates = [0.05;0.06;0.07];
Compounding = 1;
StartDates = ['jan-1-2007';'jan-1-2008';'jan-1-2009'];
EndDates = ['jan-1-2008';'jan-1-2009';'jan-1-2010'];
ValuationDate = 'jan-1-2007';
```

Create a `RateSpec`.

```
RateSpec = intenvset('Rates', Rates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate);
```

Build the HJM tree with the following data.

```
VolSpec = hjmvolspec('Constant', 0.01);
TimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding);
HJMTree = hjmtree(VolSpec, RateSpec, TimeSpec);
```

Define the callable bond instruments.

```
Settle = '01-Jan-2007';
Maturity = {'01-Jan-2009';'01-Jan-2010'};
CouponRate = {'01-Jan-2009' .0325;'01-Jan-2010' .0375};
OptSpec='call';
Strike= [90;92];
ExerciseDates= {'01-Jan-2009';'01-Jan-2010'};
```

Price the instruments.

```
[Price, PriceTree]= optembndbyhjm(HJMTree, CouponRate, Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', 1, 'AmericanOpt',1)
```

```
Price = 2x1
```

```
86.0874
84.1482
```

```
PriceTree = struct with fields:
    FinObj: 'HJMPriceTree'
    tObs: [0 1 2 3]
    PBush: {1x4 cell}
    ProbBush: {[1] [1x1x2 double] [1x2x2 double] [1x4 double]}
    ExBush: {1x4 cell}
    ExProbBush: {1x4 cell}
    ExProbsByBushLevel: [2x4 double]
```

Examine the output `PriceTree.ExBush`. `PriceTree.ExBush` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it is not.

```
PriceTree.ExBush{4}
```

```
ans = 2x4
```

```
    0    0    0    0
    1    1    1    1
```

There is no exercise for instrument 1 and instrument 2 is exercised at all nodes.

```
PriceTree.ExBush{3}
```

```
ans =
ans(:,:,1) =
```

```
    1    1
    0    0
```

```
ans(:,:,2) =
```

```
    1    1
    0    0
```

There is exercise for instrument 1 at all nodes and no exercise for instrument 2.

```
PriceTree.ExBush{2}
```

```
ans =
ans(:,:,1) =
```

```
    0
    0
```

```
ans(:,:,2) =
```

```
    0
    0
```

There is no exercise for instrument 1 or instrument 2.

Next view the probability of reaching each node from the root node using `PriceTree.ProbBush`.

```
PriceTree.ProbBush{2}
```

```
ans =
ans(:,:,1) =
    0.5000
```

```
ans(:,:,2) =
    0.5000
```

```
PriceTree.ProbBush{3}
```

```
ans =
ans(:,:,1) =
    0.2500    0.2500
```

```
ans(:,:,2) =
    0.2500    0.2500
```

```
PriceTree.ProbBush{4}
```

```
ans = 1x4
    0.2500    0.2500    0.2500    0.2500
```

View the exercise probabilities using `PriceTree.ExProbBush`. `PriceTree.ExProbBush` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceTree.ExProbBush{4}
```

```
ans = 2x4
     0     0     0     0
    0.2500  0.2500  0.2500  0.2500
```

```
PriceTree.ExProbBush{3}
```

```
ans =
ans(:,:,1) =
    0.2500    0.2500
     0         0
```

```
ans(:,:,2) =
    0.2500    0.2500
     0         0
```

```
PriceTree.ExProbBush{2}
```

```
ans =
ans(:,:,1) =
```

```
0
0
```

```
ans(:,:,2) =
```

```
0
0
```

View the exercise probabilities at each tree level using `PriceTree.ExProbsByBushLevel`. `PriceTree.ExProbsByBushLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

```
PriceTree.ExProbsByBushLevel
```

```
ans = 2×4
```

```
0    0    1    0
0    0    0    1
```

### Price Single Stepped Callable Bonds Using an HJM Interest-Rate Tree Model

Price the following single stepped callable bonds using the following data: The data for the interest rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2010';
StartDates = ValuationDate;
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'};
Compounding = 1;

% Create RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% Instrument
Settle = '01-Jan-2010';
Maturity = {'01-Jan-2013'; '01-Jan-2014'};
CouponRate = {'01-Jan-2012' .0425; '01-Jan-2014' .0750};
OptSpec='call';
Strike=100;
ExerciseDates='01-Jan-2012'; %Callable in two years

% Build the tree with the following data
Volatility = [.2; .19; .18; .17];
CurveTerm = [1; 2; 3; 4];
HJMTimeSpec = hjmtimespec(ValuationDate, EndDates);
HJMVolSpec = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
```

```

HJMT = hjmtree(HJMVolspec, RS, HJMTimeSpec);

% The first row corresponds to the price of the callable bond with maturity
% of three years. The second row corresponds to the price of the callable
% bond with maturity of four years.
PHJM= optembndbyhjm(HJMT, CouponRate, Settle, Maturity ,OptSpec, Strike,...
ExerciseDates, 'Period', 1)

PHJM = 2x1

    100.0484
     99.8009

```

### Price a Sinking Fund Bond Using an HJM Interest-Rate Tree Model

A corporation issues a three year bond with a sinking fund obligation requiring the company to sink 1/3 of face value after the first year and 1/3 after the second year. The company has the option to buy the bonds in the market or call them at \$99. The following data describes the details needed for pricing the sinking fund bond:

```

Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2011';
StartDates = ValuationDate;
EndDates = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
Compounding = 1;

```

Create the RateSpec.

```

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)

```

```

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [4x1 double]
    Rates: [4x1 double]
    EndTimes: [4x1 double]
    StartTimes: [4x1 double]
    EndDates: [4x1 double]
    StartDates: 734504
    ValuationDate: 734504
    Basis: 0
    EndMonthRule: 1

```

Build the HJM tree.

```

Sigma = 0.1;
HJMTimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding);
HJMVolspec = hjmvolspec('Constant', Sigma);
HJMT = hjmtree(HJMVolspec, RateSpec, HJMTimeSpec)

HJMT = struct with fields:
    FinObj: 'HJMTree'
    VolSpec: [1x1 struct]

```

```

TimeSpec: [1x1 struct]
RateSpec: [1x1 struct]
  tObs: [0 1 2 3]
  dObs: [734504 734869 735235 735600]
  TFwd: {[4x1 double] [3x1 double] [2x1 double] [3]}
  CFLOWT: {[4x1 double] [3x1 double] [2x1 double] [4]}
  FwdTree: {[4x1 double] [3x1x2 double] [2x2x2 double] [1x4x2 double]}

```

Define the sinking fund instrument. The bond has a coupon rate of 4.5%, a period of one year and matures in 1-Jan-2013. Face decreases 1/3 after the first year.

```

CouponRate = 0.045;
Settle = 'Jan-1-2011';
Maturity = 'Jan-1-2013';
Period = 1;
Face = { {'Jan-1-2012' 100; ...
         'Jan-1-2013' 66.6666}};

```

Define the option provision.

```

OptSpec = 'call';
Strike = 99;
ExerciseDates = 'Jan-1-2012';

```

Price of non-sinking fund bond.

```
PNSF = bondbyhjm(HJMT, CouponRate, Settle, Maturity, Period)
```

```
PNSF = 100.5663
```

Price of the bond with the option sinking provision.

```

PriceSF = optembndbyhjm(HJMT, CouponRate, Settle, Maturity, ...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face)

```

```
PriceSF = 98.8736
```

### Price an Amortizing Callable Bond Using an HJM Interest-Rate Tree Model

This example shows how to price an amortizing callable bond and a vanilla callable bond using an HJM lattice model.

Create a RateSpec.

```

Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

```

Build a HJM tree.

```
VolSpec = hjmvolspec('Constant', 0.01)
```

```
VolSpec = struct with fields:
    FinObj: 'HJMVolSpec'
    FactorModels: {'Constant'}
    FactorArgs: {{1x1 cell}}
    SigmaShift: 0
    NumFactors: 1
    NumBranch: 2
    PBranch: [0.5000 0.5000]
    Fact2Branch: [-1 1]
```

```
TimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding)
```

```
TimeSpec = struct with fields:
    FinObj: 'HJMTimeSpec'
    ValuationDate: 734869
    Maturity: [4x1 double]
    Compounding: 1
    Basis: 0
    EndMonthRule: 1
```

```
HJMTree = hjmtree(VolSpec, RS, TimeSpec)
```

```
HJMTree = struct with fields:
    FinObj: 'HJMTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2 3]
    dObs: [734869 735235 735600 735965]
    TFwd: {[4x1 double] [3x1 double] [2x1 double] [3]}
    CFlowT: {[4x1 double] [3x1 double] [2x1 double] [4]}
    FwdTree: {[4x1 double] [3x1x2 double] [2x2x2 double] [1x4x2 double]}
```

Define the callable bond.

```
CouponRate = 0.05;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2016';
Period = 1;

Face = {
    {'Jan-1-2014' 100;
     'Jan-1-2015' 70;
     'Jan-1-2016' 50};
};
```

```
OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates = {'Jan-1-2014' 'Jan-1-2015' 'Jan-1-2016'};
```

Price a callable amortizing bond using the HJM tree.

```
BondType = 'amortizing';
Pcallbonds = optembndbyhjm(HJMTree, CouponRate, Settle, Maturity, OptSpec, Strike, ...
ExerciseDates, 'Period', 1, 'Face', Face, 'BondType', BondType)

Pcallbonds = 98.6000
```

## Input Arguments

### HJMTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmTree`.

Data Types: `struct`

### CouponRate — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST-by-1` decimal annual rate or `NINST-by-1` cell array, where each element is a `NumDates-by-2` cell array. The first column of the `NumDates-by-2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

### Settle — Settlement date

serial date number | date character vector

Settlement date for the bond option, specified as a `NINST-by-1` vector of serial date numbers or date character vectors.

---

**Note** The `Settle` date for every bond is set to the `ValuationDate` of the HJM tree. The bond argument `Settle` is ignored.

---

Data Types: `double` | `char`

### Maturity — Maturity date

serial date number | date character vector

Maturity date, specified as an `NINST-by-1` vector of serial date numbers or date character vectors.

Data Types: `double` | `char`

### OptSpec — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a `NINST-by-1` cell array of character vectors.

Data Types: `char`

### Strike — Option strike price values

nonnegative integer

Option strike price value, specified as a `NINST-by-1` or `NINST-by-NSTRIKES` depending on the type of option:

- European option — `NINST-by-1` vector of strike price values.

- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

### ExerciseDates — Option exercise dates

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

Data Types: double | char

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: Price =  
optembndbyhjm(HJMTTree, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'Period', 1, 'AmericanOp', 1)

### AmericanOpt — Option type

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

### Period — Coupons per year

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

#### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

#### **IssueDate — Bond issue date**

serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | char

#### **FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char`

### **LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of '`LastCouponDate`' and a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `char` | `double`

### **StartDate — Forward starting date of payments**

serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of '`StartDate`' and a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Data Types: `char` | `double`

### **Face — Face value**

100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of '`Face`' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

---

**Note** Instruments without a Face schedule are treated as either vanilla bonds or stepped coupon bonds with embedded options.

---

Data Types: `double`

### **BondType — Type of underlying bond**

'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla', 'amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of '`BondType`' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.

- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: char | string

### Options — Derivatives pricing options

structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with `derivset`.

Data Types: struct

## Output Arguments

### Price — Expected prices of embedded option at time 0

matrix

Expected price of the embedded option at time 0, returned as a NINST-by-1 matrix.

### PriceTree — Structure containing trees of vectors of instrument prices and exercise probabilities for each node

structure

Structure containing trees of vectors of instrument prices, a vector of observation times for each node, and exercise probabilities. Values are:

- `PriceTree.ExBush` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.ProbBush` contains the probability of reaching each node from root node.
- `PriceTree.ExProbBush` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.
- `PriceTree.ExProbsByBushLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

## More About

### Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

### **Stepped Coupon Bond with Callable and Puttable Features**

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

### **Sinking Fund Bond with Call Embedded Option**

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

### **Amortizing Callable or Puttable Bond**

Amortizing callable or puttable bonds work under a scheduled Face.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the Face amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

## optembndbyhw

Price bonds with embedded options by Hull-White interest-rate tree

### Syntax

```
[Price,PriceTree] = optembndbyhw(HWTree,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optembndbyhw( ____,Name,Value)
```

### Description

[Price,PriceTree] = optembndbyhw(HWTree,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates) calculates price for bonds with embedded options from a Hull-White interest-rate tree and returns exercise probabilities in PriceTree.

optembndbyhw computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1344.

[Price,PriceTree] = optembndbyhw( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price a Callable Bond Using an HW Interest-Rate Tree Model

Create a HWTree with the following data:

```
ZeroRates = [ 0.035;0.04;0.045];
Compounding = 1;
StartDates = ['jan-1-2007';'jan-1-2008';'jan-1-2009'];
EndDates = ['jan-1-2008';'jan-1-2009';'jan-1-2010'];
ValuationDate = 'jan-1-2007';
```

Create a RateSpec.

```
RateSpec = intenvset('Rates', ZeroRates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [3x1 double]
    Rates: [3x1 double]
    EndTimes: [3x1 double]
    StartTimes: [3x1 double]
    EndDates: [3x1 double]
    StartDates: 733043
    ValuationDate: 733043
    Basis: 0
```

```
EndMonthRule: 1
```

Create a VolSpec.

```
VolDates = ['jan-1-2008'; 'jan-1-2009'; 'jan-1-2010'];
VolCurve = 0.01;
AlphaDates = 'jan-1-2010';
AlphaCurve = 0.1;
HWVolSpec = hwwolspec(ValuationDate, VolDates, VolCurve, AlphaDates, AlphaCurve)
```

```
HWVolSpec = struct with fields:
    FinObj: 'HWVolSpec'
    ValuationDate: 733043
    VolDates: [3x1 double]
    VolCurve: [3x1 double]
    AlphaCurve: 0.1000
    AlphaDates: 734139
    VolInterpMethod: 'linear'
```

Create a TimeSpec.

```
HWTimeSpec = hwtimespec(ValuationDate, EndDates, Compounding)
```

```
HWTimeSpec = struct with fields:
    FinObj: 'HWTimeSpec'
    ValuationDate: 733043
    Maturity: [3x1 double]
    Compounding: 1
    Basis: 0
    EndMonthRule: 1
```

Build the HWTtree.

```
HWTtree = hwtree(HWVolSpec, RateSpec, HWTimeSpec)
```

```
HWTtree = struct with fields:
    FinObj: 'HWFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2]
    dObs: [733043 733408 733774]
    CFlowT: {[3x1 double] [2x1 double] [3]}
    Probs: {[3x1 double] [3x3 double]}
    Connect: {[2] [2 3 4]}
    FwdTree: {[1.0350] [1.0633 1.0451 1.0271] [1x5 double]}
```

Compute the price of an American puttable bond that pays an annual coupon of 5.25%, matures on January 1, 2010, and is puttable from January 1, 2008 to January 1, 2010.

```
BondSettlement = 'jan-1-2007';
BondMaturity = 'jan-1-2010';
CouponRate = 0.0525;
Period = 1;
OptSpec = 'put';
```

```

Strike = [100];
ExerciseDates = {'jan-1-2008' '01-Jan-2010'};
AmericanOpt = 1;

PricePutBondHW = optembndbyhw(HWTree, CouponRate, BondSettlement, BondMaturity,...
OptSpec, Strike, ExerciseDates, 'Period', 1, 'AmericanOpt', 1)

PricePutBondHW = 102.9127

```

### Obtain Callable Bond Exercise Information Using an HW Interest-Rate Tree Model

Create a HWTree with the following data:

```

Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2019';
StartDates = ValuationDate;
EndDates = {'Jan-1-2020'; 'Jan-1-2021'; 'Jan-1-2022'; 'Jan-1-2023'};
Compounding = 1;

```

Create a RateSpec.

```

RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

```

Define the callable bond instruments.

```

Settle = '01-Jan-2019';
Maturity = {'01-Jan-2022'; '01-Jan-2023'};
CouponRate = {'01-Jan-2021' .0425; '01-Jan-2023' .0450};
OptSpec='call';
Strike= [98;95];
ExerciseDates= {'01-Jan-2021'; '01-Jan-2022'};

```

Build the HW tree with the following data.

```

VolDates = ['1-Jan-2020'; '1-Jan-2021'; '1-Jan-2022'; '1-Jan-2023'];
VolCurve = 0.05;
AlphaDates = '01-01-2023';
AlphaCurve = 0.05;

```

```

HWVolSpec = hwwolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RS.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RS, HWTimeSpec);

```

Price the instruments.

```

[Price, PriceTree]= optembndbyhw(HWT, CouponRate, Settle, Maturity,OptSpec, Strike,...
ExerciseDates, 'Period', 1)

```

```

Price = 2×1

    96.4131
    92.9341

```

```
PriceTree = struct with fields:
    FinObj: 'HWPriceTree'
    tObs: [0 1 2 3 4]
    PTree: {1x5 cell}
    ProbTree: {1x5 cell}
    ExTree: {1x5 cell}
    ExProbTree: {1x5 cell}
    ExProbsByTreeLevel: [2x5 double]
    Connect: {[2] [2 3 4] [2 3 4 5 6]}
```

Examine the output `PriceTree.ExTree`. `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it is not.

```
PriceTree.ExTree{5}
```

```
ans = 2x7
```

```
    0    0    0    0    0    0    0
    0    0    0    0    0    0    0
```

There is no exercise for instrument 1 or 2.

```
PriceTree.ExTree{4}
```

```
ans = 2x7
```

```
    0    0    0    0    0    0    0
    0    0    0    1    1    1    1
```

There is no exercise for instrument 1 and instrument 2 is exercised at some nodes.

```
PriceTree.ExTree{3}
```

```
ans = 2x5
```

```
    0    0    1    1    1
    0    0    0    0    0
```

There is the exercise for instrument 1 at some node and no exercise for instrument 2.

```
PriceTree.ExTree{2}
```

```
ans = 2x3
```

```
    0    0    0
    0    0    0
```

There is no exercise for instrument 1 or 2.

Next view the probability of reaching each node from the root node using `PriceTree.ProbTree`.

```
PriceTree.ProbTree{2}
```

```
ans = 1×3
```

```
    0.1667    0.6667    0.1667
```

```
PriceTree.ProbTree{3}
```

```
ans = 1×5
```

```
    0.0238    0.2218    0.5087    0.2218    0.0238
```

```
PriceTree.ProbTree{4}
```

```
ans = 1×7
```

```
    0.0029    0.0473    0.2374    0.4247    0.2374    0.0473    0.0029
```

```
PriceTree.ProbTree{5}
```

```
ans = 1×7
```

```
    0.0029    0.0473    0.2374    0.4247    0.2374    0.0473    0.0029
```

Then view the exercise probabilities using `PriceTree.ExProbTree`. `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceTree.ExProbTree{5}
```

```
ans = 2×7
```

```
    0    0    0    0    0    0    0
    0    0    0    0    0    0    0
```

```
PriceTree.ExProbTree{4}
```

```
ans = 2×7
```

```
    0    0    0    0    0    0    0
    0    0    0    0.4247    0.2374    0.0473    0.0029
```

```
PriceTree.ExProbTree{3}
```

```
ans = 2×5
```

```
    0    0    0.5087    0.2218    0.0238
    0    0    0    0    0
```

```
PriceTree.ExProbTree{2}
```

```
ans = 2×3
```

```
    0    0    0
    0    0    0
```

View the exercise probabilities at each tree level using `PriceTree.ExProbsByTreeLevel`. `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

```
PriceTree.ExProbsByTreeLevel
```

```
ans = 2x5
```

```

    0         0    0.7544         0         0
    0         0         0    0.7124         0

```

### Price Single Stepped Callable Bonds Using an HW Interest-Rate Tree Model

Price the following single stepped callable bonds using the following data: The data for the interest rate term structure is as follows:

```

Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2010';
StartDates = ValuationDate;
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'};
Compounding = 1;

% Create RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% Instrument
Settle = '01-Jan-2010';
Maturity = {'01-Jan-2013'; '01-Jan-2014'};
CouponRate = {'01-Jan-2012' .0425; '01-Jan-2014' .0750};
OptSpec='call';
Strike=100;
ExerciseDates='01-Jan-2012'; %Callable in two years

% Build the tree with the following data
VolDates = ['1-Jan-2011'; '1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'];
VolCurve = 0.01;
AlphaDates = '01-01-2014';
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RS.ValuationDate, VolDates, VolCurve, ...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RS.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RS, HWTimeSpec);

% The first row corresponds to the price of the callable bond with maturity
% of three years. The second row corresponds to the price of the callable
% bond with maturity of four years.

PHW= optembndbyhw(HWT, CouponRate, Settle, Maturity, OptSpec, Strike, ...
ExerciseDates, 'Period', 1)

PHW = 2x1

```

```
100.0326
99.7987
```

### Price a Sinking Fund Bond Using an HW Interest-Rate Tree Model

A corporation issues a two year bond with a sinking fund obligation requiring the company to sink 1/3 of face value after the first year. The company has the option to buy the bonds in the market or call them at \$99. The following data describes the details needed for pricing the sinking fund bond:

```
Rates = [0.1;0.1;0.1;0.1];
ValuationDate = 'Jan-1-2011';
StartDates = ValuationDate;
EndDates = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
Compounding = 1;

% Create RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% Build the HW tree
% The data to build the tree is as follows:
VolDates = ['1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'];
VolCurve = 0.01;
AlphaDates = '01-01-2015';
AlphaCurve = 0.1;

HWVolSpec = hwwolspec(RateSpec.ValuationDate, VolDates, VolCurve, ...
AlphaDates, AlphaCurve);
HWTTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTTimeSpec);

% Instrument
% The bond has a coupon rate of 9%, a period of one year and matures in
% 1-Jan-2013. Face decreases 1/3 after the first year.
CouponRate = 0.09;
Settle = 'Jan-1-2011';
Maturity = 'Jan-1-2013';
Period = 1;
Face = { ...
        {'Jan-1-2012' 100; ...
         'Jan-1-2013' 66.6666}; ...
};

% Option provision
OptSpec = 'call';
Strike = 99;
ExerciseDates = 'Jan-1-2012';

% Price of non-sinking fund bond.
PNSF = bondbyhw(HWT, CouponRate, Settle, Maturity, Period)

PNSF = 98.2645

Price of the bond with the option sinking provision.
```

```
PriceSF = optembndbyhw(HWT, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face)
```

```
PriceSF = 98.1553
```

## Price an Amortizing Callable Bond Using an HW Interest-Rate Tree Model

This example shows how to price an amortizing callable bond and a vanilla callable bond using an HW lattice model.

Create a RateSpec.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);
```

Build a HW tree.

```
VolDates = ['1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'];
VolCurve = 0.01;
AlphaDates = '01-01-2016';
AlphaCurve = 0.1;
```

```
HWVolSpec = hwwolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RS.ValuationDate, EndDates, Compounding);
HWT = hwtree(HWVolSpec, RS, HWTimeSpec);
```

Define the callable bond.

```
CouponRate = 0.05;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2016';
Period = 1;

Face = {
    {'Jan-1-2014' 100;
     'Jan-1-2015' 70;
     'Jan-1-2016' 50};
};
```

```
OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates = {'Jan-1-2014' 'Jan-1-2015' 'Jan-1-2016'};
```

Price a callable amortizing bond using the HW tree.

```
BondType = 'amortizing';
Pcallbonds = optembndbyhw(HWT, CouponRate, Settle, Maturity ,OptSpec, Strike,...
ExerciseDates, 'Period', 1, 'Face', Face, 'BondType', BondType)
```

```
Pcallbonds = 98.6554
```

## Input Arguments

### **HWTtree — Interest-rate tree structure**

structure

Interest-rate tree structure, specified by using hwtree.

Data Types: struct

### **CouponRate — Bond coupon rate**

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

### **Settle — Settlement date**

serial date number | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

---

**Note** The Settle date for every bond is set to the ValuationDate of the HW tree. The bond argument Settle is ignored.

---

Data Types: double | char

### **Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char

### **OptSpec — Definition of option**

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: char

### **Strike — Option strike price values**

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.

- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

### ExerciseDates — Option exercise dates

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

Data Types: double | char

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: Price =  
`optembndbyhw(HWTree, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'Period', 1, 'AmericanOp', 1)`

### AmericanOpt — Option type

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

### Period — Coupons per year

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

#### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

#### **IssueDate — Bond issue date**

serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | char

#### **FirstCouponDate — Irregular first coupon date**

serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using serial date numbers date or date character vectors.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char`

### **LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of '`LastCouponDate`' and a NINST-by-1 vector using serial date numbers or date character vectors.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `char` | `double`

### **StartDate — Forward starting date of payments**

serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of '`StartDate`' and a NINST-by-1 vector using serial date numbers or date character vectors.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Data Types: `char` | `double`

### **Face — Face value**

100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of '`Face`' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

---

**Note** Instruments without a Face schedule are treated as either vanilla bonds or stepped coupon bonds with embedded options.

---

Data Types: `double`

### **BondType — Type of underlying bond**

'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla', 'amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of '`BondType`' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.

- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: char | string

### **Options — Derivatives pricing options**

structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with `derivset`.

Data Types: struct

## **Output Arguments**

### **Price — Expected prices of embedded option at time 0**

matrix

Expected price of the embedded option at time 0, returned as a NINST-by-1 matrix.

### **PriceTree — Structure containing trees of vectors of instrument prices and exercise probabilities for each node**

structure

Structure containing trees of vectors of instrument prices, a vector of observation times for each node, and exercise probabilities. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.
- `PriceTree.ProbTree` contains the probability of reaching each node from root node.
- `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.
- `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

## **More About**

### **Vanilla Bond with Embedded Option**

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

## **Stepped Coupon Bond with Callable and Puttable Features**

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

## **Sinking Fund Bond with Call Embedded Option**

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

## **Amortizing Callable or Puttable Bond**

Amortizing callable or puttable bonds work under a scheduled Face.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the Face amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

## optemfloatbybdt

Price embedded option on floating-rate note for Black-Derman-Toy interest-rate tree

### Syntax

```
[Price,PriceTree] = optemfloatbybdt(BDTree,Spread,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optemfloatbybdt( ____,Name,Value)
```

### Description

[Price,PriceTree] = optemfloatbybdt(BDTree,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates) prices embedded options on floating-rate notes from a Black-Derman-Toy interest rate tree. optemfloatbybdt computes prices of vanilla floating-rate notes with embedded options.

[Price,PriceTree] = optemfloatbybdt( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price Callable Embedded Option for Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
```

Create the RateSpec.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [4x1 double]
    Rates: [4x1 double]
    EndTimes: [4x1 double]
    StartTimes: [4x1 double]
    EndDates: [4x1 double]
    StartDates: 734869
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1
```

Build the BDT tree and assume a volatility of 10%.

```

Sigma = 0.1;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates)));
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);

```

Define the floater instruments with the embedded call option.

```

Spread = 10;
Settle = 'Jan-1-2012';
Maturity = {'Jan-1-2015'; 'Jan-1-2016'};
Period = 1;
OptSpec = {'call'};
Strike = 101;
ExerciseDates = 'Jan-1-2015';

```

Compute the price of the floaters with the embedded call.

```

Price= optemfloatbybdt(BDTT, Spread, Settle, Maturity, OptSpec, Strike,...
ExerciseDates)

```

```

Price = 2x1

    100.2800
    100.3655

```

## Input Arguments

### **BDTtree** — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `bdttree`.

Data Types: `struct`

### **Spread** — Number of basis points over the reference rate

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: `single` | `double`

### **Settle** — Settlement dates of floating-rate note

ValuationDate of BDT Tree (default) | serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Settlement dates of floating-rate note specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

---

**Note** The `Settle` date for every floating-rate note with an embedded option is set to the `ValuationDate` of the BDT tree. The floating-rate note argument `Settle` is ignored.

---

Data Types: `double` | `cell` | `char`

**Maturity — Floating-rate note maturity date**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Floating-rate note maturity date specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

Data Types: double | cell | char

**OptSpec — Definition of option**

character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: cell | char

**Strike — Option strike price values**

nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as NINST-by-NSTRIKES vector of strike price values.

Data Types: single | double

**ExerciseDates — Exercise date for option (European, Bermuda, or American)**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Exercise date for option (European, Bermuda, or American) specified as serial date numbers or date character vectors using a NINST-by-NSTRIKES or NINST-by-2 vector of for the option exercise dates.

- If a European or Bermuda option, the ExerciseDates is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one ExerciseDate on the option expiry date.
- If an American option, then ExerciseDates is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-NaN date, or if ExerciseDates is 1-by-1, the option exercises between the Settle date and the single listed ExerciseDate.

Data Types: double | char | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: [Price, PriceTree] =  
optemfloatbybdt(BDTree, Spread, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'AmericanOpt', 1, 'FloatReset', 6, 'Basis', 8)

**AmericanOpt — Option type**

scalar | vector of positive integers [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

### **FloatReset — Frequency of payments per year**

1 (default) | positive integer from the set [1, 2, 3, 4, 6, 12] | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values [1, 2, 3, 4, 6, 12] in a NINST-by-1 vector.

---

**Note** Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

---

Data Types: double

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. The Basis value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

### Principal — Principal values

100 (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of 'Principal' and nonnegative values using a NINST-by-1 vector or NINST-by-1 cell array of notional principal amounts. When using a NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: double | cell

### Options — Structure containing derivatives pricing options

structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using derivset.

Data Types: struct

## Output Arguments

### Price — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 are returned as a scalar or an NINST-by-1 vector.

### PriceTree — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- PriceTree.PTree contains option prices.
- PriceTree.tObs contains the observation times.

## More About

### Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A FRN with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

For more information, see “Floating-Rate Note with Embedded Options” on page 2-10.

## optemfloatbybk

Price embedded option on floating-rate note for Black-Karasinski interest-rate tree

### Syntax

```
[Price,PriceTree] = optemfloatbybk(BKTree,Spread,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optemfloatbybk( ____,Name,Value)
```

### Description

[Price,PriceTree] = optemfloatbybk(BKTree,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates) prices embedded options on floating-rate notes from a Black-Karasinski interest rate tree. optemfloatbybk computes prices of vanilla floating-rate notes with embedded options.

[Price,PriceTree] = optemfloatbybk( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price European Callable Embedded Option for Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
```

Create the RateSpec.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [4x1 double]
    Rates: [4x1 double]
    EndTimes: [4x1 double]
    StartTimes: [4x1 double]
    EndDates: [4x1 double]
    StartDates: 734869
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1
```

Build the BK tree.

```

VolDates = ['1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'];
VolCurve = 0.01;
AlphaDates = '01-01-2016';
AlphaCurve = 0.1;

BKVolspec = bkvolspec(RateSpec.ValuationDate, VolDates, VolCurve, ...
    AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RateSpec.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolspec, RateSpec, BKTimeSpec)

BKT = struct with fields:
    FinObj: 'BKFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2 3]
    dObs: [734869 735235 735600 735965]
    CFlowT: {[4x1 double] [3x1 double] [2x1 double] [4]}
    Probs: {[3x1 double] [3x3 double] [3x5 double]}
    Connect: {[2] [2 3 4] [2 3 4 5 6]}
    FwdTree: {[1.0300] [1.0387 1.0380 1.0373] [1x5 double] [1x7 double]}

```

The floater instrument has a spread of 15, a period of one year, and matures and is callable on Jan-1-2015.

```

Spread = 15;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2015';
Period = 1;
OptSpec = {'call'};
Strike = 101;
ExerciseDates = 'Jan-1-2015';

```

Compute the price of the floater with the embedded call.

```

Price = optemfloatbybk(BKT, Spread, Settle, Maturity, ...
    OptSpec, Strike, ExerciseDates)

Price = 100.4201

```

## Input Arguments

### **BKTree — Interest-rate tree structure**

binomial tree structure

Interest-rate tree specified as a structure by using `bktree`.

Data Types: `struct`

### **Spread — Number of basis points over the reference rate**

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: `single` | `double`

**Settle — Settlement dates of floating-rate note**

ValuationDate of BDT Tree (default) | serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Settlement dates of floating-rate note specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

---

**Note** The **Settle** date for every floating-rate note with an embedded option is set to the **ValuationDate** of the BK tree. The floating-rate note argument **Settle** is ignored.

---

Data Types: double | cell | char

**Maturity — Floating-rate note maturity date**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Floating-rate note maturity date specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

Data Types: double | cell | char

**OptSpec — Definition of option**

character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: cell | char

**Strike — Option strike price values**

nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as NINST-by-NSTRIKES vector of strike price values.

Data Types: single | double

**ExerciseDates — Exercise date for option (European, Bermuda, or American)**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Exercise date for option (European, Bermuda, or American) specified as serial date numbers or date character vectors using a NINST-by-NSTRIKES or NINST-by-2 vector of for the option exercise dates.

- If a European or Bermuda option, the **ExerciseDates** is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one **ExerciseDate** on the option expiry date.
- If an American option, then **ExerciseDates** is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-NaN date, or if **ExerciseDates** is 1-by-1, the option exercises between the **Settle** date and the single listed **ExerciseDate**.

Data Types: double | char | cell

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree] = optemfloatbybk(BKTree, Spread, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'AmericanOpt', 1, 'FloatReset', 6, 'Basis', 8)`

### AmericanOpt — Option type

scalar | vector of positive integers [0, 1]

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

### FloatReset — Frequency of payments per year

1 (default) | positive integer from the set [1, 2, 3, 4, 6, 12] | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and positive integers for the values [1, 2, 3, 4, 6, 12] in a NINST-by-1 vector.

---

**Note** Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

---

Data Types: double

### Basis — Day-count basis of the instrument

0 (actual/actual) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a NINST-by-1 vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

### **Principal — Principal values**

100 (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of 'Principal' and nonnegative values using a NINST-by-1 vector or NINST-by-1 cell array of notional principal amounts. When using a NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

### **Options — Structure containing derivatives pricing options**

structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

## **Output Arguments**

### **Price — Expected prices of the floating-rate note option at time 0**

scalar | vector

Expected prices of the floating-rate note option at time 0 are returned as a scalar or an NINST-by-1 vector.

## **PriceTree — Structure of trees containing vectors of option prices at each node**

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains option prices.
- `PriceTree.tObs` contains the observation times.

## **More About**

### **Floating-Rate Note with Embedded Options**

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A FRN with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

For more information, see “Floating-Rate Note with Embedded Options” on page 2-10.

## optemfloatbycir

Price embedded option on floating-rate note for Cox-Ingersoll-Ross interest-rate tree

### Syntax

```
[Price,PriceTree] = optemfloatbycir(CIRTree,Spread,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optemfloatbycir( ____,Name,Value)
```

### Description

[Price,PriceTree] = optemfloatbycir(CIRTree,Spread,Settle,Maturity,OptSpec, Strike,ExerciseDates) prices embedded options on floating-rate notes from a Cox-Ingersoll-Ross (CIR) interest rate tree. optemfloatbycir computes prices of vanilla floating-rate notes with embedded options using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

[Price,PriceTree] = optemfloatbycir( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price European Callable Embedded Option for a Floating-Rate Note Using a CIR Interest-Rate Tree

Create a RateSpec using the intenvset function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndDates)
```

Create a CIR tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = '01-Jan-2017';
Maturity = '01-Jan-2020';
CIRTimeSpec = cirtimespec(Settle, Maturity, 3);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)

CIRT = struct with fields:
    FinObj: 'CIRFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
```

```

tObs: [0 1 2]
dObs: [736696 737061 737426]
FwdTree: {[1.0350] [1.0790 1.0500 1.0298] [1x5 double]}
Connect: {[3x1 double] [3x3 double]}
Probs: {[3x1 double] [3x3 double]}

```

Define the floater instruments with the embedded call option.

```

Spread = 10;
Settle = 'Jan-1-2017';
Maturity = {'Jan-1-2019'; 'Jan-1-2020'};
Period = 1;
OptSpec = {'call'};
Strike = 101;
ExerciseDates = 'Jan-1-2019';

```

Compute the price of the floaters with the embedded call.

```
[Price, PriceTree] = optemfloatbycir(CIRT, Spread, Settle, Maturity, OptSpec, Strike, ExerciseDates)
```

```
Price = 2x1
```

```

100.1887
100.2757

```

```

PriceTree = struct with fields:
  FinObj: 'CIRPriceTree'
  tObs: [0 1 2 3]
  PTree: {[2x1 double] [2x3 double] [2x5 double] [2x5 double]}

```

## Input Arguments

### **CIRTree — Interest-rate tree structure**

structure

Interest-rate tree specified as a structure by using `cirtree`.

Data Types: `struct`

### **Spread — Number of basis points over the reference rate**

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST-by-1).

Data Types: `single` | `double`

### **Settle — Settlement dates of floating-rate note**

ValuationDate of CIR tree (default) | serial date number | vector of serial date numbers | date character vector | cell array of date character vectors | string array | `datetime`

Settlement dates of floating-rate note specified as serial date numbers, date character vectors, string arrays, or `datetime` arrays using a NINST-by-1 vector of dates.

---

**Note** The `Settle` date for every floating-rate note with an embedded option is set to the `ValuationDate` of the CIR tree. The floating-rate note argument `Settle` is ignored.

---

Data Types: `double` | `cell` | `char` | `string` | `datetime`

### **Maturity — Floating-rate note maturity date**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors | string array | `datetime`

Floating-rate note maturity date specified as serial date numbers, date character vectors, string arrays, or `datetime` arrays using a NINST-by-1 vector of dates.

Data Types: `double` | `cell` | `char` | `string` | `datetime`

### **OptSpec — Definition of option**

character vector with value of 'call' or 'put' | cell array of character vectors with value of 'call' or 'put' | string array with value of "call" or "put"

Definition of option, specified as a NINST-by-1 cell array of character vectors or string arrays with a value of 'call' or 'put'.

Data Types: `cell` | `char` | `string`

### **Strike — Option strike price values**

nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as NINST-by-NSTRIKES vector of strike price values.

Data Types: `single` | `double`

### **ExerciseDates — Exercise date for option (European, Bermuda, or American)**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors | string array | `datetime`

Exercise date for option (European, Bermuda, or American) specified as serial date numbers, date character vectors, string arrays, or `datetime` arrays using an NINST-by-NSTRIKES or an NINST-by-2 vector of for the option exercise dates.

- For a European or Bermuda option, the `ExerciseDates` is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, the `ExerciseDates` is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-NaN date, or if `ExerciseDates` is 1-by-1, the option exercises between the `Settle` date and the single listed `ExerciseDates`.

Data Types: `double` | `char` | `cell` | `string` | `datetime`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: [Price,PriceTree] =  
 optemfloatbycir(CIRTree,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates,'  
 AmericanOpt',1,'FloatReset',6,'Basis',8)

### AmericanOpt – Option type

scalar | vector of positive integers [0,1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a NINST-by-1 vector of flags with values:

- 0 – European/Bermuda
- 1 – American

Data Types: double

### FloatReset – Frequency of payments per year

1 (default) | positive integer from the set [1,2,3,4,6,12] | vector of positive integers from the set [1,2,3,4,6,12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values [1,2,3,4,6,12] in a NINST-by-1 vector.

---

**Note** Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

---

Data Types: double

### Basis – Day-count basis of the instrument

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. The Basis value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

### **Principal — Principal values**

100 (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of 'Principal' and nonnegative values using a NINST-by-1 vector or NINST-by-1 cell array of notional principal amounts.

When using a NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates, and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

### **Options — Structure containing derivatives pricing options**

structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and the output from `derivset`.

Data Types: `struct`

## **Output Arguments**

### **Price — Expected prices of the floating-rate note option at time 0**

scalar | vector

Expected prices of the floating-rate note option at time 0 are returned as a scalar or an NINST-by-1 vector.

### **PriceTree — Structure of trees containing vectors of option prices at each node**

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.PTree` contains option prices.

## More About

### Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A FRN with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

For more information, see “Floating-Rate Note with Embedded Options” on page 2-10.

## Introduced in R2018a

## optemfloatbyhjm

Price embedded option on floating-rate note for Heath-Jarrow-Morton interest-rate tree

### Syntax

```
[Price,PriceTree] = optemfloatbyhjm(HJMTTree,Spread,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optemfloatbyhjm( ____,Name,Value)
```

### Description

[Price,PriceTree] = optemfloatbyhjm(HJMTTree,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates) prices embedded options on floating-rate notes from a Heath-Jarrow-Morton interest rate tree. optemfloatbyhjm computes prices of vanilla floating-rate notes with embedded options.

[Price,PriceTree] = optemfloatbyhjm( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price European Callable Embedded Option for a Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.035;0.040;0.045];
ValuationDate = 'Jan-1-2012';
StartDates = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
```

Create the RateSpec.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [4x1 double]
    Rates: [4x1 double]
    EndTimes: [4x1 double]
    StartTimes: [4x1 double]
    EndDates: [4x1 double]
    StartDates: [4x1 double]
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1
```

Build the HJM tree.

```

VolSpec = hjmvolspec('Constant', 0.01);
TimeSpec = hjmtimespec(RateSpec.ValuationDate, EndDates, Compounding);
HJMTree = hjmtree(VolSpec, RateSpec, TimeSpec)

HJMTree = struct with fields:
    FinObj: 'HJMfwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2 3]
    dObs: [734869 735235 735600 735965]
    TFwd: {[4x1 double] [3x1 double] [2x1 double] [3]}
    CFlowT: {[4x1 double] [3x1 double] [2x1 double] [4]}
    FwdTree: {[4x1 double] [3x1x2 double] [2x2x2 double] [1x4x2 double]}

```

The floater instrument has a spread of 15, a period of one year, and matures and is callable on Jan-1-2016.

```

Spread = 15;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2016';
Period = 1;
OptSpec = {'call'};
Strike = 95;
ExerciseDates = 'Jan-1-2016';

```

Compute the price of the floater with the embedded call.

```

Price = optemfloatbyhjm(HJMTree, Spread, Settle, Maturity, ...
    OptSpec, Strike, ExerciseDates)

```

```

Price = 96.2355

```

## Input Arguments

### HJMTree — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `hjmtree`.

Data Types: `struct`

### Spread — Number of basis points over the reference rate

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: `single` | `double`

### Settle — Settlement dates of floating-rate note

ValuationDate of BDT Tree (default) | serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Settlement dates of floating-rate note specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

---

**Note** The `Settle` date for every floating-rate note with an embedded option is set to the `ValuationDate` of the HJM tree. The floating-rate note argument `Settle` is ignored.

---

Data Types: `double` | `cell` | `char`

### **Maturity — Floating-rate note maturity date**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Floating-rate note maturity date specified as serial date numbers or date character vectors using a `NINST-by-1` vector of dates.

Data Types: `double` | `cell` | `char`

### **OptSpec — Definition of option**

character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a `NINST-by-1` cell array of character vectors for 'call' or 'put'.

Data Types: `cell` | `char`

### **Strike — Option strike price values**

nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as `NINST-by-NSTRIKES` vector of strike price values.

Data Types: `single` | `double`

### **ExerciseDates — Exercise date for option (European, Bermuda, or American)**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Exercise date for option (European, Bermuda, or American) specified as serial date numbers or date character vectors using a `NINST-by-NSTRIKES` or `NINST-by-2` vector of for the option exercise dates.

- If a European or Bermuda option, the `ExerciseDates` is a `1-by-1` (European) or `1-by-NSTRIKES` (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- If an American option, then `ExerciseDates` is a `1-by-2` vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-`NaN` date, or if `ExerciseDates` is `1-by-1`, the option exercises between the `Settle` date and the single listed `ExerciseDate`.

Data Types: `double` | `cell` | `char`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Price, PriceTree] = optemfloatbyhjm(HJMTree, Spread, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'AmericanOpt', 1, 'FloatReset', 6, 'Basis', 8)`

**AmericanOpt – Option type**

scalar | vector of positive integers [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer scalar flags with values:

- 0 – European/Bermuda
- 1 – American

Data Types: double

**FloatReset – Frequency of payments per year**

1 (default) | positive integer from the set [1, 2, 3, 4, 6, 12] | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values [1, 2, 3, 4, 6, 12] in a NINST-by-1 vector.

---

**Note** Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

---

Data Types: double

**Basis – Day-count basis of the instrument**

0 (actual/actual) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. The Basis value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

### **Principal — Principal values**

100 (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of 'Principal' and nonnegative values using a NINST-by-1 vector or NINST-by-1 cell array of notional principal amounts. When using a NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: double | cell

### **Options — Structure containing derivatives pricing options**

structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: struct

## **Output Arguments**

### **Price — Expected prices of the floating-rate note option at time 0**

scalar | vector

Expected prices of the floating-rate note option at time 0 are returned as a scalar or an NINST-by-1 vector.

### **PriceTree — Structure of trees containing vectors of option prices at each node**

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PBush` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

## More About

### Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A FRN with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

Price embedded option on floating-rate note for Hull-White interest-rate tree

### Syntax

```
[Price,PriceTree] = optemfloatbyhw(HWTree,Spread,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optemfloatbyhw( ____,Name,Value)
```

### Description

[Price,PriceTree] = optemfloatbyhw(HWTree,Spread,Settle,Maturity,OptSpec, Strike,ExerciseDates) prices embedded options on floating-rate notes from a Hull-White interest rate tree. optemfloatbyhw computes prices of vanilla floating-rate notes with embedded options.

[Price,PriceTree] = optemfloatbyhw( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price European Callable Embedded Option for Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
```

Create the RateSpec.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [4x1 double]
    Rates: [4x1 double]
    EndTimes: [4x1 double]
    StartTimes: [4x1 double]
    EndDates: [4x1 double]
    StartDates: 734869
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1
```

Build the HW tree using the following:

```

VolDates = ['1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'];
VolCurve = 0.01;
AlphaDates = '01-01-2016';
AlphaCurve = 0.1;

HWVolSpec = hwwolspec(RateSpec.ValuationDate, VolDates, VolCurve, ...
    AlphaDates, AlphaCurve);
HWTTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTTimeSpec)

HWT = struct with fields:
    FinObj: 'HWFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2 3]
    dObs: [734869 735235 735600 735965]
    CFlowT: {[4x1 double] [3x1 double] [2x1 double] [4]}
    Probs: {[3x1 double] [3x3 double] [3x5 double]}
    Connect: {[2] [2 3 4] [2 3 4 5 6]}
    FwdTree: {[1.0300] [1.0562 1.0381 1.0202] [1x5 double] [1x7 double]}

```

Define the floater instruments with the embedded call option.

```

Spread = 10;
Settle = 'Jan-1-2012';
Maturity = {'Jan-1-2015'; 'Jan-1-2016'};
Period = 1;
OptSpec = {'call'};
Strike = 101;
ExerciseDates = 'Jan-1-2015';

```

Compute the price of the floaters with the embedded call.

```

Price = optemfloatbyhw(HWT, Spread, Settle, Maturity, OptSpec, Strike, ...
    ExerciseDates)

```

```

Price = 2x1

    100.2800
    100.3655

```

## Input Arguments

### HWTTree — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using hwtree.

Data Types: struct

### Spread — Number of basis points over the reference rate

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: `single` | `double`

### **Settle — Settlement dates of floating-rate note**

ValuationDate of BDT Tree (default) | serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Settlement dates of floating-rate note specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

---

**Note** The `Settle` date for every floating-rate note with an embedded option is set to the `ValuationDate` of the HW tree. The floating-rate note argument `Settle` is ignored.

---

Data Types: `double` | `cell` | `char`

### **Maturity — Floating-rate note maturity date**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Floating-rate note maturity date specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

Data Types: `double` | `cell` | `char`

### **OptSpec — Definition of option**

character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: `cell` | `char`

### **Strike — Option strike price values**

nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as NINST-by-NSTRIKES vector of strike price values.

Data Types: `single` | `double`

### **ExerciseDates — Exercise date for option (European, Bermuda, or American)**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Exercise date for option (European, Bermuda, or American) specified as serial date numbers or date character vectors using a NINST-by-NSTRIKES or NINST-by-2 vector of for the option exercise dates.

- If a European or Bermuda option, the `ExerciseDates` is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- If an American option, then `ExerciseDates` is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only

one non-NaN date, or if `ExerciseDates` is 1-by-1, the option exercises between the `Settle` date and the single listed `ExerciseDate`.

Data Types: `double` | `char` | `cell`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree] = optemfloatbyhw(HWTree, Spread, Settle, Maturity, OptSpec, Strike, ExerciseDates, 'AmericanOpt', 1, 'FloatReset', 6, 'Basis', 8)`

### AmericanOpt — Option type

scalar | vector of positive integers [0, 1]

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: `double`

### FloatReset — Frequency of payments per year

1 (default) | positive integer from the set [1, 2, 3, 4, 6, 12] | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and positive integers for the values [1, 2, 3, 4, 6, 12] in a NINST-by-1 vector.

---

**Note** Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

---

Data Types: `double`

### Basis — Day-count basis of the instrument

0 (actual/actual) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a NINST-by-1 vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

#### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

#### **Principal — Principal values**

100 (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of 'Principal' and nonnegative values using a NINST-by-1 vector or NINST-by-1 cell array of notional principal amounts. When using a NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

#### **Options — Structure containing derivatives pricing options**

structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

## Output Arguments

### Price — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 are returned as a scalar or an NINST-by-1 vector.

### PriceTree — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains embedded option prices.
- `PriceTree.tObs` contains the observation times.

## More About

### Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A FRN with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

For more information, see “Floating-Rate Note with Embedded Options” on page 2-10.

### Introduced in R2013a

## optfloatbybdt

Price options on floating-rate notes for Black-Derman-Toy interest-rate tree

### Syntax

```
[Price,PriceTree] = optfloatbybdt(BDTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,Spread,Settle,Maturity)
[Price,PriceTree] = optfloatbybdt( ____,Name,Value)
```

### Description

[Price,PriceTree] = optfloatbybdt(BDTree,OptSpec,Strike,ExerciseDates, AmericanOpt,Spread,Settle,Maturity) prices options on floating-rate notes from a Black-Derman-Toy interest rate tree. optfloatbybdt computes prices of options on vanilla floating-rate notes.

[Price,PriceTree] = optfloatbybdt( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute the Price of American Call and Put Options on a Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
```

Create the RateSpec.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [4x1 double]
    Rates: [4x1 double]
    EndTimes: [4x1 double]
    StartTimes: [4x1 double]
    EndDates: [4x1 double]
    StartDates: 734869
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1
```

Build the BDT tree and assume a volatility of 10%.

```

Sigma = 0.1;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates)));
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec)

BDTT = struct with fields:
    FinObj: 'BDTFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2 3]
    dObs: [734869 735235 735600 735965]
    TFwd: {[4x1 double] [3x1 double] [2x1 double] [3]}
    CFlowT: {[4x1 double] [3x1 double] [2x1 double] [4]}
    FwdTree: {1x4 cell}

```

The floater instrument has a spread of 10, a period of one year, and matures on Jan-1-2016.

```

Spread = 10;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2016';
Period = 1;

```

Define the option for the floating-rate note.

```

OptSpec = {'call'; 'put'};
Strike = [100;101];
ExerciseDates = 'Jan-1-2015';
AmericanOpt = 1;

```

Compute the price of the call and put options.

```

Price= optfloatbybdt(BDTT, OptSpec, Strike, ExerciseDates,AmericanOpt, Spread,...
Settle, Maturity)

```

```

Price = 2x1

    0.3655
    0.8087

```

## Input Arguments

### BDTTree — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `bdttree`.

Data Types: `struct`

### OptSpec — Definition of option

character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: `cell` | `char`

**Strike — Option strike price values**

nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as NINST-by-NSTRIKES vector of strike price values.

Data Types: single | double

**ExerciseDates — Exercise date for option (European, Bermuda, or American)**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Exercise date for option (European, Bermuda, or American) specified as serial date numbers or date character vectors using a NINST-by-NSTRIKES or NINST-by-2 vector of for the option exercise dates.

- If a European or Bermuda option, the ExerciseDates is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one ExerciseDate on the option expiry date.
- If an American option, then ExerciseDates is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-NaN date, or if ExerciseDates is 1-by-1, the option exercises between the Settle date and the single listed ExerciseDate.

Data Types: double | char | cell

**AmericanOpt — Option type**

scalar | vector of positive integers [0, 1]

Option type specified as NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: single | double

**Spread — Number of basis points over the reference rate**

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: single | double

**Settle — Settlement dates of floating-rate note**

ValuationDate of BDT Tree (default) | serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Settlement dates of floating-rate note specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

---

**Note** The Settle date for every floating-rate note is set to the ValuationDate of the BDT tree. The floating-rate note argument Settle is ignored.

---

Data Types: double | cell | char

**Maturity — Floating-rate note maturity date**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Floating-rate note maturity date specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

Data Types: double | cell | char

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside quotes. You can specify several name and value pair arguments in any order as *Name1*, *Value1*, . . . , *NameN*, *ValueN*.

Example:

```
[Price,PriceTree]=optfloatbybdt(BDTree,OptSpec,Strike,ExerciseDates,American
Opt,Spread,Settle,Maturity,'FloatReset',4,'Basis',7)
```

**FloatReset — Frequency of payments per year**

1 (default) | positive integer from the set [1,2,3,4,6,12] | vector of positive integers from the set [1,2,3,4,6,12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values [1,2,3,4,6,12] in a NINST-by-1 vector.

---

**Note** Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

---

Data Types: double

**Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. The *Basis* value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)

- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### Principal — Principal values

100 (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of 'Principal' and nonnegative values using a NINST-by-1 vector or NINST-by-1 cell array of notional principal amounts. When using a NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: double | cell

### Options — Structure containing derivatives pricing options

structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and structure obtained from using `derivset`.

Data Types: struct

### EndMonthRule — End-of-month rule flag

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

## Output Arguments

### Price — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 is returned as a scalar or an NINST-by-1 vector.

### PriceTree — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains option prices.
- `PriceTree.tObs` contains the observation times.

## More About

### Floating-Rate Note Options

A floating-rate note option is a put or call option on a floating-rate note.

Financial Instruments Toolbox supports three types of put and call options on floating-rate notes:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly.

For more information, see “Floating-Rate Note Options” on page 2-10.

## Introduced in R2013a

## optfloatbybk

Price options on floating-rate notes for Black-Karasinski interest-rate tree

### Syntax

```
[Price,PriceTree] = optfloatbybdt(BKTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,Spread,Settle,Maturity)
[Price,PriceTree] = optfloatbybdt( ____,Name,Value)
```

### Description

[Price,PriceTree] = optfloatbybdt(BKTree,OptSpec,Strike,ExerciseDates, AmericanOpt,Spread,Settle,Maturity) prices options on floating-rate notes from a Black-Karasinski interest rate tree. optfloatbybk computes prices of options on vanilla floating-rate notes.

[Price,PriceTree] = optfloatbybdt( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute the Price of American and European Call Options on a Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
```

Create the RateSpec.

```
RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',StartDates,...
'EndDates',EndDates,'Rates',Rates,'Compounding',Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [4x1 double]
    Rates: [4x1 double]
    EndTimes: [4x1 double]
    StartTimes: [4x1 double]
    EndDates: [4x1 double]
    StartDates: 734869
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1
```

Build the BK tree.

```

VolDates = ['1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'];
VolCurve = 0.01;
AlphaDates = '01-01-2016';
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RateSpec.ValuationDate,VolDates,VolCurve,...
AlphaDates,AlphaCurve);
BKTimeSpec = bktimespec(RateSpec.ValuationDate,VolDates,Compounding);
BKT = bktree(BKVolSpec,RateSpec,BKTimeSpec)

BKT = struct with fields:
    FinObj: 'BKFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734869 735235 735600 735965]
    CFlowT: {[4x1 double] [3x1 double] [2x1 double] [4]}
    Probs: {[3x1 double] [3x3 double] [3x5 double]}
    Connect: {[2] [2 3 4] [2 3 4 5 6]}
    FwdTree: {[1.0300] [1.0387 1.0380 1.0373] [1x5 double] [1x7 double]}

```

The floater instrument has a spread of 10, a period of one year, and matures on Jan-1-2016.

```

Spread = 10;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2016';
Period = 1;

```

Define the option for the floating-rate note.

```

OptSpec = {'call'};
Strike = 95;
ExerciseDates = 'Jan-1-2016';
AmericanOpt = [0;1];

```

Compute the price of the call options.

```

Price = optfloatbybk(BKT,OptSpec,Strike,ExerciseDates,AmericanOpt,...
Spread,Settle,Maturity)

```

```

Price = 2x1

    4.2740
    5.3655

```

## Input Arguments

### BKTree — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `bktree`.

Data Types: `struct`

**OptSpec — Definition of option**

character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: cell | char

**Strike — Option strike price values**

nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as NINST-by-NSTRIKES vector of strike price values.

Data Types: single | double

**ExerciseDates — Exercise date for option (European, Bermuda, or American)**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Exercise date for option (European, Bermuda, or American) specified as serial date numbers or date character vectors using a NINST-by-NSTRIKES or NINST-by-2 vector of for the option exercise dates.

- If a European or Bermuda option, the ExerciseDates is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one ExerciseDate on the option expiry date.
- If an American option, then ExerciseDates is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-NaN date, or if ExerciseDates is 1-by-1, the option exercises between the Settle date and the single listed ExerciseDate.

Data Types: double | char | cell

**AmericanOpt — Option type**

scalar | vector of positive integers [0, 1]

Option type specified as NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: single | double

**Spread — Number of basis points over the reference rate**

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: single | double

**Settle — Settlement dates of floating-rate note**

ValuationDate of BK tree (default) | serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Settlement dates of floating-rate note specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

---

**Note** The `Settle` date for every floating-rate note is set to the `ValuationDate` of the BK tree. The floating-rate note argument `Settle` is ignored.

---

Data Types: double | cell | char

### **Maturity — Floating-rate note maturity date**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Floating-rate note maturity date specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

Data Types: double | cell | char

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree] = optfloatbybk(BKTree, OptSpec, Strike, ExerciseDates, AmericanOpt, Spread, Settle, Maturity, 'FloatReset', 4, 'Basis', 7)`

### **FloatReset — Frequency of payments per year**

1 (default) | positive integer from the set [1, 2, 3, 4, 6, 12] | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values [1, 2, 3, 4, 6, 12] in a NINST-by-1 vector.

---

**Note** Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

---

Data Types: double

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual

- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Principal — Principal values**

100 (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of 'Principal' and nonnegative values using a NINST-by-1 vector or NINST-by-1 cell array of notional principal amounts. When using a NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: double | cell

### **Options — Structure containing derivatives pricing options**

structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: struct

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

## Output Arguments

### Price — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 is returned as a scalar or an NINST-by-1 vector.

### PriceTree — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

## More About

### Floating-Rate Note Options

A floating-rate note option is a put or call option on a floating-rate note.

Financial Instruments Toolbox supports three types of put and call options on floating-rate notes:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly.

For more information, see “Floating-Rate Note Options” on page 2-10.

## optfloatbycir

Price options on floating-rate notes for Cox-Ingersoll-Ross interest-rate tree

### Syntax

```
[Price,PriceTree] = optfloatbycir(CIRTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,Spread,Settle,Maturity)
[Price,PriceTree] = optfloatbycir( ____,Name,Value)
```

### Description

[Price,PriceTree] = optfloatbycir(CIRTree,OptSpec,Strike,ExerciseDates, AmericanOpt,Spread,Settle,Maturity) prices options on floating-rate notes from a Cox-Ingersoll-Ross (CIR) interest-rate tree. optfloatbycir computes prices of options on vanilla floating-rate notes using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

[Price,PriceTree] = optfloatbycir( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute the Price of American and European Call Options on a Floating-Rate Note Using a CIR Interest-Rate Tree

Create a RateSpec using the intenvset function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndDates)
```

Create a CIR tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = '01-Jan-2017';
Maturity = '01-Jan-2021';
CIRTimeSpec = cirtimespec(Settle, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);
```

```
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
    FinObj: 'CIRFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
```

```

tObs: [0 1 2 3]
dObs: [736696 737061 737426 737791]
FwdTree: {[1.0350] [1.0790 1.0500 1.0298] [1x5 double] [1x7 double]}
Connect: {[3x1 double] [3x3 double] [3x5 double]}
Probs: {[3x1 double] [3x3 double] [3x5 double]}

```

The floater instrument has a spread of 10, a period of one year, and matures on Jan-1-2018.

```

Spread = 10;
Settle = 'Jan-1-2017';
Maturity = 'Jan-1-2019';
Period = 1;

```

Define the option for the floating-rate note.

```

OptSpec = {'call'};
Strike = 95;
ExerciseDates = 'Jan-1-2018';
AmericanOpt = [0;1];

```

Compute the price of the call options.

```

[Price,PriceTree] = optfloatbycir(CIRT, OptSpec,Strike,ExerciseDates,AmericanOpt,...
Spread, Settle, Maturity)

```

```

Price = 2x1

```

```

4.9230
5.1887

```

```

PriceTree = struct with fields:
  FinObj: 'CIRPriceTree'
  PTree: {1x5 cell}
  AITree: {1x5 cell}
  tObs: [0 1 2 3 4]
  Connect: {[3x1 double] [3x3 double] [3x5 double]}
  Probs: {[3x1 double] [3x3 double] [3x5 double]}

```

## Input Arguments

### CIRTree — Interest-rate tree structure

structure

Interest-rate tree specified as a structure by using `cirtree`.

Data Types: struct

### OptSpec — Definition of option

character vector with values 'call' or 'put' | cell array of character vectors with values of 'call' or 'put' | string array with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors or string arrays with values of 'call' or 'put'.

Data Types: cell | char | string

### Strike — Option strike price values

nonnegative integer | vector of nonnegative integers

Option strike price values, specified as nonnegative integers using an NINST-by-NSTRIKES vector of strike price values.

Data Types: single | double

### ExerciseDates — Exercise date for option (European, Bermuda, or American)

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors | string array | datetime

Exercise date for option (European, Bermuda, or American) specified as serial date numbers, date character vectors, string arrays, or datetime arrays using a NINST-by-NSTRIKES or NINST-by-2 vector of for the option exercise dates.

- For a European or Bermuda option, the ExerciseDates is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one ExerciseDate on the option expiry date.
- For an American option, the ExerciseDates is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-NaN date, or if ExerciseDates is 1-by-1, the option exercises between the Settle date and the single listed ExerciseDate.

Data Types: double | char | cell | string | datetime

### AmericanOpt — Option type

scalar | vector of positive integers[0, 1]

Option type specified as NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: single | double

### Spread — Number of basis points over the reference rate

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: single | double

### Settle — Settlement dates of floating-rate note

ValuationDate of CIR tree (default) | serial date number | vector of serial date numbers | date character vector | cell array of date character vectors | string array | datetime

Settlement dates of floating-rate note specified as serial date numbers, date character vectors, string arrays, or datetime arrays using a NINST-by-1 vector of dates.

---

**Note** The Settle date for every floating-rate note is set to the ValuationDate of the CIR tree. The floating-rate note argument Settle is ignored.

---

Data Types: double | cell | char | string

### **Maturity — Floating-rate note maturity date**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors | string array | datetime

Floating-rate note maturity date specified as serial date numbers, date character vectors, string arrays, or datetime arrays using a NINST-by-1 vector of dates.

Data Types: double | cell | char | string | datetime

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: [Price, PriceTree] =  
optfloatbybk(CIRTree, OptSpec, Strike, ExerciseDates, AmericanOpt, Spread, Settle, Maturity, 'FloatReset', 4, 'Basis', 7)

### **FloatReset — Frequency of payments per year**

1 (default) | positive integer from the set [1, 2, 3, 4, 6, 12] | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values [1, 2, 3, 4, 6, 12] in a NINST-by-1 vector.

---

**Note** Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

---

Data Types: double

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. The Basis value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### Principal — Principal values

100 (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of 'Principal' and nonnegative values using a NINST-by-1 vector or NINST-by-1 cell array of notional principal amounts.

When using a NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates, and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: double | cell

### Options — Structure containing derivatives pricing options

structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and the output from derivset.

Data Types: struct

### EndMonthRule — End-of-month rule flag

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

## Output Arguments

### Price — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 is returned as a scalar or an NINST-by-1 vector.

## PriceTree — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

## More About

### Floating-Rate Note Options

A floating-rate note option is a put or call option on a floating-rate note.

Financial Instruments Toolbox supports three types of put and call options on floating-rate notes:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly.

## optfloatbyhjm

Price options on floating-rate notes for Heath-Jarrow-Morton interest-rate tree

### Syntax

```
[Price,PriceTree] = optfloatbyhjm(HJMTTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,Spread,Settle,Maturity)
[Price,PriceTree] = optfloatbyhjm( ____,Name,Value)
```

### Description

[Price,PriceTree] = optfloatbyhjm(HJMTTree,OptSpec,Strike,ExerciseDates, AmericanOpt,Spread,Settle,Maturity) prices options on floating-rate notes from a Heath-Jarrow-Morton interest rate tree. optfloatbyhjm computes prices of options on vanilla floating-rate notes.

[Price,PriceTree] = optfloatbyhjm( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute the Price of American and European Call Options on a Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.035;0.040;0.045];
ValuationDate = 'Jan-1-2012';
StartDates = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
```

Create the RateSpec.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [4x1 double]
    Rates: [4x1 double]
    EndTimes: [4x1 double]
    StartTimes: [4x1 double]
    EndDates: [4x1 double]
    StartDates: [4x1 double]
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1
```

Build the HJM tree.

```

VolSpec = hjmvolspec('Constant', 0.01);
TimeSpec = hjmtimespec(RateSpec.ValuationDate, EndDates, Compounding);
HJMTree = hjmtree(VolSpec, RateSpec, TimeSpec)

HJMTree = struct with fields:
    FinObj: 'HJMTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2 3]
    dObs: [734869 735235 735600 735965]
    TFwd: {[4x1 double] [3x1 double] [2x1 double] [3]}
    CFlowT: {[4x1 double] [3x1 double] [2x1 double] [4]}
    FwdTree: {[4x1 double] [3x1x2 double] [2x2x2 double] [1x4x2 double]}

```

The floater instrument has a spread of 10, a period of one year, and matures on Jan-1-2015.

```

Spread = 10;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2015';
Period = 1;

```

Define the option for the floating-rate note.

```

OptSpec = {'call'};
Strike = 95;
ExerciseDates = 'Jan-1-2015';
AmericanOpt = [0;1];

```

Compute the price of the call options.

```

Price = optfloatbyhjm(HJMTree, OptSpec, Strike, ExerciseDates, AmericanOpt, ...
Spread, Settle, Maturity)

```

```

Price = 2x1

    4.5098
    5.2811

```

## Input Arguments

### HJMTree — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `hjmTree`.

Data Types: `struct`

### OptSpec — Definition of option

character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: `cell` | `char`

**Strike — Option strike price values**

nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as NINST-by-NSTRIKES vector of strike price values.

Data Types: single | double

**ExerciseDates — Exercise date for option (European, Bermuda, or American)**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Exercise date for option (European, Bermuda, or American) specified as serial date numbers or date character vectors using a NINST-by-NSTRIKES or NINST-by-2 vector of for the option exercise dates.

- If a European or Bermuda option, the ExerciseDates is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one ExerciseDate on the option expiry date.
- If an American option, then ExerciseDates is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-NaN date, or if ExerciseDates is 1-by-1, the option exercises between the Settle date and the single listed ExerciseDate.

Data Types: double | char | cell

**AmericanOpt — Option type**

scalar | vector of positive integers [0, 1]

Option type specified as NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: single | double

**Spread — Number of basis points over the reference rate**

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: single | double

**Settle — Settlement dates of floating-rate note**

ValuationDate of HJM tree (default) | serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Settlement dates of floating-rate note specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

---

**Note** The Settle date for every floating-rate note is set to the ValuationDate of the HJM tree. The floating-rate note argument Settle is ignored.

---

Data Types: double | cell | char

**Maturity — Floating-rate note maturity date**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Floating-rate note maturity date specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

Data Types: double | cell | char

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree] = optfloatbyhjm(HJMTree, OptSpec, Strike, ExerciseDates, AmericanOpt, Spread, Settle, Maturity, 'FloatReset', 4, 'Basis', 7)`

**FloatReset — Frequency of payments per year**

1 (default) | positive integer from the set [1, 2, 3, 4, 6, 12] | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values [1, 2, 3, 4, 6, 12] in a NINST-by-1 vector.

---

**Note** Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

---

Data Types: double

**Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)

- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### Principal — Principal values

100 (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of 'Principal' and nonnegative values using a NINST-by-1 vector or NINST-by-1 cell array of notional principal amounts. When using a NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: double | cell

### Options — Structure containing derivatives pricing options

structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: struct

### EndMonthRule — End-of-month rule flag

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

## Output Arguments

### Price — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 is returned as a scalar or an NINST-by-1 vector.

### PriceTree — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PBush` contains the clean prices.
- `PriceTree.AIBush` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

## More About

### Floating-Rate Note Options

A floating-rate note option is a put or call option on a floating-rate note.

Financial Instruments Toolbox supports three types of put and call options on floating-rate notes:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly.

For more information, see “Floating-Rate Note Options” on page 2-10.

### Introduced in R2013a

## optfloatbyhw

Price options on floating-rate notes for Hull-White interest-rate tree

### Syntax

```
[Price,PriceTree] = optfloatbyhw(HWTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,Spread,Settle,Maturity)
[Price,PriceTree] = optfloatbyhw( ____,Name,Value)
```

### Description

[Price,PriceTree] = optfloatbyhw(HWTree,OptSpec,Strike,ExerciseDates, AmericanOpt,Spread,Settle,Maturity) prices options on floating-rate notes from a Hull-White interest rate tree. optfloatbyhw computes prices of options on vanilla floating-rate notes.

[Price,PriceTree] = optfloatbyhw( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute the Price of American and European Call Options on a Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
```

Create the RateSpec.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [4x1 double]
    Rates: [4x1 double]
    EndTimes: [4x1 double]
    StartTimes: [4x1 double]
    EndDates: [4x1 double]
    StartDates: 734869
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1
```

Build the HW tree using the following:

```

VolDates = ['1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'];
VolCurve = 0.01;
AlphaDates = '01-01-2016';
AlphaCurve = 0.1;

HWVolSpec = hwwolspec(RateSpec.ValuationDate, VolDates, VolCurve, ...
    AlphaDates, AlphaCurve);
HWTTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTTimeSpec)

HWT = struct with fields:
    FinObj: 'HWFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2 3]
    dObs: [734869 735235 735600 735965]
    CFlowT: {[4x1 double] [3x1 double] [2x1 double] [4]}
    Probs: {[3x1 double] [3x3 double] [3x5 double]}
    Connect: {[2] [2 3 4] [2 3 4 5 6]}
    FwdTree: {[1.0300] [1.0562 1.0381 1.0202] [1x5 double] [1x7 double]}

```

The floater instrument has a spread of 10, a period of one year, and matures on Jan-1-2016.

```

Spread = 10;
Settle = 'Jan-1-2012';
Maturity = 'Jan-1-2016';
Period = 1;

```

Define the option for the floating-rate note.

```

OptSpec = {'call'};
Strike = 95;
ExerciseDates = 'Jan-1-2016';
AmericanOpt = [0;1];

```

Compute the price of the call options.

```

Price= optfloatbyhw(HWT, OptSpec, Strike, ExerciseDates,AmericanOpt,...
    Spread, Settle, Maturity)

```

```

Price = 2x1

    4.2740
    5.3655

```

## Input Arguments

### HWTtree — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using hwtree.

Data Types: struct

**OptSpec — Definition of option**

character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: cell | char

**Strike — Option strike price values**

nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as NINST-by-NSTRIKES vector of strike price values.

Data Types: single | double

**ExerciseDates — Exercise date for option (European, Bermuda, or American)**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Exercise date for option (European, Bermuda, or American) specified as serial date numbers or date character vectors using a NINST-by-NSTRIKES or NINST-by-2 vector of for the option exercise dates.

- If a European or Bermuda option, the ExerciseDates is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one ExerciseDate on the option expiry date.
- If an American option, then ExerciseDates is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-NaN date, or if ExerciseDates is 1-by-1, the option exercises between the Settle date and the single listed ExerciseDate.

Data Types: double | char | cell

**AmericanOpt — Option type**

scalar | vector of positive integers [0, 1]

Option type specified as NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: single | double

**Spread — Number of basis points over the reference rate**

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: single | double

**Settle — Settlement dates of floating-rate note**

ValuationDate of HW tree (default) | serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Settlement dates of floating-rate note specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

---

**Note** The `Settle` date for every floating-rate note is set to the `ValuationDate` of the HW tree. The floating-rate note argument `Settle` is ignored.

---

Data Types: double | cell | char

### **Maturity — Floating-rate note maturity date**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Floating-rate note maturity date specified as serial date numbers or date character vectors using a NINST-by-1 vector of dates.

Data Types: double | cell | char

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example:

```
[Price, PriceTree]=optfloatbyhw(HWTree, OptSpec, Strike, ExerciseDates, AmericanOpt, Spread, Settle, Maturity, 'FloatReset', 4, 'Basis', 7)
```

### **FloatReset — Frequency of payments per year**

1 (default) | positive integer from the set [1, 2, 3, 4, 6, 12] | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values [1, 2, 3, 4, 6, 12] in a NINST-by-1 vector.

---

**Note** Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

---

Data Types: double

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual

- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Principal — Principal values**

100 (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of 'Principal' and nonnegative values using a NINST-by-1 vector or NINST-by-1 cell array of notional principal amounts. When using a NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: double | cell

### **Options — Structure containing derivatives pricing options**

structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: struct

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

## Output Arguments

### Price — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 is returned as a scalar or an NINST-by-1 vector.

### PriceTree — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

## More About

### Floating-Rate Note Options

A floating-rate note option is a put or call option on a floating-rate note.

Financial Instruments Toolbox supports three types of put and call options on floating-rate notes:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly.

# optsensbysabr

Calculate option sensitivities using SABR model

## Syntax

```
Sens = optsensbysabr(ZeroCurve,Alpha,Beta,Rho,Nu,Settle,ExerciseDate,
ForwardValue,Strike,OptSpec)
Sens = optsensbysabr( ____,Name,Value)
```

## Description

`Sens = optsensbysabr(ZeroCurve,Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,Strike,OptSpec)` returns the sensitivities of an option value by using the SABR stochastic volatility model.

`Sens = optsensbysabr( ____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Calculate the Sensitivity Values for an Interest-Rate Swaption

Define the interest rate and the model parameters.

```
SwapRate = 0.0357;
Strike = 0.03;
Alpha = 0.036;
Beta = 0.5;
Rho = -0.25;
Nu = 0.35;
Rates = 0.05;
```

Define the `Settle`, `ExerciseDate`, and `OptSpec` for an interest-rate swaption.

```
Settle = datenum('15-Sep-2013');
ExerciseDate = datenum('15-Sep-2015');
OptSpec = 'call';
```

Define the `RateSpec` for the interest-rate curve.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', ExerciseDate, 'Rates', Rates, 'Compounding', -1, 'Basis', 1)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9048
    Rates: 0.0500
    EndTimes: 2
    StartTimes: 0
    EndDates: 736222
```

```

    StartDates: 735492
    ValuationDate: 735492
        Basis: 1
    EndMonthRule: 1

```

Calculate the Delta and Vega sensitivity values for the interest-rate swaption.

```
[SABRDelta, SABRVega] = optsensbysabr(RateSpec, Alpha, Beta, Rho, Nu, Settle, ...
ExerciseDate, SwapRate, Strike, OptSpec, 'OutSpec', {'Delta', 'Vega'})
```

```
SABRDelta = 0.7025
```

```
SABRVega = 0.0772
```

### Calculate the Sensitivity Values for a Swaption Using the Shifted SABR Model

Define the interest rate and the model parameters.

```

SwapRate = 0.0002;
Strike = -0.001; % -0.1% strike.
Alpha = 0.01;
Beta = 0.5;
Rho = -0.1;
Nu = 0.15;
Shift = 0.005; % 0.5 percent shift
Rates = 0.0002;

```

Define the Settle, ExerciseDate, and OptSpec for the swaption.

```

Settle = datenum('1-Mar-2016');
ExerciseDate = datenum('1-Mar-2017');
OptSpec = 'call';

```

Define the RateSpec for the interest-rate curve.

```
RateSpec = intenvset('ValuationDate',Settle,'StartDates',Settle, ...
'EndDates',ExerciseDate,'Rates',Rates,'Compounding',-1,'Basis',1)
```

```

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9998
    Rates: 2.0000e-04
    EndTimes: 1
    StartTimes: 0
    EndDates: 736755
    StartDates: 736390
    ValuationDate: 736390
    Basis: 1
    EndMonthRule: 1

```

Calculate the Delta and Vega sensitivity values for the swaption.

```
[ShiftedSABRDelta,ShiftedSABRVega] = optsensbysabr(RateSpec, ...
Alpha,Beta,Rho,Nu,Settle,ExerciseDate,SwapRate,Strike,OptSpec, ...
'OutSpec',{ 'Delta','Vega'},'Shift',Shift)
```

```
ShiftedSABRDelta = 0.9628
```

```
ShiftedSABRVega = 0.0060
```

### Calculate the Sensitivity Values for an Interest-Rate Swaption with Normal (Bachelier) Implied Volatility

This example shows how to use `optsensbysabr` to calculate sensitivities for an interest-rate swaption using the Normal model for the case where the Beta parameter is  $> 0$  and where Beta = 0.

For the case where the Beta parameter is  $> 0$ , select the Normal (Bachelier) implied volatility model in `optsensbysabr`, specify the 'Model' name-value pair to 'normal'.

```
% Define the interest rate and the model parameters.
```

```
SwapRate = 0.025;
Strike = 0.02;
Alpha = 0.044;
Beta = 0.5;
Rho = -0.21;
Nu = 0.31;
Rates = 0.028;
```

```
% Define the Settle, ExerciseDate, and OptSpec for the swaption.
```

```
Settle = datenum('7-Mar-2018');
ExerciseDate = datenum('7-Mar-2020');
OptSpec = 'call';
```

```
% Define the RateSpec for the interest-rate curve.
```

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', ExerciseDate, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);
```

```
% Calculate the Delta and Vega sensitivity values for the swaption. Set the
% 'Model' name-value pair to 'normal' in order to select the Normal
% (Bachelier) implied volatility model.
```

```
[SABRDelta, SABRVega] = optsensbysabr(RateSpec, Alpha, Beta, Rho, Nu, ...
Settle, ExerciseDate, SwapRate, Strike, OptSpec, ...
'OutSpec', { 'Delta', 'Vega'}, 'Model', 'normal')
```

```
SABRDelta = 0.7171
```

```
SABRVega = 0.0686
```

### Calculate Sensitivities for a Swaption with Normal Implied Volatility Using the Normal SABR Model

When the Beta parameter is set to zero, the SABR model becomes the Normal SABR model. Negative interest rates are allowed when the Normal SABR model is used in combination with Normal

(Bachelier) implied volatility. To select the Normal (Bachelier) implied volatility model in `optsensbysabr`, specify the 'Model' name-value pair to 'normal'.

```
% Define the interest rate and the model parameters.

SwapRate = -0.00254;
Strike = -0.002;
Alpha = 0.0047;
Beta = 0; % Set the Beta parameter to zero to use the Normal SABR model
Rho = -0.20;
Nu = 0.28;
Rates = 0.0001;

% Define the Settle, ExerciseDate, and OptSpec for the swaption.

Settle = datenum('11-Apr-2018');
ExerciseDate = datenum('11-Apr-2019');
OptSpec = 'call';

% Define the RateSpec for the interest-rate curve.

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', ExerciseDate, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);

% Calculate the Delta and Vega sensitivity values for the swaption. Set the
% 'Model' name-value pair to 'normal' in order to select the Normal
% (Bachelier) implied volatility model.

[SABRDelta, SABRVega] = optsensbysabr(RateSpec, Alpha, Beta, Rho, Nu, ...
    Settle, ExerciseDate, SwapRate, Strike, OptSpec, ...
    'OutSpec', {'Delta', 'Vega'}, 'Model', 'normal')

SABRDelta = 0.4644
SABRVega = 0.3987
```

## Input Arguments

### ZeroCurve — Annualized interest-rate term structure for zero-coupon bonds

structure

Annualized interest-rate term structure for zero-coupon bonds, specified by using the `RateSpec` obtained from `intenvset` or an `IRDataCurve` with multiple rates using the `IRDataCurve` constructor.

Data Types: struct

### Alpha — Current SABR volatility

scalar numeric

Current SABR volatility, specified as a scalar numeric.

Data Types: double

### Beta — SABR constant elasticity of variance (CEV) exponent

scalar numeric

SABR CEV exponent, specified as a scalar numeric.

Data Types: double

### **Rho — Correlation between forward value and volatility**

scalar numeric

Correlation between forward value and volatility, specified as a scalar numeric.

Data Types: double

### **Nu — Volatility of volatility**

scalar numeric

Volatility of volatility, specified as a scalar numeric.

Data Types: double

### **Settle — Settlement date**

scalar for serial nonnegative date number | scalar for date character vector

Settlement date, specified as a scalar using a serial nonnegative date number or date character vector.

Data Types: double | char

### **ExerciseDate — Option exercise date**

scalar for serial nonnegative date number | scalar for date character vector

Option exercise date, specified as a scalar using a serial nonnegative date number or date character vector.

Data Types: double | char

### **ForwardValue — Current forward value of underlying asset**

scalar numeric | vector

Current forward value of the underlying asset, specified as a scalar numeric or vector of size NINST-by-1.

Data Types: double

### **Strike — Option strike price values**

scalar numeric | vector

Option strike price values, specified as a scalar numeric or a vector of size NINST-by-1.

Data Types: double

### **OptSpec — Definition of option**

character vector with value of 'call' or 'put'

Definition of the option, specified as 'call' or 'put' using a character vector.

Data Types: char

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `ModifiedSABRDelta = optsensbysabr(RateSpec, Alpha, Beta, Rho, Nu, Settle, ExerciseDate, ForwardValue, Strike, OptSpec, 'OutSpec', 'ModifiedDelta')`

### OutSpec — Sensitivity outputs

'Delta' (default) | character vector with values 'Delta', 'Vega', 'ModifiedDelta', 'ModifiedVega', 'dSigmaF', 'dSigmaAlpha' | cell array of character vectors with values 'Delta', 'Vega', 'ModifiedDelta', 'ModifiedVega', 'dSigmaF', 'dSigmaAlpha'

Sensitivity outputs, specified as the comma-separated pair consisting of 'OutSpec' and an NOUT-by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Delta', 'Vega', 'ModifiedDelta', 'ModifiedVega', 'dSigmaF', and 'dSigmaAlpha' where:

- 'Delta' is SABR Delta by Hagan et al. (2002).
- 'Vega' is SABR Vega by Hagan et al. (2002).
- 'ModifiedDelta' is SABR Delta modified by Bartlett (2006).
- 'ModifiedVega' is SABR Vega modified by Bartlett (2006).
- 'dSigmaF' is the sensitivity of implied volatility with respect to the underlying current forward value,  $F$ . The implied volatility type depends on `Shift` and `Model`.
- 'dSigmaAlpha' is the sensitivity of implied volatility with respect to the Alpha parameter. The implied volatility type depends on `Shift` and `Model`.

Example: `OutSpec = {'Delta', 'Vega', 'ModifiedDelta', 'ModifiedVega', 'dSigmaF', 'dSigmaAlpha'}`

Data Types: char | cell

### Shift — Shift in decimals for shifted SABR model

0 (no shift) (default) | scalar positive decimal

Shift in decimals for the shifted SABR model (to be used with the Shifted Black model), specified as the comma-separated pair consisting of 'Shift' and a scalar positive decimal value. Set this parameter to a positive shift in decimals to add a positive shift to `ForwardValue` and `Strike`, which effectively sets a negative lower bound for `ForwardValue` and `Strike`. For example, a `Shift` value of 0.01 is equal to a 1% positive shift.

---

**Note** If the `Model` is set to 'normal', the `Shift` parameter must be 0.

---

Data Types: double

### Model — Model used by the implied volatility sigma

'lognormal' (default) | character vector with value 'lognormal' or 'normal' | string with value "lognormal" or "normal"

Model used by the implied volatility sigma, specified as the comma-separated pair consisting of 'Model' and a character vector with a value of 'lognormal' or 'normal', or a string with a value of "lognormal" or "normal".

---

**Note** The setting for `Model` affects the interpretation of the implied volatility "sigma". Depending on the setting for `Model`, the "sigma" has the following interpretations:

- If `Model` is 'lognormal' (default), "sigma" can be either Implied Black (no shift) or Implied Shifted Black volatility.
- If `Model` is 'normal', "sigma" is the Implied Normal (Bachelier) volatility and `Shift` must be zero.

Data Types: char | string

## Output Arguments

### Sens — Sensitivity values

array

Sensitivity values, returned as an NINST-by-1 array as defined by the `OutSpec`.

## Algorithms

In the SABR model, an option with value  $V$  is defined by the modified Black formula  $B$ , where  $\sigma_B$  is the SABR implied Black volatility.

$$V = B(F, K, T, \sigma_B(\alpha, \beta, \rho, \nu, F, K, T))$$

The Delta and Vega sensitivities under the SABR model are expressed in terms of partial derivatives in the original paper by Hagan (2002).

$$\text{SABR Delta} = \frac{\partial V}{\partial F} = \frac{\partial B}{\partial F} + \frac{\partial B}{\partial \sigma_B} \frac{\partial \sigma_B}{\partial F}$$

$$\text{SABR Vega} = \frac{\partial V}{\partial \alpha} = \frac{\partial B}{\partial \sigma_B} \frac{\partial \sigma_B}{\partial \alpha}$$

Later, Bartlett (2006) made better use of the model dynamics by incorporating the correlated changes between  $F$  and  $\alpha$

$$\text{Modified SABR Delta} = \frac{\partial B}{\partial F} + \frac{\partial B}{\partial \sigma_B} \left( \frac{\partial \sigma_B}{\partial F} + \frac{\partial \sigma_B}{\partial \alpha} \frac{\rho \nu}{F^\beta} \right)$$

$$\text{Modified SABR Vega} = \frac{\partial B}{\partial \sigma_B} \left( \frac{\partial \sigma_B}{\partial \alpha} + \frac{\partial \sigma_B}{\partial F} \frac{\rho F^\beta}{\nu} \right)$$

where  $\frac{\partial B}{\partial F}$  is the classic Black Delta and  $\frac{\partial B}{\partial \sigma_B}$  is the classic Black Vega. The Black implied volatility  $\sigma_B$  is computed internally by calling `blackvolbysabr`, while its partial derivatives  $\frac{\partial \sigma_B}{\partial F}$  and  $\frac{\partial \sigma_B}{\partial \alpha}$  are computed using closed-form expressions by `optsensbysabr`.

Similar expressions apply to the implied Normal volatility  $\sigma_N$ . For more information, see `normalvolbysabr`.

# optstockbybaw

Calculate American options prices using Barone-Adesi and Whaley option pricing model

## Syntax

Price = optstockbybaw(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)

## Description

Price = optstockbybaw(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike) calculates American options prices using the Barone-Adesi and Whaley option pricing model.

## Examples

### Compute American Option Prices Using the Barone-Adesi and Whaley Option Pricing Model

Consider an American call option with an exercise price of \$120. The option expires on Jan 1, 2018. The stock has a volatility of 14% per annum, and the annualized continuously compounded risk-free rate is 4% per annum as of Jan 1, 2016. Using this data, calculate the price of the American call, assuming the price of the stock is \$125 and pays a dividend of 2%.

```
StartDate = 'Jan-1-2016';
EndDate = 'jan-1-2018';
Basis = 1;
Compounding = -1;
Rates = 0.04;
```

Define the RateSpec.

```
RateSpec = intenvset('ValuationDate',StartDate,'StartDate',StartDate,'EndDate',EndDate, ...
'Rates',Rates,'Basis',Basis,'Compounding',Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9231
    Rates: 0.0400
    EndTimes: 2
    StartTimes: 0
    EndDates: 737061
    StartDates: 736330
    ValuationDate: 736330
    Basis: 1
    EndMonthRule: 1
```

Define the StockSpec.

```
Dividend = 0.02;
AssetPrice = 125;
Volatility = 0.14;
```

```
StockSpec = stockspec(Volatility,AssetPrice,'Continuous',Dividend)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1400
    AssetPrice: 125
    DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []
```

Define the American option.

```
OptSpec = 'call';
Strike = 120;
Settle = 'Jan-1-2016';
Maturity = 'jan-1-2018';
```

Compute the price for the American option.

```
Price = optstockbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)
```

```
Price = 14.5180
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspect`.

`stockspect` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement date

serial date number | date character vector | datetime object

Settlement date for the American option, specified as a NINST-by-1 matrix using a serial date number, a date character vector, or a datetime object.

Data Types: `double` | `char` | `datetime`

### Maturity — Maturity date

serial date number | date character vector | datetime object

Maturity date for the American option, specified as a NINST-by-1 matrix using a serial date number, a date character vector, or a datetime object.

Data Types: double | char | datetime

### **OptSpec — Definition of option**

character vector with values 'call' or 'put' | cell array of character vectors with values 'call' or 'put' | string array with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors or string arrays with values 'call' or 'put'.

Data Types: char | cell | string

### **Strike — American option strike price value**

nonnegative scalar | nonnegative vector

American Option strike price value, specified as a nonnegative scalar or NINST-by-1 matrix of strike price values. Each row is the schedule for one option.

Data Types: single | double

## **Output Arguments**

### **Price — Expected prices for American options**

vector

Expected prices for American options, returned as a NINST-by-1 vector.

## **More About**

### **Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

    EndTimes: 2
    StartTimes: 0
    EndDates: 737061
    StartDates: 736330
    ValuationDate: 736330
```

```
Basis: 1
EndMonthRule: 1
```

Define the StockSpec.

```
Dividend = 0.02;
AssetPrice = 125;
Volatility = 0.14;
```

```
StockSpec = stockspec(Volatility,AssetPrice,'Continuous',Dividend)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1400
    AssetPrice: 125
    DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []
```

Define the American option.

```
OptSpec = 'call';
Strike = 120;
Settle = 'Jan-1-2016';
Maturity = 'jan-1-2018';
```

Compute the price and sensitivities for the American option.

```
OutSpec = {'price';'delta';'theta'};
```

```
[Price,Delta,Theta] = optstocksensbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,'OutSpec');
```

```
Price = 14.5180
```

```
Delta = 0.6672
```

```
Theta = -3.1861
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: struct

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### **Settle — Settlement date**

serial date number | date character vector | datetime object

Settlement date for the American option, specified as a NINST-by-1 matrix using a serial date number, a date character vector, or a datetime object.

Data Types: `double` | `char` | `datetime`

### **Maturity — Maturity date**

serial date number | date character vector | datetime object

Maturity date for the American option, specified as a NINST-by-1 matrix using a serial date number, a date character vector, or a datetime object.

Data Types: `double` | `char` | `datetime`

### **OptSpec — Definition of option**

character vector with values 'call' or 'put' | string array with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors or string arrays with values 'call' or 'put'.

Data Types: `char` | `string`

### **Strike — American option strike price value**

nonnegative scalar | nonnegative vector

American option strike price value, specified as a nonnegative scalar or NINST-by-1 matrix of strike price values. Each row is the schedule for one option.

Data Types: `single` | `double`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Price,Delta,Theta] =`

```
optstocksensbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,'OutSpec',OutSpec)
```

### **OutSpec — Define outputs**

{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

`OutSpec = {'All'}` specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}`

Data Types: `char | cell`

## Output Arguments

### PriceSens — Expected prices or sensitivities for American options

matrix

Expected prices or sensitivities for American options, returned as a NINST-by-1 matrix.

---

**Note** All sensitivities are evaluated by computing a discrete approximation of the partial derivative. This means that the option is revalued with a fractional change for each relevant parameter. The change in the option value divided by the increment is the approximated sensitivity value.

---

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

## optstockbybjs

Price American options using Bjerksund-Stensland 2002 option pricing model

### Syntax

Price = optstockbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)

### Description

Price = optstockbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike) computes American option prices with continuous dividend yield using the Bjerksund-Stensland 2002 option pricing model.

---

**Note** optstockbybjs computes prices of American options with continuous dividend yield using the Bjerksund-Stensland option pricing model.

---

### Examples

#### Compute the American Option Prices With Continuous Dividend Yield Using the Bjerksund-Stensland 2002 Option Pricing Model

This example shows how to compute the American option prices with continuous dividend yield using the Bjerksund-Stensland 2002 option pricing model. Consider two American stock options (a call and a put) with an exercise price of \$100. The options expire on April 1, 2008. Assume the underlying stock pays a continuous dividend yield of 4% as of January 1, 2008. The stock has a volatility of 20% per annum and the annualized continuously compounded risk-free rate is 8% per annum. Using this data, calculate the price of the American call and put, assuming the following current prices of the stock: \$90 (for the call) and \$120 (for the put).

```
Settle = 'Jan-1-2008';
Maturity = 'April-1-2008';
Strike = 100;
AssetPrice = [90;120];
DivYield = 0.04;
Rate = 0.08;
Sigma = 0.20;

% define the RateSpec and StockSpec
StockSpec = stockspec(Sigma, AssetPrice, {'continuous'}, DivYield);

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1);

% define the option type
OptSpec = {'call'; 'put'};

Price = optstockbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)

Price = 2x1
```

```
0.8420
0.1108
```

The first element of the `Price` vector represents the price of the call (\$0.84); the second element represents the price of the put option (\$0.11).

## Input Arguments

### **RateSpec** — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### **StockSpec** — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### **Settle** — Settlement or trade date

serial date number | date character vector

Settlement or trade date, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: `double` | `char`

### **Maturity** — Maturity date for option

serial date number | date character vector

Maturity date for option, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: `double` | `char`

### **OptSpec** — Definition of option

cell array of character vectors with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors with values 'call' or 'put'.

Data Types: `char` | `cell`

### **Strike** — Option strike price value

nonnegative vector

Option strike price value, specified as a nonnegative NINST-by-1 vector.

Data Types: `double`

## Output Arguments

### Price — Expected option prices

vector

Expected option prices, returned as a NINST-by-1 vector.

Data Types: `double`

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

## optstockbyblk

Price options on futures and forwards using Black option pricing model

### Syntax

```
Price = optstockbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)
Price = optstockbyblk( ____, Name, Value)
```

### Description

Price = optstockbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike) computes option prices on futures or forward using the Black option pricing model.

---

**Note** optstockbyblk calculates option prices on futures and forwards. If ForwardMaturity is not passed, the function calculates prices of future options. If ForwardMaturity is passed, the function computes prices of forward options. This function handles several types of underlying assets, for example, stocks and commodities. For more information on the underlying asset specification, see stockspec.

---

Price = optstockbyblk( \_\_\_\_, Name, Value) adds an optional name-value pair argument for ForwardMaturity to compute option prices on forwards using the Black option pricing model.

### Examples

#### Compute Option Prices on Futures Using the Black Option Pricing Model

This example shows how to compute option prices on futures using the Black option pricing model. Consider two European call options on a futures contract with exercise prices of \$20 and \$25 that expire on September 1, 2008. Assume that on May 1, 2008 the contract is trading at \$20, and has a volatility of 35% per annum. The risk-free rate is 4% per annum. Using this data, calculate the price of the call futures options using the Black model.

```
Strike = [20; 25];
AssetPrice = 20;
Sigma = .35;
Rates = 0.04;
Settle = 'May-01-08';
Maturity = 'Sep-01-08';

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1);

StockSpec = stockspec(Sigma, AssetPrice);

% define the call options
OptSpec = {'call'};
```

```
Price = optstockbyblk(RateSpec, StockSpec, Settle, Maturity,...
OptSpec, Strike)
```

```
Price = 2×1
```

```
1.5903
0.3037
```

### Compute Option Prices on a Forward

This example shows how to compute option prices on forwards using the Black pricing model. Consider two European options, a call and put on the Brent Blend forward contract that expires on January 1, 2015. The options expire on October 1, 2014 with an exercise price of \$200 and \$90 respectively. Assume that on January 1, 2014 the forward price is at \$107, the annualized continuously compounded risk-free rate is 3% per annum and volatility is 28% per annum. Using this data, compute the price of the options.

Define the RateSpec.

```
ValuationDate = 'Jan-1-2014';
EndDates = 'Jan-1-2015';
Rates = 0.03;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, ...
'StartDates', ValuationDate, 'EndDates', EndDates, 'Rates', Rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9704
    Rates: 0.0300
    EndTimes: 1
    StartTimes: 0
    EndDates: 735965
    StartDates: 735600
    ValuationDate: 735600
    Basis: 1
    EndMonthRule: 1
```

Define the StockSpec.

```
AssetPrice = 107;
Sigma = 0.28;
StockSpec = stockspec(Sigma, AssetPrice);
```

Define the options.

```
Settle = 'Jan-1-2014';
Maturity = 'Oct-1-2014'; %Options maturity
Strike = [200;90];
OptSpec = {'call'; 'put'};
```

Price the forward call and put options.

```
ForwardMaturity = 'Jan-1-2015'; % Forward contract maturity
Price = optstockbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike,...
'ForwardMaturity', ForwardMaturity)
```

```
Price = 2×1
```

```
    0.0535
    3.2111
```

### Compute the Option Price on a Future

Consider a call European option on the Crude Oil Brent futures. The option expires on December 1, 2014 with an exercise price of \$120. Assume that on April 1, 2014 futures price is at \$105, the annualized continuously compounded risk-free rate is 3.5% per annum and volatility is 22% per annum. Using this data, compute the price of the option.

Define the RateSpec.

```
ValuationDate = 'January-1-2014';
EndDates = 'January-1-2015';
Rates = 0.035;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9656
    Rates: 0.0350
    EndTimes: 1
    StartTimes: 0
    EndDates: 735965
    StartDates: 735600
    ValuationDate: 735600
    Basis: 1
    EndMonthRule: 1
```

Define the StockSpec.

```
AssetPrice = 105;
Sigma = 0.22;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.2200
    AssetPrice: 105
    DividendType: []
    DividendAmounts: 0
```

```
ExDividendDates: []
```

Define the option.

```
Settle = 'April-1-2014';
Maturity = 'Dec-1-2014';
Strike = 120;
OptSpec = {'call'};
```

Price the futures call option.

```
Price = optstockbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)
```

```
Price = 2.5847
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector

Settlement or trade date, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: `double` | `cell`

### Maturity — Maturity date for option

serial date number | date character vector

Maturity date for option, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: `double` | `cell`

### OptSpec — Definition of option

cell array of character vectors with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors with values 'call' or 'put'.

Data Types: cell

### **Strike — Option strike price value**

nonnegative vector

Option strike price value, specified as a nonnegative NINST-by-1 vector.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `Price =`

```
optstockbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, 'ForwardMaturity', ForwardMaturity)
```

### **ForwardMaturity — Maturity date or delivery date of forward contract**

Maturity of option (default) | serial date number | date character vector

Maturity date or delivery date of forward contract, specified as the comma-separated pair consisting of 'ForwardMaturity' and a NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | cell

## **Output Arguments**

### **Price — Expected option prices**

vector

Expected option prices, returned as a NINST-by-1 vector.

## **More About**

### **Futures Option**

A futures option is a standardized contract between two parties to buy or sell a specified asset of standardized quantity and quality for a price agreed upon today (the futures price) with delivery and payment occurring at a specified future date, the delivery date.

The futures contracts are negotiated at a futures exchange, which acts as an intermediary between the two parties. The party agreeing to buy the underlying asset in the future, the "buyer" of the contract, is said to be "long," and the party agreeing to sell the asset in the future, the "seller" of the contract, is said to be "short."

A futures contract is the delivery of item  $J$  at time  $T$  and:

- There exists in the market a quoted price  $F(t, T)$ , which is known as the futures price at time  $t$  for delivery of  $J$  at time  $T$ .

- The price of entering a futures contract is equal to zero.
- During any time interval  $[t,s]$ , the holder receives the amount  $F(s, T) - F(t, T)$  (this reflects instantaneous marking to market).
- At time  $T$ , the holder pays  $F(T, T)$  and is entitled to receive  $J$ . Note that  $F(T, T)$  should be the spot price of  $J$  at time  $T$ .

For more information, see “Futures Option” on page 3-31.

### Forwards Option

A forwards option is a non-standardized contract between two parties to buy or to sell an asset at a specified future time at a price agreed upon today.

The buyer of a forwards option contract has the right to hold a particular forward position at a specific price any time before the option expires. The forwards option seller holds the opposite forward position when the buyer exercises the option. A call option is the right to enter into a long forward position and a put option is the right to enter into a short forward position. A closely related contract is a futures contract. A forward is like a futures in that it specifies the exchange of goods for a specified price at a specified future date.

The payoff for a forwards option, where the value of a forward position at maturity depends on the relationship between the delivery price ( $K$ ) and the underlying price ( $S_T$ ) at that time, is:

- For a long position:  $f_T = S_T - K$
- For a short position:  $f_T = K - S_T$

For more information, see “Forwards Option” on page 3-30.

### Introduced in R2008b

## optstockbybls

Price options using Black-Scholes option pricing model

### Syntax

Price = optstockbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)

### Description

Price = optstockbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)  
returns option prices using the Black-Scholes option pricing model.

---

**Note** When using StockSpec with optstockbybls, you can modify StockSpec to handle other types of underliers when pricing instruments that use the Black-Scholes model.

When pricing Futures (Black model), enter the following in StockSpec:

```
DivType = 'Continuous';
DivAmount = RateSpec.Rates;
```

For example, see “Compute Option Prices Using the Black-Scholes Option Pricing Model” on page 11-1436.

When pricing Foreign Currencies (Garman-Kohlhagen model), enter the following in StockSpec:

```
DivType = 'Continuous';
DivAmount = ForeignRate;
```

where ForeignRate is the continuously compounded, annualized risk free interest rate in the foreign country. For example, see “Compute Option Prices on Foreign Currencies Using the Garman-Kohlhagen Option Pricing Model” on page 11-1437.

---

## Examples

### Compute Option Prices Using the Black-Scholes Option Pricing Model

This example shows how to compute option prices using the Black-Scholes option pricing model. Consider two European options, a call and a put, with an exercise price of \$29 on January 1, 2008. The options expire on May 1, 2008. Assume that the underlying stock for the call option provides a cash dividend of \$0.50 on February 15, 2008. The underlying stock for the put option provides a continuous dividend yield of 4.5% per annum. The stocks are trading at \$30 and have a volatility of 25% per annum. The annualized continuously compounded risk-free rate is 5% per annum. Using this data, compute the price of the options using the Black-Scholes model.

```
Strike = 29;
AssetPrice = 30;
Sigma = .25;
Rates = 0.05;
Settle = 'Jan-01-2008';
```

```

Maturity = 'May-01-2008';

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates',...
Maturity, 'Rates', Rates, 'Compounding', -1);

DividendType = {'cash'; 'continuous'};
DividendAmounts = [0.50; 0.045];
ExDividendDates = {'Feb-15-2008'; NaN};

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts,...
ExDividendDates);

OptSpec = {'call'; 'put'};

Price = optstockbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)

Price = 2x1

    2.2030
    1.2025

```

### Compute Option Prices on Foreign Currencies Using the Garman-Kohlhagen Option Pricing Model

This example shows how to compute option prices on foreign currencies using the Garman-Kohlhagen option pricing model. Consider a European put option on a currency with an exercise price of \$0.50 on October 1, 2015. The option expires on June 1, 2016. Assume that the current exchange rate is \$0.52 and has a volatility of 12% per annum. The annualized continuously compounded domestic risk-free rate is 4% per annum and the foreign risk-free rate is 8% per annum. Using this data, compute the price of the option using the Garman-Kohlhagen model.

```

Settle = 'October-01-2015';
Maturity = 'June-01-2016';
AssetPrice = 0.52;
Strike = 0.50;
Sigma = .12;
Rates = 0.04;
ForeignRate = 0.08;

```

Define the RateSpec.

```

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates',...
Maturity, 'Rates', Rates, 'Compounding', -1)

```

```

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9737
    Rates: 0.0400
    EndTimes: 0.6667
    StartTimes: 0
    EndDates: 736482
    StartDates: 736238

```

```
ValuationDate: 736238
             Basis: 0
             EndMonthRule: 1
```

Define the StockSpec.

```
DividendType = 'Continuous';
DividendAmounts = ForeignRate;
```

```
StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1200
    AssetPrice: 0.5200
    DividendType: {'continuous'}
    DividendAmounts: 0.0800
    ExDividendDates: []
```

Price the European put option.

```
OptSpec = {'put'};
Price = optstockbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)

Price = 0.0162
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: struct

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspect`.

`stockspect` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: struct

### Settle — Settlement or trade date

serial date number | date character vector

Settlement or trade date, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: double | char

**Maturity — Maturity date for option**

serial date number | date character vector

Maturity date for option, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: double | char

**OptSpec — Definition of option**

cell array of character vectors with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors with values 'call' or 'put'.

Data Types: char | cell

**Strike — Option strike price value**

nonnegative vector

Option strike price value, specified as a nonnegative NINST-by-1 vector.

Data Types: double

**Output Arguments****Price — Expected option prices**

vector

Expected option prices, returned as a NINST-by-1 vector.

Data Types: double

**More About****Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

## **Introduced in R2008b**

# optstockbycrr

Price stock option from Cox-Ross-Rubinstein tree

## Syntax

```
[Price,PriceTree] = optstockbycrr(CRRTree,OptSpec,Strike,Settle,
ExerciseDates)
[Price,PriceTree] = optstockbycrr( ____,AmericanOpt)
```

## Description

[Price,PriceTree] = optstockbycrr(CRRTree,OptSpec,Strike,Settle,ExerciseDates) returns the price of a European, Bermuda, or American stock option from a Cox-Ross-Rubinstein tree.

[Price,PriceTree] = optstockbycrr( \_\_\_\_,AmericanOpt) adds an optional argument for AmericanOpt.

## Examples

### Price an American Stock Option Using a CRR Binomial Tree

This example shows how to price an American stock option using a CRR binomial tree by loading the file `deriv.mat`, which provides `CRRTree`. The `CRRTree` structure contains the stock specification and time information needed to price the American option.

```
load deriv.mat;

OptSpec = 'Call';
Strike = 105;
Settle = '01-Jan-2003';
ExerciseDates = '01-Jan-2005';
AmericanOpt = 1;

Price = optstockbycrr(CRRTree, OptSpec, Strike, Settle, ...
ExerciseDates, AmericanOpt)

Price = 8.2863
```

### Price a Bermudan Stock Option Using a CRR Binomial Tree

Load the file `deriv.mat`, which provides `CRRTree`. The `CRRTree` structure contains the stock specification and time information needed to price the Bermudan option.

```
load deriv.mat;

% Option
OptSpec = 'Call';
```

```
Strike = 105;
Settle = '01-Jan-2003';
ExerciseDatesBerm={'01-Jan-2004', '01-Jul-2004', '01-Jan-2005', '01-Jul-2005'};
```

Price the Bermudan option.

```
Price = optstockbycrr(CRRTree, OptSpec, Strike, Settle, ExerciseDatesBerm)
```

```
Price = 9.6381
```

## Input Arguments

### **CRRTree** — Stock tree structure

structure

Stock tree structure, specified by using `crrtree`.

Data Types: `struct`

### **OptSpec** — Definition of option

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as 'call' or 'put' using a NINST-by-1 cell array of character vectors.

Data Types: `char` | `cell`

### **Strike** — Option strike price values

nonnegative integer

Option strike price value, specified with a NINST-by-1 or NINST-by-NSTRIKES depending on the option type:

- For a European option, use a NINST-by-1 vector of strike prices.
- For a Bermuda option, use a NINST-by-NSTRIKES matrix of strike prices. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American option, use a NINST-by-1 of strike prices.

---

**Note** The interpretation of the `Strike` and `ExerciseDates` arguments depends upon the setting of the `AmericanOpt` argument. If `AmericanOpt` = 0, NaN, or is unspecified, the option is a European or Bermuda option. If `AmericanOpt` = 1, the option is an American option.

---

Data Types: `double`

### **Settle** — Settlement date or trade date

serial date number | date character vector

Settlement date or trade date, specified as a NINST-by-1 vector of date character vectors or serial date numbers.

---

**Note** The `Settle` date for every option is set to the `ValuationDate` of the stock tree. The option argument `Settle` is ignored.

---

Data Types: char | double

### **ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the option type:

- For a European option, use a NINST-by-1 vector of dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a NINST-by-1 vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

---

**Note** The interpretation of the `Strike` and `ExerciseDates` arguments depends upon the setting of the `AmericanOpt` argument. If `AmericanOpt` = 0, `NaN`, or is unspecified, the option is a European or Bermuda option. If `AmericanOpt` = 1, the option is an American option.

---

Data Types: double | char

### **AmericanOpt — Option type**

0 European or Bermuda (default) | integer with values of 0 or 1

(Optional) Option type, specified as NINST-by-1 vector of integer flags with values:

- 0 — European or Bermuda
- 1 — American

Data Types: single | double

## **Output Arguments**

### **Price — Expected price of option at time 0**

vector

Expected price of the vanilla option at time 0, returned as a NINST-by-1 vector.

### **PriceTree — Structure containing trees of vectors of instrument prices for each node**

structure

Structure containing trees of vectors of instrument prices and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.

- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

# optstockbyeqp

Price stock option from Equal Probabilities binomial tree

## Syntax

```
[Price,PriceTree] = optstockbyeqp(EQPTree,OptSpec,Strike,Settle,
ExerciseDates)
[Price,PriceTree] = optstockbyeqp( ____,AmericanOpt)
```

## Description

[Price,PriceTree] = optstockbyeqp(EQPTree,OptSpec,Strike,Settle,ExerciseDates) returns the price of a European, Bermuda, or American stock option from an Equal Probabilities binomial tree.

[Price,PriceTree] = optstockbyeqp( \_\_\_\_,AmericanOpt) adds an optional argument for AmericanOpt.

## Examples

### Price an American Stock Option Using an EQP Equity Tree

This example shows how to price an American stock option using an EQP equity tree by loading the file `deriv.mat`, which provides `EQPTree`. The `EQPTree` structure contains the stock specification and time information needed to price the American option.

```
load deriv.mat

OptSpec = 'Call';
Strike = 105;
Settle = '01-Jan-2003';
ExerciseDates = '01-Jan-2006';
AmericanOpt = 1;

Price = optstockbyeqp(EQPTree, OptSpec, Strike, Settle, ...
ExerciseDates, AmericanOpt)

Price = 12.2632
```

### Price a Bermudan Stock Option Using a EQP Equity Tree

Load the file `deriv.mat`, which provides `EQPTree`. The `EQPTree` structure contains the stock specification and time information needed to price the Bermudan option.

```
load deriv.mat;

% Option
OptSpec = 'Call';
```

```
Strike = 105;
Settle = '01-Jan-2003';
ExerciseDatesBerm={'15-Jan-2004', '15-Jul-2004', '15-Jan-2005', '15-Jul-2005'};
```

Price the Bermudan option.

```
Price= optstockbyeqp(EQPTree, OptSpec, Strike, Settle, ExerciseDatesBerm)
```

Warning: Some ExerciseDates are not aligned with tree nodes. Result will be approximated.

```
Price = 12.0255
```

## Input Arguments

### EQPTree — Stock tree structure

structure

Stock tree structure, specified by using eqptree.

Data Types: struct

### OptSpec — Definition of option

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as 'call' or 'put' using a NINST-by-1 cell array of character vectors.

Data Types: char | cell

### Strike — Option strike price values

nonnegative integer

Option strike price value, specified with a NINST-by-1 or NINST-by-NSTRIKES depending on the option type:

- For a European option, use a NINST-by-1 vector of strike prices.
- For a Bermuda option, use a NINST-by-NSTRIKES matrix of strike prices. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American option, use a NINST-by-1 of strike prices.

---

**Note** The interpretation of the Strike and ExerciseDates arguments depends upon the setting of the AmericanOpt argument. If AmericanOpt = 0, NaN, or is unspecified, the option is a European or Bermuda option. If AmericanOpt = 1, the option is an American option.

---

Data Types: double

### Settle — Settlement date or trade date

serial date number | date character vector

Settlement date or trade date, specified as a NINST-by-1 vector of date character vectors or serial date numbers.

---

**Note** The `Settle` date for every option is set to the `ValuationDate` of the stock tree. The option argument `Settle` is ignored.

---

Data Types: char | double

### **ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the option type:

- For a European option, use a NINST-by-1 vector of dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a NINST-by-1 vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

---

**Note** The interpretation of the `Strike` and `ExerciseDates` arguments depends upon the setting of the `AmericanOpt` argument. If `AmericanOpt` = 0, `NaN`, or is unspecified, the option is a European or Bermuda option. If `AmericanOpt` = 1, the option is an American option.

---

Data Types: double | char

### **AmericanOpt — Option type**

0 European or Bermuda (default) | integer with values of 0 or 1

(Optional) Option type, specified as NINST-by-1 vector of integer flags with values:

- 0 — European or Bermuda
- 1 — American

Data Types: single | double

## **Output Arguments**

### **Price — Expected price of option at time 0**

vector

Expected price of the vanilla option at time 0, returned as a NINST-by-1 vector.

### **PriceTree — Structure containing trees of vectors of instrument prices for each node**

structure

Structure containing trees of vectors of instrument prices and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.

- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

# optstockbyfd

Calculate vanilla option prices using finite difference method

## Syntax

```
[Price,PriceGrid,AssetPrices,Times] = optstockbyfd(RateSpec,StockSpec,
OptSpec,Strike,Settle,ExerciseDates)
[Price,PriceGrid,AssetPrices,Times] = optstockbyfd( ____,Name,Value)
```

## Description

[Price,PriceGrid,AssetPrices,Times] = optstockbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates) calculates vanilla option prices using the finite difference method.

[Price,PriceGrid,AssetPrices,Times] = optstockbyfd( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Price a Vanilla Call Option Using Finite Difference Method

Create a RateSpec.

```
AssetPrice = 50;
Strike = 45;
Rate = 0.035;
Volatility = 0.30;
Settle = '01-Jan-2015';
Maturity = '01-Jan-2016';
Basis = 1;
```

```
RateSpec = intenvset('ValuationDate',Settle,'StartDates',Settle,'EndDates',...
Maturity,'Rates',Rate,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9656
    Rates: 0.0350
    EndTimes: 1
    StartTimes: 0
    EndDates: 736330
    StartDates: 735965
    ValuationDate: 735965
    Basis: 1
    EndMonthRule: 1
```

Create a StockSpec.

```
StockSpec = stockspec(Volatility,AssetPrice)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3000
    AssetPrice: 50
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Calculate the price of a European vanilla call option using the finite difference method.

```
ExerciseDates = 'may-1-2015';
OptSpec = 'Call';
Price = optstockbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)

Price = 6.7352
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspect`.

`stockspect` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with values 'call' or 'put' | string array with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a character vector or string array with values 'call' or 'put'.

Data Types: `char` | `string`

### Strike — Option strike price value

nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or vector.

- For a European option, use a scalar of strike price.

- For a Bermuda option, use a 1-by-NSTRIKES vector of strike prices.
- For an American option, use a scalar of strike price.

Data Types: `single` | `double`

### **Settle — Settlement or trade date**

serial date number | date character vector | datetime object

Settlement or trade date for the barrier option, specified as a serial date number, a date character vector, or a datetime object.

Data Types: `double` | `char` | `datetime`

### **ExerciseDates — Option exercise dates**

serial date number | date character vector | datetime object

Option exercise dates, specified as a serial date number, a date character vector, or a datetime object:

- For a European option, use a 1-by-1 vector of dates, specified as a nonnegative scalar integer, a date character vector, or a datetime object. For a Bermuda option, use a 1-by-NSTRIKES vector of dates, specified as a nonnegative scalar integer, date character vector, or datetime object.
- For an American option, use a 1-by-2 cell array of date character vectors. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is a 1-by-1 vector of serial date numbers or a cell array of date character vectors, the option can be exercised between `Settle` and the single listed date in `ExerciseDates`.

Data Types: `double` | `char` | `cell` | `datetime`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Price = optstockbyfd(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates, 'AssetGridSize', 1000)`

### **AssetGridSize — Size of asset grid used for finite difference grid**

400 (default) | positive scalar

Size of the asset grid used for a finite difference grid, specified as the comma-separated pair consisting of `'AssetGridSize'` and a positive scalar.

Data Types: `double`

### **AssetPriceMax — Maximum price for price grid boundary**

if unspecified, `StockSpec` values are calculated using asset distributions at maturity (default) | positive scalar

Maximum price for price grid boundary, specified as the comma-separated pair consisting of `'AssetPriceMax'` as a positive scalar.

Data Types: `single` | `double`

**TimeGridSize — Size of time grid used for finite difference grid**

100 (default) | positive scalar

Size of the time grid used for a finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive scalar.

Data Types: double

**AmericanOpt — Option type**

0 (European/Bermuda) (default) | scalar with values [0,1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

**Output Arguments****Price — Expected prices for vanilla options**

scalar

Expected prices for vanilla options, returned as a 1-by-1 matrix.

**PriceGrid — Grid containing prices calculated by finite difference method**

grid

Grid containing prices calculated by the finite difference method, returned as a grid that is two-dimensional with size PriceGridSize\*length(Times). The number of columns does not have to be equal to the TimeGridSize, because ex-dividend dates in the StockSpec are added to the time grid. The price for  $t = 0$  is contained in PriceGrid(:, end).

**AssetPrices — Prices of asset defined by StockSpec**

vector

Prices of the asset defined by the StockSpec corresponding to the first dimension of PriceGrid, returned as a vector.

**Times — Times corresponding to second dimension of PriceGrid**

vector

Times corresponding to second dimension of the PriceGrid, returned as a vector.

**More About****Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see "Vanilla Option" on page 3-26.

## optstocksensbyfd

Calculate vanilla option prices or sensitivities using finite difference method

### Syntax

```
[PriceSens,PriceGrid,AssetPrices,Times] = optstocksensbyfd(RateSpec,
StockSpec,OptSpec,Strike,Settle,ExerciseDates)
[PriceSens,PriceGrid,AssetPrices,Times] = optstocksensbyfd( ____,Name,Value)
```

### Description

[PriceSens,PriceGrid,AssetPrices,Times] = optstocksensbyfd(RateSpec, StockSpec,OptSpec,Strike,Settle,ExerciseDates) calculates vanilla option prices or sensitivities using the finite difference method.

[PriceSens,PriceGrid,AssetPrices,Times] = optstocksensbyfd( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Calculate the Price and Sensitivities for a Vanilla Call Option Using Finite Difference Method

Create a RateSpec.

```
AssetPrice = 50;
Strike = 45;
Rate = 0.035;
Volatility = 0.30;
Settle = '01-Jan-2015';
Maturity = '01-Jan-2016';
Basis = 1;
```

```
RateSpec = intenvset('ValuationDate',Settle,'StartDates',Settle,'EndDates',...
Maturity,'Rates',Rate,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9656
    Rates: 0.0350
    EndTimes: 1
    StartTimes: 0
    EndDates: 736330
    StartDates: 735965
    ValuationDate: 735965
    Basis: 1
    EndMonthRule: 1
```

Create a StockSpec.

```
StockSpec = stockspec(Volatility,AssetPrice)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3000
    AssetPrice: 50
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Calculate the price and sensitivities for of a European vanilla call option using the finite difference method.

```
ExerciseDates = 'may-1-2015';
OptSpec = 'Call';
OutSpec = {'price'; 'delta'; 'theta'};
[PriceSens, Delta, Theta] = optstocksensbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,...
ExerciseDates,'OutSpec',OutSpec)
```

```
PriceSens = 6.7352
```

```
Delta = 0.7765
```

```
Theta = -4.9999
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with values 'call' or 'put' | string array with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a character vector or string array with values 'call' or 'put'.

Data Types: `char` | `string`

**Strike — Option strike price value**

nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or vector.

- For a European option, use a scalar of strike price.
- For a Bermuda option, use a 1-by-NSTRIKES vector of strike prices.
- For an American option, use a scalar of strike price.

Data Types: single | double

**Settle — Settlement or trade date**

serial date number | date character vector | datetime object

Settlement or trade date for the barrier option, specified as a serial date number, a date character vector, or a datetime object.

Data Types: double | char | datetime

**ExerciseDates — Option exercise dates**

date character vector | nonnegative scalar integer | datetime object

Option exercise dates, specified as a nonnegative scalar integer, date character vector, or datetime object:

- For a European option, use a 1-by-1 vector of dates, specified as a nonnegative scalar integer, a date character vector, or a datetime object. For a Bermuda option, use a 1-by-NSTRIKES vector of dates, specified as a nonnegative scalar integer, date character vector, or datetime object.
- For an American option, use a 1-by-2 cell array of date character vectors. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is a 1-by-1 vector of serial date numbers or a cell array of date character vectors, the option can be exercised between `Settle` and the single listed date in `ExerciseDates`.

Data Types: double | char | cell | datetime

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `PriceSens =`

```
optstocksensbyfd(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates, 'OutSpec', {'All'}, 'AssetGridSize', 1000)
```

**OutSpec — Define outputs**

{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

`OutSpec = {'All'}` specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}`

Data Types: char | cell

### **AssetGridSize — Size of asset grid used for finite difference grid**

400 (default) | positive scalar

Size of asset grid used for finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a positive scalar.

Data Types: double

### **AssetPriceMax — Maximum price for price grid boundary**

if unspecified, `StockSpec` values are calculated using asset distributions at maturity (default) | positive scalar

Maximum price for price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar.

Data Types: single | double

### **TimeGridSize — Size of time grid used for finite difference grid**

100 (default) | positive scalar

Size of the time grid used for a finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive scalar.

Data Types: double

### **AmericanOpt — Option type**

0 (European/Bermuda) (default) | scalar with values [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

## **Output Arguments**

### **PriceSens — Expected prices or sensitivities for vanilla options**

scalar

Expected price or sensitivities (defined by `OutSpec`) of the vanilla option, returned as a 1-by-1 array.

### **PriceGrid — Grid containing prices calculated by finite difference method**

grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with size `PriceGridSize*length(Times)`. The number of columns does not have to be equal to the `TimeGridSize`, because ex-dividend dates in the `StockSpec` are added to the time grid. The price for  $t = 0$  is contained in `PriceGrid(:, end)`.

**AssetPrices — Prices of asset defined by StockSpec**

vector

Prices of the asset defined by the StockSpec corresponding to the first dimension of PriceGrid, returned as a vector.

**Times — Times corresponding to second dimension of PriceGrid**

vector

Times corresponding to second dimension of the PriceGrid, returned as a vector.

**More About****Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

**Introduced in R2016b**

# optstockbyitt

Price options on stocks using implied trinomial tree (ITT)

## Syntax

```
[Price,PriceTree] = optstockbyitt(ITTTree,OptSpec,Strike,Settle,
ExerciseDates)
[Price,PriceTree] = optstockbyitt( ____,AmericanOpt)
```

## Description

[Price,PriceTree] = optstockbyitt(ITTTree,OptSpec,Strike,Settle,ExerciseDates) returns the price of a European, Bermuda, or American stock option from an implied trinomial tree (ITT).

[Price,PriceTree] = optstockbyitt( \_\_\_\_,AmericanOpt) adds an optional argument for AmericanOpt.

## Examples

### Price an American Stock Option Using an ITT Equity Tree

This example shows how to price an American stock option using an ITT equity tree by loading the file `deriv.mat`, which provides the `ITTTree`. The `ITTTree` structure contains the stock specification and time information needed to price the American option.

```
load deriv.mat

OptSpec = 'Put';
Strike = 30;
Settle = '01-Jan-2006';
ExerciseDates = ' 01-Jan-2010 ';
AmericanOpt = 1;

Price = optstockbyitt(ITTTree, OptSpec, Strike, Settle,ExerciseDates, AmericanOpt)

Price = 0.1271
```

### Price a Bermudan Stock Option Using an ITT Equity Tree

Load the file `deriv.mat`, which provides an `ITTTree`. The `ITTTree` structure contains the stock specification and time information needed to price the Bermudan option.

```
load deriv.mat;

% Option
OptSpec = 'Put';
Strike = 30;
Settle = '01-Jan-2006';
ExerciseDatesBerm={'1-Jan-2007','1-Jul-2007','1-Jan-2008','1-Jul-2008'};
```

Price the Bermudan option.

```
Price = optstockbyitt(ITTTree, OptSpec, Strike, Settle, ExerciseDatesBerm)
```

Warning: Some ExerciseDates are not aligned with tree nodes. Result will be approximated.

```
> In procoptions at 171
  In optstockbystocktree at 22
  In optstockbyitt at 68
```

```
Price =
    0.0664
```

## Input Arguments

### ITTTree — Stock tree structure

structure

Stock tree structure, specified by using `itttree`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as 'call' or 'put' using a NINST-by-1 cell array of character vectors.

Data Types: `char` | `cell`

### Strike — Option strike price values

nonnegative integer

Option strike price value, specified with a NINST-by-1 or NINST-by-NSTRIKES depending on the option type:

- For a European option, use a NINST-by-1 vector of strike prices.
- For a Bermuda option, use a NINST-by-NSTRIKES matrix of strike prices. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American option, use a NINST-by-1 of strike prices.

---

**Note** The interpretation of the `Strike` and `ExerciseDates` arguments depends upon the setting of the `AmericanOpt` argument. If `AmericanOpt` = 0, NaN, or is unspecified, the option is a European or Bermuda option. If `AmericanOpt` = 1, the option is an American option.

---

Data Types: `double`

### Settle — Settlement date or trade date

serial date number | date character vector

Settlement date or trade date, specified as a NINST-by-1 vector of date character vectors or serial date numbers.

---

**Note** The `Settle` date for every option is set to the `ValuationDate` of the stock tree. The option argument `Settle` is ignored.

---

Data Types: char | double

### ExerciseDates — Option exercise dates

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the option type:

- For a European option, use a NINST-by-1 vector of dates. Each row is the schedule for one option. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

---

**Note** The interpretation of the Strike and ExerciseDates arguments depends upon the setting of the AmericanOpt argument. If AmericanOpt = 0, NaN, or is unspecified, the option is a European or Bermuda option. If AmericanOpt = 1, the option is an American option.

---

Data Types: double | char

### AmericanOpt — Option type

0 European or Bermuda (default) | integer with values of 0 or 1

(Optional) Option type, specified as NINST-by-1 vector of integer flags with values:

- 0 — European or Bermuda
- 1 — American

Data Types: single | double

## Output Arguments

### Price — Expected price of option at time 0

vector

Expected price of the vanilla option at time 0, returned as a NINST-by-1 vector.

### PriceTree — Structure containing trees of vectors of instrument prices for each node

structure

Structure containing trees of vectors of instrument prices and a vector of observation times for each node. Values are:

- PriceTree.PTree contains the clean prices.
- PriceTree.tObs contains the observation times.
- PriceTree.dObs contains the observation dates.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

## Introduced in R2007a

# optstockbylr

Price options on stocks using Leisen-Reimer binomial tree model

## Syntax

```
[Price,PriceTree] = optstockbylr(LRTree,OptSpec,Strike,Settle,ExerciseDates)
[Price,PriceTree] = optstockbylr( ____,Name,Value)
```

## Description

[Price,PriceTree] = optstockbylr(LRTree,OptSpec,Strike,Settle,ExerciseDates) computes option prices on stocks using the Leisen-Reimer binomial tree model.

[Price,PriceTree] = optstockbylr( \_\_\_\_,Name,Value) adds an optional name-value pair argument for AmericanOpt.

## Examples

### Price Options on Stocks Using the Leisen-Reimer Binomial Tree Model

This example shows how to price options on stocks using the Leisen-Reimer binomial tree model. Consider European call and put options with an exercise price of \$95 that expire on July 1, 2010. The underlying stock is trading at \$100 on January 1, 2010, provides a continuous dividend yield of 3% per annum and has a volatility of 20% per annum. The annualized continuously compounded risk-free rate is 8% per annum. Using this data, compute the price of the options using the Leisen-Reimer model with a tree of 15 and 55 time steps.

```
AssetPrice = 100;
Strike = 95;

ValuationDate = 'Jan-1-2010';
Maturity = 'July-1-2010';

% define StockSpec
Sigma = 0.2;
DividendType = 'continuous';
DividendAmounts = 0.03;

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts);

% define RateSpec
Rates = 0.08;
Settle = ValuationDate;
Basis = 1;
Compounding = -1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);

% build the Leisen-Reimer (LR) tree with 15 and 55 time steps
```

```
LRTTimeSpec15 = lrtimespec(ValuationDate, Maturity, 15);
LRTTimeSpec55 = lrtimespec(ValuationDate, Maturity, 55);

% use the PP2 method
LRMethod = 'PP2';

LRTree15 = lrtree(StockSpec, RateSpec, LRTTimeSpec15, Strike, 'method', LRMethod);
LRTree55 = lrtree(StockSpec, RateSpec, LRTTimeSpec55, Strike, 'method', LRMethod);

% price the call and the put options using the LR model:
OptSpec = {'call'; 'put'};

PriceLR15 = optstockbylr(LRTree15, OptSpec, Strike, Settle, Maturity);
PriceLR55 = optstockbylr(LRTree55, OptSpec, Strike, Settle, Maturity);

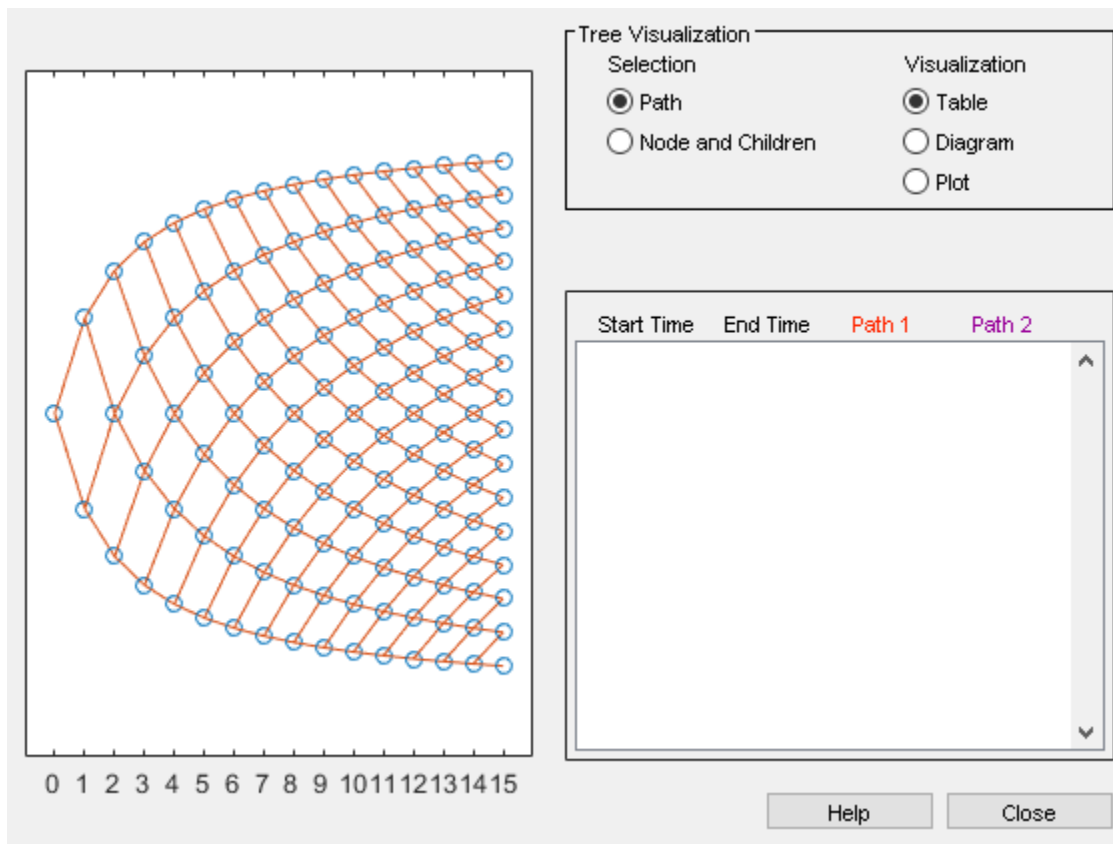

% calculate price using the Black-Scholes model (BLS) to compare values with
% the LR model:
PriceBLS = optstockbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike);

% compare values of BLS and LR
[PriceBLS PriceLR15 PriceLR55]

ans = 2x3

    9.7258    9.7252    9.7257
    2.4896    2.4890    2.4895

% use treeviewer to display LRTree of 15 time steps
treeviewer(LRTree15)
```

## Input Arguments

### LRTree — Stock tree structure

structure

Stock tree structure, specified by `lrtree`.

Data Types: `struct`

### OptSpec — Definition of option

cell array of character vectors with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors with values 'call' or 'put'.

Data Types: `char` | `cell`

### Strike — Option strike price values

vector of nonnegative integers

Option strike price value, specified with nonnegative integer:

- For a European option, use a NINST-by-1 vector of strike prices.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of strike prices. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.

- For an American option, use a NINST-by-1 vector of strike prices.

Data Types: double

### **Settle — Settlement or trade date**

serial date number | date character vector

Settlement or trade date, specified as an NINST-by-1 matrix using serial date numbers or date character vectors.

Data Types: double | char

### **ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a vector of date character vectors or serial date numbers where each row is the schedule for one option and the last element of each row must be the same as the maturity of the tree.

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKEDATES vector of dates.
- For an American option, use a NINST-by-1 vector of exercise dates. For the American type, the option can be exercised on any tree data between the `ValuationDate` and tree maturity.

Data Types: double | char

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Price, PriceTree] = optstockbylr(LRTree, OptSpec, Strike, Settle, ExerciseDates, 'AmericanOpt', '1')`

### **AmericanOpt — Option type**

0 European or Bermuda (default) | values: [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a NINST-by-1 vector of flags with values:

- 0 — European or Bermuda
- 1 — American

Data Types: double

## **Output Arguments**

### **Price — Expected prices at time 0**

vector

expected prices at time 0, returned as a NINST-by-1 vector.

**PriceTree – Tree structure**

structure

Tree structure, returned as a vector of instrument prices at each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.

**More About****Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

## optstockbyls

Price European, Bermudan, or American vanilla options using Monte Carlo simulations

### Syntax

```
Price = optstockbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates)
Price = optstockbyls( ___, Name, Value)
```

```
[Price, Path, Times, Z] = optstockbyls(RateSpec, StockSpec, OptSpec, Strike, Settle,
ExerciseDates)
[Price, Path, Times, Z] = optstockbyls( ___, Name, Value)
```

### Description

`Price = optstockbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates)` returns vanilla option prices using the Longstaff-Schwartz model. `optstockbyls` computes prices of European, Bermudan, and American vanilla options.

For American and Bermudan options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

`Price = optstockbyls( ___, Name, Value)` adds optional name-value pair arguments.

`[Price, Path, Times, Z] = optstockbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates)` returns vanilla option prices using the Longstaff-Schwartz model.

`[Price, Path, Times, Z] = optstockbyls( ___, Name, Value)` adds optional name-value pair arguments.

### Examples

#### Compute the Price of a Vanilla Option

Define the `RateSpec`.

```
StartDates = 'Jan-1-2013';
EndDates = 'Jan-1-2015';
Rates = 0.05;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: 0.9060
    Rates: 0.0500
    EndTimes: 4
    StartTimes: 0
    EndDates: 735965
    StartDates: 735235
```

```
ValuationDate: 735235
      Basis: 0
      EndMonthRule: 1
```

Define the StockSpec for the asset.

```
AssetPrice = 100;
Sigma = 0.1;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1000
    AssetPrice: 100
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the vanilla option.

```
OptSpec = 'put';
Settle = 'Jan-1-2013';
ExerciseDates = 'Jan-1-2015';
Strike = 105;
```

Compute the vanilla option price using the Longstaff-Schwartz model.

```
Antithetic = true;
Price = optstockbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ...
ExerciseDates, 'Antithetic', Antithetic)
```

```
Price = 3.2292
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using StockSpec obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities.

Data Types: `struct`

**OptSpec — Definition of option**

character vector with value 'call' or 'put'

Definition of option, specified as 'call' or 'put' using a character vector.

Data Types: char

**Strike — Option strike price values**

nonnegative scalar integer

Option strike price value, specified with nonnegative scalar integer:

- For a European option, use a scalar of strike price.
- For a Bermuda option, use a 1-by-NSTRIKES vector of strike prices.
- For an American option, use a scalar of strike price.

Data Types: single | double

**Settle — Settlement date or trade date**

date character vector | nonnegative scalar integer

Settlement date or trade date for the vanilla option, specified as a date character vector or nonnegative scalar integer.

Data Types: double | char

**ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a date character vector or serial date number:

- For a European option, use a 1-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a 1-by-NSTRIKES vector of dates.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a 1-by-1 vector of serial date numbers or cell array of character vectors, the option can be exercised between Settle and the single listed ExerciseDates.

Data Types: double | char

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: Price =

```
optstockbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates, 'American  
Opt', '1', 'NumTrials', '2000')
```

**AmericanOpt — Option type**

0 European or Bermuda (default) | scalar with values [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and positive integer scalar flags with values:

- 0 — European or Bermuda
- 1 — American

---

**Note** For American and Bermudan options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see <https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf>.

---

Data Types: `single` | `double`

### **NumTrials — Simulation trials**

1000 (default) | scalar

Simulation trials, specified as a scalar number of independent sample paths.

Data Types: `double`

### **NumPeriods — Simulation periods per trial**

100 (default) | scalar

Simulation periods per trial, specified as a scalar number. `NumPeriods` is considered only when pricing European vanilla options. For American and Bermuda vanilla options, `NumPeriod` is equal to the number of `Exercise` days during the life of the option.

Data Types: `double`

### **Z — Dependent random variates**

scalar | nonnegative integer

Dependent random variates used to generate the Brownian motion vector (that is, Wiener processes) that drive the simulation, specified as a be `NumPeriods-by-1-by-NumTrials` 3-D time series array.

Data Types: `single` | `double`

### **Antithetic — Indicator for antithetic sampling**

false (default) | logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified with a value of `true` or `false`.

Data Types: `logical`

## **Output Arguments**

### **Price — Expected price of vanilla option**

scalar

Expected price of the vanilla option, returned as a 1-by-1 scalar.

### **Path — Simulated paths of correlated state variables**

vector

Simulated paths of correlated state variables, returned as a `(NumPeriods + 1)-by-1-by-NumTrials` 3-D time series array. Each row of `Paths` is the transpose of the state vector  $X(t)$  at time  $t$  for a given trial.

**Times — Observation times associated with simulated paths**

vector

Observation times associated with simulated paths, returned as a  $(\text{NumPeriods} + 1)$ -by-1 column vector of observation times associated with the simulated paths. Each element of **Times** is associated with the corresponding row of **Paths**.

**Z — Dependent random variates**

vector

Dependent random variates, if **Z** is specified as an optional input argument, the same value is returned. Otherwise, **Z** contains the random variates generated internally.

**More About****Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

**Introduced in R2013b**

## optstocksensbyls

Calculate price and sensitivities for European, Bermudan, or American vanilla options using Monte Carlo simulations

### Syntax

```
PriceSens = optstocksensbyls(RateSpec, StockSpec, OptSpec, Strike, Settle,
ExerciseDates)
```

```
PriceSens = optstocksensbyls( ___, Name, Value)
```

```
[PriceSens, Path, Times, Z] = optstocksensbyls(RateSpec, StockSpec, OptSpec,
Strike, Settle, ExerciseDates)
```

```
[PriceSens, Path, Times, Z] = optstocksensbyls( ___, Name, Value)
```

### Description

`PriceSens = optstocksensbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates)` returns vanilla option prices or sensitivities using the Longstaff-Schwartz model. `optstocksensbyls` computes prices or sensitivities of European, Bermudan, and American vanilla options.

For American and Bermudan options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

`PriceSens = optstocksensbyls( ___, Name, Value)` adds optional name-value pair arguments.

`[PriceSens, Path, Times, Z] = optstocksensbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates)` returns vanilla option prices or sensitivities using the Longstaff-Schwartz model.

`[PriceSens, Path, Times, Z] = optstocksensbyls( ___, Name, Value)` adds optional name-value pair arguments.

### Examples

#### Compute the Price and Sensitivities of a Vanilla Option

Define the `RateSpec`.

```
StartDates = 'Jan-1-2013';
EndDates = 'Jan-1-2015';
Rates = 0.05;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: 0.9060
    Rates: 0.0500
```

```
    EndTimes: 4
    StartTimes: 0
    EndDates: 735965
    StartDates: 735235
    ValuationDate: 735235
    Basis: 0
    EndMonthRule: 1
```

Define the StockSpec for the asset.

```
AssetPrice = 100;
Sigma = 0.1;
DivType = 'continuous';
DivAmounts = 0.04;
StockSpec = stockspect(Sigma, AssetPrice, DivType, DivAmounts)

StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1000
    AssetPrice: 100
    DividendType: {'continuous'}
    DividendAmounts: 0.0400
    ExDividendDates: []
```

Define the vanilla option.

```
OptSpec = 'call';
Settle = 'jan-1-2013';
ExerciseDates = 'jan-1-2015';
Strike = 105;
```

Compute the Delta sensitivity for the vanilla option using the Longstaff-Schwartz model.

```
Antithetic = true;
OutSpec = {'Delta'};
PriceSens = optstocksensbyls(RateSpec, StockSpec, OptSpec, Strike, ...
    Settle, ExerciseDates, 'Antithetic', Antithetic, 'OutSpec', OutSpec)

PriceSens = 0.3945
```

To display the output for Price, Delta, Path, and Times, use the following:

```
OutSpec = {'Price', 'Delta'};
[Price, Delta, Path, Times] = optstocksensbyls(RateSpec, StockSpec, OptSpec, Strike, ...
    Settle, ExerciseDates, 'Antithetic', Antithetic, 'OutSpec', OutSpec);
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: struct

**StockSpec — Stock specification for underlying asset**

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities.

Data Types: `struct`

**OptSpec — Definition of option**

character vector values 'call' or 'put'

Definition of option, specified as 'call' or 'put' using a character vector.

Data Types: `char`

**Strike — Option strike price value**

nonnegative scalar integer

Option strike price value, specified with a nonnegative scalar integer:

- For a European option, use a scalar of strike price.
- For a Bermuda option, use a 1-by-NSTRIKES vector of strike price.
- For an American option, use a scalar of strike price.

Data Types: `single` | `double`

**Settle — Settlement date or trade date**

serial date number | date character vector

Settlement date or trade date for the vanilla option, specified as a date character vector or a serial date number.

Data Types: `double` | `char`

**ExerciseDates — Option exercise date**

serial date number | date character vector

Option exercise date, specified as a date character vector or serial date number:

- For a European option, use a 1-by-1 vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a 1-by-NSTRIKES vector of dates.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a 1-by-1 vector of serial date numbers or cell array of character vectors, the option can be exercised between `Settle` and the single listed `ExerciseDates`.

Data Types: `double` | `char`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Price = optstocksensbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates, 'AmericanOpt', '1', 'NumTrials', '2000', 'OutSpec', {'Price', 'Delta', 'Gamma'})`

**AmericanOpt — Option type**

0 European or Bermuda (default) | scalar with values [0,1]

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a positive integer scalar flag with values:

- 0 — European or Bermuda
- 1 — American

---

**Note** For American and Bermudan options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see <https://people.math.ethz.ch/%7Ehjurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf>.

---

Data Types: single | double

**NumTrials — Simulation trials**

1000 (default) | scalar

Simulation trials, specified as the comma-separated pair consisting of `'NumTrials'` and a scalar number of independent sample paths.

Data Types: double

**NumPeriods — Simulation periods per trial**

100 (default) | scalar

Simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar number. `NumPeriods` is considered only when pricing European vanilla options. For American and Bermuda vanilla options, `NumPeriod` is equal to the number of Exercise days during the life of the option.

Data Types: double

**Z — Dependent random variates**

scalar | nonnegative integer

Dependent random variates used to generate the Brownian motion vector (that is, Wiener processes) that drive the simulation, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods-by-1-by-NumTrials` 3-D time series array.

Data Types: single | double

**Antithetic — Indicator for antithetic sampling**

false (default) | logical flag with value of true or false

Indicator for antithetic sampling, specified as the comma-separated pair consisting of 'Antithetic' and a value of true or false.

Data Types: logical

### OutSpec — Define outputs

{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values: 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity:

Example: OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}

Data Types: char | cell

## Output Arguments

### PriceSens — Expected price or sensitivities of vanilla option

scalar

Expected price or sensitivities (defined by OutSpec) of the vanilla option, returned as a 1-by-1 array.

### Path — Simulated paths of correlated state variables

vector

Simulated paths of correlated state variables, returned as a (NumPeriods + 1)-by-1-by-NumTrials 3-D time series array. Each row of Paths is the transpose of the state vector  $X(t)$  at time  $t$  for a given trial.

### Times — Observation times associated with simulated paths

vector

Observation times associated with simulated paths, returned as a (NumPeriods + 1)-by-1 column vector of observation times associated with the simulated paths. Each element of Times is associated with the corresponding row of Paths.

### Z — Dependent random variates

vector

Dependent random variates, if Z is specified as an optional input argument, the same value is returned. Otherwise, Z contains the random variates generated internally.

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

## optstockbyrgw

Determine American call option prices using Roll-Geske-Whaley option pricing model

### Syntax

Price = optstockbyrgw(RateSpec, StockSpec, Settle, Maturity, Strike)

### Description

Price = optstockbyrgw(RateSpec, StockSpec, Settle, Maturity, Strike) computes the American call option prices using the Roll-Geske-Whaley option pricing model.

---

**Note** optstockbyrgw computes prices of American calls with a single cash dividend using the Roll-Geske-Whaley option pricing model.

---

### Examples

#### Determine American Call Option Prices Using Roll-Geske-Whaley Option Pricing Model

This example shows how to determine American call option prices using Roll-Geske-Whaley option pricing model. Consider an American call option with an exercise price of \$22 that expires on February 1, 2009. The underlying stock is trading at \$20 on June 1, 2008 and has a volatility of 20% per annum. The annualized continuously compounded risk-free rate is 6.77% per annum. The stock pays a single dividend of \$2 on September 1, 2008. Using this data, compute price of the American call option using the Roll-Geske-Whaley option pricing model.

```
Settle = 'Jun-01-2008';
Maturity = 'Feb-01-2009';
AssetPrice = 20;
Strike = 22;
Sigma = 0.2;
Rate = 0.0677;
DivAmount = 2;
DivDate = 'Sep-01-2008';

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rate, 'Compounding', -1, 'Basis', 0);

StockSpec = stockspec(Sigma, AssetPrice, {'cash'}, DivAmount, DivDate);

Price = optstockbyrgw(RateSpec, StockSpec, Settle, Maturity, Strike)

Price = 0.3359
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector

Settlement or trade date, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: `double` | `char`

### Maturity — Maturity date for option

serial date number | date character vector

Maturity date for option, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: `double` | `char`

### Strike — Option strike price value

nonnegative vector

Option strike price value, specified as a nonnegative NINST-by-1 vector.

Data Types: `double`

## Output Arguments

### Price — Expected call option prices

vector

Expected call option prices, returned as a NINST-by-1 vector.

Data Types: `double`

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

## optstocksensbybjs

Determine American option prices or sensitivities using Bjerksund-Stensland 2002 option pricing model

### Syntax

```
PriceSens = optstocksensbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec,
Strike)
PriceSens = optstocksensbybjs( ____, Name, Value)
```

### Description

PriceSens = optstocksensbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike) computes American option prices or sensitivities using the Bjerksund-Stensland 2002 option pricing model.

---

**Note** optstocksensbybjs computes prices of American options with continuous dividend yield using the Bjerksund-Stensland option pricing model. All sensitivities are evaluated by computing a discrete approximation of the partial derivative. This means that the option is revalued with a fractional change for each relevant parameter, and the change in the option value divided by the increment, is the approximated sensitivity value.

---

PriceSens = optstocksensbybjs( \_\_\_\_, Name, Value) adds an optional name-value pair argument for OutSpec.

### Examples

#### Compute American Option Prices and Sensitivities Using the Bjerksund-Stensland 2002 Option Pricing Model

This example shows how to compute American option prices and sensitivities using the Bjerksund-Stensland 2002 option pricing model. Consider four American put options with an exercise price of \$100. The options expire on October 1, 2008. Assume the underlying stock pays a continuous dividend yield of 4% and has a volatility of 40% per annum. The annualized continuously compounded risk-free rate is 8% per annum. Using this data, calculate the **delta**, **gamma**, and **price** of the American put options, assuming the following current prices of the stock on July 1, 2008: \$90, \$100, \$110 and \$120.

```
Settle = 'July-1-2008';
Maturity = 'October-1-2008';
Strike = 100;
AssetPrice = [90;100;110;120];
Rate = 0.08;
Sigma = 0.40;
DivYield = 0.04;

% define the RateSpec and StockSpec
```

```

StockSpec = stockspec(Sigma, AssetPrice, {'continuous'}, DivYield);

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1);

% define the option type
OptSpec = {'put'};

OutSpec = {'Delta', 'Gamma', 'Price'};

[Delta, Gamma, Price] = optstocksensbybjs(RateSpec, StockSpec, Settle, Maturity,...
OptSpec, Strike, 'OutSpec', OutSpec)

Delta = 4×1

    -0.6572
    -0.4434
    -0.2660
    -0.1442

Gamma = 4×1

    0.0217
    0.0202
    0.0150
    0.0095

Price = 4×1

    12.9467
     7.4571
     3.9539
     1.9495

```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: struct

**Settle — Settlement or trade date**

serial date number | date character vector

Settlement or trade date, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: double | char

**Maturity — Maturity date for option**

serial date number | date character vector

Maturity date for option, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: double | char

**OptSpec — Definition of option**

cell array of character vectors with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors with values 'call' or 'put'.

Data Types: char | cell

**Strike — Option strike price value**

nonnegative vector

Option strike price value, specified as a nonnegative NINST-by-1 vector.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: [Delta, Gamma, Price] =

```
optstocksensbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, 'OutSpec', OutSpec)
```

**OutSpec — Define outputs**

{'Price'} (default) | cell array of character vectors with values: 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity:

Example: OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}

Data Types: char | cell

## Output Arguments

### PriceSens — Expected future prices or sensitivities values

vector

Expected future prices or sensitivities values, returned as a NINST-by-1 vector.

Data Types: double

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Introduced in R2008b

## optstocksensbyblk

Determine option prices or sensitivities on futures and forwards using Black option pricing model

### Syntax

```
PriceSens = optstocksensbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec,
Strike)
PriceSens = optstocksensbyblk( ____, Name, Value)
```

### Description

PriceSens = optstocksensbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike) computes option prices on futures and forwards using the Black option pricing model.

---

**Note** optstocksensbyblk calculates option prices or sensitivities on futures and forwards. If ForwardMaturity is not passed, the function calculates prices or sensitivities of future options. If ForwardMaturity is passed, the function computes prices or sensitivities of forward options. This function handles several types of underlying assets, for example, stocks and commodities. For more information on the underlying asset specification, see stockspect.

---

PriceSens = optstocksensbyblk( \_\_\_\_, Name, Value) adds optional name-value pair arguments for ForwardMaturity and OutSpec to compute option prices or sensitivities on forwards using the Black option pricing model.

### Examples

#### Compute Option Prices and Sensitivities on Futures Using the Black Pricing Model

This example shows how to compute option prices and sensitivities on futures using the Black pricing model. Consider a European put option on a futures contract with an exercise price of \$60 that expires on June 30, 2008. On April 1, 2008 the underlying stock is trading at \$58 and has a volatility of 9.5% per annum. The annualized continuously compounded risk-free rate is 5% per annum. Using this data, compute delta, gamma, and the price of the put option.

```
AssetPrice = 58;
Strike = 60;
Sigma = .095;
Rates = 0.05;
Settle = 'April-01-08';
Maturity = 'June-30-08';

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);

StockSpec = stockspect(Sigma, AssetPrice);

% define the options
```

```

OptSpec = {'put'};

OutSpec = {'Delta', 'Gamma', 'Price'};
[Delta, Gamma, Price] = optstocksensbyblk(RateSpec, StockSpec, Settle, ...
Maturity, OptSpec, Strike, 'OutSpec', OutSpec)

Delta = -0.7469

Gamma = 0.1130

Price = 2.3569

```

### Compute Forward Option Prices and Delta Sensitivities

This example shows how to compute option prices and sensitivities on forwards using the Black pricing model. Consider two European call options on the Brent Blend forward contract that expires on January 1, 2015. The options expire on October 1, 2014 and Dec 1, 2014 with an exercise price % of \$120 and \$150 respectively. Assume that on January 1, 2014 the forward price is at \$107, the annualized continuously compounded risk-free rate is 3% per annum and volatility is 28% per annum. Using this data, compute the price and delta of the options.

Define the RateSpec.

```

ValuationDate = 'Jan-1-2014';
EndDates = 'Jan-1-2015';
Rates = 0.03;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ...
ValuationDate, 'EndDates', EndDates, 'Rates', Rates, ...
'Compounding', Compounding, 'Basis', Basis);

```

Define the StockSpec.

```

AssetPrice = 107;
Sigma = 0.28;
StockSpec = stockspec(Sigma, AssetPrice);

```

Define the options.

```

Settle = 'Jan-1-2014';
Maturity = {'Oct-1-2014'; 'Dec-1-2014'}; %Options maturity
Strike = [120;150];
OptSpec = {'call'; 'call'};

```

Price the forward call options and return the Delta sensitivities.

```

ForwardMaturity = 'Jan-1-2015'; % Forward contract maturity
OutSpec = {'Delta'; 'Price'};
[Delta, Price] = optstocksensbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, ...
Strike, 'ForwardMaturity', ForwardMaturity, 'OutSpec', OutSpec)

```

```

Delta = 2×1

    0.3518

```

0.1262

Price = 2×1

5.4808

1.6224

## Input Arguments

### **RateSpec — Interest-rate term structure**

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### **StockSpec — Stock specification for underlying asset**

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### **Settle — Settlement or trade date**

serial date number | date character vector

Settlement or trade date, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: `double` | `char`

### **Maturity — Maturity date for option**

serial date number | date character vector

Maturity date for option, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: `double` | `char`

### **OptSpec — Definition of option**

cell array of character vectors with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors with values 'call' or 'put'.

Data Types: `char` | `cell`

### **Strike — Option strike price value**

nonnegative vector

Option strike price value, specified as a nonnegative NINST-by-1 vector.

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Delta, Gamma, Price] = optstocksensbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, 'OutSpec', OutSpec)`

### ForwardMaturity — Maturity date or delivery date of forward contract

Maturity of option (default) | serial date number | date character vector

Maturity date or delivery date of forward contract, specified as the comma-separated pair consisting of `'ForwardMaturity'` and a NINST-by-1 vector using serial date numbers or date character vectors.

Data Types: double | cell

### OutSpec — Define outputs

`{'Price'}` (default) | cell array of character vectors with values: `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a NOUT-by-1 or 1-by-NOUT cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}`

Data Types: char | cell

## Output Arguments

### PriceSens — Expected future prices or sensitivities values

vector

Expected future prices or sensitivities values, returned as a NINST-by-1 vector.

Data Types: double

## More About

### Futures Option

A futures option is a standardized contract between two parties to buy or sell a specified asset of standardized quantity and quality for a price agreed upon today (the futures price) with delivery and payment occurring at a specified future date, the delivery date.

The futures contracts are negotiated at a futures exchange, which acts as an intermediary between the two parties. The party agreeing to buy the underlying asset in the future, the "buyer" of the

contract, is said to be "long," and the party agreeing to sell the asset in the future, the "seller" of the contract, is said to be "short."

A futures contract is the delivery of item  $J$  at time  $T$  and:

- There exists in the market a quoted price  $F(t, T)$ , which is known as the futures price at time  $t$  for delivery of  $J$  at time  $T$ .
- The price of entering a futures contract is equal to zero.
- During any time interval  $[t, s]$ , the holder receives the amount  $F(s, T) - F(t, T)$  (this reflects instantaneous marking to market).
- At time  $T$ , the holder pays  $F(T, T)$  and is entitled to receive  $J$ . Note that  $F(T, T)$  should be the spot price of  $J$  at time  $T$ .

For more information, see "Futures Option" on page 3-31.

### **Forwards Option**

A forwards option is a non-standardized contract between two parties to buy or to sell an asset at a specified future time at a price agreed upon today.

The buyer of a forwards option contract has the right to hold a particular forward position at a specific price any time before the option expires. The forwards option seller holds the opposite forward position when the buyer exercises the option. A call option is the right to enter into a long forward position and a put option is the right to enter into a short forward position. A closely related contract is a futures contract. A forward is like a futures in that it specifies the exchange of goods for a specified price at a specified future date.

The payoff for a forwards option, where the value of a forward position at maturity depends on the relationship between the delivery price ( $K$ ) and the underlying price ( $S_T$ ) at that time, is:

- For a long position:  $f_T = S_T - K$
- For a short position:  $f_T = K - S_T$

For more information, see "Forwards Option" on page 3-30.

## optstocksensbybls

Determine option prices or sensitivities using Black-Scholes option pricing model

### Syntax

```
PriceSens = optstocksensbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec,
Strike)
PriceSens = optstocksensbybls( ____, Name, Value)
```

### Description

PriceSens = optstocksensbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike) computes option prices or sensitivities using the Black-Scholes option pricing model.

---

**Note** When using StockSpec with optstocksensbybls, you can modify StockSpec to handle other types of underliers when pricing instruments that use the Black-Scholes model.

When pricing Futures (Black model), enter the following in StockSpec:

```
DivType = 'Continuous';
DivAmount = RateSpec.Rates;
```

When pricing Foreign Currencies (Garman-Kohlhagen model), enter the following in StockSpec:

```
DivType = 'Continuous';
DivAmount = ForeignRate;
```

where ForeignRate is the continuously compounded, annualized risk free interest rate in the foreign country.

---

PriceSens = optstocksensbybls( \_\_\_\_, Name, Value) adds an optional name-value pair argument for OutSpec.

### Examples

#### Compute Option Prices and Sensitivities Using the Black-Scholes Option Pricing Model

This example shows how to compute option prices and sensitivities using the Black-Scholes option pricing model. Consider a European call and put options with an exercise price of \$30 that expires on June 1, 2008. The underlying stock is trading at \$30 on January 1, 2008 and has a volatility of 30% per annum. The annualized continuously compounded risk-free rate is 5% per annum. Using this data, compute the delta, gamma, and price of the options using the Black-Scholes model.

```
AssetPrice = 30;
Strike = 30;
Sigma = .30;
Rates = 0.05;
Settle = 'January-01-2008';
```

```

Maturity = 'June -01-2008';

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates',...
Maturity, 'Rates', Rates, 'Compounding',-1, 'Basis', 1);

StockSpec = stockspec(Sigma, AssetPrice);

% define the options
OptSpec = {'call', 'put'};

OutSpec = {'Delta','Gamma','Price'};
[Delta, Gamma, Price] = optstocksensbybls(RateSpec, StockSpec, Settle,...
Maturity, OptSpec, Strike, 'OutSpec', OutSpec)

Delta = 2×1

    0.5810
   -0.4190

Gamma = 2×1

    0.0673
    0.0673

Price = 2×1

    2.6126
    1.9941

```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector

Settlement or trade date, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: double | char

### **Maturity – Maturity date for option**

serial date number | date character vector

Maturity date for option, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: double | char

### **OptSpec – Definition of option**

cell array of character vectors with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors with values 'call' or 'put'.

Data Types: char | cell

### **Strike – Option strike price value**

nonnegative vector

Option strike price value, specified as a nonnegative NINST-by-1 vector.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: [Delta, Gamma, Price] =

```
optstocksensbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike, 'OutSpec', 'OutSpec')
```

### **OutSpec – Define outputs**

{'Price'} (default) | cell array of character vectors with values: 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity:

Example: OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}

Data Types: char | cell

## **Output Arguments**

### **PriceSens – Expected future prices or sensitivities values**

vector

Expected future prices or sensitivities values, returned as a NINST-by-1 vector.

Data Types: `double`

## **More About**

### **Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

# optstocksensbylr

Determine option prices or sensitivities using Leisen-Reimer binomial tree model

## Syntax

```
PriceSens = optstockbylr(LRTree,OptSpec,Strike,Settle,ExerciseDates)
PriceSens = optstockbylr( ____,Name,Value)
```

## Description

PriceSens = optstockbylr(LRTree,OptSpec,Strike,Settle,ExerciseDates) calculates option prices or sensitivities using a Leisen-Reimer binomial tree model.

PriceSens = optstockbylr( \_\_\_\_,Name,Value) adds optional name-value pair arguments for AmericanOpt and OutSpec.

## Examples

### Compute Option Prices and Sensitivities Using a Leisen-Reimer Binomial Tree Model

This example shows how to compute option prices and sensitivities using a Leisen-Reimer binomial tree model. Consider European call and put options with an exercise price of \$100 that expire on December 1, 2010. The underlying stock is trading at \$100 on June 1, 2010 and has a volatility of 30% per annum. The annualized continuously compounded risk-free rate is 7% per annum. Using this data, compute the price, delta and gamma of the options using the Leisen-Reimer model with a tree of 25 time steps and the PP2 method.

```
AssetPrice = 100;
Strike = 100;

ValuationDate = 'June-1-2010';
Maturity = 'December-1-2010';

% define StockSpec
Sigma = 0.3;

StockSpec = stockspec(Sigma, AssetPrice);

% define RateSpec
Rates = 0.07;
Settle = ValuationDate;
Basis = 1;
Compounding = -1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);

% build the Leisen-Reimer (LR) tree with 25 time steps
LRTimeSpec = lrtimespec(ValuationDate, Maturity, 25);
```

```

% use the PP2 method
LRMethod = 'PP2';

TreeLR = lrtree(StockSpec, RateSpec, LRTimeSpec, Strike, 'method', LRMethod);

% compute prices and sensitivities using the LR model:
OptSpec = {'call'; 'put'};
OutSpec = {'Price', 'Delta', 'Gamma'};

[Price, Delta, Gamma] = optstocksensbylr(TreeLR, OptSpec, Strike, Settle, ...
Maturity, 'OutSpec', OutSpec)

Price = 2×1

    10.1332
     6.6937

Delta = 2×1

     0.6056
    -0.3944

Gamma = 2×1

     0.0185
     0.0185

```

## Input Arguments

### LRTree — Stock tree structure

structure

Stock tree structure, specified by `lrtree`.

Data Types: `struct`

### OptSpec — Definition of option

cell array of character vectors with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors with values 'call' or 'put'.

Data Types: `char` | `cell`

### Strike — Option strike price values

vector of nonnegative integers

Option strike price value, specified with nonnegative integer:

- For a European option, use a NINST-by-1 vector of strike prices.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of strike prices. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.

- For an American option, use a NINST-by-1 vector of strike prices.

Data Types: double

### Settle — Settlement or trade date

serial date number | date character vector

Settlement or trade date, specified as an NINST-by-1 matrix using serial date numbers or date character vectors.

Data Types: double | char

### ExerciseDates — Option exercise dates

serial date number | date character vector

Option exercise dates, specified as a vector of date character vectors or serial date numbers where each row is the schedule for one option and the last element of each row must be the same as the maturity of the tree.

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDate on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKEDATES vector of dates.
- For an American option, use a NINST-by-1 vector of exercise dates. For the American type, the option can be exercised on any tree data between the ValuationDate and tree maturity.

Data Types: double | char

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: [Price,Delta,Gamma] =  
optstocksensbylr(LRTree,OptSpec,Strike,Settle,ExerciseDates,'OutSpec',OutSpec)

### AmericanOpt — Option type

0 European or Bermuda (default) | values: [0,1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a NINST-by-1 vector of flags with values:

- 0 — European or Bermuda
- 1 — American

Data Types: double

### OutSpec — Define outputs

{'Price'} (default) | cell array of character vectors with values: 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

`OutSpec = {'All'}` specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}`

Data Types: `char` | `cell`

## Output Arguments

### PriceSens — Expected future prices or sensitivities values

vector

Expected future prices or sensitivities values, returned as a NINST-by-1 vector.

Data Types: `double`

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

where:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

## optstocksensbyrgw

Determine American call option prices or sensitivities using Roll-Geske-Whaley option pricing model

### Syntax

```
PriceSens = optstocksensbyrgw(RateSpec, StockSpec, Settle, Maturity, OptSpec,
Strike)
PriceSens = optstocksensbyrgw( ____, Name, Value)
```

### Description

PriceSens = optstocksensbyrgw(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike) computes American call option prices or sensitivities using the Roll-Geske-Whaley option pricing model.

---

**Note** optstocksensbyrgw computes prices of American calls with a single cash dividend using the Roll-Geske-Whaley option pricing model. All sensitivities are evaluated by computing a discrete approximation of the partial derivative. This means that the option is revalued with a fractional change for each relevant parameter, and the change in the option value divided by the increment, is the approximated sensitivity value.

---

PriceSens = optstocksensbyrgw( \_\_\_\_, Name, Value) adds an optional name-value pair argument for OutSpec.

### Examples

#### Compute American Call Option Prices and Sensitivities Using the Roll-Geske-Whaley Option Pricing Model

This example shows how to compute American call option prices and sensitivities using the Roll-Geske-Whaley option pricing model. Consider an American stock option with an exercise price of \$82 on January 1, 2008 that expires on May 1, 2008. Assume the underlying stock pays dividends of \$4 on April 1, 2008. The stock is trading at \$80 and has a volatility of 30% per annum. The risk-free rate is 6% per annum. Using this data, calculate the price and the value of delta and gamma of the American call using the Roll-Geske-Whaley option pricing model.

```
AssetPrice = 80;
Settle = 'Jan-01-2008';
Maturity = 'May-01-2008';
Strike = 82;
Rate = 0.06;
Sigma = 0.3;
DivAmount = 4;
DivDate = 'Apr-01-2008';

% define the RateSpec and StockSpec
StockSpec = stockspec(Sigma, AssetPrice, {'cash'}, DivAmount, DivDate);
```

```

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1, 'Basis', 1);

% define the OutSpec
OutSpec = {'Price', 'Delta', 'Gamma'};

[Price, Delta, Gamma] = optstocksensbyrgw(RateSpec, StockSpec, Settle,...
Maturity, Strike, 'OutSpec', OutSpec)

Price = 4.3860
Delta = 0.5022
Gamma = 0.0336

```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector

Settlement or trade date, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: `double` | `char`

### Maturity — Maturity date for option

serial date number | date character vector

Maturity date for option, specified as serial date number or date character vector using a NINST-by-1 vector.

Data Types: `double` | `char`

### OptSpec — Definition of option

cell array of character vectors with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors with values 'call' or 'put'.

Data Types: char | cell

### Strike — Option strike price value

nonnegative vector

Option strike price value, specified as a nonnegative NINST-by-1 vector.

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `[Delta,Gamma,Price] =`

```
optstocksensbyrgw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,'OutSpec',
,OutSpec)
```

### OutSpec — Define outputs

{'Price'} (default) | cell array of character vectors with values: 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

`OutSpec = {'All'}` specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: char | cell

## Output Arguments

### PriceSens — Expected future prices or sensitivities values

vector

Expected future prices or sensitivities values, returned as a NINST-by-1 vector.

Data Types: double

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

## optstockbystt

Price vanilla options on stocks using standard trinomial tree

### Syntax

```
[Price,PriceTree] = optstockbystt(STTTree,OptSpec,Strike,Settle,
ExerciseDates)
[Price,PriceTree] = optstockbystt( ____,Name,Value)
```

### Description

[Price,PriceTree] = optstockbystt(STTTree,OptSpec,Strike,Settle,ExerciseDates) returns vanilla option (American, European, or Bermudan) prices on stocks using a standard trinomial (STT) tree.

[Price,PriceTree] = optstockbystt( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price Call and Put Stock Options Using the Standard Trinomial Tree Model

Create a RateSpec.

```
StartDates = 'Jan-1-2009';
EndDates = 'Jan-1-2013';
Rates = 0.035;
Basis = 1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.8694
    Rates: 0.0350
    EndTimes: 4
    StartTimes: 0
    EndDates: 735235
    StartDates: 733774
    ValuationDate: 733774
    Basis: 1
    EndMonthRule: 1
```

Create a StockSpec.

```
AssetPrice = 85;
Sigma = 0.15;
StockSpec = stockspec(Sigma, AssetPrice)
```

```

StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1500
    AssetPrice: 85
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []

```

Create an STTtree.

```

NumPeriods = 4;
TimeSpec = stttimespec(StartDates, EndDates, 4);
STTtree = stttree(StockSpec, RateSpec, TimeSpec)

```

```

STTtree = struct with fields:
    FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2 3 4]
    dObs: [733774 734139 734504 734869 735235]
    STree: {1x5 cell}
    Probs: {[3x1 double] [3x3 double] [3x5 double] [3x7 double]}

```

Define the call and put options and compute the price.

```

Settle = '1/1/09';
ExerciseDates = [datenum('1/1/11'); datenum('1/1/12')];
OptSpec = {'call'; 'put'};
Strike = [100; 80];

```

```

Price = optstockbystt(STTtree, OptSpec, Strike, Settle, ExerciseDates)

```

```

Price = 2x1

```

```

    4.5025
    3.0603

```

## Input Arguments

### STTtree — Stock tree structure for standard trinomial tree

structure

Stock tree structure for a standard trinomial tree, specified by using stttree.

Data Types: struct

### OptSpec — Definition of option

character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as 'call' or 'put' using a character vector.

Data Types: char | cell

**Strike — Option strike price values**

nonnegative integer

Option strike price value, specified with a NINST-by-1 or NINST-by-NSTRIKES depending on the option type:

- For a European option, use a NINST-by-1 vector of strike prices.
- For a Bermuda option, use a NINST-by-NSTRIKES matrix of strike prices. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American option, use a NINST-by-1 of strike prices.

Data Types: double

**Settle — Settlement date or trade date**

serial date number | date character vector

Settlement date or trade date for the vanilla option, specified as a NINST-by-1 vector of date character vectors or serial date numbers.

---

**Note** The `Settle` date for every vanilla option is set to the `ValuationDate` of the stock tree. The vanilla option argument `Settle` is ignored.

---

Data Types: char | double

**ExerciseDates — Option exercise dates**

serial date number | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES using serial date numbers or date character vectors, depending on the option type:

- For a European option, use a NINST-by-1 vector of dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a NINST-by-1 vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

Data Types: double | char

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Price = optstockbystt(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates, 'AmericanOpt', '1')`

**AmericanOpt — Option type**

0 European or Bermuda (default) | integer with values of 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a NINST-by-1 vector of integer flags with values:

- 0 — European or Bermuda
- 1 — American

Data Types: single | double

**Output Arguments****Price — Expected price of vanilla option at time 0**

vector

Expected price of the vanilla option at time 0, returned as a NINST-by-1 vector.

**PriceTree — Structure containing trees of vectors of instrument prices and accrued interest for each node**

structure

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- PriceTree.PTree contains the clean prices.
- PriceTree.tObs contains the observation times.
- PriceTree.dObs contains the observation dates.

**More About****Vanilla Option**

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

# optpricebysim

Price option given simulated underlying values

## Syntax

```
Price = optpricebysim(RateSpec, SimulatedPrices, Times, OptSpec, Strike,
ExerciseTimes)
Price = optpricebysim( ____, Name, Value)
```

## Description

Price = optpricebysim(RateSpec, SimulatedPrices, Times, OptSpec, Strike, ExerciseTimes) calculates the price of European, American, and Bermudan call/put options based on risk-neutral simulation of the underlying asset. For American and Bermudan options, the Longstaff-Schwartz least squares method calculates the early exercise premium.

Price = optpricebysim( \_\_\_\_, Name, Value) adds optional name-value pair arguments.

## Examples

### Compute the Price of an American Option Using Monte Carlo Simulation Based on Geometric Brownian Motion

Define the option.

```
S0 = 100; % Initial price of underlying asset
Sigma = .2; % Volatility of underlying asset
Strike = 110; % Strike
OptSpec = 'call'; % Call option
Settle = '1-Jan-2013'; % Settlement date of option
Maturity = '1-Jan-2014'; % Maturity date of option
r = .05; % Risk-free rate (annual, continuous compounding)
Compounding = -1; % Continuous compounding
Basis = 0; % Act/Act day count convention
T = yearfrac(Settle, Maturity, Basis); % Time to expiration in years
```

Set up the gbm object and run the Monte Carlo simulation based on Geometric Brownian Motion (GBM) using the simBySolution method from Financial Toolbox™.

```
NTRIALS = 1000;
NPERIODS = daysact(Settle, Maturity);
dt = T/NPERIODS;
OptionGBM = gbm(r, Sigma, 'StartState', S0);
[Paths, Times, Z] = simBySolution(OptionGBM, NPERIODS, ...
'NTRIALS', NTRIALS, 'DeltaTime', dt, 'Antithetic', true);
```

Create the interest-rate term structure to define RateSpec.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rate', r, 'Compounding', Compounding, ...
'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9512
    Rates: 0.0500
    EndTimes: 1
    StartTimes: 0
    EndDates: 735600
    StartDates: 735235
    ValuationDate: 735235
    Basis: 0
    EndMonthRule: 1
```

Price an American option.

```
SimulatedPrices = squeeze(Paths);
OptPrice = optpricebysim(RateSpec, SimulatedPrices, Times, OptSpec, ...
    Strike, T, 'AmericanOpt', 1)

OptPrice = 6.2028
```

### Compute the Price of an American Asian Option Using Monte Carlo Simulation Based on Geometric Brownian Motion

Define the option.

```
S0 = 100; % Initial price of underlying asset
Sigma = .2; % Volatility of underlying asset
Strike = 110; % Strike
OptSpec = 'call'; % Call option
Settle = '1-Jan-2013'; % Settlement date of option
Maturity = '1-Jan-2014'; % Maturity date of option
r = .05; % Risk-free rate (annual, continuous compounding)
Compounding = -1; % Continuous compounding
Basis = 0; % Act/Act day count convention
T = yearfrac(Settle, Maturity, Basis); % Time to expiration in years
```

Set up the gbm object and run the Monte Carlo simulation based on Geometric Brownian Motion (GBM) using the `simBySolution` method from Financial Toolbox™.

```
NTRIALS = 1000;
NPERIODS = daysact(Settle, Maturity);
dt = T/NPERIODS;
OptionGBM = gbm(r, Sigma, 'StartState', S0);
[Paths, Times, Z] = simBySolution(OptionGBM, NPERIODS, ...
    'NTRIALS', NTRIALS, 'DeltaTime', dt, 'Antithetic', true);
```

Create the interest-rate term structure to define RateSpec.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rate', r, 'Compounding', Compounding, ...
    'Basis', Basis)

RateSpec = struct with fields:
    FinObj: 'RateSpec'
```

```

Compounding: -1
  Disc: 0.9512
  Rates: 0.0500
  EndTimes: 1
  StartTimes: 0
  EndDates: 735600
  StartDates: 735235
ValuationDate: 735235
  Basis: 0
EndMonthRule: 1

```

Price an American Asian option (arithmetic mean) by finding the average price over periods.

```

AvgPrices = zeros(NPERIODS+1, NTRIALS);
for i = 1:NPERIODS+1
    AvgPrices(i,:) = mean(squeeze(Paths(1:i, :, :)));
end
AsianPrice = optpricebysim(RateSpec, AvgPrices, Times, OptSpec, ...
    Strike, T, 'AmericanOpt', 1)

AsianPrice = 1.8540

```

### Compute the Price of an American Lookback Option Using Monte Carlo Simulation Based on Geometric Brownian Motion

Define the option.

```

S0 = 100; % Initial price of underlying asset
Sigma = .2; % Volatility of underlying asset
Strike = 110; % Strike
OptSpec = 'call'; % Call option
Settle = '1-Jan-2013'; % Settlement date of option
Maturity = '1-Jan-2014'; % Maturity date of option
r = .05; % Risk-free rate (annual, continuous compounding)
Compounding = -1; % Continuous compounding
Basis = 0; % Act/Act day count convention
T = yearfrac(Settle, Maturity, Basis); % Time to expiration in years

```

Set up the gbm object and run the Monte Carlo simulation based on Geometric Brownian Motion (GBM) using the `simBySolution` method from Financial Toolbox™.

```

NTRIALS = 1000;
NPERIODS = daysact(Settle, Maturity);
dt = T/NPERIODS;
OptionGBM = gbm(r, Sigma, 'StartState', S0);
[Paths, Times, Z] = simBySolution(OptionGBM, NPERIODS, ...
    'NTRIALS', NTRIALS, 'DeltaTime', dt, 'Antithetic', true);

```

Create the interest-rate term structure to define RateSpec.

```

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rate', r, 'Compounding', Compounding, ...
    'Basis', Basis)

RateSpec = struct with fields:
    FinObj: 'RateSpec'

```

```

    Compounding: -1
        Disc: 0.9512
        Rates: 0.0500
    EndTimes: 1
    StartTimes: 0
    EndDates: 735600
    StartDates: 735235
    ValuationDate: 735235
        Basis: 0
    EndMonthRule: 1

```

Price an American lookback option by finding the maximum price over periods.

```

MaxPrices = zeros(NPERIODS+1, NTRIALS);
LastPrice = squeeze(Paths(1,:,:));
for i = 1:NPERIODS+1;
    MaxPrices(i,:) = max([LastPrice; Paths(i,:)]);
    LastPrice = MaxPrices(i,:);
end
LookbackPrice = optpricebysim(RateSpec, MaxPrices, Times, OptSpec, ...
    Strike, T, 'AmericanOpt', 1)

LookbackPrice = 10.4084

```

### Compute the Price of a Bermudan Option Using Monte Carlo Simulation Based on Geometric Brownian Motion

Define the option.

```

S0 = 80; % Initial price of underlying asset
Sigma = .3; % Volatility of underlying asset
Strike = 75; % Strike
OptSpec = 'put'; % Put option
Settle = '1-Jan-2013'; % Settlement date of option
Maturity = '1-Jan-2014'; % Maturity date of option
ExerciseDates = {'1-Jun-2013', '1-Jan-2014'}; % Exercise dates of option
r = .05; % Risk-free rate (annual, continuous compounding)
Compounding = -1; % Continuous compounding
Basis = 0; % Act/Act day count convention
T = yearfrac(Settle, Maturity, Basis); % Time to expiration in years
ExerciseTimes = yearfrac(Settle, ExerciseDates, Basis); % Exercise times

```

Set up the `gbm` object and run the Monte Carlo simulation based on Geometric Brownian Motion (GBM) using the `simBySolution` method from Financial Toolbox™.

```

NTRIALS = 1000;
NPERIODS = daysact(Settle, Maturity);
dt = T/NPERIODS;
OptionGBM = gbm(r, Sigma, 'StartState', S0);
[Paths, Times, Z] = simBySolution(OptionGBM, NPERIODS, ...
    'NTRIALS', NTRIALS, 'DeltaTime', dt, 'Antithetic', true);

```

Create the interest-rate term structure to define `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rate', r, 'Compounding', Compounding, ...
    'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9512
    Rates: 0.0500
    EndTimes: 1
    StartTimes: 0
    EndDates: 735600
    StartDates: 735235
    ValuationDate: 735235
    Basis: 0
    EndMonthRule: 1
```

Price the Bermudan option.

```
SimulatedPrices = squeeze(Paths);
BermudanPrice = optpricebysim(RateSpec, SimulatedPrices, Times, ...
    OptSpec, Strike, ExerciseTimes)
```

```
BermudanPrice = 5.3950
```

### Compute the Price of an American Spread Option Using Monte Carlo Simulation Based on Geometric Brownian Motion

Define the option.

```
S1 = 110; % Price of first underlying asset
S2 = 100; % Price of second underlying asset
Sigma1 = .1; % Volatility of first underlying asset
Sigma2 = .15; % Volatility of second underlying asset
Strike = 15; % Strike
Rho = .3; % Correlation between underlyings
OptSpec = 'put'; % Put option
Settle = '1-Jan-2013'; % Settlement date of option
Maturity = '1-Jan-2014'; % Maturity date of option
r = .05; % Risk-free rate (annual, continuous compounding)
Compounding = -1; % Continuous compounding
Basis = 0; % Act/Act day count convention
T = yearfrac(Settle, Maturity, Basis); % Time to expiration in years
```

Set up the gbm object and run the Monte Carlo simulation based on Geometric Brownian Motion (GBM) using the simBySolution method from Financial Toolbox™.

```
NTRIALS = 1000;
NPERIODS = daysact(Settle, Maturity);
dt = T/NPERIODS;
SpreadGBM = gbm(r*eye(2), diag([Sigma1;Sigma2]), 'Correlation', ...
    [1 Rho;Rho 1], 'StartState', [S1;S2]);
[Paths, Times, Z] = simBySolution(SpreadGBM, NPERIODS, 'NTRIALS', NTRIALS, ...
    'DeltaTime', dt, 'Antithetic', true);
```

Create the interest-rate term structure to define RateSpec.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rate', r, 'Compounding', Compounding, ...
    'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9512
    Rates: 0.0500
    EndTimes: 1
    StartTimes: 0
    EndDates: 735600
    StartDates: 735235
    ValuationDate: 735235
    Basis: 0
    EndMonthRule: 1
```

Price the American spread option.

```
Spread = squeeze(Paths(:,1,:) - Paths(:,2,:));
SpreadPrice = optpricebysim(RateSpec, Spread, Times, OptSpec, Strike, ...
    T, 'AmericanOpt', 1)
```

```
SpreadPrice = 9.0007
```

## Input Arguments

### RateSpec — Interest-rate term structure of risk-free rates

structure

Interest-rate term structure of risk-free rates (annualized and continuously compounded), specified by the RateSpec obtained from intenvset. The valuation date must be at the settlement date of the option, and the day-count basis and end-of-month rule must be the same as those used to calculate the Times input. For information on the interest-rate specification, see intenvset.

Data Types: struct

### SimulatedPrices — Simulated prices

matrix

Simulated prices, specified using a (NumPeriods + 1)-by-NumTrials matrix of risk-neutral simulated prices. The first element of SimulatedPrices is the initial value at time 0.

Data Types: single | double

### Times — Annual time factors associated with simulated prices

vector

Annual time factors associated with simulated prices, specified using a (NumPeriods + 1)-by-1 column vector. Each element of Times is associated with the corresponding row of SimulatedPrices. The first element of Times must be 0 (current time).

Data Types: single | double

**OptSpec — Definition of option**

character vector with values 'call' or 'put'

Definition of option as 'call' or 'put', specified as a character vector.

Data Types: char

**Strike — Option strike price values**

scalar | function handle

Option strike price values, specified as a scalar value `Strike` price. `Strike` for Bermudan options can be specified as a 1-by-NSTRIKES vector or a function handle that returns the value of the strike given the time of the strike.

Data Types: single | double | function\_handle

**ExerciseTimes — Exercise time for option**

vector of exercise times

Exercise time for the option, specified as a vector of exercise times as follows:

- For a European or Bermudan option, `ExerciseTimes` is a 1-by-1 (European) or 1-by-NSTRIKES (Bermudan) vector of exercise times. For a European option, there is only one `ExerciseTimes` on the option expiry date.
- For an American option, `ExerciseTimes` is a 1-by-2 vector of exercise time boundaries. The option exercises on any date between, or including, the pair of times on that row. If `ExerciseTimes` is 1-by-1, the option exercises between time 0 and the single listed `ExerciseTimes`.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Price =`

```
optpricebysim(RateSpec, Prices, Times, OptSpec, Settle, Strike, ExerciseTimes, 'AmericanOpt', 1)
```

**AmericanOpt — Option type**

0 European or Bermudan (default) | scalar flag with value [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and an integer scalar flag with values:

- 0 — European or Bermudan
- 1 — American

For American options, the Longstaff-Schwartz least squares method calculates the early exercise premium.

Data Types: single | double

## Output Arguments

### Price — Price of option

scalar

Price of the option, returned as a scalar value.

## rangefloatbybdt

Price range floating note using Black-Derman-Toy tree

### Syntax

```
[Price,PriceTree] = rangefloatbybdt(BDTree,Spread,Settle,Maturity,RateSched)
[Price,PriceTree] = rangefloatbybdt( ____,Name,Value)
```

### Description

[Price,PriceTree] = rangefloatbybdt(BDTree,Spread,Settle,Maturity,RateSched) prices range floating note using a Black-Derman-Toy tree.

Payments on range floating notes are determined by the effective interest-rate between reset dates. If the reset period for a range spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

[Price,PriceTree] = rangefloatbybdt( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute the Price of a Range Note Using a Black-Derman-Toy Tree

This example shows how to compute the price of a range note using a Black-Derman-Toy tree with the following interest-rate term structure data.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2011';
StartDates = ValuationDate;
EndDates = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
Compounding = 1;

% define RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% range note instrument matures in Jan-1-2014 and has the following RateSchedule:
Spread = 100;
Settle = 'Jan-1-2011';
Maturity = 'Jan-1-2014';
RateSched(1).Dates = {'Jan-1-2012'; 'Jan-1-2013' ; 'Jan-1-2014'};
RateSched(1).Rates = [0.045 0.055 ; 0.0525 0.0675; 0.06 0.08];

% data to build the tree is as follows:
% assume the volatility is 10%.
Sigma = 0.1;
BDTTS = bdttimespec(ValuationDate, EndDates, Compounding);
```

```
BDTVS = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates))');  
BDTT = bdttree(BDTV, RS, BDTTS);  
  
% price the instrument  
Price = rangefloatbybdt(BDTT, Spread, Settle, Maturity, RateSched)  
  
Price = 97.5267
```

## Input Arguments

### **BDTT** — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

### **Spread** — Number of basis points over reference rate

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: `double`

### **Settle** — Settlement date for floating range note

serial date number | date character vector | cell array of date character vectors

Settlement date for the floating range note, specified as a NINST-by-1 vector of serial date numbers or date character vectors. The `Settle` date for every range floating instrument is set to the `ValuationDate` of the BDT tree. The floating range note argument `Settle` is ignored.

Data Types: `double` | `char` | `cell`

### **Maturity** — Maturity date for floating range note

serial date number | date character vector | cell array of date character vectors

Maturity date for the floating-rate note, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### **RateSched** — Range of rates within which cash flows are nonzero

structure

Range of rates within which cash flows are nonzero, specified as a NINST-by-1 vector of structures. Each element of the structure array contains two fields:

- `RateSched.Dates` — NDates-by-1 cell array of dates corresponding to the range schedule.
- `RateSched.Rates` — NDates-by-2 array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date `RateSched.Dates(n)` is nonzero for rates in the range `RateSched.Rates(n,1) < Rate < RateSched.Rates(n,2)`.

Data Types: `struct`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree] = rangefloatbybdt(BDTree, Spread, Settle, Maturity, RateSched, 'Reset', 4, 'Basis', 5, 'Principal', 10000)`

### Reset — Frequency payment per year

1 (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and a `NINST-by-1` vector.

Data Types: double

### Basis — Day-count basis of instrument

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST-by-1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### Principal — Notional principal amount

100 (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST-by-1` vector.

Data Types: double

**Options — Derivatives pricing options structure**

structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

**EndMonthRule — End-of-month rule flag for generating caplet dates**

1 (in effect) (default) | nonnegative integer with value 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer with a value of 0 or 1 using a NINST-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

**Output Arguments****Price — Expected prices of range floating notes at time 0**

vector

Expected prices of the range floating notes at time 0, returned as a NINST-by-1 vector.

**PriceTree — Tree structure of instrument prices**

structure

Tree structure of instrument prices, returned as a structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

**More About****Range Note**

A range note is a structured (market-linked) security whose coupon rate is equal to the reference rate as long as the reference rate is within a certain range.

If the reference rate is outside of the range, the coupon rate is 0 for that period. This type of instrument entitles the holder to cash flows that depend on the level of some reference interest rate and are floored to be positive. The note holder gets direct exposure to the reference rate. In return for the drawback that no interest is paid for the time the range is left, they offer higher coupon rates than comparable standard products, like vanilla floating notes. For more information, see “Range Note” on page 2-12.

## Introduced in R2012a

## rangefloatbybk

Price range floating note using Black-Karasinski tree

### Syntax

```
[Price,PriceTree] = rangefloatbybk(BKTree,Spread,Settle,Maturity,RateSched)
[Price,PriceTree] = rangefloatbybk( ____,Name,Value)
```

### Description

[Price,PriceTree] = rangefloatbybk(BKTree,Spread,Settle,Maturity,RateSched) prices range floating note using a Black-Karasinski tree.

Payments on range floating notes are determined by the effective interest-rate between reset dates. If the reset period for a range spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

[Price,PriceTree] = rangefloatbybk( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute the Price of a Range Note Using a Black-Karasinski Tree

This example shows how to compute the price of a range note using a Black-Karasinski tree with the following interest-rate term structure data.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2011';
StartDates = ValuationDate;
EndDates = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
Compounding = 1;

% define RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% range note instrument matures in Jan-1-2014 and has the following RateSchedule:
Spread = 100;
Settle = 'Jan-1-2011';
Maturity = 'Jan-1-2014';
RateSched(1).Dates = {'Jan-1-2012'; 'Jan-1-2013' ; 'Jan-1-2014'};
RateSched(1).Rates = [0.045 0.055 ; 0.0525 0.0675; 0.06 0.08];

% data to build the tree is as follows:
VolDates = ['1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'];
VolCurve = 0.01;
AlphaDates = '01-01-2015';
```

```

AlphaCurve = 0.1;

BKVS = bkvlspec(RS.ValuationDate, VolDates, VolCurve, ...
AlphaDates, AlphaCurve);
BKTS = bktimespec(RS.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVS, RS, BKTS);

% price the instrument
Price = rangefloatbybk(BKT, Spread, Settle, Maturity, RateSched)

Price = 102.7574

```

## Input Arguments

### **BKTree** — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

### **Spread** — Number of basis points over reference rate

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: `double`

### **Settle** — Settlement date for floating range note

serial date number | date character vector | cell array of date character vectors

Settlement date for the floating range note, specified as a NINST-by-1 vector of serial date numbers or date character vectors. The `Settle` date for every range floating instrument is set to the `ValuationDate` of the BK tree. The floating range note argument `Settle` is ignored.

Data Types: `double` | `char` | `cell`

### **Maturity** — Maturity date for floating range note

serial date number | date character vector | cell array of date character vectors

Maturity date for the floating-rate note, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### **RateSched** — Range of rates within which cash flows are nonzero

structure

Range of rates within which cash flows are nonzero, specified as a NINST-by-1 vector of structures. Each element of the structure array contains two fields:

- `RateSched.Dates` — NDates-by-1 cell array of dates corresponding to the range schedule.
- `RateSched.Rates` — NDates-by-2 array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date `RateSched.Dates(n)` is nonzero for rates in the range `RateSched.Rates(n,1) < Rate < RateSched.Rates(n,2)`.

Data Types: struct

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree] = rangefloatbybk(BKTree, Spread, Settle, Maturity, RateSched, 'Reset', 4, 'Basis', 5, 'Principal', 10000)`

### Reset — Frequency payment per year

1 (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of 'Reset' and a NINST-by-1 vector.

Data Types: double

### Basis — Day-count basis of instrument

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### Principal — Notional principal amount

100 (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of 'Principal' and a NINST-by-1 vector.

Data Types: double

**Options — Derivatives pricing options structure**

structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

**EndMonthRule — End-of-month rule flag for generating caplet dates**

1 (in effect) (default) | nonnegative integer with value 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer with a value of 0 or 1 using a NINST-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

**Output Arguments****Price — Expected prices of range floating notes at time 0**

vector

Expected prices of the range floating notes at time 0, returned as a NINST-by-1 vector.

**PriceTree — Tree structure of instrument prices**

structure

Tree structure of instrument prices, returned as a structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

**More About****Range Note**

A range note is a structured (market-linked) security whose coupon rate is equal to the reference rate as long as the reference rate is within a certain range.

If the reference rate is outside of the range, the coupon rate is 0 for that period. This type of instrument entitles the holder to cash flows that depend on the level of some reference interest rate and are floored to be positive. The note holder gets direct exposure to the reference rate. In return for the drawback that no interest is paid for the time the range is left, they offer higher coupon rates than comparable standard products, like vanilla floating notes. ## Introduced in R2012a

## rangefloatbycir

Price range floating note using Cox-Ingersoll-Ross tree

### Syntax

```
[Price,PriceTree] = rangefloatbycir(CIRTree,Spread,Settle,Maturity,RateSched)
[Price,PriceTree] = rangefloatbycir( ____,Name,Value)
```

### Description

[Price,PriceTree] = rangefloatbycir(CIRTree,Spread,Settle,Maturity,RateSched) prices range floating note with a Cox-Ingersoll-Ross (CIR) interest-rate tree using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

[Price,PriceTree] = rangefloatbycir( \_\_\_\_,Name,Value) adds additional name-value pair arguments.

### Examples

#### Price a Range Floating-Rate Note Using a CIR Interest-Rate Tree

Create a RateSpec using the intenvset function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates', EndDates)
```

Create a CIR tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = '01-Jan-2017';
Maturity = '01-Jan-2020';
CIRTimeSpec = cirtimespec(Settle, Maturity, 3);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
    FinObj: 'CIRFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2]
    dObs: [736696 737061 737426]
    FwdTree: {[1.0350] [1.0790 1.0500 1.0298] [1x5 double]}
```

```
Connect: {[3x1 double] [3x3 double]}
Probs: {[3x1 double] [3x3 double]}
```

Define the range note instrument that matures in Jan-1-2014 and has the following RateSchedule:

```
Spread = 100;
Settle = 'Jan-1-2017';
Maturity = 'Jan-1-2020';
RateSched(1).Dates = {'Jan-1-2018'; 'Jan-1-2019' ; 'Jan-1-2020'};
RateSched(1).Rates = [0.045 0.055 ; 0.0525 0.0675; 0.06 0.08];
```

Compute the price of the range floating note.

```
[Price,PriceTree] = rangefloatbycir(CIRT,Spread,Settle,Maturity,RateSched)
```

```
Price = 91.6849
```

```
PriceTree = struct with fields:
  FinObj: 'CIRPriceTree'
  PTree: {1x4 cell}
  AITree: {[0] [0 0 0] [0 0 0 0 0] [0 0 0 0 0]}
  tObs: [0 1 2 3]
  Connect: {[3x1 double] [3x3 double]}
  Probs: {[3x1 double] [3x3 double]}
```

## Input Arguments

### CIRTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: struct

### Spread — Number of basis points over reference rate

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: double

### Settle — Settlement date for floating range note

serial date number | date character vector | cell array of date character vectors | string array | datetime

Settlement date for the floating range note, specified as a NINST-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays. The `Settle` date for every range floating instrument is set to the `ValuationDate` of the CIR tree. The floating range note argument `Settle` is ignored.

Data Types: double | char | cell | string | datetime

### Maturity — Maturity date for floating range note

serial date number | date character vector | cell array of date character vectors | string array | datetime

Maturity date for the floating-rate note, specified as a NINST-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

Data Types: `double` | `char` | `cell` | `string` | `datetime`

### **RateSched — Range of rates within which cash flows are nonzero** structure

Range of rates within which cash flows are nonzero, specified as a NINST-by-1 vector of structures. Each element of the structure array contains two fields:

- `RateSched.Dates` — NDates-by-1 cell array of dates corresponding to the range schedule.
- `RateSched.Rates` — NDates-by-2 array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date `RateSched.Dates(n)` is nonzero for rates in the range `RateSched.Rates(n,1) < Rate < RateSched.Rates(n,2)`.

Data Types: `struct`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Price, PriceTree] =`

```
rangefloatbycir(CIRTree, Spread, Settle, Maturity, RateSched, 'Reset', 4, 'Basis', 5, 'Principal', 10000)
```

### **Reset — Frequency payment per year**

1 (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of 'Reset' and a NINST-by-1 vector.

---

**Note** Payments on range floating notes are determined by the effective interest-rate between reset dates. If the reset period for a range spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

---

Data Types: `double`

### **Basis — Day-count basis of instrument**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **Principal — Notional principal amount**

100 (default) | `numeric`

Notional principal amount, specified as the comma-separated pair consisting of 'Principal' and a NINST-by-1 vector.

Data Types: `double`

### **EndMonthRule — End-of-month rule flag for generating caplet dates**

1 (in effect) (default) | `nonnegative integer with value 0 or 1`

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer with a value of 0 or 1 using a NINST-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

## **Output Arguments**

### **Price — Expected prices of range floating notes at time 0**

`vector`

Expected prices of the range floating notes at time 0, returned as a NINST-by-1 vector.

### **PriceTree — Tree structure of instrument prices**

`structure`

Tree structure of instrument prices, returned as a structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.

- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

## More About

### Range Note

A range note is a structured (market-linked) security whose coupon rate is equal to the reference rate as long as the reference rate is within a certain range.

If the reference rate is outside of the range, the coupon rate is 0 for that period. This type of instrument entitles the holder to cash flows that depend on the level of some reference interest rate and are floored to be positive. The note holder gets direct exposure to the reference rate. In return for the drawback that no interest is paid for the time the range is left, they offer higher coupon rates than comparable standard products, vanilla floating notes. For more information, see “Range Note” on page 2-12.

## Introduced in R2018a

## rangefloatbyhjm

Price range floating note using Heath-Jarrow-Morton tree

### Syntax

```
[Price,PriceTree] = rangefloatbyhjm(HJMTree,Spread,Settle,Maturity,RateSched)
[Price,PriceTree] = rangefloatbyhjm( ___ Name,Value)
```

### Description

[Price,PriceTree] = rangefloatbyhjm(HJMTree,Spread,Settle,Maturity,RateSched) prices range floating note using a Heath-Jarrow-Morton tree.

Payments on range floating notes are determined by the effective interest-rate between reset dates. If the reset period for a range spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

[Price,PriceTree] = rangefloatbyhjm( \_\_\_ Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute the Price of a Range Note Using a Heath-Jarrow-Morton Tree

This example shows how to compute the price of a range note using a Heath-Jarrow-Morton tree with the following interest-rate term structure data.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2011';
StartDates = ValuationDate;
EndDates = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
Compounding = 1;

% define RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% range note instrument matures in Jan-1-2014 and has the following RateSchedule:
Spread = 100;
Settle = 'Jan-1-2011';
Maturity = 'Jan-1-2014';
RateSched(1).Dates = {'Jan-1-2012'; 'Jan-1-2013' ; 'Jan-1-2014'};
RateSched(1).Rates = [0.045 0.055 ; 0.0525 0.0675; 0.06 0.08];

% data to build the tree is as follows:
Volatility = [.2; .19; .18; .17];
CurveTerm = [ 1; 2; 3; 4];
MaTree = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
```

```

HJMTree = hjmtreespec(ValuationDate, MaTree);
HJMVS = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
HJMT = hjmtree(HJMVS, RS, HJMTree);

% price the instrument
Price = rangefloatbyhjm(HJMT, Spread, Settle, Maturity, RateSched)

Price = 90.2348

```

## Input Arguments

### HJMTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmTree`.

Data Types: `struct`

### Spread — Number of basis points over reference rate

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: `double`

### Settle — Settlement date for floating range note

serial date number | date character vector | cell array of date character vectors

Settlement date for the floating range note, specified as a NINST-by-1 vector of serial date numbers or date character vectors. The `Settle` date for every range floating instrument is set to the `ValuationDate` of the HJM tree. The floating range note argument `Settle` is ignored.

Data Types: `double` | `char` | `cell`

### Maturity — Maturity date for floating range note

serial date number | date character vector | cell array of date character vectors

Maturity date for the floating-rate note, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### RateSched — Range of rates within which cash flows are nonzero

structure

Range of rates within which cash flows are nonzero, specified as a NINST-by-1 vector of structures. Each element of the structure array contains two fields:

- `RateSched.Dates` — NDates-by-1 cell array of dates corresponding to the range schedule.
- `RateSched.Rates` — NDates-by-2 array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date `RateSched.Dates(n)` is nonzero for rates in the range `RateSched.Rates(n,1) < Rate < RateSched.Rates(n,2)`.

Data Types: `struct`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree] = rangefloatbyhjm(HJMTTree, Spread, Settle, Maturity, RateSched, 'Reset', 4, 'Basis', 5, 'Principal', 10000)`

### Reset — Frequency payment per year

1 (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and a `NINST-by-1` vector.

Data Types: double

### Basis — Day-count basis of instrument

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST-by-1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### Principal — Notional principal amount

100 (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST-by-1` vector.

Data Types: double

**Options — Derivatives pricing options structure**

structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

**EndMonthRule — End-of-month rule flag for generating caplet dates**

1 (in effect) (default) | nonnegative integer with value 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer with a value of 0 or 1 using a NINST-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

**Output Arguments****Price — Expected prices of range floating notes at time 0**

vector

Expected prices of the range floating notes at time 0, returned as a NINST-by-1 vector.

**PriceTree — Tree structure of instrument prices**

structure

Tree structure of instrument prices, returned as a structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

**More About****Range Note**

A range note is a structured (market-linked) security whose coupon rate is equal to the reference rate as long as the reference rate is within a certain range.

If the reference rate is outside of the range, the coupon rate is 0 for that period. This type of instrument entitles the holder to cash flows that depend on the level of some reference interest rate and are floored to be positive. The note holder gets direct exposure to the reference rate. In return for the drawback that no interest is paid for the time the range is left, they offer higher coupon rates than comparable standard products, like vanilla floating notes. For more information, see "Range Note" on page 2-12.

## Introduced in R2012a

# rangefloatbyhw

Price range floating note using Hull-White tree

## Syntax

```
[Price,PriceTree] = rangefloatbyhw(HWTree,Spread,Settle,Maturity,RateSched)
[Price,PriceTree] = rangefloatbyhw( ____,Name,Value)
```

## Description

[Price,PriceTree] = rangefloatbyhw(HWTree,Spread,Settle,Maturity,RateSched) prices range floating note using a Hull-White tree.

Payments on range floating notes are determined by the effective interest-rate between reset dates. If the reset period for a range spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

[Price,PriceTree] = rangefloatbyhw( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Compute the Price of a Range Note Using a Hull-White Tree

This example shows how to compute the price of a range note using a Hull-White tree with the following interest-rate term structure data.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2011';
StartDates = ValuationDate;
EndDates = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
Compounding = 1;

% define RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% range note instrument matures in Jan-1-2014 and has the following RateSchedule:
Spread = 100;
Settle = 'Jan-1-2011';
Maturity = 'Jan-1-2014';
RateSched(1).Dates = {'Jan-1-2012'; 'Jan-1-2013' ; 'Jan-1-2014'};
RateSched(1).Rates = [0.045 0.055 ; 0.0525 0.0675; 0.06 0.08];

% data to build the tree is as follows:
VolDates = ['1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'];
VolCurve = 0.01;
AlphaDates = '01-01-2015';
```

```

AlphaCurve = 0.1;

HWVS = hvwolspec(RS.ValuationDate, VolDates, VolCurve, ...
AlphaDates, AlphaCurve);
HWTS = hwtimespec(RS.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVS, RS, HWTS);

% price the instrument
Price = rangefloatbyhw(HWT, Spread, Settle, Maturity, RateSched)

Price = 96.6107

```

## Input Arguments

### **HWTree** — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

### **Spread** — Number of basis points over reference rate

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: `double`

### **Settle** — Settlement date for floating range note

serial date number | date character vector | cell array of date character vectors

Settlement date for the floating range note, specified as a NINST-by-1 vector of serial date numbers or date character vectors. The `Settle` date for every range floating instrument is set to the `ValuationDate` of the HW tree. The floating range note argument `Settle` is ignored.

Data Types: `double` | `char` | `cell`

### **Maturity** — Maturity date for floating range note

serial date number | date character vector | cell array of date character vectors

Maturity date for the floating-rate note, specified as a NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### **RateSched** — Range of rates within which cash flows are nonzero

structure

Range of rates within which cash flows are nonzero, specified as a NINST-by-1 vector of structures. Each element of the structure array contains two fields:

- `RateSched.Dates` — NDates-by-1 cell array of dates corresponding to the range schedule.
- `RateSched.Rates` — NDates-by-2 array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date `RateSched.Dates(n)` is nonzero for rates in the range `RateSched.Rates(n,1) < Rate < RateSched.Rates(n,2)`.

Data Types: struct

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree] =`

```
rangefloatbyhw(HWTree, Spread, Settle, Maturity, RateSched, 'Reset', 4, 'Basis', 5, 'Principal', 10000)
```

### Reset — Frequency payment per year

1 (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of 'Reset' and a NINST-by-1 vector.

Data Types: double

### Basis — Day-count basis of instrument

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### Principal — Notional principal amount

100 (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of 'Principal' and a NINST-by-1 vector.

Data Types: double

**Options — Derivatives pricing options structure**

structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

**EndMonthRule — End-of-month rule flag for generating caplet dates**

1 (in effect) (default) | nonnegative integer with value 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer with a value of 0 or 1 using a NINST-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

**Output Arguments****Price — Expected prices of range floating notes at time 0**

vector

Expected prices of the range floating notes at time 0, returned as a NINST-by-1 vector.

**PriceTree — Tree structure of instrument prices**

structure

Tree structure of instrument prices, returned as a structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

**More About****Range Note**

A range note is a structured (market-linked) security whose coupon rate is equal to the reference rate as long as the reference rate is within a certain range.

If the reference rate is outside of the range, the coupon rate is 0 for that period. This type of instrument entitles the holder to cash flows that depend on the level of some reference interest rate and are floored to be positive. The note holder gets direct exposure to the reference rate. In return for the drawback that no interest is paid for the time the range is left, they offer higher coupon rates than comparable standard products, like vanilla floating notes. For more information, see “Range Note” on page 2-12.

## Introduced in R2012a

## rate2disc

Discount factors from interest rates

### Syntax

**Usage 1:** Interval points are input as times in periodic units.

```
Disc = rate2disc(Compounding,Rates,EndTimes)
```

```
Disc = rate2disc(Compounding,Rates,EndTimes,StartTimes)
```

**Usage 2:** ValuationDate is passed and interval points are input as dates.

```
[Disc,EndTimes,StartTimes] = rate2disc(Compounding,Rates,EndDates,StartDates,ValuationDate)
```

```
[Disc,EndTimes,StartTimes] = rate2disc(Compounding,Rates,EndDates,StartDates,ValuationDate,Basis)
```

### Arguments

Compounding	<p>Scalar value representing the rate at which the input zero rates were compounded when annualized. This argument determines the formula for the discount factors (Disc):</p> <ul style="list-style-type: none"> <li>• Compounding = 0 for simple interest <ul style="list-style-type: none"> <li>• <math>Disc = 1/(1 + Z * T)</math>, where T is time in years and simple interest assumes annual times <math>F = 1</math>.</li> </ul> </li> <li>• Compounding = 1, 2, 3, 4, 6, 12 <ul style="list-style-type: none"> <li>• <math>Disc = (1 + Z/F)^{-T}</math>, where F is the compounding frequency, Z is the zero rate, and T is the time in periodic units, for example, <math>T = F</math> is one year.</li> </ul> </li> <li>• Compounding = 365 <ul style="list-style-type: none"> <li>• <math>Disc = (1 + Z/F)^{-T}</math>, where F is the number of days in the basis year and T is a number of days elapsed computed by basis.</li> </ul> </li> <li>• Compounding = -1 <ul style="list-style-type: none"> <li>• <math>Disc = \exp(-T*Z)</math>, where T is time in years.</li> </ul> </li> </ul>
Rates	<p>Number of points (NPOINTS) by number of curves (NCURVES) matrix of rates in decimal form. For example, 5% is 0.05 in Rates. Rates are the yields over investment intervals from StartTimes, when the cash flow is valued, to EndTimes, when the cash flow is received.</p>
EndTimes	<p>NPOINTS-by-1 vector or scalar of times in periodic units ending the interval to discount over.</p> <hr/> <p><b>Note</b> When ValuationDate is not passed, the third and fourth arguments (EndTimes and StartTimes) are interpreted as times.</p>

StartTimes	(Optional) NPOINTS-by-1 vector or scalar of times in periodic units starting the interval to discount over. Default = 0.
EndDates	NPOINTS-by-1 vector or scalar of serial maturity dates ending the interval to discount over.  <b>Note</b> : When ValuationDate is passed, the third and fourth arguments (EndDates and StartDates) are interpreted as dates. The date ValuationDate is used as the zero point for computing the times.
StartDates	(Optional) NPOINTS-by-1 vector or scalar of serial dates starting the interval to discount over. StartDates must be earlier than EndDates.  Default = ValuationDate.
ValuationDate	Scalar value in serial date number form representing the observation date of the investment horizons entered in StartDates and EndDates. Required in <b>Usage 2</b> . Omitted or passed as an empty matrix to invoke <b>Usage 1</b> .
Basis	(Optional) Day-count basis of the instrument when using <b>Usage 2</b> . A vector of integers.  <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> For more information, see "Basis" on page 2-129.
EndMonthRule	(Optional) End-of-month rule when using <b>Usage 2</b> . A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.

## Description

**Usage 1:** `Disc = rate2disc(Compounding, Rates, EndTimes)` or `Disc = rate2disc(Compounding, Rates, EndTimes, StartTimes)` where interval points are input as times in periodic units.

**Usage 2:** `[Disc, EndTimes, StartTimes] = rate2disc(Compounding, Rates, EndDates, StartDates, ValuationDate)` or `[Disc, EndTimes, StartTimes] = rate2disc(Compounding, Rates, EndDates, StartDates, ValuationDate, Basis, EndMonthRule)` where `ValuationDate` is passed and interval points are input as dates.

`rate2disc` computes the discounts over a series of `NPOINTS` time intervals given the annualized yield over those intervals. `NCURVES` different rate curves can be translated at once if they have the same time structure. The time intervals can represent a zero curve or a forward curve.

The output `Disc` is an `NPOINTS`-by-`NCURVES` column vector of discount factors in decimal form representing the value at time `StartTime` of a unit cash flow received at time `EndTime`.

You can specify the investment intervals either with input times (**Usage 1**) or with input dates (**Usage 2**). Entering `ValuationDate` invokes the date interpretation; omitting `ValuationDate` invokes the default time interpretations.

For **Usage 1**:

- `StartTimes` is an `NPOINTS`-by-1 column vector of times starting the interval to discount over, measured in periodic units.
- `EndTimes` is an `NPOINTS`-by-1 column vector of times ending the interval to discount over, measured in periodic units.

For **Usage 2**:

- `StartDates` is an `NPOINTS`-by-1 column vector of serial dates starting the interval to discount over, measured in days.
- `EndDates` is an `NPOINTS`-by-1 column vector of serial dates ending the interval to discount over, measured in days.

If `Compounding = 365` (daily), `StartDates` and `EndDates` are measured in days as in **Usage 2**. Otherwise, in **Usage 1**, the arguments contain values, `T`, computed from SIA semiannual time factors, `Tsemi`, by the formula  $T = Tsemi/2 * F$ , where `F` is the compounding frequency.

## Examples

**Example 1** demonstrates **Usage 1**. Compute discounts from a zero curve at 6 months, 12 months, and 24 months. The times to the cash flows are 1, 2, and 4. You are computing the present value (at time 0) of the cash flows.

```
Compounding = 2;
Rates = [0.05; 0.06; 0.065];
EndTimes = [1; 2; 4];
Disc = rate2disc(Compounding, Rates, EndTimes)
```

```
Disc =
    0.9756
```

```
0.9426
0.8799
```

**Example 2** demonstrates **Usage 2**. Compute discounts from a zero curve at 6 months, 12 months, and 24 months. Use dates to specify the ending time horizon.

```
Compounding = 2;
Rates = [0.05; 0.06; 0.065];
EndDates = ['10/15/97'; '04/15/98'; '04/15/99'];
ValuationDate = '4/15/97';
Disc = rate2disc(Compounding, Rates, EndDates, [], ValuationDate)
```

```
Disc =
    0.9756
    0.9426
    0.8799
```

**Example 3** demonstrates **Usage 1**. Compute discounts from the 1-year forward rates beginning now, in six months, and in 12 months. Use monthly compounding. The times to the cash flows are 12, 18, 24, and the forward times are 0, 6, 12.

```
Compounding = 12;
Rates = [0.05; 0.04; 0.06];
EndTimes = [12; 18; 24];
StartTimes = [0; 6; 12];
Disc = rate2disc(Compounding, Rates, EndTimes, StartTimes)
```

```
Disc =
    0.9513
    0.9609
    0.9419
```

## ratetimes

Change time intervals defining interest-rate environment

### Syntax

Usage 1: ValuationDate not passed; third through sixth arguments are interpreted as times.

[Rates, EndTimes, StartTimes] = ratetimes(Compounding, RefRates, RefEndTimes, RefStartTimes, EndTimes, S)

Usage 2: ValuationDate passed and interval points input as dates.

[Rates, EndTimes, StartTimes] = ratetimes(Compounding, RefRates, RefEndDates, RefStartDates, EndDates, S)

### Arguments

Compounding	<p>Scalar value representing the rate at which the input zero rates were compounded when annualized. This argument determines the formula for the discount factors (Disc):</p> <ul style="list-style-type: none"> <li>• Compounding = 0 for simple interest <ul style="list-style-type: none"> <li>• <math>Disc = 1 / (1 + Z * T)</math>, where T is time in years and simple interest assumes annual times <math>F = 1</math>.</li> </ul> </li> <li>• Compounding = 1, 2, 3, 4, 6, 12 <ul style="list-style-type: none"> <li>• <math>Disc = (1 + Z/F)^{-T}</math>, where F is the compounding frequency, Z is the zero rate, and T is the time in periodic units, for example, <math>T = F</math> is one year.</li> </ul> </li> <li>• Compounding = 365 <ul style="list-style-type: none"> <li>• <math>Disc = (1 + Z/F)^{-T}</math>, where F is the number of days in the basis year and T is a number of days elapsed computed by basis.</li> </ul> </li> <li>• Compounding = -1 <ul style="list-style-type: none"> <li>• <math>Disc = \exp(-T*Z)</math>, where T is time in years.</li> </ul> </li> </ul>
RefRates	NREFPTS-by-NCURVES matrix of reference rates in decimal form. RefRates are the yields over investment intervals from RefStartTimes, when the cash flow is valued, to RefEndTimes, when the cash flow is received.
RefEndTimes	NREFPTS-by-1 vector or scalar of times in periodic units ending the intervals corresponding to RefRates.
RefStartTimes	(Optional) NREFPTS-by-1 vector or scalar of times in periodic units starting the intervals corresponding to RefRates. Default = 0.
EndTimes	NPOINTS-by-1 vector or scalar of times in periodic units ending the interval to discount over.

StartTimes	(Optional) NPOINTS-by-1 vector or scalar of times in periodic units starting the interval to discount over. Default = 0.
RefEndDates	NREFPTS-by-1 vector or scalar of serial dates ending the intervals corresponding to RefRates.
RefStartDates	(Optional) NREFPTS-by-1 vector or scalar of serial dates starting the intervals corresponding to RefRates. Default = ValuationDate.
EndDates	NPOINTS-by-1 vector or scalar of serial maturity dates ending the interval to discount over.
StartDates	(Optional) NPOINTS-by-1 vector or scalar of serial dates starting the interval to discount over. StartDates must be earlier than EndDates. Default = ValuationDate.
ValuationDate	Scalar value in serial date number form representing the observation date of the investment horizons entered in StartDates and EndDates. Required in Usage 2. Omitted or passed as an empty matrix to invoke Usage 1.

## Description

[Rates, EndTimes, StartTimes] = ratetimes(Compounding, RefRates, RefEndTimes, RefStartTimes, EndTimes, StartTimes) and [Rates, EndTimes, StartTimes] = ratetimes(Compounding, RefRates, RefEndDates, RefStartDates, EndDates, StartDates, ValuationDate) change time intervals defining an interest-rate environment.

ratetimes takes an interest-rate environment defined by yields over one collection of time intervals and computes the yields over another set of time intervals. The zero rate is assumed to be piecewise linear in time.

Rates is an NPOINTS-by-NCURVES matrix of rates implied by the reference interest-rate structure and sampled at new intervals.

StartTimes is an NPOINTS-by-1 column vector of times starting the new intervals where rates are desired, measured in periodic units.

EndTimes is an NPOINTS-by-1 column vector of times ending the new intervals, measured in periodic units.

If Compounding = 365 (daily), StartTimes and EndTimes are measured in days. The arguments otherwise contain values, T, computed from SIA semiannual time factors, Tsemi, by the formula  $T = T_{\text{semi}}/2 * F$ , where F is the compounding frequency.

You can specify the investment intervals either with input times (Usage 1) or with input dates (Usage 2). Entering the argument ValuationDate invokes the date interpretation; omitting ValuationDate invokes the default time interpretations.

## Examples

**Example 1.** The reference environment is a collection of zero rates at 6, 12, and 24 months. Create a collection of 1-year forward rates beginning at 0, 6, and 12 months.

```
RefRates = [0.05; 0.06; 0.065];
RefEndTimes = [1; 2; 4];
```

```
StartTimes = [0; 1; 2];
EndTimes   = [2; 3; 4];
Rates = ratetimes(2, RefRates, RefEndTimes, 0, EndTimes,...
StartTimes)
```

```
Rates =
    0.0600
    0.0688
    0.0700
```

**Example 2.** Interpolate a zero yield curve to different dates. Zero curves start at the default date of `ValuationDate`.

```
RefRates = [0.04; 0.05; 0.052];
RefDates = [729756; 729907; 730121];
Dates    = [730241; 730486];
ValuationDate = 729391;
Rates = ratetimes(2, RefRates, RefDates, [], Dates, [],...
ValuationDate)
```

```
Rates =
    0.0520
    0.0520
```

# spreadbykirk

Price European spread options using Kirk pricing model

## Syntax

```
Price = spreadbykirk(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec,
Strike, Corr)
```

## Description

Price = spreadbykirk(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr) returns the price for a European spread option using the Kirk pricing model.

## Examples

### Compute the Price of a Spread Option Using the Kirk Model

Define the spread option dates.

```
Settle = '01-Jan-2012';
Maturity = '01-April-2012';
```

Define asset 1. Price and volatility of RBOB gasoline

```
Price1gallon = 2.85;           % $/gallon
Price1 = Price1gallon * 42;    % $/barrel
Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
Price2 = 93.20;              % $/barrel
Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the RateSpec.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
```

```
Compounding: -1
  Disc: 0.9876
  Rates: 0.0500
  EndTimes: 0.2500
  StartTimes: 0
  EndDates: 734960
  StartDates: 734869
ValuationDate: 734869
  Basis: 1
  EndMonthRule: 1
```

Define the `StockSpec` for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
  FinObj: 'StockSpec'
  Sigma: 0.2900
  AssetPrice: 119.7000
  DividendType: []
  DividendAmounts: 0
  ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
  FinObj: 'StockSpec'
  Sigma: 0.3600
  AssetPrice: 93.2000
  DividendType: []
  DividendAmounts: 0
  ExDividendDates: []
```

Compute the European spread option price based on the Kirk model.

```
Price = spreadbykirk(RateSpec, StockSpec1, StockSpec2, Settle, ...
Maturity, OptSpec, Strike, Corr)
```

```
Price = 11.1904
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec1 — Stock specification for underlying asset 1

structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### **StockSpec2 — Stock specification for underlying asset 2**

structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### **Settle — Settlement dates for spread option**

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Settlement dates for the spread option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `double` | `char` | `cell`

### **Maturity — Maturity date for spread option**

serial date number | vector of serial date numbers | date character vector | cell array of date character vectors

Maturity date for spread option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `double` | `char` | `cell`

### **OptSpec — Definition of option**

character vector with values 'call' or 'put' | cell array of character vectors

Definition of option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors.

Data Types: `cell` | `char`

### **Strike — Option strike price values**

integer | vector of integers

Option strike price values, specified as an integer using a NINST-by-1 vector of strike price values.

If `Strike` is equal to 0, the function computes the price of an exchange option.

Data Types: `single` | `double`

### **Corr — Correlation between underlying asset prices**

integer | vector of integers

Correlation between underlying asset prices, specified as an integer using a NINST-by-1 vector.

Data Types: `single` | `double`

## Output Arguments

### Price — Expected prices of spread option

vector

Expected prices of the spread option, returned as a NINST-by-1 vector.

## More About

### Spread Option

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets  $X1$  and  $X2$  would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

$K$  is the strike price.

For more information, see “Spread Option” on page 3-29.

# spreadbybjs

Price European spread options using Bjerksund-Stensland pricing model

## Syntax

```
Price = spreadbybjs(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec,
Strike, Corr)
```

## Description

Price = spreadbybjs(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr) returns the price for a European spread option using the Bjerksund-Stensland pricing model.

## Examples

### Compute the Price of a Spread Option Using the Bjerksund-Stensland Model

Define the spread option dates.

```
Settle = '01-Jan-2012';
Maturity = '01-April-2012';
```

Define asset 1. Price and volatility of RBOB gasoline

```
Price1gallon = 2.85;           % $/gallon
Price1 = Price1gallon * 42;    % $/barrel
Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
Price2 = 93.20;               % $/barrel
Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the RateSpec.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9876
    Rates: 0.0500
    EndTimes: 0.2500
    StartTimes: 0
    EndDates: 734960
    StartDates: 734869
    ValuationDate: 734869
    Basis: 1
    EndMonthRule: 1
```

Define the StockSpec for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.2900
    AssetPrice: 119.7000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3600
    AssetPrice: 93.2000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the European spread option price based on the Bjerksund-Stensland model.

```
Price = spreadbybjs(RateSpec, StockSpec1, StockSpec2, Settle, ...
    Maturity, OptSpec, Strike, Corr)
```

```
Price = 11.2000
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: struct

# spreadbyfd

Price European or American spread options using finite difference method

## Syntax

```
Price = spreadbyfd(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec,
Strike, Corr)
```

```
Price = spreadbyfd( ____, Name, Value)
```

```
[Price, PriceGrid, AssetPrice1, AssetPrice2, Times] = spreadbyfd(RateSpec,
StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)
```

```
[Price, PriceGrid, AssetPrice1, AssetPrice2, Times] = spreadbyfd( ____, Name, Value)
```

## Description

`Price = spreadbyfd(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)` returns the price of European or American call or put spread options using the Alternate Direction Implicit (ADI) finite difference method. The spread is between the asset defined in `StockSpec1` minus the asset defined in `StockSpec2`.

`Price = spreadbyfd( ____, Name, Value)` adds optional name-value pair arguments.

`[Price, PriceGrid, AssetPrice1, AssetPrice2, Times] = spreadbyfd(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)` returns the `Price`, `PriceGrid`, `AssetPrice1`, `AssetPrice2`, and `Times` for a European or American call or put spread options using the Alternate Direction Implicit (ADI) finite difference method. The spread is between the asset defined in `StockSpec1` minus the asset defined in `StockSpec2`.

`[Price, PriceGrid, AssetPrice1, AssetPrice2, Times] = spreadbyfd( ____, Name, Value)` returns the `Price`, `PriceGrid`, `AssetPrice1`, `AssetPrice2`, and `Times` and adds optional name-value pair arguments.

## Examples

### Compute the Price of a Spread Option Using the Alternate Direction Implicit (ADI) Finite Difference Method

Define the spread option dates.

```
Settle = '01-Jan-2012';
Maturity = '01-April-2012';
```

Define asset 1. Price and volatility of RBOB gasoline

```
Price1gallon = 2.85;           % $/gallon
Price1 = Price1gallon * 42;    % $/barrel
Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
Price2 = 93.20;           % $/barrel
Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the RateSpec.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9876
    Rates: 0.0500
    EndTimes: 0.2500
    StartTimes: 0
    EndDates: 734960
    StartDates: 734869
    ValuationDate: 734869
    Basis: 1
    EndMonthRule: 1
```

Define the StockSpec for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.2900
    AssetPrice: 119.7000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3600
    AssetPrice: 93.2000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the spread option price based on the Alternate Direction Implicit (ADI) finite difference method.

```
[Price, PriceGrid, AssetPrice1, AssetPrice2, Times] = ...
spreadbyfd(RateSpec, StockSpec1, StockSpec2, Settle, ...
Maturity, OptSpec, Strike, Corr);
```

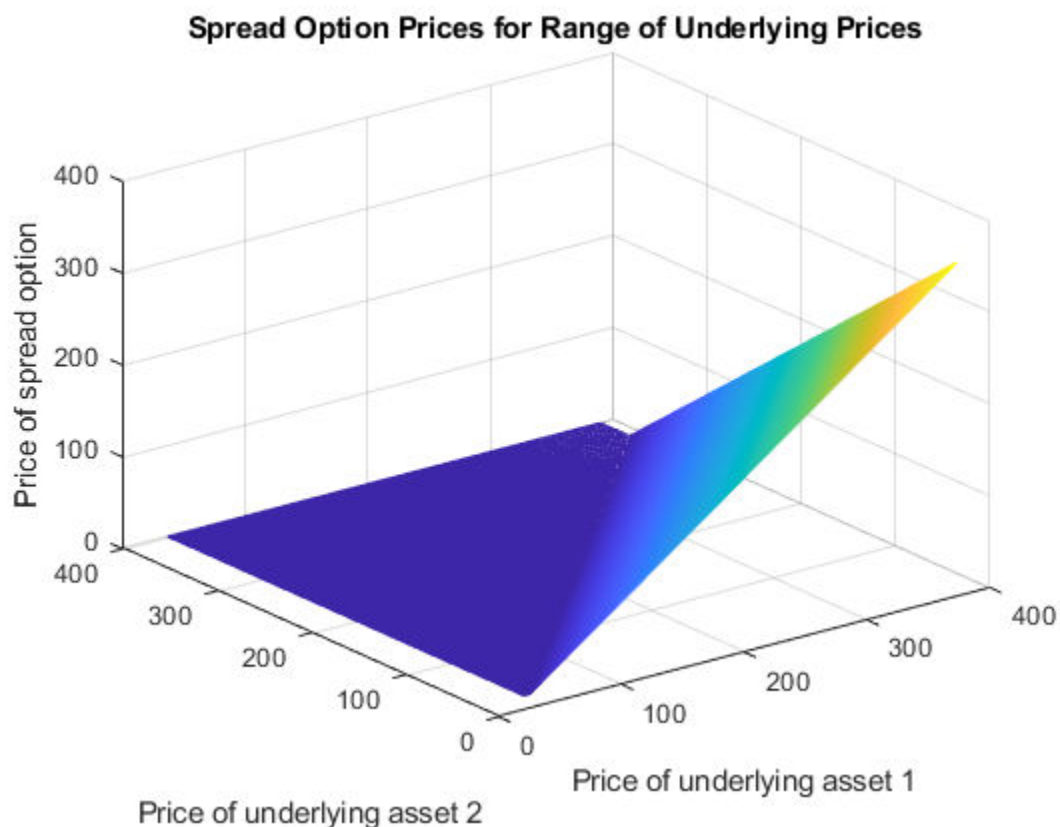

Display the price.

```
Price
```

```
Price = 11.1998
```

Plot the finite difference grid.

```
mesh(AssetPrice1, AssetPrice2, PriceGrid(:, :, 1)');
title('Spread Option Prices for Range of Underlying Prices');
xlabel('Price of underlying asset 1');
ylabel('Price of underlying asset 2');
zlabel('Price of spread option');
```

## Input Arguments

**RateSpec** — Interest-rate term structure  
structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### **StockSpec1 — Stock specification for underlying asset 1**

structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### **StockSpec2 — Stock specification for underlying asset 2**

structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### **Settle — Settlement dates for spread option**

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Settlement dates for the spread option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `double` | `char` | `cell`

### **Maturity — Maturity date for spread option**

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Maturity date for spread option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `double` | `char` | `cell`

### **OptSpec — Definition of option**

character vector with values 'call' or 'put' | cell array of character vectors

Definition of option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors.

Data Types: `char` | `cell`

### **Strike — Option strike price values**

integer | vector of integers

Option strike price values, specified as an integer using a NINST-by-1 vector of strike price values.

Data Types: `single` | `double`

**Corr — Correlation between underlying asset prices**

integer | vector of integers

Correlation between underlying asset prices, specified as an integer using a NINST-by-1 vector.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Price, PriceGrid, AssetPrice1, AssetPrice2, Times] = spreadbyfd(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr, 'AssetPriceMin', 'AssetPriceMax', 'PriceGridSize', 'TimeGridSize', 'AmericanOpt', 0)`

**AssetPriceMin — Minimum price for price grid boundary**if unspecified, `StockSpec` values are calculated based on asset distributions at maturity (default) | array

Minimum price for price grid boundary, specified as the comma-separated pair consisting of `'AssetPriceMin'` and a 1-by-2 array. The first entry in the array corresponds to the first asset defined by `StockSpec1` and the second entry corresponds to the second asset defined by `StockSpec2`.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments `AssetPriceMin`, `AssetPriceMax`, `PriceGridSize`, and `TimeGridSize` to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: single | double

**AssetPriceMax — Maximum price for price grid boundary**if unspecified, `StockSpec` values are calculated based on asset distributions at maturity (default) | array

Maximum price for price grid boundary, specified as the comma-separated pair consisting of `'AssetPriceMax'` and a 1-by-2 array. The first entry in the array corresponds to the first asset defined by `StockSpec1` and the second entry corresponds to the second asset defined by `StockSpec2`.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments `AssetPriceMin`, `AssetPriceMax`, `PriceGridSize`, and `TimeGridSize` to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: single | double

**PriceGridSize — Size for finite difference grid**`[300, 300]` (default) | array

Size for finite difference grid, specified as the comma-separated pair consisting of `'PriceGridSize'` and a 1-by-2 array. The first entry corresponds to the first asset defined by `StockSpec1` and the second entry corresponds to the second asset defined by `StockSpec2`.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments `AssetPriceMax`, `PriceGridSize`, and `TimeGridSize` to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: `single` | `double`

#### **TimeGridSize — Size of the time grid for finite difference grid**

100 (default) | scalar | nonnegative integer

Size of the time grid for finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a nonnegative integer.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments `AssetPriceMax`, `PriceGridSize`, and `TimeGridSize` to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: `single` | `double`

#### **AmericanOpt — Option type**

0 European (default) | scalar | vector of positive integers [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer scalar flags with values:

- 0 — European
- 1 — American

Data Types: `single` | `double`

## **Output Arguments**

#### **Price — Expected prices of spread option**

vector

Expected prices of the spread option, returned as a NINST-by-1 vector.

#### **PriceGrid — Grid containing prices calculated by finite difference method**

array

Grid containing prices calculated by finite difference method, returned as a 3-D grid with a size of `PriceGridSize(1) * PriceGridSize(2) * TimeGridSize`. The price for  $t = 0$  is contained in `PriceGrid(:, :, 1)`.

#### **AssetPrice1 — Prices for first asset defined by StockSpec1**

vector

Prices for first asset defined by `StockSpec1`, corresponding to the first dimension of `PriceGrid`, returned as a vector.

#### **AssetPrice2 — Prices for second asset defined by StockSpec2**

vector

Prices for second asset defined by `StockSpec2`, corresponding to the second dimension of `PriceGrid`, returned as a vector.

### **Times — Times corresponding to third dimension of PriceGrid**

vector

Times corresponding to third dimension of `PriceGrid`, returned as a vector.

## **More About**

### **Spread Option**

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets  $X1$  and  $X2$  would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

$K$  is the strike price.

For more information, see “Spread Option” on page 3-29.

## spreadbyls

Price European or American spread options using Monte Carlo simulations

### Syntax

```
Price = spreadbyls(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec,
Strike, Corr)
```

```
Price = spreadbyls( ____, Name, Value)
```

```
[Price, Paths, Times, Z] = spreadbyls(RateSpec, StockSpec1, StockSpec2, Settle,
Maturity, OptSpec, Strike, Corr)
```

```
[Price, Paths, Times, Z] = spreadbyls( ____, Name, Value)
```

### Description

`Price = spreadbyls(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)` returns the price of a European or American call or put spread option using Monte Carlo simulations.

For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

`Price = spreadbyls( ____, Name, Value)` returns the price of a European or American call or put spread option using Monte Carlo simulations using optional name-value pair arguments.

`[Price, Paths, Times, Z] = spreadbyls(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)` returns the Price, Paths, Times, and Z of a European or American call or put spread option using Monte Carlo simulations.

`[Price, Paths, Times, Z] = spreadbyls( ____, Name, Value)` returns the Price, Paths, Times, and Z of a European or American call or put spread option using Monte Carlo simulations using optional name-value pair arguments.

### Examples

#### Compute the Price of a Spread Option Using Monte Carlo Simulation

Define the spread option dates.

```
Settle = '01-Jan-2012';
Maturity = '01-April-2012';
```

Define asset 1. Price and volatility of RBOB gasoline

```
Price1gallon = 2.85;           % $/gallon
Price1 = Price1gallon * 42;    % $/barrel
Voll = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
Price2 = 93.20;           % $/barrel
Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the RateSpec.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9876
    Rates: 0.0500
    EndTimes: 0.2500
    StartTimes: 0
    EndDates: 734960
    StartDates: 734869
    ValuationDate: 734869
    Basis: 1
    EndMonthRule: 1
```

Define the StockSpec for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.2900
    AssetPrice: 119.7000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3600
    AssetPrice: 93.2000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the spread option price using Monte Carlo simulation based on the Longstaff-Schwartz model.

```
Price = spreadbyls(RateSpec, StockSpec1, StockSpec2, Settle, ...  
Maturity, OptSpec, Strike, Corr)
```

```
Price = 11.0799
```

## Input Arguments

### **RateSpec — Interest-rate term structure**

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### **StockSpec1 — Stock specification for underlying asset 1**

structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### **StockSpec2 — Stock specification for underlying asset 2**

structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### **Settle — Settlement date for spread option**

date character vector | nonnegative scalar integer

Settlement date for the spread option specified, as a date character vector or nonnegative scalar integer.

Data Types: `char` | `double`

### **Maturity — Maturity date for spread option**

date character vector | nonnegative scalar integer

Maturity date for spread option, specified as a date character vector or a nonnegative scalar integer.

Data Types: `char` | `double`

### **OptSpec — Definition of option**

character vector with values 'call' or 'put'

Definition of option as 'call' or 'put', specified as a character vector.

Data Types: char

### **Strike — Option strike price value**

nonnegative scalar integer

Option strike price value, specified, as a nonnegative scalar integer.

Data Types: single | double

### **Corr — Correlation between underlying asset prices**

scalar integer

Correlation between underlying asset prices, specified as a scalar integer.

Data Types: single | double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: Price =

```
spreadbyls(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr, 'AmericanOpt', 1)
```

### **AmericanOpt — Option type**

0 European (default) | scalar with value [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and an integer scalar flag with value:

- 0 — European
- 1 — American

---

**Note** For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see <https://people.math.ethz.ch/~Ehlfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf>.

---

Data Types: single | double

### **NumTrials — Scalar number of independent sample paths**

1000 (default) | nonnegative scalar integer

Scalar number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of 'NumTrials' and a nonnegative integer.

Data Types: single | double

### **NumPeriods — Scalar number of simulation periods per trial**

100 (default) | nonnegative scalar integer

Scalar number of simulation periods per trial, specified as the comma-separated pair consisting of 'NumPeriods' and a nonnegative integer. NumPeriods is considered only when pricing European basket options. For American spread options, NumPeriod is equal to the number of exercise days during the life of the option.

Data Types: `single` | `double`

### **Z — Time series array of dependent random variates**

vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of 'Z' and a NumPeriods-by-2-by-NumTrials 3-D array. The Z value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: `single` | `double`

### **Antithetic — Indicator for antithetic sampling**

`false` (default) | scalar logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified as the comma-separated pair consisting of 'Antithetic' and a value of `true` or `false`.

Data Types: `logical`

## **Output Arguments**

### **Price — Expected price of spread option**

scalar

Expected price of the spread option, returned as a 1-by-1 scalar.

### **Paths — Simulated paths of correlated state variables**

vector

Simulated paths of correlated state variables, returned as a NumPeriods + 1-by-2-by-NumTrials 3-D time series array. Each row of Paths is the transpose of the state vector  $X(t)$  at time  $t$  for a given trial.

### **Times — Observation times associated with simulated paths**

vector

Observation times associated with simulated paths, returned as a NumPeriods + 1-by-1 column vector of observation times associated with the simulated paths. Each element of Times is associated with the corresponding row of Paths.

### **Z — Time series array of dependent random variates**

vector

Time series array of dependent random variates, returned as a NumPeriods-by-2-by-NumTrials 3-D array when Z is specified as an input argument. If the Z input argument is not specified, then the Z output argument contains the random variates generated internally.

## More About

### Spread Option

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets  $X_1$  and  $X_2$  would have the following pay off at maturity:

$$\max(X_1 - X_2 - K, 0)$$

where:

$K$  is the strike price.

For more information, see “Spread Option” on page 3-29.

## spreadsensbykirk

Calculate European spread option prices or sensitivities using Kirk pricing model

### Syntax

```
PriceSens = spreadbykirk(RateSpec, StockSpec1, StockSpec2, Settle, Maturity,
OptSpec, Strike, Corr)
PriceSens = spreadsensbykirk( ____, Name, Value)
```

### Description

PriceSens = spreadbykirk(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr) returns the European spread option prices or sensitivities using the Kirk pricing model.

PriceSens = spreadsensbykirk( \_\_\_\_, Name, Value) adds optional name-value pair arguments.

### Examples

#### Compute the Price and Sensitivities of a Spread Option Using the Kirk Model

Define the spread option dates.

```
Settle = '01-Jun-2012';
Maturity = '01-Sep-2012';
```

Define asset 1. Price and volatility of RBOB gasoline

```
Price1gallon = 2.85;           % $/gallon
Price1 = Price1gallon * 42;    % $/barrel
Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
Price2 = 93.20;              % $/barrel
Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the RateSpec.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
```

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9876
    Rates: 0.0500
    EndTimes: 0.2500
    StartTimes: 0
    EndDates: 735113
    StartDates: 735021
    ValuationDate: 735021
    Basis: 1
    EndMonthRule: 1
```

Define the StockSpec for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.2900
    AssetPrice: 119.7000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3600
    AssetPrice: 93.2000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the spread option price and sensitivities based on the Kirk model.

```
OutSpec = {'Price', 'Delta', 'Gamma'};
[Price, Delta, Gamma] = spreadsensbykirk(RateSpec, StockSpec1, StockSpec2, Settle, ...
Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec)
```

```
Price = 11.1904
```

```
Delta = 1x2
```

```
    0.6722    -0.6067
```

```
Gamma = 1x2
```

```
    0.0191    0.0217
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec1 — Stock specification for underlying asset 1

structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### StockSpec2 — Stock specification for underlying asset 2

structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement dates for spread option

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Settlement dates for the spread option, specified as date character vectors or as serial date numbers using a `NINST-by-1` vector or cell array of character vector dates.

Data Types: `char` | `cell` | `double`

### Maturity — Maturity date for spread option

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Maturity date for spread option, specified as date character vectors or as serial date numbers using a `NINST-by-1` vector or cell array of character vector dates.

Data Types: `char` | `cell` | `double`

### OptSpec — Definition of option

character vector with values 'call' or 'put' | cell array of character vectors

Definition of option as 'call' or 'put', specified as a `NINST-by-1` cell array of character vectors.

Data Types: `char` | `cell`

**Strike — Option strike price values**

integer | vector of integers

Option strike price values, specified as an integer using as NINST-by-1 vector of strike price values.

If `Strike` is equal to zero, this function computes the price and sensitivities of an exchange option.

Data Types: single | double

**Corr — Correlation between underlying asset prices**

integer | vector of integers

Correlation between underlying asset prices, specified as an integer using as NINST-by-1 vector.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `PriceSens = spreadsensbykirk(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr, OutSpec, {'All'})`

**OutSpec — Define outputs**

`{'Price'}`  (default) | character vector with values  `'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta',`  and  `'All'`  | cell array of character vectors with values  `'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta',`  and  `'All'`

Define outputs, specified as the comma-separated pair consisting of  `'OutSpec'`  and a NOUT-by-1 or 1-by-NOUT cell array of character vectors with possible values of  `'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta',`  and  `'All'` .

`OutSpec = {'All'}`  specifies that the output should be  `Delta, Gamma, Vega, Lambda, Rho, Theta,`  and  `Price,`  in that order. This is the same as specifying  `OutSpec`  to include each sensitivity:

Example:  `OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}`

Data Types: char | cell

**Output Arguments****PriceSens — Expected price or sensitivities values of spread option**

vector

Expected price or sensitivities values (defined by  `OutSpec` ) of the spread option, returned as a NINST-by-1 or NINST-by-2 vector.

**More About****Spread Option**

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets  $X1$  and  $X2$  would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

$K$  is the strike price.

For more information, see “Spread Option” on page 3-29.

## spreadsensbybjs

Calculate European spread option prices or sensitivities using Bjerksund-Stensland pricing model

### Syntax

```
PriceSens = spreadbybjs(RateSpec, StockSpec1, StockSpec2, Settle, Maturity,
OptSpec, Strike, Corr)
PriceSens = spreadsensbybjs( ____, Name, Value)
```

### Description

PriceSens = spreadbybjs(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr) returns the European spread option prices or sensitivities using the Bjerksund-Stensland pricing model.

PriceSens = spreadsensbybjs( \_\_\_\_, Name, Value) adds optional name-value pair arguments.

### Examples

#### Compute the Price and Sensitivities of a Spread Option Using the Bjerksund-Stensland Model

Define the spread option dates.

```
Settle = '01-Jun-2012';
Maturity = '01-Sep-2012';
```

Define asset 1. Price and volatility of RBOB gasoline

```
Price1gallon = 2.85;           % $/gallon
Price1 = Price1gallon * 42;    % $/barrel
Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
Price2 = 93.20;               % $/barrel
Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the RateSpec.

```
rates = 0.05;
Compounding = -1;
```

```

Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...

    0.6737    -0.6082

```

```

Gamma = 1×2

```

```

    0.0190    0.0216

```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec1 — Stock specification for underlying asset 1

structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### StockSpec2 — Stock specification for underlying asset 2

structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement dates for spread option

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Settlement dates for the spread option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `char` | `cell` | `double`

### Maturity — Maturity date for spread option

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Maturity date for spread option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `char` | `cell` | `double`

### OptSpec — Definition of option

character vector with values 'call' or 'put' | cell array of character vectors

Definition of option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors.

Data Types: `char` | `cell`

**Strike — Option strike price values**

integer | vector of integers

Option strike price values, specified as an integer using a NINST-by-1 vector of strike price values.

If `Strike` is equal to zero the function computes the price and sensitivities of an exchange option.

Data Types: single | double

**Corr — Correlation between underlying asset prices**

integer | vector of integers

Correlation between underlying asset prices, specified as an integer using a NINST-by-1 vector.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `PriceSens = spreadsensbykirk(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr, OutSpec, {'All'})`

**OutSpec — Define outputs**

`{'Price'}` (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

`OutSpec = {'All'}` specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}`

Data Types: char | cell

**Output Arguments****PriceSens — Expected prices or sensitivities values of spread option**

vector

Expected prices or sensitivities values (defined by `OutSpec`) of the spread option, returned as a NINST-by-1 or NINST-by-2 vector.

**More About****Spread Option**

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets  $X_1$  and  $X_2$  would have the following pay off at maturity:

$$\max(X_1 - X_2 - K, 0)$$

where:

$K$  is the strike price.

For more information, see "Spread Option" on page 3-29.

## spreadsensbyls

Calculate price and sensitivities for European or American spread options using Monte Carlo simulations

### Syntax

```
PriceSens = spreadsensbyls(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,
OptSpec,Strike,Corr)
```

```
PriceSens = spreadsensbyls( ___,Name,Value)
```

```
[PriceSens,Paths,Times,Z] = spreadsensbyls(RateSpec,StockSpec1,StockSpec2,
Settle,Maturity,OptSpec,Strike,Corr)
```

```
[PriceSens,Paths,Times,Z] = spreadsensbyls( ___,Name,Value)
```

### Description

`PriceSens = spreadsensbyls(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr)` returns the price of a European or American call or put spread option using Monte Carlo simulations.

For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

`PriceSens = spreadsensbyls( ___,Name,Value)` adds optional name-value pair arguments.

`[PriceSens,Paths,Times,Z] = spreadsensbyls(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr)` returns the `PriceSens`, `Paths`, `Times`, and `Z` of a European or American call or put spread option using Monte Carlo simulations.

`[PriceSens,Paths,Times,Z] = spreadsensbyls( ___,Name,Value)` returns the `PriceSens`, `Paths`, `Times`, and `Z` and adds optional name-value pair arguments.

### Examples

#### Compute the Price and Sensitivities of a Spread Option Using Monte Carlo Simulation

Define the spread option dates.

```
Settle = '01-Jun-2012';
Maturity = '01-Sep-2012';
```

Define asset 1. Price and volatility of RBOB gasoline

```
Price1gallon = 2.85;           % $/gallon
Price1 = Price1gallon * 42;   % $/barrel
Voll = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
Price2 = 93.20;           % $/barrel
Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the RateSpec.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9876
    Rates: 0.0500
    EndTimes: 0.2500
    StartTimes: 0
    EndDates: 735113
    StartDates: 735021
    ValuationDate: 735021
    Basis: 1
    EndMonthRule: 1
```

Define the StockSpec for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.2900
    AssetPrice: 119.7000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3600
    AssetPrice: 93.2000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the spread option price and sensitivities using Monte Carlo simulation based on the Longstaff-Schwartz model.

```
OutSpec = {'Price', 'Delta', 'Gamma'};
[Price, Delta, Gamma] = spreadsensbyls(RateSpec, StockSpec1, StockSpec2, ...
Settle, Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec)
```

```
Price = 11.0799
```

```
Delta = 1×2
```

```
    0.6626    -0.5972
```

```
Gamma = 1×2
```

```
    0.0209    0.0240
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec1 — Stock specification for underlying asset 1

structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### StockSpec2 — Stock specification for underlying asset 2

structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement date for spread option

date character vector | nonnegative scalar integer

Settlement date for the spread option, specified as a date character vector or as a nonnegative scalar integer.

Data Types: char | double

### **Maturity — Maturity date for spread option**

date character vector | nonnegative scalar integer

Maturity date for spread option, specified as a date character vector or as a nonnegative scalar integer.

Data Types: char | double

### **OptSpec — Definition of option**

character vector with values 'call' or 'put'

Definition of option as 'call' or 'put', specified as a character vector.

Data Types: char

### **Strike — Option strike price value**

nonnegative scalar integer

Option strike price value, specified as a scalar integer.

Data Types: single | double

### **Corr — Correlation between underlying asset prices**

scalar integer

Correlation between underlying asset prices, specified as a scalar integer.

Data Types: single | double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `PriceSens = spreadbyls(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr, 'AmericanOpt', 1)`

### **AmericanOpt — Option type**

0 European (default) | scalar with values [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a scalar integer flag with values:

- 0 — European
- 1 — American

---

**Note** For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see <https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf>.

---

Data Types: single | double

**NumTrials — Number of independent sample paths**

1000 (default) | nonnegative scalar integer

Number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of 'NumTrials' and a nonnegative scalar integer.

Data Types: single | double

**NumPeriods — Number of simulation periods per trial**

100 (default) | nonnegative scalar integer

Number of simulation periods per trial, specified as the comma-separated pair consisting of 'NumPeriods' and a nonnegative scalar integer. NumPeriods is considered only when pricing European basket options. For American spread options, NumPeriods is equal to the number of exercise days during the life of the option.

Data Types: single | double

**Z — Time series array of dependent random variates**

vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of 'Z' and a NumPeriods-by-2-by-NumTrials 3-D array. The Z value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: single | double

**Antithetic — Indicator for antithetic sampling**

false (default) | logical flag with value of true or false

Indicator for antithetic sampling, specified as the comma-separated pair consisting of 'Antithetic' and a value of true or false.

Data Types: logical

**OutSpec — Define outputs**

{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity:

Example: OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}

Data Types: char | cell

**Output Arguments****PriceSens — Expected price or sensitivities of spread option**

scalar

Expected price or sensitivities of the spread option, returned as a 1-by-1 array as defined by `OutSpec`.

### **Paths — Simulated paths of correlated state variables**

vector

Simulated paths of correlated state variables, returned as a `NumPeriods + 1`-by-2-by-`NumTrials` 3-D time series array. Each row of `Paths` is the transpose of the state vector  $X(t)$  at time  $t$  for a given trial.

### **Times — Observation times associated with simulated paths**

vector

Observation times associated with simulated paths, returned as a `NumPeriods + 1`-by-1 column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

### **Z — Time series array of dependent random variates**

vector

Time series array of dependent random variates, returned as a `NumPeriods`-by-2-by-`NumTrials` 3-D array when `Z` is specified as an input argument. If the `Z` input argument is not specified, then the `Z` output argument contains the random variates generated internally.

## **More About**

### **Spread Option**

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets  $X1$  and  $X2$  would have the following payoff at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

$K$  is the strike price.

For more information, see “Spread Option” on page 3-29.

## spreadsensbyfd

Calculate price and sensitivities of European or American spread options using finite difference method

### Syntax

```
PriceSens = spreadsensbyfd(RateSpec, StockSpec1, StockSpec2, Settle, Maturity,
OptSpec, Strike, Corr)
```

```
PriceSens = spreadsensbyfd( ____, Name, Value)
```

```
[PriceSens, PriceGrid, AssetPrice1, AssetPrice2, Times] = spreadsensbyfd(
RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)
```

```
[PriceSens, PriceGrid, AssetPrice1, AssetPrice2, Times] = spreadsensbyfd( ____,
Name, Value)
```

### Description

`PriceSens = spreadsensbyfd(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)` returns the price and sensitivities of European or American call or put spread options using the Alternate Direction Implicit (ADI) finite difference method. The spread is between the asset defined in `StockSpec1` minus the asset defined in `StockSpec2`.

`PriceSens = spreadsensbyfd( ____, Name, Value)` adds optional name-value pair arguments.

`[PriceSens, PriceGrid, AssetPrice1, AssetPrice2, Times] = spreadsensbyfd(RateSpec, StockSpec1, StockSpec2, Settle, Maturity, OptSpec, Strike, Corr)` returns the `PriceSens`, `PriceGrid`, `AssetPrice1`, `AssetPrice2`, and `Times` for European or American call or put spread options using the Alternate Direction Implicit (ADI) finite difference method. The spread is between the asset defined in `StockSpec1` minus the asset defined in `StockSpec2`.

`[PriceSens, PriceGrid, AssetPrice1, AssetPrice2, Times] = spreadsensbyfd( ____, Name, Value)` returns the `PriceSens`, `PriceGrid`, `AssetPrice1`, `AssetPrice2`, and `Times` and adds optional name-value pair arguments.

### Examples

#### Compute the Price of a Spread Option Using the Alternate Direction Implicit (ADI) Finite Difference Method

Define the spread option dates.

```
Settle = '01-Jun-2012';
Maturity = '01-Sep-2012';
```

Define asset 1. Price and volatility of RBOB gasoline

```
Price1gallon = 2.85;           % $/gallon
Price1 = Price1gallon * 42;   % $/barrel
Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
Price2 = 93.20;           % $/barrel
Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the RateSpec.

```
rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9876
    Rates: 0.0500
    EndTimes: 0.2500
    StartTimes: 0
    EndDates: 735113
    StartDates: 735021
    ValuationDate: 735021
    Basis: 1
    EndMonthRule: 1
```

Define the StockSpec for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.2900
    AssetPrice: 119.7000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.3600
    AssetPrice: 93.2000
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the spread option price and sensitivities based on the Alternate Direction Implicit (ADI) finite difference method.

```
OutSpec = {'Price', 'Delta', 'Gamma'};
[Price, Delta, Gamma, PriceGrid, AssetPrice1, AssetPrice2, Times] = ...
spreadsensbyfd(RateSpec, StockSpec1, StockSpec2, Settle, ...
Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec);
```

Display the price and sensitivities.

Price

```
Price = 11.1998
```

Delta

```
Delta = 1×2
```

```
    0.6736    -0.6082
```

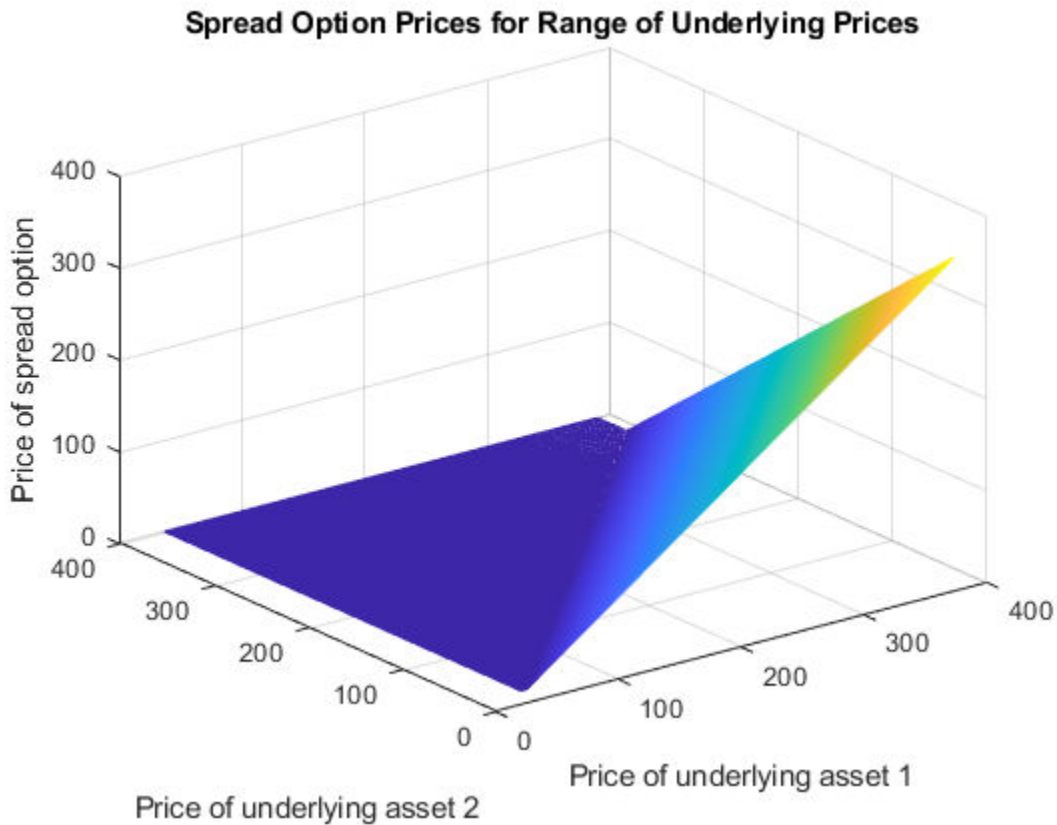

Gamma

```
Gamma = 1×2
```

```
    0.0190    0.0214
```

Plot the finite difference grid.

```
mesh(AssetPrice1, AssetPrice2, PriceGrid(:, :, 1));
title('Spread Option Prices for Range of Underlying Prices');
xlabel('Price of underlying asset 1');
ylabel('Price of underlying asset 2');
zlabel('Price of spread option');
```

## Input Arguments

**RateSpec — Interest-rate term structure**  
structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

**StockSpec1 — Stock specification for underlying asset 1**  
structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

**StockSpec2 — Stock specification for underlying asset 2**  
structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

### **Settle – Settlement dates for spread option**

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Settlement dates for the spread option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `char` | `cell` | `double`

### **Maturity – Maturity date for spread option**

serial date number | vector of serial date numbers | date character vector | cell array of character vectors

Maturity date for spread option, specified as date character vectors or as serial date numbers using a NINST-by-1 vector or cell array of character vector dates.

Data Types: `char` | `cell` | `double`

### **OptSpec – Definition of option**

character vector with values 'call' or 'put' | cell array of character vectors

Definition of option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors.

Data Types: `char` | `cell`

### **Strike – Option strike price values**

integer | vector of integers

Option strike price values, specified as an integer using a NINST-by-1 vector of strike price values.

Data Types: `single` | `double`

### **Corr – Correlation between underlying asset prices**

integer | vector of integers

Correlation between underlying asset prices, specified as an integer using a NINST-by-1 vector.

Data Types: `single` | `double`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `[PriceSens,PriceGrid,AssetPrice1,AssetPrice2,Times] = spreadsensbyfd(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr,'AssetPriceMin','AssetPriceMax','PriceGridSize','TimeGridSize','AmericanOpt',0,'OutSpec',{'All'})`

**OutSpec — Define outputs**

{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity:

Example: OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}

Data Types: char | cell

**AssetPriceMin — Minimum price for price grid boundary**

if unspecified, StockSpec values are calculated based on asset distributions at maturity (default) | array

Minimum price for price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMin' and a 1-by-2 array. The first entry in the array corresponds to the first asset defined by StockSpec1 and the second entry corresponds to the second asset defined by StockSpec2.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments AssetPriceMin, AssetPriceMax, PriceGridSize, and TimeGridSize to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: single | double

**AssetPriceMax — Maximum price for price grid boundary**

if unspecified, StockSpec values are calculated based on asset distributions at maturity (default) | array

Maximum price for price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a 1-by-2 array. The first entry in the array corresponds to the first asset defined by StockSpec1 and the second entry corresponds to the second asset defined by StockSpec2.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments AssetPriceMin, AssetPriceMax, PriceGridSize, and TimeGridSize to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: single | double

**PriceGridSize — Size for finite difference grid**

[300, 300] (default) | array

Size for finite difference grid, specified as the comma-separated pair consisting of 'PriceGridSize' and a 1-by-2 array. The first entry corresponds to the first asset defined by StockSpec1 and the second entry corresponds to the second asset defined by StockSpec2.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments AssetPriceMax,

PriceGridSize, and TimeGridSize to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: single | double

### **TimeGridSize — Size of time grid for finite difference grid**

100 (default) | scalar | nonnegative integer

Size of time grid for finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a nonnegative integer.

For the finite difference method, the composition of the grid affects the quality of the output and the execution time. It is highly recommended to use the optional arguments AssetPriceMax, PriceGridSize, and TimeGridSize to control the composition of the grid to ensure the quality of the output and a reasonable execution time.

Data Types: single | double

### **AmericanOpt — Option type**

0 European (default) | scalar | vector of positive integers [0, 1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer scalar flags with values:

- 0 — European
- 1 — American

Data Types: single | double

## **Output Arguments**

### **PriceSens — Expected prices or sensitivities of spread option**

scalar

Expected price or sensitivities of the spread option, returned as a 1-by-1 array as defined by OutSpec.

### **PriceGrid — Grid containing prices calculated by finite difference method**

array

Grid containing prices calculated by finite difference method, returned as a 3-D grid with a size of PriceGridSize(1) \* PriceGridSize(2) \* TimeGridSize. The price for  $t = 0$  is contained in PriceGrid(:, :, 1).

### **AssetPrice1 — Prices for first asset defined by StockSpec1**

vector

Prices for first asset defined by StockSpec1, corresponding to the first dimension of PriceGrid, returned as a vector.

### **AssetPrice2 — Prices for second asset defined by StockSpec2**

vector

Prices for second asset defined by StockSpec2, corresponding to the second dimension of PriceGrid, returned as a vector.

**Times – Times corresponding to third dimension of PriceGrid**  
vector

Times corresponding to third dimension of PriceGrid, returned as a vector.

**More About****Spread Option**

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets  $X1$  and  $X2$  would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

$K$  is the strike price.

For more information, see “Spread Option” on page 3-29.

# stockoptspec

Specify European stock option structure

## Syntax

```
StockOptSpec = stockoptspec(OptPrice,Strike,Settle,Maturity,OptSpec,  
InterpMethod)  
StockOptSpec = stockoptspec( ____,InterpMethod)
```

## Description

StockOptSpec = stockoptspec(OptPrice,Strike,Settle,Maturity,OptSpec,InterpMethod) creates a structure encapsulating the properties of a stock option structure.

StockOptSpec = stockoptspec( \_\_\_\_,InterpMethod) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Specify a European Stock Option Structure

This example shows how to specify a European stock option structure using the following data quoted from liquid options in the market with varying strikes and maturity.

```
Settle = '01/01/06';  
Maturity = ['07/01/06';  
            '07/01/06';  
            '07/01/06';  
            '01/01/07';  
            '01/01/07';  
            '01/01/07';  
            '01/01/07';  
            '07/01/07';  
            '07/01/07';  
            '07/01/07';  
            '07/01/07';  
            '01/01/08';  
            '01/01/08';  
            '01/01/08';  
            '01/01/08'];  
Strike = [113;  
          101;  
          100;  
          88;  
          128;  
          112;  
          100;  
          78;
```

```
144;  
112;  
100;  
69;  
162;  
112;  
100;  
61];  
  
OptPrice = [ 0;  
4.807905472659144;

    Strike: [16x1 double]  
    Settle: 732678  
    Maturity: [16x1 double]  
    OptSpec: {16x1 cell}  
    InterpMethod: 'price'
```

## Input Arguments

### OptPrice — European option prices

vector

European option prices, specified as an NINST-by-1 vector.

Data Types: double

### Strike — Strike prices

vector

Strike prices, specified as an NINST-by-1 vector.

Data Types: double

### Settle — Settlement date

scalar numeric date

Settlement date, specified as a scalar numeric date.

Data Types: double

### Maturity — Maturity dates

vector

Maturity dates, specified as an NINST-by-1 vector.

Data Types: double

### OptSpec — Option type

cell array of character vectors with a value of 'call' or 'put'

Option type, specified as an NINST-by-1 cell array of character vectors with a value of 'call' or 'put'.

Data Types: cell

### InterpMethod — Interpolation method for option prices

'price' (default) | scalar character vector with value of 'price' or 'vol'

(Optional) Interpolation method for option prices, specified as a scalar character vector with one of the following values:

- 'price' indicates that prices are used for interpolation purposes.
- 'vol' indicates that implied volatilities are used for interpolation purposes. The interpolated values are then used to calculate the implicit interpolated prices.

.

Data Types: char

## Output Arguments

### StockOptSpec — Structure encapsulating the properties of a stock options structure

structure

Structure encapsulating the properties of a stock options structure, returned as a structure.

**See Also**

`ittprice` | `itttree` | `stockspec`

# stockspec

Create stock structure

## Syntax

```
StockSpec = stockspec(Sigma,AssetPrice)
StockSpec = stockspec( ____,DividendType,DividendAmounts,ExDividendDates)
```

## Description

StockSpec = stockspec(Sigma,AssetPrice) creates a MATLAB structure containing the properties of a stock.

---

**Note** StockSpec handles other types of underliers when pricing instruments other than equities.

---

StockSpec = stockspec( \_\_\_\_,DividendType,DividendAmounts,ExDividendDates) adds optional arguments for DividendType, DividendAmounts, and ExDividendDates.

## Examples

### Create a StockSpec for Stocks With Cash Dividends

Consider a stock that provides four cash dividends of \$0.50 on January 3, 2008, April 1, 2008, July 5, 2008 and October 1, 2008. The stock is trading at \$50, and has a volatility of 20% per annum. Using this data, create the structure StockSpec:

```
AssetPrice = 50;
Sigma = 0.20;

DividendType = {'cash'};
DividendAmounts = [0.50, 0.50, 0.50, 0.50];
ExDividendDates = {'03-Jan-2008', '01-Apr-2008', '05-July-2008', '01-Oct-2008'};

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts, ExDividendDates)

StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.2000
    AssetPrice: 50
    DividendType: {'cash'}
    DividendAmounts: [0.5000 0.5000 0.5000 0.5000]
    ExDividendDates: [733410 733499 733594 733682]
```

Examine the StockSpec structure.

```
datedisp(StockSpec.ExDividendDates)

03-Jan-2008    01-Apr-2008    05-Jul-2008    01-Oct-2008
```

```
StockSpec.DividendType
```

```
ans = 1x1 cell array
    {'cash'}
```

The `StockSpec` structure encapsulates the information of the stock and its four cash dividends.

### Create a `StockSpec` for Stocks With Cash and Continuous Dividends

Consider two stocks that are trading at \$40 and \$35. The first one provides two cash dividends of \$0.25 on March 1, 2008 and June 1, 2008. The second stock provides a continuous dividend yield of 3%. The stocks have a volatility of 30% per annum. Using this data, create the structure `StockSpec`:

```
AssetPrice = [40; 35];
Sigma = .30;
```

```
DividendType = {'cash'; 'continuous'};
DividendAmount = [0.25, 0.25 ; 0.03 NaN];
```

```
DividendDate1 = 'March-01-2008';
DividendDate2 = 'Jun-01-2008';
```

```
StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmount,...
{ DividendDate1, DividendDate2 ; NaN NaN})
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: [2x1 double]
    AssetPrice: [2x1 double]
    DividendType: {2x1 cell}
    DividendAmounts: [2x2 double]
    ExDividendDates: [2x2 double]
```

Examine the `StockSpec` structure.

```
datedisp(StockSpec.ExDividendDates)
```

```
01-Mar-2008    01-Jun-2008
    NaN          NaN
```

```
StockSpec.DividendType
```

```
ans = 2x1 cell
    {'cash'      }
    {'continuous'}
```

The `StockSpec` structure encapsulates the information of the two stocks and their dividends.

## Input Arguments

**Sigma** — Annual price volatility of underlying security

decimal

Annual price volatility of underlying security, specified as a NINST-by-1 decimal.

Data Types: double

### **AssetPrice — Underlying asset price values at time 0**

vector

Underlying asset price values at time 0, specified as a NINST-by-1 vector.

Data Types: double

### **DividendType — Stock dividend type**

cell array of date character vectors

(Optional) Stock dividend type, specified as a NINST-by-1 cell array of character vectors.

Dividend type must be either `cash` for actual dollar dividends, `constant` for constant dividend yield, or `continuous` for continuous dividend yield. This function does not handle stock option dividends.

---

**Note** Dividends are assumed to be paid in cash. Noncash dividends (stock) are not allowed. When combining two or more types of dividends, shorter rows should be padded with the value `NaN`.

---

Data Types: char | cell

### **DividendAmounts — Dividend amounts**

matrix | vector

(Optional) Dividend amounts, specified as a NINST-by-NDIV matrix of cash dividends or NINST-by-1 vector representing a constant or continuous annualized dividend yield.

Data Types: double

### **ExDividendDates — Ex-dividend dates**

matrix | vector

(Optional) Ex-dividend dates, specified as a NINST-by-NDIV matrix of ex-dividend dates for a cash `DividendType` or NINST-by-1 vector of ex-dividend dates for constant `DividendType`. For continuous `DividendType`, this argument should be ignored.

Data Types: double | cell

## **Output Arguments**

### **StockSpec — Properties of stock structure**

structure

Properties of stock structure, returned as a structure encapsulating the properties of a stock.

## **See Also**

# sttprice

Price instruments using standard trinomial tree

## Syntax

```
[Price,PriceTree] = sttprice(STTTree,InstSet)
[Price,PriceTree] = sttprice( ___,Name,Value)
```

## Description

[Price,PriceTree] = sttprice(STTTree,InstSet) prices instruments using a standard trinomial (STT) tree.

[Price,PriceTree] = sttprice( \_\_\_,Name,Value) prices instruments using a standard trinomial (STT) tree with an optional name-value pair argument for Options.

## Examples

### Price a stttree Instrument Set

Load the data into the MATLAB® workspace.

```
load deriv.mat
```

STTTree and STTInstSet are the input arguments required to call the function sttprice. Use the command instdisp to examine the set of instruments contained in the variable STTInstSet.

```
instdisp(STTInstSet)
```

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	Name	Quantity
1	OptStock	call	100	01-Jan-2009	01-Jan-2011	1	Call1	10
2	OptStock	put	80	01-Jan-2009	01-Jan-2012	0	Put1	5

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	BarrierSpec	Barrier	Rebate
3	Barrier	call	105	01-Jan-2009	01-Jan-2012	1	ui	115	0

Index	Type	UOptSpec	UStrike	USettle	UExerciseDates	UAmericanOpt	COptSpec	CStrike	CSettle
4	Compound	call	95	01-Jan-2009	01-Jan-2012	1	put	5	01-Jan-2012

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	Name	Quantity
5	Lookback	call	90	01-Jan-2009	01-Jan-2012	0	Lookback1	7
6	Lookback	call	95	01-Jan-2009	01-Jan-2013	0	Lookback2	9

Index	Type	OptSpec	Strike	Settle	ExerciseDates	AmericanOpt	AvgType	AvgPrice	AvgDate
7	Asian	call	100	01-Jan-2009	01-Jan-2012	0	arithmetic	NaN	NaN
8	Asian	call	100	01-Jan-2009	01-Jan-2013	0	arithmetic	NaN	NaN

The instrument set contains eight instruments:

- Two vanilla options (Call1, Put1)
- One barrier option (Barrier1)
- One compound option (Compound1)
- Two lookback options (Lookback1, Lookback2)
- Two Asian options (Asian1, Asian2)

Use `sttprice` to calculate the price of each instrument in the instrument set.

```
Price = sttprice(STTtree, STTInstSet)
```

```
Price = 8×1
```

## Input Arguments

### **STTtree — Stock tree structure for standard trinomial tree**

structure

Stock tree structure for a standard trinomial tree, specified by using `stttree`.

Data Types: `struct`

### **InstSet — Variable containing a collection instruments**

structure

Variable containing a collection of NINST instruments, specified as a structure. Instruments are broken down by type and each type can have different data fields.

Data Types: `struct`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Price, PriceTree] = sttprice(STTtree, InstSet, 'Options', deriv)`

### **Options — Derivatives pricing options**

structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

## Output Arguments

### Price — Expected prices for each instrument at time 0

matrix

Expected prices for each instrument at time 0, returned as a NINST-by-1 vector. The prices are computed by backward dynamic programming on the standard trinomial (STT) stock tree. If an instrument cannot be priced, a NaN is returned in that entry.

### PriceTree — Structure with vector of instrument prices at each node

tree structure

Structure with a vector of instrument prices at each node, returned as a tree structure.

PriceTree is a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node.

PriceTree.PTree contains the prices.

PriceTree.tObs contains the observation times.

PriceTree.dObs contains the observation dates.

## sttsens

Instrument sensitivities and prices using standard trinomial tree

### Syntax

```
[Delta, Gamma, Vega, Price] = sttsens(STTtree, InstSet)
[Delta, Gamma, Vega, Price] = sttsens( ___, Name, Value)
```

### Description

[Delta, Gamma, Vega, Price] = sttsens(STTtree, InstSet) to generate instrument sensitivities and prices using a standard trinomial (STT) tree.

[Delta, Gamma, Vega, Price] = sttsens( \_\_\_, Name, Value) to generate instrument sensitivities and prices using a standard trinomial (STT) tree with an optional name-value pair argument for Options.

### Examples

#### Determine the Price and Sensitivities for a stttree Instrument Set

Load the data into the MATLAB® workspace.

```
load deriv.mat
```

STTtree and STTInstSet are the input arguments required to call the function sttprice. Use the command instdisp to examine the set of instruments contained in the variable STTInstSet.

```
instdisp(STTInstSet)
```

**Determine Price and Sensitivities for Convertible Bond Instruments Using a stttree**

Create a RateSpec.

```
StartDates = 'Jan-1-2015';
EndDates = 'Jan-1-2020';
Rates = 0.025;
Basis = 1;
```

```
RateSpec = intenvset('ValuationDate',StartDates,'StartDates',StartDates,...
'EndDates',EndDates,'Rates',Rates,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.8825
    Rates: 0.0250
    EndTimes: 5
    StartTimes: 0
    EndDates: 737791
    StartDates: 735965
    ValuationDate: 735965
    Basis: 1
    EndMonthRule: 1
```

Create a StockSpec.

```
AssetPrice = 80;
Sigma = 0.12;
StockSpec = stockspec(Sigma,AssetPrice)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.1200
    AssetPrice: 80
    DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Create a STTTree.

```
TimeSpec = stttimespec(StartDates, EndDates, 20);
STTTree = stttree(StockSpec, RateSpec, TimeSpec)
```

```
STTTree = struct with fields:
    FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [1x21 double]
    dObs: [1x21 double]
```

```
STree: {1x21 cell}
Probs: {1x20 cell}
```

Define the convertible bond. The convertible bond can be called starting on Jan 1, 2016 with a strike price of 95.

```
CouponRate = 0.03;
Settle = 'Jan-1-2015';
Maturity = 'April-1-2018';
Period = 1;
CallStrike = 95;
CallExDates = [datenum('Jan-1-2016') datenum('April-1-2018')];
ConvRatio = 1;
Spread = 0.025;
```

Price the convertible bond using the standard trinomial tree model.

```
[Price,PriceTree,EqtTre,DbtTree] = cbondbystt(STTTree,CouponRate,Settle,Maturity,ConvRatio,...
'Period',Period,'Spread',Spread,'CallExDates',CallExDates,'CallStrike',CallStrike,'AmericanCall')
```

```
Price = 90.2511
```

```
PriceTree = struct with fields:
  FinObj: 'TrinPriceTree'
  PTree: {1x21 cell}
  tObs: [1x21 double]
  dObs: [1x21 double]
```

```
EqTTree = struct with fields:
  FinObj: 'TrinPriceTree'
  PTree: {1x21 cell}
  tObs: [1x21 double]
  dObs: [1x21 double]
```

```
DbtTree = struct with fields:
  FinObj: 'TrinPriceTree'
  PTree: {1x21 cell}
  tObs: [1x21 double]
  dObs: [1x21 double]
```

Compute the delta and gamma of the convertible bond.

```
InstSet= instcbond(CouponRate,Settle,Maturity,ConvRatio,'Spread',Spread,...
'CallExDates',CallExDates,'CallStrike',CallStrike,'AmericanCall',1);
[Delta,Gamma] = sttsens(STTTree,InstSet)
```

```
Delta = 0.3945
```

```
Gamma = 0.0324
```

## Input Arguments

**STTTree** — Stock tree structure for standard trinomial tree structure

Stock tree structure for a standard trinomial tree, specified by using `sttree`.

Data Types: `struct`

### **InstSet — Variable containing a collection instruments**

structure

Variable containing a collection of NINST instruments, specified as a structure. Instruments are broken down by type and each type can have different data fields.

Data Types: `struct`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Delta, Gamma, Vega, Price] = sttsens(STTtree, InstSet, 'Options', deriv)`

### **Options — Derivatives pricing options**

structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with `derivset`.

Data Types: `struct`

## **Output Arguments**

### **Delta — Rate of change of instruments prices with respect to changes in the stock price**

vector of deltas

Rate of change of instrument prices with respect to changes in the stock price, returned as a NINST-by-1 vector of deltas. For more information on the stock tree, see `sttree`.

### **Gamma — Rate of change of instrument deltas with respect to changes in the stock price**

vector of gammas

Rate of change of instrument deltas with respect to changes in the stock price, returned as a NINST-by-1 vector of gammas.

### **Vega — Rate of change of instrument prices with respect to changes in the volatility of the stock price**

vector of vegas

Rate of change of instrument prices with respect to changes in the volatility of the stock price, returned as a NINST-by-1 vector of vegas. For more information on the stock tree, see `sttree`.

### **Price — Expected prices for each instrument at time 0**

matrix

Expected prices for each instrument at time 0, returned as a NINST-by-1 vector. The prices are computed by backward dynamic programming on the standard trinomial (STT) stock tree. If an instrument cannot be priced, a NaN is returned in that entry.

## stttimespec

Specify time structure for standard trinomial tree

### Syntax

```
TimeSpec = stttimespec(ValuationDate,Maturity,NumPeriods)
```

### Description

TimeSpec = stttimespec(ValuationDate,Maturity,NumPeriods) creates a time spec for a standard trinomial (STT) tree.

### Examples

#### Create a stttimespec to Build a STTtree

Create a RateSpec.

```
StartDates = 'Jan-1-2014';  
EndDates = 'Jan-1-2018';  
Rates = 0.025;  
Basis = 1;  
Compounding = -1;
```

```
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, 'EndDates', ...  
EndDates, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:  
    FinObj: 'RateSpec'  
    Compounding: -1  
    Disc: 0.9048  
    Rates: 0.0250  
    EndTimes: 4  
    StartTimes: 0  
    EndDates: 737061  
    StartDates: 735600  
    ValuationDate: 735600  
    Basis: 1  
    EndMonthRule: 1
```

Create a StockSpec.

```
AssetPrice = 110;  
Sigma = 0.22;  
Div = 0.02;  
StockSpec = stockspec(Sigma, AssetPrice, 'continuous', Div)
```

```
StockSpec = struct with fields:  
    FinObj: 'StockSpec'  
    Sigma: 0.2200
```

```

    AssetPrice: 110
    DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []

```

Create a STTTimespec and STTTree.

```

NumPeriods = length(cfdates(StartDates,EndDates,12));
TimeSpec = stttimespec(StartDates, EndDates, NumPeriods)

```

```

TimeSpec = struct with fields:
    FinObj: 'STTTimespec'
    ValuationDate: 735600
    Maturity: 737061
    NumPeriods: 48
    Basis: 0
    EndMonthRule: 1
    tObs: [1x49 double]
    dObs: [1x49 double]

```

```

STTT = stttree(StockSpec, RateSpec, TimeSpec)

```

```

STTT = struct with fields:
    FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [1x49 double]
    dObs: [1x49 double]
    STree: {1x49 cell}
    Probs: {1x48 cell}

```

## Input Arguments

### ValuationDate — Date marking the pricing date and first observation tree

serial date number | date character vector

Date marking the pricing date and first observation in the tree, specified as a scalar using a serial date number or date character vector.

Data Types: double | char

### Maturity — Date marking the depth of tree

serial date number | date character vector

Date marking the depth of the tree, specified as a scalar using a serial date number or date character vector.

Data Types: double | char

### NumPeriods — Determines how many time steps are in tree

nonnegative integer

Determines how many time steps are in tree, specified as a scalar using a nonnegative integer value.

Data Types: double

## **Output Arguments**

**TimeSpec** – Time layout for standard trinomial (STT) tree  
structure

Time layout for standard trinomial (STT) tree, returned as a structure.

## **See Also**

# stttree

Build standard trinomial tree

## Syntax

```
STTTree = stttree(StockSpec,RateSpec,TimeSpec)
```

## Description

STTTree = stttree(StockSpec,RateSpec,TimeSpec) builds a standard trinomial (STT) tree.

## Examples

### Build a STTTree

Create a RateSpec.

```
StartDates = 'Jan-1-2014';
EndDates = 'Jan-1-2018';
Rates = 0.025;
Basis = 1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: 0.9048
    Rates: 0.0250
    EndTimes: 4
    StartTimes: 0
    EndDates: 737061
    StartDates: 735600
    ValuationDate: 735600
    Basis: 1
    EndMonthRule: 1
```

Create a StockSpec.

```
AssetPrice = 55;
Sigma = 0.22;
Div = 0.02;
StockSpec = stockspec(Sigma, AssetPrice, 'continuous', Div)
```

```
StockSpec = struct with fields:
    FinObj: 'StockSpec'
    Sigma: 0.2200
    AssetPrice: 55
    DividendType: {'continuous'}
    DividendAmounts: 0.0200
```

```
ExDividendDates: []
```

Create a Standard Trinomial Tree (STTTree).

```
NumSteps = 8;
TimeSpec = stttimespec(StartDates, EndDates, NumSteps);
STTT = stttree(StockSpec, RateSpec, TimeSpec)
```

```
STTT = struct with fields:
    FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 0.5000 1 1.5000 2 2.5000 3 3.5000 4]
    dObs: [1x9 double]
    STree: {1x9 cell}
    Probs: {1x8 cell}
```

## Input Arguments

### StockSpec — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using StockSpec obtained from stockspec. For information on the stock specification, see stockspec.

stockspect can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in StockSpec, dividends are assumed to be 0.

Data Types: struct

### RateSpec — Interest-rate term specification of initial risk-free rate curve

structure

Interest-rate term specification of initial risk-free rate curve, specified by the RateSpec obtained from intenvset. For information on the interest-rate specification, see intenvset.

Data Types: struct

### TimeSpec — Tree time layout specification

structure

Tree time layout specification, specified using stttimespec to define the observation dates of the standard trinomial (STT) tree.

Data Types: struct

## Output Arguments

### STTTree — Tree specifying stock and time information for a standard trinomial (STT) tree

tree structure

Tree specifying stock and time information for a standard trinomial (STT) tree, returned as a tree structure.

**See Also**

sttimespec

**Introduced in R2015b**

## supersharebybls

Determine price of supershare digital options using Black-Scholes model

### Syntax

Price = supersharebybls(RateSpec, StockSpec, Settle, Maturity, StrikeLow, StrikeHigh)

### Description

Price = supersharebybls(RateSpec, StockSpec, Settle, Maturity, StrikeLow, StrikeHigh) computes supershare digital options using the Black-Scholes option pricing model.

### Examples

#### Compute the Price of Supershare Digital Options Using Black-Scholes Model

This example shows how to compute the price of supershare digital options using Black-Scholes model. Consider a supershare based on a portfolio of nondividend paying stocks with a lower strike of 350 and an upper strike of 450. The value of the portfolio on November 1, 2008 is 400. The risk-free rate is 4.5% and the volatility is 18%. Using this data, calculate the price of the supershare option on February 1, 2009.

```
Settle = 'Nov-1-2008';
Maturity = 'Feb-1-2009';
Rates = 0.045;
Basis = 1;
Compounding = -1;

% create the RateSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);

% define the StockSpec
AssetPrice = 400;
Sigma = .18;
StockSpec = stockspec(Sigma, AssetPrice);

% define the high and low strike points
StrikeLow = 350;
StrikeHigh = 450;

% calculate the price
Pssh = supersharebybls(RateSpec, StockSpec, Settle, Maturity, ...
    StrikeLow, StrikeHigh)

Pssh = 0.9411
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector

Settlement or trade date for the basket option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### Maturity — Maturity date

serial date number | date character vector

Maturity date for the basket option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### StrikeLow — Low strike price values

vector

Low strike price values, specified as an NINST-by-1 vector.

Data Types: `double`

### StrikeHigh — High strike price values

vector

High strike price values, specified as an NINST-by-1 vector.

Data Types: `double`

## Output Arguments

### Price — Expected prices for supershare option

vector

Expected prices for supershare option, returned as a NINST-by-1 vector.

## **More About**

### **Supershare Option**

A supershare option pays out a proportion of the assets underlying a portfolio if the asset lies between a lower and an upper bound at the expiry of the option.

For more information, see “Digital Option” on page 3-25.

# supersharesensbyls

Determine price or sensitivities of supershare digital options using Black-Scholes model

## Syntax

```
PriceSens = supersharesensbyls(RateSpec, StockSpec, Settle, Maturity, StrikeLow,
StrikeHigh)
PriceSens = supersharesensbyls( ____, Name, Value)
```

## Description

PriceSens = supersharesensbyls(RateSpec, StockSpec, Settle, Maturity, StrikeLow, StrikeHigh) computes price or sensitivities of supershare digital options using the Black-Scholes option pricing model.

PriceSens = supersharesensbyls( \_\_\_\_, Name, Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute Price and Sensitivities of Supershare Digital Options Using Black-Scholes Model

This example shows how to compute price and sensitivities of supershare digital options using a Black-Scholes model. Consider a supershare based on a portfolio of nondividend paying stocks with a lower strike of 350 and an upper strike of 450. The value of the portfolio on November 1, 2008 is 400. The risk-free rate is 4.5% and the volatility is 18%. Using this data, calculate the price and sensitivity of the supershare option on February 1, 2009.

```
Settle = 'Nov-1-2008';
Maturity = 'Feb-1-2009';
Rates = 0.045;
Basis = 1;
Compounding = -1;

% define the RateSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);

% define the StockSpec
AssetPrice = 400;
Sigma = .18;
StockSpec = stockspec(Sigma, AssetPrice);

% define the high and low strike points
StrikeLow = 350;
StrikeHigh = 450;

% calculate the price
Pssh = supersharebybls(RateSpec, StockSpec, Settle, Maturity, ...
StrikeLow, StrikeHigh)
```

```
Pssh = 0.9411

% compute the delta and theta of the supershare option
OutSpec = { 'delta'; 'theta' };
[Delta, Theta] = supersharesensbybls(RateSpec, StockSpec, Settle, ...
Maturity, StrikeLow, StrikeHigh, 'OutSpec', OutSpec)

Delta = -0.0010
Theta = -1.0102
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector

Settlement or trade date for the basket option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### Maturity — Maturity date

serial date number | date character vector

Maturity date for the basket option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### StrikeLow — Low strike price values

vector

Low strike price values, specified as an NINST-by-1 vector.

Data Types: `double`

**StrikeHigh — High strike price values**

vector

High strike price values, specified as an NINST-by-1 vector.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Gamma, Theta, Price] = supersharesensbyls(RateSpec, StockSpec, Settle, Maturity, StrikeLow, StrikeHigh, 'OutSpec', {'gamma'; 'theta'; 'price'})`

**OutSpec — Define outputs**

`{'Price'}` (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT-by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

`OutSpec = {'All'}` specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}`

Data Types: char | cell

**Output Arguments****PriceSens — Expected prices or sensitivities for supershare option**

vector

Expected prices or sensitivities for supershare option, returned as a NINST-by-1 vector.

**More About****Supershare Option**

A supershare option pays out a proportion of the assets underlying a portfolio if the asset lies between a lower and an upper bound at the expiry of the option.

For more information, see “Digital Option” on page 3-25.

## swapbybdt

Price swap instrument from Black-Derman-Toy interest-rate tree

### Syntax

```
[Price,PriceTree,CFTree,SwapRate] = swapbybdt(BDTree,LegRate,Settle,
Maturity)
[Price,PriceTree,CFTree,SwapRate] = swapbybdt( ____,Name,Value)
```

### Description

[Price,PriceTree,CFTree,SwapRate] = swapbybdt(BDTree,LegRate,Settle, Maturity) prices a swap instrument from a Black-Derman-Toy interest-rate tree. swapbybdt computes prices of vanilla swaps, amortizing swaps and forward swaps.

[Price,PriceTree,CFTree,SwapRate] = swapbybdt( \_\_\_\_,Name,Value) adds additional name-value pair arguments.

### Examples

#### Price an Interest-Rate Swap

Price an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year, and the notional principal amount is \$100. The values for the remaining arguments are:

- Coupon rate for fixed leg: 0.15 (15%)
- Spread for floating leg: 10 basis points
- Swap settlement date: Jan. 01, 2000
- Swap maturity date: Jan. 01, 2003

Based on the information above, set the required arguments and build the LegRate, LegType, and LegReset matrices:

```
Settle = '01-Jan-2000';
Maturity = '01-Jan-2003';
Basis = 0;
Principal = 100;
LegRate = [0.15 10]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Price the swap using the BDTree included in the MAT-file deriv.mat. BDTree contains the time and forward-rate information needed to price the instrument.

```
load deriv.mat;
```

Use swapbybdt to compute the price of the swap.

```
Price = swapbybdt(BDTree, LegRate, Settle, Maturity, ...
LegReset, Basis, Principal, LegType)
```

```
Price = 7.4222
```

Using the previous data, calculate the swap rate, the coupon rate for the fixed leg, such that the swap price at time = 0 is zero.

```
LegRate = [NaN 20];
```

```
[Price, PriceTree, CFTree, SwapRate] = swapbybdt(BDTree,...
LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
Price = -1.4211e-14
```

```
PriceTree = struct with fields:
  FinObj: 'BDTPriceTree'
  tObs: [0 1 2 3 4]
  PTree: {1x5 cell}
```

```
CFTree = struct with fields:
  FinObj: 'BDTCFTree'
  tObs: [0 1 2 3 4]
  CFTree: {[NaN] [NaN NaN] [NaN NaN NaN] [NaN NaN NaN NaN] [1x4 double]}
```

```
SwapRate = 0.1205
```

### Price an Amortizing Swap

Price an amortizing swap using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```
Rates = 0.035;
ValuationDate = '1-Jan-2011';
StartDates = ValuationDate;
EndDates = '1-Jan-2017';
Compounding = 1;
```

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
  FinObj: 'RateSpec'
  Compounding: 1
  Disc: 0.8135
  Rates: 0.0350
  EndTimes: 6
  StartTimes: 0
  EndDates: 736696
  StartDates: 734504
  ValuationDate: 734504
  Basis: 0
  EndMonthRule: 1
```

Create the swap instrument using the following data:

```
Settle = '1-Jan-2011';
Maturity = '1-Jan-2017';
Period = 1;
LegRate = [0.04 10];
```

Define the swap amortizing schedule.

```
Principal = {'1-Jan-2013' 100; '1-Jan-2014' 80; '1-Jan-2015' 60; '1-Jan-2016' 40; '1-Jan-2017' 20};
```

Build the BDT tree and assume volatility is 10%.

```
MatDates = {'1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'; '1-Jan-2017'};
BDTTimeSpec = bdttimespec(ValuationDate, MatDates);
Volatility = 0.10;
BDTVolSpec = bdtvolspec(ValuationDate, MatDates, Volatility*ones(1,length(MatDates)));
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);
```

Compute the price of the amortizing swap.

```
Price = swapbybdt(BDTT, LegRate, Settle, Maturity, 'Principal', Principal)
```

```
Price = 1.4574
```

## Price a Forward Swap

Price a forward swap using the `StartDate` input argument to define the future starting date of the swap.

Create the `RateSpec`.

```
Rates = 0.0325;
ValuationDate = '1-Jan-2012';
StartDates = ValuationDate;
EndDates = '1-Jan-2018';
Compounding = 1;
```

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: 0.8254
    Rates: 0.0325
    EndTimes: 6
    StartTimes: 0
    EndDates: 737061
    StartDates: 734869
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1
```

Build the tree with a volatility of 10%.

```
MatDates = {'1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'; '1-Jan-2017'; '1-Jan-2018'};
BDTTimeSpec = bdttimespec(ValuationDate, MatDates);
```

```
Volatility = 0.10;
BDTVolSpec = bdtvolSpec(ValuationDate, MatDates, Volatility*ones(1,length(MatDates))');
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);
```

Compute the price of a forward swap that starts in two years (Jan 1, 2014) and matures in three years with a forward swap rate of 3.85%.

```
Settle = '1-Jan-2012';
Maturity = '1-Jan-2017';
StartDate = '1-Jan-2014';
LegRate = [0.0385 10];
```

```
Price = swapbybdt(BDTT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = 1.3203
```

Using the previous data, compute the forward swap rate, the coupon rate for the fixed leg, such that the forward swap price at time = 0 is zero.

```
LegRate = [NaN 10];
[Price, ~,~, SwapRate] = swapbybdt(BDTT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = -4.9738e-12
```

```
SwapRate = 0.0335
```

## Input Arguments

### BDTTree — Interest-rate structure

structure

Interest-rate tree structure, created by `bdttree`

Data Types: `struct`

### LegRate — Leg rate

matrix

Leg rate, specified as a NINST-by-2 matrix, with each row defined as one of the following:

- [CouponRate Spread] (fixed-float)
- [Spread CouponRate] (float-fixed)
- [CouponRate CouponRate] (fixed-fixed)
- [Spread Spread] (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

### Settle — Settlement date

serial date number | character vector

Settlement date, specified either as a scalar or NINST-by-1 vector of serial date numbers or date character vectors.

The `Settle` date for every swap is set to the `ValuationDate` of the BDT tree. The swap argument `Settle` is ignored.

Data Types: `char` | `double`

### **Maturity – Maturity date**

serial date number | character vector

Maturity date, specified as a NINST-by-1 vector of serial date numbers or date character vectors representing the maturity date for each swap.

Data Types: `char` | `double`

### **Name-Value Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree, CFTree, SwapRate] = swapbybdt(BDTree, LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)`

### **LegReset – Reset frequency per year for each swap**

[1 1] (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of 'LegReset' and a NINST-by-2 vector.

Data Types: `double`

### **Basis – Day-count basis representing the basis for each leg**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 array (or NINST-by-2 if `Basis` is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **Principal — Notional principal amounts or principal value schedules**

100 (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of 'Principal' and a vector or cell array.

Principal accepts a NINST-by-1 vector or NINST-by-1 cell array (or NINST-by-2 if Principal is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a NumDates-by-2 array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

### **LegType — Leg type**

[1 0] for each instrument (default) | matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float)

Leg type, specified as the comma-separated pair consisting of 'LegType' and a NINST-by-2 matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float). Each row represents an instrument. Each column indicates if the corresponding leg is fixed (1) or floating (0). This matrix defines the interpretation of the values entered in LegRate. LegType allows [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float) swaps

Data Types: `double`

### **Options — Derivatives pricing options structure**

structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

### **EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 (or NINST-by-2 if EndMonthRule is different for each leg).

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

### **AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count**

false (default) | value of 0 (false) or 1 (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a NINST-by-1 (or NINST-by-2 if AdjustCashFlowsBasis is different for each leg) of logicals with values of 0 (false) or 1 (true).

Data Types: `logical`

### **BusinessDayConvention — Business day conventions**

`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or a N-by-1 (or NINST-by-2 if BusinessDayConvention is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

### **Holidays — Holidays used in computing business days**

if not specified, the default is to use `holidays.m` (default) | MATLAB date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and MATLAB date numbers using a `NHolidays-by-1` vector.

Data Types: `double`

### **StartDate — Date swap actually starts**

Settle date (default) | serial date number | character vector

Date swap actually starts, specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector of dates using a serial date number or a character vector.

Use this argument to price forward swaps, that is, swaps that start in a future date

Data Types: `char` | `double`

## **Output Arguments**

### **Price — Expected swap prices at time 0**

vector

Expected swap prices at time 0, returned as a NINST-by-1 vector.

### **PriceTree — Tree structure of instrument prices**

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

### **CFTree — Swap cash flows**

structure

Swap cash flows, returned as a tree structure with a vector of the swap cash flows at each node. This structure contains only NaNs because with binomial recombining trees, cash flows cannot be computed accurately at each node of a tree.

### **SwapRate — Rates applicable to fixed leg**

matrix

Rates applicable to the fixed leg, returned as a NINST-by-1 vector of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in `LegRate` is NaN. The `SwapRate` output is padded with NaN for those instruments in which `CouponRate` is not set to NaN.

## **More About**

### **Amortizing Swap**

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

### **Forward Swap**

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

### **Introduced before R2006a**

# swapbybk

Price swap instrument from Black-Karasinski interest-rate tree

## Syntax

```
[Price,PriceTree,CFTree,SwapRate] = swapbybk(BKTree,LegRate,Settle,Maturity)
[Price,PriceTree,CFTree,SwapRate] = swapbybk( ____,Name,Value)
```

## Description

[Price,PriceTree,CFTree,SwapRate] = swapbybk(BKTree,LegRate,Settle,Maturity) prices a swap instrument from a Black-Karasinski interest-rate tree. swapbybk computes prices of vanilla swaps, amortizing swaps and forward swaps.

[Price,PriceTree,CFTree,SwapRate] = swapbybk( \_\_\_\_,Name,Value) adds additional name-value pair arguments.

## Examples

### Price an Interest-Rate Swap

Price an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year, and the notional principal amount is \$100. The values for the remaining arguments are:

- Coupon rate for fixed leg: 0.06 (6%)
- Spread for floating leg: 20 basis points
- Swap settlement date: Jan. 01, 2004
- Swap maturity date: Jan. 01, 2006

Based on the information above, set the required arguments and build the LegRate, LegType, and LegReset matrices:

```
Settle = '01-Jan-2004';
Maturity = '01-Jan-2006';
Basis = 0;
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Price the swap using the BKTree included in the MAT-file deriv.mat. BKTree contains the time and forward-rate information needed to price the instrument.

```
load deriv.mat;
```

Use swapbybk to price of the swap.

```
Price = swapbybk(BKTree, LegRate, ...
Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
Price = 5.0425
```

Using the previous data, calculate the swap rate, which is the coupon rate for the fixed leg, such that the swap price at time = 0 is zero.

```
LegRate = [NaN 20];
```

```
[Price, PriceTree, SwapRate] = swapbybk(BKTree, LegRate, ...
Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
Price = -2.8422e-14
```

```
PriceTree = struct with fields:
```

```
  FinObj: 'BKPriceTree'
  PTree: {1x5 cell}
  tObs: [0 1 2 3 4]
  Connect: {[2] [2 3 4] [2 2 3 4 4]}
  Probs: {[3x1 double] [3x3 double] [3x5 double]}
```

```
SwapRate = 0.0336
```

### Price an Amortizing Swap

Price an amortizing swap using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```
Rates = 0.035;
ValuationDate = '1-Jan-2011';
StartDates = ValuationDate;
EndDates = '1-Jan-2017';
Compounding = 1;
```

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
```

```
  FinObj: 'RateSpec'
  Compounding: 1
  Disc: 0.8135
  Rates: 0.0350
  EndTimes: 6
  StartTimes: 0
  EndDates: 736696
  StartDates: 734504
  ValuationDate: 734504
  Basis: 0
  EndMonthRule: 1
```

Create the swap instrument using the following data:

```
Settle = '1-Jan-2011';
Maturity = '1-Jan-2017';
Period = 1;
LegRate = [0.04 10];
```

Define the swap amortizing schedule.

```
Principal = {'1-Jan-2013' 100; '1-Jan-2014' 80; '1-Jan-2015' 60; '1-Jan-2016' 40; '1-Jan-2017' 20};
```

Build the BK tree and assume volatility is 10%.

```
MatDates = {'1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'; '1-Jan-2017'};
BKTimeSpec = bktimespec(ValuationDate, MatDates);
Volatility = 0.10;
AlphaDates = '01-01-2017';
AlphaCurve = 0.1;
BKVolSpec = bkvolspec(ValuationDate, MatDates, Volatility*ones(1,length(MatDates))',...
AlphaDates, AlphaCurve);
BKT = bktree(BKVolSpec, RateSpec, BKTimeSpec);
```

Compute the price of the amortizing swap.

```
Price = swapbybk(BKT, LegRate, Settle, Maturity, 'Principal' , Principal)
```

```
Price = 1.4574
```

### Price a Forward Swap

Price a forward swap using the `StartDate` input argument to define the future starting date of the swap.

Create the `RateSpec`.

```
Rates = 0.0374;
ValuationDate = '1-Jan-2012';
StartDates = ValuationDate;
EndDates = '1-Jan-2018';
Compounding = 1;
```

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: 0.8023
    Rates: 0.0374
    EndTimes: 6
    StartTimes: 0
    EndDates: 737061
    StartDates: 734869
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1
```

Build a BK tree.

```
VolDates = {'1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'; '1-Jan-2017'; '1-Jan-2018'};
VolCurve = 0.1;
AlphaDates = '01-01-2018';
```

```
AlphaCurve = 0.1;
```

```
BKVolSpec = bkvolspec(RateSpec.ValuationDate, VolDates, VolCurve, ...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RateSpec.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RateSpec, BKTimeSpec);
```

Compute the price of a forward swap that starts in a year (Jan 1, 2013) and matures in four years with a forward swap rate of 4.25%.

```
Settle = '1-Jan-2012';
Maturity = '1-Jan-2017';
StartDate = '1-Jan-2013';
LegRate = [0.0425 10];
```

```
Price = swapbybk(BKT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = 1.4434
```

Using the previous data, compute the forward swap rate, the coupon rate for the fixed leg, such that the forward swap price at time = 0 is zero.

```
LegRate = [NaN 10];
[Price, ~, SwapRate] = swapbybk(BKT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = 1.4211e-14
```

```
SwapRate = 0.0384
```

## Input Arguments

### **BKTree** — Interest-rate structure

structure

Interest-rate tree structure, created by `bktree`

Data Types: `struct`

### **LegRate** — Leg rate

matrix

Leg rate, specified as a NINST-by-2 matrix, with each row defined as one of the following:

- [CouponRate Spread] (fixed-float)
- [Spread CouponRate] (float-fixed)
- [CouponRate CouponRate] (fixed-fixed)
- [Spread Spread] (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

### **Settle** — Settlement date

serial date number | character vector

Settlement date, specified either as a scalar or NINST-by-1 vector of serial date numbers or date character vectors.

The `Settle` date for every swap is set to the `ValuationDate` of the BK tree. The swap argument `Settle` is ignored.

Data Types: char | double

### **Maturity – Maturity date**

serial date number | character vector

Maturity date, specified as a NINST-by-1 vector of serial date numbers or date character vectors representing the maturity date for each swap.

Data Types: char | double

### **Name-Value Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree, CFTree, SwapRate] = swapbybk(BKTree, LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)`

### **LegReset – Reset frequency per year for each swap**

[1 1] (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of 'LegReset' and a NINST-by-2 vector.

Data Types: double

### **Basis – Day-count basis representing the basis for each leg**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 array (or NINST-by-2 if `Basis` is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **Principal — Notional principal amounts or principal value schedules**

100 (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of 'Principal' and a vector or cell array.

Principal accepts a NINST-by-1 vector or NINST-by-1 cell array (or NINST-by-2 if Principal is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a NumDates-by-2 array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

### **LegType — Leg type**

[1 0] for each instrument (default) | matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float)

Leg type, specified as the comma-separated pair consisting of 'LegType' and a NINST-by-2 matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float). Each row represents an instrument. Each column indicates if the corresponding leg is fixed (1) or floating (0). This matrix defines the interpretation of the values entered in LegRate. LegType allows [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float) swaps

Data Types: `double`

### **Options — Derivatives pricing options structure**

structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

### **EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 (or NINST-by-2 if EndMonthRule is different for each leg).

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

**AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count**

false (default) | value of 0 (false) or 1 (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a NINST-by-1 (or NINST-by-2 if AdjustCashFlowsBasis is different for each leg) of logicals with values of 0 (false) or 1 (true).

Data Types: logical

**BusinessDayConvention — Business day conventions**

actual (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or a N-by-1 (or NINST-by-2 if BusinessDayConvention is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- **actual** — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- **follow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- **modifiedfollow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- **previous** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- **modifiedprevious** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

**Holidays — Holidays used in computing business days**

if not specified, the default is to use holidays.m (default) | MATLAB date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and MATLAB date numbers using a NHolidays-by-1 vector.

Data Types: double

**StartDate — Date swap actually starts**

Settle date (default) | serial date number | character vector

Date swap actually starts, specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector of dates using a serial date number or a character vector.

Use this argument to price forward swaps, that is, swaps that start in a future date

Data Types: char | double

## Output Arguments

### Price — Expected swap prices at time 0

vector

Expected swap prices at time 0, returned as a NINST-by-1 vector.

### PriceTree — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

### CFTree — Swap cash flows

structure

Swap cash flows, returned as a tree structure with a vector of the swap cash flows at each node. This structure contains only NaNs because with binomial recombining trees, cash flows cannot be computed accurately at each node of a tree.

### SwapRate — Rates applicable to fixed leg

matrix

Rates applicable to the fixed leg, returned as a NINST-by-1 vector of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in `LegRate` is NaN. The `SwapRate` output is padded with NaN for those instruments in which `CouponRate` is not set to NaN.

## More About

### Amortizing Swap

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

### Forward Swap

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

## swapbycir

Price swap instrument from Cox-Ingersoll-Ross interest-rate tree

### Syntax

```
[Price,PriceTree,SwapRate] = swapbycir(CIRTree,LegRate,Settle,Maturity)
[Price,PriceTree,SwapRate] = swapbycir( ____,Name,Value)
```

### Description

[Price,PriceTree,SwapRate] = swapbycir(CIRTree,LegRate,Settle,Maturity) prices a swap instrument from a Cox-Ingersoll-Ross (CIR) interest-rate tree. swapbycir computes prices of vanilla swaps, amortizing swaps, and forward swaps using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

[Price,PriceTree,SwapRate] = swapbycir( \_\_\_\_,Name,Value) adds additional name-value pair arguments.

### Examples

#### Price an Interest-Rate Swap Using a CIR Interest-Rate Tree

Define an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year and the notional principal amount is \$100.

```
Basis = 0;
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Create a RateSpec using the intenvset function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates', EndDates);
```

Create a CIR tree.

```
NumPeriods = 5;
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = '01-Jan-2017';
Maturity = '01-Jan-2022';
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);
```

```
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
    FinObj: 'CIRFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
    tObs: [0 1 2 3 4]
    dObs: [736696 737061 737426 737791 738156]
    FwdTree: {1x5 cell}
    Connect: {[3x1 double] [3x3 double] [3x5 double] [3x7 double]}
    Probs: {[3x1 double] [3x3 double] [3x5 double] [3x7 double]}
```

Price the interest-rate swap.

```
[Price,PriceTree] = swapbycir(CIRT,LegRate,Settle,Maturity,'LegReset',LegReset,'Basis',3,'Principi
```

```
Price = 2.5522
```

```
PriceTree = struct with fields:
    FinObj: 'CIRPriceTree'
    tObs: [0 1 2 3 4 5]
    PTree: {1x6 cell}
    Connect: {[3x1 double] [3x3 double] [3x5 double] [3x7 double]}
```

## Input Arguments

### **CIRTree** — Interest-rate structure

structure

Interest-rate tree structure, created by `cirtree`

Data Types: struct

### **LegRate** — Leg rate

matrix

Leg rate, specified as a NINST-by-2 matrix, with each row defined as one of the following:

- [CouponRate Spread] (fixed-float)
- [Spread CouponRate] (float-fixed)
- [CouponRate CouponRate] (fixed-fixed)
- [Spread Spread] (float-float)

**CouponRate** is the decimal annual rate. **Spread** is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

### **Settle** — Settlement date

serial date number | character vector | string array | datetime

Settlement date, specified either as a scalar or NINST-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays.

The `Settle` date for every swap is set to the `ValuationDate` of the CIR tree. The swap argument `Settle` is ignored.

Data Types: `char` | `double` | `string` | `datetime`

### **Maturity – Maturity date**

serial date number | character vector | string array | datetime

Maturity date, specified as a NINST-by-1 vector of serial date numbers, date character vectors, string arrays, or datetime arrays representing the maturity date for each swap.

Data Types: `char` | `double` | `string` | `datetime`

### **Name-Value Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree, SwapRate] = swapbycir(CIRTree, LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)`

### **LegReset – Reset frequency per year for each swap**

`[1 1]` (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of `'LegReset'` and a NINST-by-2 vector.

Data Types: `double`

### **Basis – Day-count basis representing the basis for each leg**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of `'Basis'` and a NINST-by-1 array (or NINST-by-2 if `Basis` is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Principal — Notional principal amounts or principal value schedules**

100 (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of 'Principal' and a vector or cell array.

Principal accepts a NINST-by-1 vector or NINST-by-1 cell array (or NINST-by-2 if Principal is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a NumDates-by-2 array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: cell | double

### **LegType — Leg type**

[1 0] for each instrument (default) | matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float)

Leg type, specified as the comma-separated pair consisting of 'LegType' and a NINST-by-2 matrix with values:

- [1 1] (fixed-fixed) swap
- [1 0] (fixed-float) swap
- [0 1] (float-fixed) swap
- [0 0] (float-float) swap

Each row represents an instrument. Each column indicates if the corresponding leg is fixed (1) or floating (0). This matrix defines the interpretation of the values entered in LegRate.

Data Types: double

### **EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 (or NINST-by-2 if EndMonthRule is different for each leg).

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

### **AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count**

false (default) | value of 0 (false) or 1 (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a NINST-by-1 (or NINST-by-2 if AdjustCashFlowsBasis is different for each leg) of logicals with values of 0 (false) or 1 (true).

Data Types: `logical`

### **BusinessDayConvention — Business day conventions**

`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or a N-by-1 (or NINST-by-2 if BusinessDayConvention is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

### **Holidays — Holidays used in computing business days**

if not specified, the default is to use `holidays.m` (default) | MATLAB date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and MATLAB date numbers using a NHolidays-by-1 vector.

Data Types: `double`

### **StartDate — Date swap actually starts**

Settle date (default) | serial date number | character vector | string array | datetime

Date swap actually starts, specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector of dates using a serial date number, character vector, string array, or string array.

Use this argument to price forward swaps, that is, swaps that start in a future date

Data Types: `char` | `double` | `string` | `datetime`

## **Output Arguments**

### **Price — Expected swap prices at time 0**

vector

Expected swap prices at time 0, returned as a NINST-by-1 vector.

### PriceTree — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within PriceTree:

- PriceTree.tObs contains the observation times.
- PriceTree.PTree contains the clean prices.

### SwapRate — Rates applicable to fixed leg

matrix

Rates applicable to the fixed leg, returned as a NINST-by-1 vector of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in LegRate is NaN. The SwapRate output is padded with NaN for those instruments in which CouponRate is not set to NaN.

## More About

### Amortizing Swap

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

### Forward Swap

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

## swapbyhjm

Price swap instrument from Heath-Jarrow-Morton interest-rate tree

### Syntax

```
[Price,PriceTree,CFTree,SwapRate] = swapbyhjm(HJMTtree,LegRate,Settle,
Maturity)
[Price,PriceTree,CFTree,SwapRate] = swapbyhjm( ____,Name,Value)
```

### Description

[Price,PriceTree,CFTree,SwapRate] = swapbyhjm(HJMTtree,LegRate,Settle, Maturity) prices a swap instrument from a Heath-Jarrow-Morton interest-rate tree. swapbyhjm computes prices of vanilla swaps, amortizing swaps and forward swaps.

[Price,PriceTree,CFTree,SwapRate] = swapbyhjm( \_\_\_\_,Name,Value) adds additional name-value pair arguments.

### Examples

#### Price an Interest-Rate Swap

This example shows how to price an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year, and the notional principal amount is \$100. The values for the remaining arguments are:

- Coupon rate for fixed leg: 0.06 (6%)
- Spread for floating leg: 20 basis points
- Swap settlement date: Jan. 01, 2000
- Swap maturity date: Jan. 01, 2003

Based on the information above, set the required arguments and build the LegRate, LegType, and LegReset matrices:

```
Settle = '01-Jan-2000';
Maturity = '01-Jan-2003';
Basis = 0;
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Price the swap using the HJMTtree included in the MAT-file deriv.mat. The HJMTtree structure contains the time and forward-rate information needed to price the instrument.

```
load deriv.mat;
```

Use swapbyhjm to compute the price of the swap.

```
[Price, PriceTree, CFTree] = swapbyhjm(HJMTree, LegRate, ...
Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
Price =
```

```
3.6923
```

```
PriceTree =
```

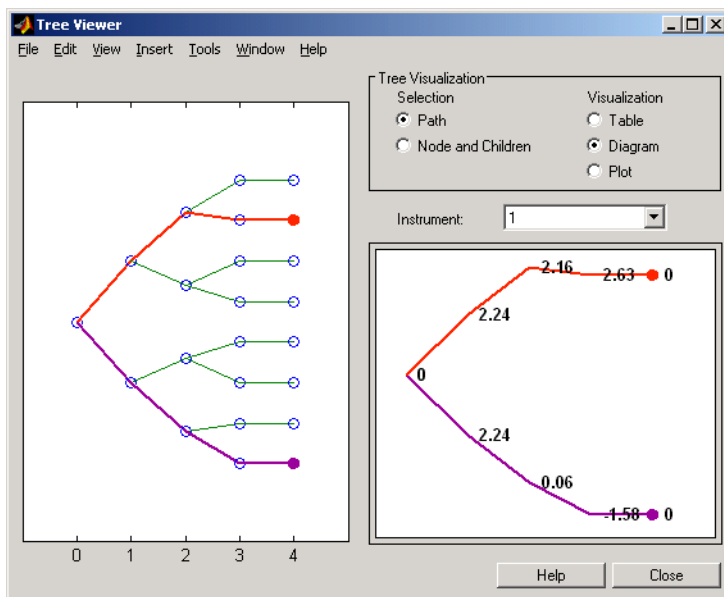

```
FinObj: 'HJMPriceTree'
tObs: [0 1 2 3 4]
PBush: {1x5 cell}
```

```
CFTree =
```

```
FinObj: 'HJMCFTree'
tObs: [0 1 2 3 4]
CFBush: {[0] [1x1x2 double] [1x2x2 double] ... [1x8 double]}
```

Use `treeviewer` to examine `CFTree` graphically and see the cash flows from the swap along both the up and the down branches. A positive cash flow indicates an inflow (income - payments > 0), while a negative cash flow indicates an outflow (income - payments < 0).

```
treeviewer(CFTree)
```

In this example, you have sold a swap (receive fixed rate and pay floating rate). At time  $t = 3$ , if interest rates go down, your cash flow is positive (\$2.63), meaning that you receive this amount. But if interest rates go up, your cash flow is negative (-\$1.58), meaning that you owe this amount.

`treeviewer` price tree diagrams follow the convention that increasing prices appear on the upper branch of a tree and, so, decreasing prices appear on the lower branch. Conversely, for interest-rate displays, *decreasing* interest rates appear on the upper branch (prices are rising) and *increasing* interest rates on the lower branch (prices are falling).

Using the previous data, calculate the swap rate, which is the coupon rate for the fixed leg, such that the swap price at time = 0 is zero.

```

LegRate = [NaN 20];

[Price, PriceTree, CFTree, SwapRate] = swapbyhjm(HJMTree,...
LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)

Price =

    0

PriceTree =

FinObj: 'HJMPriceTree'
  tObs: [0 1 2 3 4]
  PBush:{[0] [1x1x2 double] [1x2x2 double] ... [1x8 double]}

CFTree =

FinObj: 'HJMCFTree'
  tObs: [0 1 2 3 4]
  CFBush:{[0] [1x1x2 double] [1x2x2 double] ... [1x8 double]}

SwapRate =

    0.0466

```

### Price an Amortizing Swap

Price an amortizing swap using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```

Rates = 0.035;
ValuationDate = '1-Jan-2011';
StartDates = ValuationDate;
EndDates = '1-Jan-2017';
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: 0.8135
    Rates: 0.0350
    EndTimes: 6
    StartTimes: 0
    EndDates: 736696
    StartDates: 734504
    ValuationDate: 734504
    Basis: 0
    EndMonthRule: 1

```

Create the swap instrument using the following data:

```

Settle = '1-Jan-2011';
Maturity = '1-Jan-2017';

```

```
Period = 1;
LegRate = [0.04 10];
```

Define the swap amortizing schedule.

```
Principal = {'1-Jan-2013' 100; '1-Jan-2014' 80; '1-Jan-2015' 60; '1-Jan-2016' 40; '1-Jan-2017' 20};
```

Build the HJM tree using the following data:

```
MatDates = {'1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'; '1-Jan-2017'};
HJMTimeSpec = hjmtimespec(RateSpec.ValuationDate, MatDates);
Volatility = [.10; .08; .06; .04];
CurveTerm = [ 1; 2; 3; 4];
HJMVolSpec = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
HJMT = hjmtree(HJMVolSpec, RateSpec, HJMTimeSpec);
```

Compute the price of the amortizing swap.

```
Price = swapbyhjm(HJMT, LegRate, Settle, Maturity, 'Principal', Principal)
```

```
Price = 1.4574
```

### Price a Forward Swap

Price a forward swap using the `StartDate` input argument to define the future starting date of the swap.

Create the `RateSpec`.

```
Rates = 0.0374;
ValuationDate = '1-Jan-2012';
StartDates = ValuationDate;
EndDates = '1-Jan-2018';
Compounding = 1;
```

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
```

```
    FinObj: 'RateSpec'
  Compounding: 1
        Disc: 0.8023
        Rates: 0.0374
    EndTimes: 6
    StartTimes: 0
    EndDates: 737061
    StartDates: 734869
ValuationDate: 734869
        Basis: 0
    EndMonthRule: 1
```

Build an HJM tree.

```
MatDates = {'1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'; '1-Jan-2017'; '1-Jan-2018'};
HJMTimeSpec = hjmtimespec(RateSpec.ValuationDate, MatDates);
```

```

Volatility = [.10; .08; .06; .04];
CurveTerm = [ 1; 2; 3; 4];
HJMVolSpec = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
HJMT = hjmtree(HJMVolSpec, RateSpec, HJMTimeSpec);

```

Compute the price of a forward swap that starts in a year (Jan 1, 2013) and matures in four years with a forward swap rate of 4.25%.

```

Settle = '1-Jan-2012';
Maturity = '1-Jan-2017';
StartDate = '1-Jan-2013';
LegRate = [0.0425 10];

```

```
Price = swapbyhjm(HJMT, LegRate, Settle, Maturity, 'StartDate', StartDate)
```

```
Price = 1.4434
```

Using the previous data, compute the forward swap rate, the coupon rate for the fixed leg, such that the forward swap price at time = 0 is zero.

```

LegRate = [NaN 10];
[Price, ~,~, SwapRate] = swapbyhjm(HJMT, LegRate, Settle, Maturity, 'StartDate', StartDate)

```

```
Price = 0
```

```
SwapRate = 0.0384
```

## Input Arguments

### HJMTree — Interest-rate structure

structure

Interest-rate tree structure, created by `hjmtree`

Data Types: `struct`

### LegRate — Leg rate

matrix

Leg rate, specified as a NINST-by-2 matrix, with each row defined as one of the following:

- [CouponRate Spread] (fixed-float)
- [Spread CouponRate] (float-fixed)
- [CouponRate CouponRate] (fixed-fixed)
- [Spread Spread] (float-float)

**CouponRate** is the decimal annual rate. **Spread** is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

### Settle — Settlement date

serial date number | character vector

Settlement date, specified either as a scalar or NINST-by-1 vector of serial date numbers or date character vectors.

The `Settle` date for every swap is set to the `ValuationDate` of the HJM tree. The swap argument `Settle` is ignored.

Data Types: char | double

### **Maturity – Maturity date**

serial date number | character vector

Maturity date, specified as a NINST-by-1 vector of serial date numbers or date character vectors representing the maturity date for each swap.

Data Types: char | double

### **Name-Value Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[Price, PriceTree, CFTree, SwapRate] = swapbyhjm(HJMTree, LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)`

### **LegReset – Reset frequency per year for each swap**

[1 1] (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of 'LegReset' and a NINST-by-2 vector.

Data Types: double

### **Basis – Day-count basis representing the basis for each leg**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 array (or NINST-by-2 if `Basis` is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **Principal — Notional principal amounts or principal value schedules**

100 (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of 'Principal' and a vector or cell array.

`Principal` accepts a NINST-by-1 vector or NINST-by-1 cell array (or NINST-by-2 if `Principal` is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a `NumDates`-by-2 array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

### **LegType — Leg type**

[1 0] for each instrument (default) | matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float)

Leg type, specified as the comma-separated pair consisting of 'LegType' and a NINST-by-2 matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float). Each row represents an instrument. Each column indicates if the corresponding leg is fixed (1) or floating (0). This matrix defines the interpretation of the values entered in `LegRate`. `LegType` allows [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float) swaps

Data Types: `double`

### **Options — Derivatives pricing options structure**

structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

### **EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 (or NINST-by-2 if `EndMonthRule` is different for each leg).

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

**AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count**

false (default) | value of 0 (false) or 1 (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a NINST-by-1 (or NINST-by-2 if AdjustCashFlowsBasis is different for each leg) of logicals with values of 0 (false) or 1 (true).

Data Types: logical

**BusinessDayConvention — Business day conventions**

actual (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or a N-by-1 (or NINST-by-2 if BusinessDayConvention is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- **actual** — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- **follow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- **modifiedfollow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- **previous** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- **modifiedprevious** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

**Holidays — Holidays used in computing business days**

if not specified, the default is to use holidays.m (default) | MATLAB date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and MATLAB date numbers using a NHolidays-by-1 vector.

Data Types: double

**StartDate — Date swap actually starts**

Settle date (default) | serial date number | character vector

Date swap actually starts, specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector of dates using a serial date number or a character vector.

Use this argument to price forward swaps, that is, swaps that start in a future date

Data Types: char | double

## Output Arguments

### Price — Expected swap prices at time 0

vector

Expected swap prices at time 0, returned as a NINST-by-1 vector.

### PriceTree — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within PriceTree:

- PriceTree.tObs contains the observation times.
- PriceTree.PBush contains the clean prices.

### CFTree — Swap cash flows

structure

Swap cash flows, returned as a tree structure with a vector of the swap cash flows at each node. This structure contains only NaNs because with binomial recombining trees, cash flows cannot be computed accurately at each node of a tree.

### SwapRate — Rates applicable to fixed leg

matrix

Rates applicable to the fixed leg, returned as a NINST-by-1 vector of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in LegRate is NaN. The SwapRate output is padded with NaN for those instruments in which CouponRate is not set to NaN.

## More About

### Amortizing Swap

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

### Forward Swap

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

# swapbyhw

Price swap instrument from Hull-White interest-rate tree

## Syntax

```
[Price,PriceTree,CFTree,SwapRate] = swapbyhw(HWTtree,LegRate,Settle,Maturity)
[Price,PriceTree,CFTree,SwapRate] = swapbyhw( ____,Name,Value)
```

## Description

[Price,PriceTree,CFTree,SwapRate] = swapbyhw(HWTtree,LegRate,Settle,Maturity) prices a swap instrument from a Hull-White interest-rate tree. swapbyhw computes prices of vanilla swaps, amortizing swaps and forward swaps.

[Price,PriceTree,CFTree,SwapRate] = swapbyhw( \_\_\_\_,Name,Value) adds additional name-value pair arguments.

## Examples

### Price an Interest-Rate Swap

Price an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year, and the notional principal amount is \$100. The values for the remaining arguments are:

- Coupon rate for fixed leg: 0.06 (6%)
- Spread for floating leg: 20 basis points
- Swap settlement date: Jan. 01, 2005
- Swap maturity date: Jan. 01, 2008

Based on the information above, set the required arguments and build the LegRate, LegType, and LegReset matrices:

```
Settle = '01-Jan-2005';
Maturity = '01-Jan-2008';
Basis = 0;
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Price the swap using the HWTtree included in the MAT-file deriv.mat. The HWTtree structure contains the time and forward-rate information needed to price the instrument.

```
load deriv.mat;
```

Use swapbyhw to compute the price of the swap.

```
[Price, PriceTree, SwapRate] = swapbyhw(HWTtree, LegRate, ...
Settle, Maturity, LegReset, Basis, Principal, LegType)
```

Warning: Swaps are valued at Tree ValuationDate rather than Settle

Price = 5.9109

```
PriceTree = struct with fields:
    FinObj: 'HWPriceTree'
    PTree: {1x5 cell}
    tObs: [0 1 2 3 4]
    Connect: {[2] [2 3 4] [2 2 3 4 4]}
    Probs: {[3x1 double] [3x3 double] [3x5 double]}
```

SwapRate = NaN

Using the previous data, calculate the swap rate, which is the coupon rate for the fixed leg, such that the swap price at time = 0 is zero.

```
LegRate = [NaN 20];
```

```
[Price, PriceTree, SwapRate] = swapbyhw(HWTree, LegRate, ...
Settle, Maturity, LegReset, Basis, Principal, LegType)
```

Warning: Swaps are valued at Tree ValuationDate rather than Settle

Price = 1.4211e-14

```
PriceTree = struct with fields:
    FinObj: 'HWPriceTree'
    PTree: {1x5 cell}
    tObs: [0 1 2 3 4]
    Connect: {[2] [2 3 4] [2 2 3 4 4]}
    Probs: {[3x1 double] [3x3 double] [3x5 double]}
```

SwapRate = 0.0438

### Price an Amortizing Swap

Price an amortizing swap using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```
Rates = 0.035;
ValuationDate = '1-Jan-2011';
StartDates = ValuationDate;
EndDates = '1-Jan-2017';
Compounding = 1;
```

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: 0.8135
    Rates: 0.0350
    EndTimes: 6
```

```

StartTimes: 0
EndDates: 736696
StartDates: 734504
ValuationDate: 734504
Basis: 0
EndMonthRule: 1

```

Create the swap instrument using the following data:

```

Settle = '1-Jan-2011';
Maturity = '1-Jan-2017';
Period = 1;
LegRate = [0.04 10];

```

Define the swap amortizing schedule.

```

Principal = {'1-Jan-2013' 100; '1-Jan-2014' 80; '1-Jan-2015' 60; '1-Jan-2016' 40; '1-Jan-2017' 20};

```

Build the HW tree using the following data:

```

VolDates = ['1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'; '1-Jan-2017'];
VolCurve = 0.1;
AlphaDates = '01-01-2017';
AlphaCurve = 0.1;

```

```

HWVolSpec = hwwolspec(RateSpec.ValuationDate, VolDates, VolCurve, ...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTimeSpec);

```

Compute the price of the amortizing swap.

```

Price = swapbyhw(HWT, LegRate, Settle, Maturity, 'Principal', Principal)

```

```

Price = 1.4574

```

## Price a Forward Swap

Price a forward swap using the `StartDate` input argument to define the future starting date of the swap.

Create the `RateSpec`.

```

Rates = 0.0374;
ValuationDate = '1-Jan-2012';
StartDates = ValuationDate;
EndDates = '1-Jan-2018';
Compounding = 1;

```

```

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)

```

```

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1

```

```

        Disc: 0.8023
        Rates: 0.0374
        EndTimes: 6
        StartTimes: 0
        EndDates: 737061
        StartDates: 734869
        ValuationDate: 734869
        Basis: 0
        EndMonthRule: 1

```

Build an HW tree.

```

VolDates = {'1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'; '1-Jan-2017'; '1-Jan-2018'};
VolCurve = 0.1;
AlphaDates = '01-01-2018';
AlphaCurve = 0.1;

HWVolSpec = hwwolSpec(RateSpec.ValuationDate, VolDates, VolCurve, ...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimeSpec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTimeSpec);

```

Compute the price of a forward swap that starts in a year (Jan 1, 2013) and matures in four years with a forward swap rate of 4.25%.

```

Settle = '1-Jan-2012';
Maturity = '1-Jan-2017';
StartDate = '1-Jan-2013';
LegRate = [0.0425 10];

Price = swapbyhw(HWT, LegRate, Settle, Maturity, 'StartDate', StartDate)

Price = 1.4434

```

Using the previous data, compute the forward swap rate, the coupon rate for the fixed leg, such that the forward swap price at time = 0 is zero.

```

LegRate = [NaN 10];
[Price, ~, SwapRate] = swapbyhw(HWT, LegRate, Settle, Maturity, 'StartDate', StartDate)

Price = 4.2633e-14

SwapRate = 0.0384

```

## Input Arguments

### HWTtree — Interest-rate structure

structure

Interest-rate tree structure, created by hwtree

Data Types: struct

### LegRate — Leg rate

matrix

Leg rate, specified as a NINST-by-2 matrix, with each row defined as one of the following:

- [CouponRate Spread] (fixed-float)
- [Spread CouponRate] (float-fixed)
- [CouponRate CouponRate] (fixed-fixed)
- [Spread Spread] (float-float)

CouponRate is the decimal annual rate. Spread is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

### Settle — Settlement date

serial date number | character vector

Settlement date, specified either as a scalar or NINST-by-1 vector of serial date numbers or date character vectors.

The Settle date for every swap is set to the ValuationDate of the HW tree. The swap argument Settle is ignored.

Data Types: char | double

### Maturity — Maturity date

serial date number | character vector

Maturity date, specified as a NINST-by-1 vector of serial date numbers or date character vectors representing the maturity date for each swap.

Data Types: char | double

### Name-Value Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: [Price, PriceTree, CFTree, SwapRate] = swapbyhw(HWTree, LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)

### LegReset — Reset frequency per year for each swap

[1 1] (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of 'LegReset' and a NINST-by-2 vector.

Data Types: double

### Basis — Day-count basis representing the basis for each leg

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 array (or NINST-by-2 if Basis is different for each leg).

- 0 = actual/actual

- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **Principal — Notional principal amounts or principal value schedules**

100 (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of 'Principal' and a vector or cell array.

Principal accepts a NINST-by-1 vector or NINST-by-1 cell array (or NINST-by-2 if Principal is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a NumDates-by-2 array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

### **LegType — Leg type**

[1 0] for each instrument (default) | matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float)

Leg type, specified as the comma-separated pair consisting of 'LegType' and a NINST-by-2 matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float). Each row represents an instrument. Each column indicates if the corresponding leg is fixed (1) or floating (0). This matrix defines the interpretation of the values entered in LegRate. LegType allows [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float) swaps

Data Types: `double`

### **Options — Derivatives pricing options structure**

structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

### **EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 (or NINST-by-2 if EndMonthRule is different for each leg).

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

### **AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count**

false (default) | value of 0 (false) or 1 (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a NINST-by-1 (or NINST-by-2 if AdjustCashFlowsBasis is different for each leg) of logicals with values of 0 (false) or 1 (true).

Data Types: logical

### **BusinessDayConvention — Business day conventions**

actual (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or a N-by-1 (or NINST-by-2 if BusinessDayConvention is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

### **Holidays — Holidays used in computing business days**

if not specified, the default is to use `holidays.m` (default) | MATLAB date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and MATLAB date numbers using a `NHolidays-by-1` vector.

Data Types: double

### **StartDate** — Date swap actually starts

Settle date (default) | serial date number | character vector

Date swap actually starts, specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector of dates using a serial date number or a character vector.

Use this argument to price forward swaps, that is, swaps that start in a future date

Data Types: char | double

## **Output Arguments**

### **Price** — Expected swap prices at time 0

vector

Expected swap prices at time 0, returned as a NINST-by-1 vector.

### **PriceTree** — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within PriceTree:

- PriceTree.PTree contains the clean prices.
- PriceTree.tObs contains the observation times.
- PriceTree.Connect contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are NumNodes elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- PriceTree.Probs contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

### **CFTree** — Swap cash flows

structure

Swap cash flows, returned as a tree structure with a vector of the swap cash flows at each node. This structure contains only NaNs because with binomial recombining trees, cash flows cannot be computed accurately at each node of a tree.

### **SwapRate** — Rates applicable to fixed leg

matrix

Rates applicable to the fixed leg, returned as a NINST-by-1 vector of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in LegRate is NaN. The SwapRate output is padded with NaN for those instruments in which CouponRate is not set to NaN.

## **More About**

### **Amortizing Swap**

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

### **Forward Swap**

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

## swapbyzero

Price swap instrument from set of zero curves and price cross-currency swaps

### Syntax

```
[Price, SwapRate, AI, RecCF, RecCFDates, PayCF, PayCFDates] = swapbyzero(RateSpec, LegRate, Settle, Maturity)
```

```
[Price, SwapRate, AI, RecCF, RecCFDates, PayCF, PayCFDates] = swapbyzero(RateSpec, LegRate, Settle, Maturity, Name, Value)
```

### Description

[Price, SwapRate, AI, RecCF, RecCFDates, PayCF, PayCFDates] = swapbyzero(RateSpec, LegRate, Settle, Maturity) prices a swap instrument. You can use swapbyzero to compute prices of vanilla swaps, amortizing swaps, and forward swaps. All inputs are either scalars or NINST-by-1 vectors unless otherwise specified. Any date can be a serial date number or date character vector. An optional argument can be passed as an empty matrix [].

[Price, SwapRate, AI, RecCF, RecCFDates, PayCF, PayCFDates] = swapbyzero(RateSpec, LegRate, Settle, Maturity, Name, Value) prices a swap instrument with additional options specified by one or more Name, Value pair arguments. You can use swapbyzero to compute prices of vanilla swaps, amortizing swaps, forward swaps, and cross-currency swaps. For more information on the name-value pairs for vanilla swaps, amortizing swaps, and forward swaps, see Vanilla Swaps, Amortizing Swaps, Forward Swaps on page 11-0 .

Specifically, you can use name-value pairs for FXRate, ExchangeInitialPrincipal, and ExchangeMaturityPrincipal to compute the price for cross-currency swaps. For more information on the name-value pairs for cross-currency swaps, see Cross-Currency Swaps on page 11-0 .

### Examples

#### Price an Interest-Rate Swap

Price an interest-rate swap with a fixed receiving leg and a floating paying leg. Payments are made once a year, and the notional principal amount is \$100. The values for the remaining arguments are:

- Coupon rate for fixed leg: 0.06 (6%)
- Spread for floating leg: 20 basis points
- Swap settlement date: Jan. 01, 2000
- Swap maturity date: Jan. 01, 2003

Based on the information above, set the required arguments and build the LegRate, LegType, and LegReset matrices:

```
Settle = '01-Jan-2000';
Maturity = '01-Jan-2003';
Basis = 0;
```

```
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

Load the file `deriv.mat`, which provides `ZeroRateSpec`, the interest-rate term structure needed to price the bond.

```
load deriv.mat;
```

Use `swapbyzero` to compute the price of the swap.

```
Price = swapbyzero(ZeroRateSpec, LegRate, Settle, Maturity,...
LegReset, Basis, Principal, LegType)
```

```
Price = 3.6923
```

Using the previous data, calculate the swap rate, which is the coupon rate for the fixed leg, such that the swap price at time = 0 is zero.

```
LegRate = [NaN 20];
```

```
[Price, SwapRate] = swapbyzero(ZeroRateSpec, LegRate, Settle,...
Maturity, LegReset, Basis, Principal, LegType)
```

```
Price = 0
```

```
SwapRate = 0.0466
```

In `swapbyzero`, if `Settle` is not on a reset date (and `'StartDate'` is not specified), the effective date is assumed to be the previous reset date before `Settle` in order to compute the accrued interest and dirty price. In this example, the effective date is ( `'15-Sep-2009'` ), which is the previous reset date before the ( `'08-Jun-2010'` ) `Settle` date.

Use `swapbyzero` with name-value pair arguments for `LegRate`, `LegType`, `LatestFloatingRate`, `AdjustCashFlowsBasis`, and `BusinessDayConvention` to calculate output for `Price`, `SwapRate`, `AI`, `RecCF`, `RecCFDates`, `PayCF`, and `PayCFDates`:

```
Settle = datenum('08-Jun-2010');
RateSpec = intenvset('Rates', [.005 .0075 .01 .014 .02 .025 .03]',...
'StartDates',Settle, 'EndDates',{ '08-Dec-2010', '08-Jun-2011',...
'08-Jun-2012', '08-Jun-2013', '08-Jun-2015', '08-Jun-2017', '08-Jun-2020' });
Maturity = datenum('15-Sep-2020');
LegRate = [.025 50];
LegType = [1 0]; % fixed/floating
LatestFloatingRate = .005;
```

```
[Price, SwapRate, AI, RecCF, RecCFDates, PayCF, PayCFDates] = ...
swapbyzero(RateSpec, LegRate, Settle, Maturity, 'LegType', LegType, ...
'LatestFloatingRate', LatestFloatingRate, 'AdjustCashFlowsBasis', true, ...
'BusinessDayConvention', 'modifiedfollow')
```

```
Price = -6.7259
```

```
SwapRate = NaN
```

```
AI = 1.4575
```

```
RecCF = 1x12
```

```

-1.8219    2.5000    2.5000    2.5137    2.4932    2.4932    2.5000    2.5000    2.5000    2.5
RecCFDates = 1x12
    734297    734396    734761    735129    735493    735857    736222    736588
PayCF = 1x12
-0.3644    0.5000    1.4048    1.9961    2.8379    3.2760    3.8218    4.1733    4.5164    4.
PayCFDates = 1x12
    734297    734396    734761    735129    735493    735857    736222    736588

```

### Price Swaps By Specifying Multiple Term Structures Using RateSpec

Price three swaps using two interest-rate curves. First, define the data for the interest-rate term structure:

```

StartDates = '01-May-2012';
EndDates = {'01-May-2013'; '01-May-2014'; '01-May-2015'; '01-May-2016'};
Rates = [[0.0356;0.041185;0.04489;0.047741],[0.0366;0.04218;0.04589;0.04974]];

```

Create the RateSpec using `intenvset`.

```

RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Compounding', 1)

```

```

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [4x2 double]
    Rates: [4x2 double]
    EndTimes: [4x1 double]
    StartTimes: [4x1 double]
    EndDates: [4x1 double]
    StartDates: 734990
    ValuationDate: 734990
    Basis: 0
    EndMonthRule: 1

```

Look at the Rates for the two interest-rate curves.

```
RateSpec.Rates
```

```
ans = 4x2
```

```

0.0356    0.0366
0.0412    0.0422
0.0449    0.0459
0.0477    0.0497

```

Define the swap instruments.

```
Settle = '01-May-2012';
Maturity = '01-May-2015';
LegRate = [0.06 10];
Principal = [100;50;100]; % Three notional amounts
```

Price three swaps using two curves.

```
Price = swapbyzero(RateSpec, LegRate, Settle, Maturity, 'Principal', Principal)
```

```
Price = 3×2
```

```
    3.9688    3.6869
    1.9844    1.8434
    3.9688    3.6869
```

### Price Swap By Specifying Multiple Term Structures Using a 1-by-2 RateSpec

Price a swap using two interest-rate curves. First, define data for the two interest-rate term structures:

```
StartDates = '01-May-2012';
EndDates = {'01-May-2013'; '01-May-2014'; '01-May-2015'; '01-May-2016'};
Rates1 = [0.0356;0.041185;0.04489;0.047741];
Rates2 = [0.0366;0.04218;0.04589;0.04974];
```

Create the RateSpec using `intenvset`.

```
RateSpecReceiving = intenvset('Rates', Rates1, 'StartDates', StartDates, ...
    'EndDates', EndDates, 'Compounding', 1);
RateSpecPaying = intenvset('Rates', Rates2, 'StartDates', StartDates, ...
    'EndDates', EndDates, 'Compounding', 1);
RateSpec=[RateSpecReceiving RateSpecPaying]
```

```
RateSpec=1×2 struct array with fields:
```

```
    FinObj
    Compounding
    Disc
    Rates
    EndTimes
    StartTimes
    EndDates
    StartDates
    ValuationDate
    Basis
    EndMonthRule
```

Define the swap instruments.

```
Settle = '01-May-2012';
Maturity = '01-May-2015';
LegRate = [0.06 10];
Principal = [100;50;100];
```

Price three swaps using the two curves.

```
Price = swapbyzero(RateSpec, LegRate, Settle, Maturity, 'Principal', Principal)
```

```
Price = 3×1
```

```
3.9693
1.9846
3.9693
```

### Compute a Forward Par Swap Rate

To compute a forward par swap rate, set the `StartDate` parameter to a future date and set the fixed coupon rate in the `LegRate` input to `NaN`.

Define the zero curve data and build a zero curve using `IRDataCurve`.

```
ZeroRates = [2.09 2.47 2.71 3.12 3.43 3.85 4.57]'/100;
Settle = datenum('1-Jan-2012');
EndDates = datemnth(Settle,12*[1 2 3 5 7 10 20]');
Compounding = 1;
```

```
ZeroCurve = IRDataCurve('Zero',Settle,EndDates,ZeroRates,'Compounding',Compounding)
```

```
ZeroCurve =
    Type: Zero
    Settle: 734869 (01-Jan-2012)
    Compounding: 1
    Basis: 0 (actual/actual)
    InterpMethod: linear
    Dates: [7x1 double]
    Data: [7x1 double]
```

Create a `RateSpec` structure using the `toRateSpec` method.

```
RateSpec = ZeroCurve.toRateSpec(EndDates)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [7x1 double]
    Rates: [7x1 double]
    EndTimes: [7x1 double]
    StartTimes: [7x1 double]
    EndDates: [7x1 double]
    StartDates: 734869
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1
```

Compute the forward swap rate (the coupon rate for the fixed leg), such that the forward swap price at time = 0 is zero. The forward swap starts in a month (1-Feb-2012) and matures in 10 years (1-Feb-2022).

```

StartDate = datenum('1-Feb-2012');
Maturity = datenum('1-Feb-2022');
LegRate = [NaN 0];

[Price, SwapRate] = swapbyzero(RateSpec, LegRate, Settle, Maturity,...
'StartDate', StartDate)

Price = 0
SwapRate = 0.0378

```

### Compute a Forward Swap Rate Using the Optional Input BusinessDayConvention

The `swapbyzero` function generates the cash flow dates based on the `Settle` and `Maturity` dates, while using the `Maturity` date as the "anchor" date from which to count backwards in regular intervals. By default, `swapbyzero` does not distinguish non-business days from business days. To make `swapbyzero` move non-business days to the following business days, you can set the optional name-value input argument `BusinessDayConvention` with a value of `follow`.

Define the zero curve data and build a zero curve using `IRDataCurve`.

```

ZeroRates = [2.09 2.47 2.71 3.12 3.43 3.85 4.57]'/100;
Settle = datenum('5-Jan-2012');
EndDates = datemnth(Settle,12*[1 2 3 5 7 10 20]');
Compounding = 1;
ZeroCurve = IRDataCurve('Zero',Settle,EndDates,ZeroRates,'Compounding',Compounding);
RateSpec = ZeroCurve.toRateSpec(EndDates);
StartDate = datenum('5-Feb-2012');
Maturity = datenum('5-Feb-2022');
LegRate = [NaN 0];

```

To demonstrate the optional input `BusinessDayConvention`, `swapbyzero` is first used without and then with the optional name-value input argument `BusinessDayConvention`. Notice that when using `BusinessDayConvention`, all days are business days.

```

[Price1,SwapRate1,~,~,RecCFDates1,~,PayCFDates1] = swapbyzero(RateSpec,LegRate,Settle,Maturity,
'StartDate',StartDate);
datestr(RecCFDates1)

ans = 11x11 char array
    '05-Jan-2012'
    '05-Feb-2013'
    '05-Feb-2014'
    '05-Feb-2015'
    '05-Feb-2016'
    '05-Feb-2017'
    '05-Feb-2018'
    '05-Feb-2019'
    '05-Feb-2020'
    '05-Feb-2021'

### Price an Amortizing Swap

Price an amortizing swap using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```

Rates = 0.035;
ValuationDate = '1-Jan-2011';
StartDates = ValuationDate;
EndDates = '1-Jan-2017';
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

```

Create the swap instrument using the following data:

```

Settle = '1-Jan-2011';
Maturity = '1-Jan-2017';
LegRate = [0.04 10];

```

Define the swap amortizing schedule.

```

Principal = {'1-Jan-2013' 100; '1-Jan-2014' 80; '1-Jan-2015' 60; '1-Jan-2016' 40; '1-Jan-2017' 20};

```

Compute the price of the amortizing swap.

```

Price = swapbyzero(RateSpec, LegRate, Settle, Maturity, 'Principal' , Principal)

```

```

Price = 1.4574

```

## Price a Forward Swap

Price a forward swap using the `StartDate` input argument to define the future starting date of the swap.

Create the `RateSpec`.

```

Rates = 0.0325;
ValuationDate = '1-Jan-2012';
StartDates = ValuationDate;
EndDates = '1-Jan-2018';
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)

```

```

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: 0.8254
    Rates: 0.0325
    EndTimes: 6
    StartTimes: 0
    EndDates: 737061
    StartDates: 734869
    ValuationDate: 734869
    Basis: 0
    EndMonthRule: 1

```

Compute the price of a forward swap that starts in a year (Jan 1, 2013) and matures in three years with a forward swap rate of 4.27%.

```
Settle = '1-Jan-2012';
StartDate = '1-Jan-2013';
Maturity = '1-Jan-2016';
LegRate = [0.0427 10];
```

```
Price = swapbyzero(RateSpec, LegRate, Settle, Maturity, 'StartDate' , StartDate)
```

```
Price = 2.5083
```

Using the previous data, compute the forward swap rate, the coupon rate for the fixed leg, such that the forward swap price at time = 0 is zero.

```
LegRate = [NaN 10];
[Price, SwapRate] = swapbyzero(RateSpec, LegRate, Settle, Maturity, ...
'StartDate' , StartDate)
```

```
Price = 0
```

```
SwapRate = 0.0335
```

### Specify the Rate at the Instrument's Starting Date When It Cannot Be Obtained from the RateSpec

If `Settle` is not on a reset date of a floating-rate note, `swapbyzero` attempts to obtain the latest floating rate before `Settle` from `RateSpec` or the `LatestFloatingRate` parameter. When the reset date for this rate is out of the range of `RateSpec` (and `LatestFloatingRate` is not specified), `swapbyzero` fails to obtain the rate for that date and generates an error. This example shows how to use the `LatestFloatingRate` input parameter to avoid the error.

Create the error condition when a swap instrument's `StartDate` cannot be determined from the `RateSpec`.

```
Settle = '01-Jan-2000';
Maturity = '01-Dec-2003';
Basis = 0;
Principal = 100;
LegRate = [0.06 20]; % [CouponRate Spread]
LegType = [1 0]; % [Fixed Float]
LegReset = [1 1]; % Payments once per year
```

```
load deriv.mat;
```

```
Price = swapbyzero(ZeroRateSpec, LegRate, Settle, Maturity, ...
'LegReset', LegReset, 'Basis', Basis, 'Principal', Principal, ...
'LegType', LegType)
```

```
Error using floatbyzero (line 256)
```

```
The rate at the instrument starting date cannot be obtained from RateSpec.
Its reset date (01-Dec-1999) is out of the range of dates contained in RateSpec.
This rate is required to calculate cash flows at the instrument starting date.
Consider specifying this rate with the 'LatestFloatingRate' input parameter.
```

```
Error in swapbyzero (line 289)
```

```
[FloatFullPrice, FloatPrice, FloatCF, FloatCFDates] = floatbyzero(FloatRateSpec, Spreads, Settle, ...
```

Here, the reset date for the rate at `Settle` was 01-Dec-1999, which was earlier than the valuation date of `ZeroRateSpec` (01-Jan-2000). This error can be avoided by specifying the rate at the swap instrument's starting date using the `LatestFloatingRate` input parameter.

Define LatestFloatingRate and calculate the floating-rate price.

```
Price = swapbyzero(ZeroRateSpec,LegRate,Settle,Maturity,...
'LegReset',LegReset,'Basis',Basis,'Principal',Principal, ...
'LegType',LegType,'LatestFloatingRate',0.03)
```

Price =

4.7594

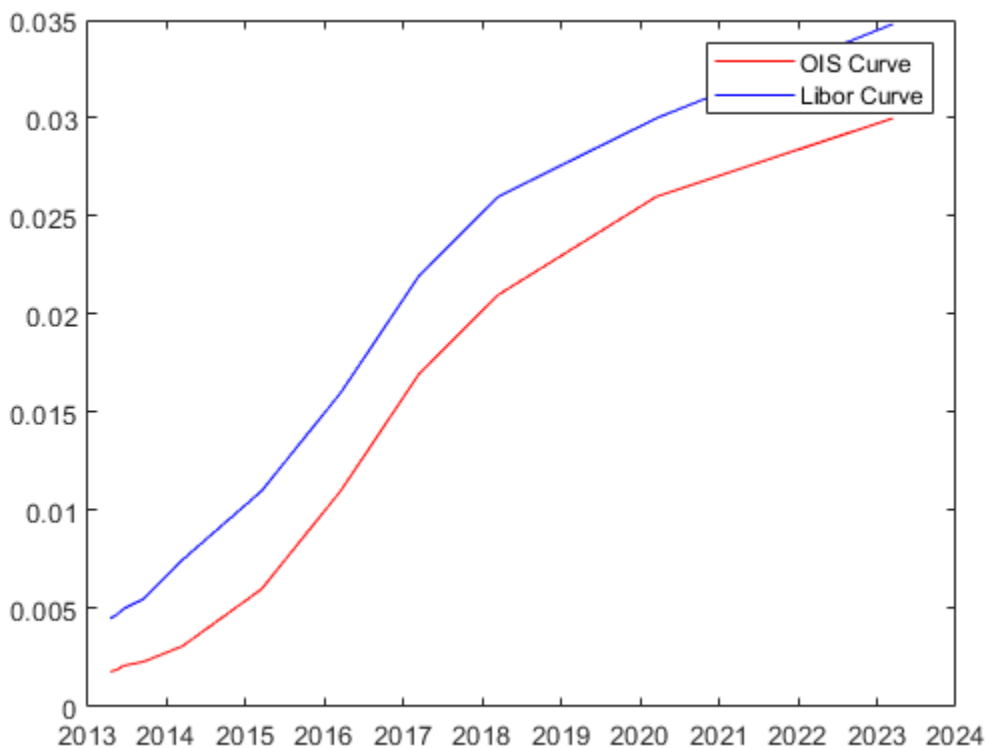

## Price a Swap Using a Different Curve to Generate the Cash Flows of the Floating Leg

Define the OIS and Libor rates.

```
Settle = datenum('15-Mar-2013');
CurveDates = daysadd(Settle,360*[1/12 2/12 3/12 6/12 1 2 3 4 5 7 10],1);
OISRates = [.0018 .0019 .0021 .0023 .0031 .006 .011 .017 .021 .026 .03]';
LiborRates = [.0045 .0047 .005 .0055 .0075 .011 .016 .022 .026 .030 .0348]';
```

Plot the dual curves.

```
figure,plot(CurveDates,OISRates,'r');hold on;plot(CurveDates,LiborRates,'b')
datetick
legend({'OIS Curve', 'Libor Curve'})
```

Create an associated RateSpec for the OIS and Libor curves.

```
OISCurve = intenvset('Rates',OISRates,'StartDate',Settle,'EndDates',CurveDates);
LiborCurve = intenvset('Rates',LiborRates,'StartDate',Settle,'EndDates',CurveDates);
```

Define the swap.

```
Maturity = datenum('15-Mar-2018'); % Five year swap
FloatSpread = 0;
FixedRate = .025;
LegRate = [FixedRate FloatSpread];
```

Compute the price of the swap instrument. The `LiborCurve` term structure will be used to generate the cash flows of the floating leg. The `OISCurve` term structure will be used for discounting the cash flows.

```
Price = swapbyzero(OISCurve, LegRate, Settle, ...
Maturity, 'ProjectionCurve', LiborCurve)
```

```
Price = -0.3697
```

Compare results when the term structure `OISCurve` is used both for discounting and also generating the cash flows of the floating leg.

```
PriceSwap = swapbyzero(OISCurve, LegRate, Settle, Maturity)
```

```
PriceSwap = 2.0517
```

### Price a Fixed-Fixed Currency Swap

Price an existing cross currency swap that receives a fixed rate of JPY and pays a fixed rate of USD at an annual frequency.

```
Settle = datenum('15-Aug-2015');
Maturity = datenum('15-Aug-2018');
Reset = 1;
LegType = [1 1]; % Fixed-Fixed
```

```
r_USD = .09;
r_JPY = .04;
```

```
FixedRate_USD = .08;
FixedRate_JPY = .05;
```

```
Principal_USD = 10000000;
Principal_JPY = 1200000000;
```

```
S = 1/110;
```

```
RateSpec_USD = intenvset('StartDate',Settle,'EndDate', Maturity,'Rates',r_USD,'Compounding',-1);
RateSpec_JPY = intenvset('StartDate',Settle,'EndDate', Maturity,'Rates', r_JPY,'Compounding',-1)
```

```
Price = swapbyzero([RateSpec_JPY RateSpec_USD], [FixedRate_JPY FixedRate_USD], ...
Settle, Maturity, 'Principal',[Principal_JPY Principal_USD], 'FXRate',[S 1], 'LegType',LegType)
```

```
Price = 1.5430e+06
```

## Price a Float-Float Currency Swap

Price a new swap where you pay a EUR float and receive a USD float.

```

Settle = datenum('22-Dec-2015');
Maturity = datenum('15-Aug-2018');
LegRate = [0 -50/10000];
LegType = [0 0]; % Float Float
LegReset = [4 4];
FXRate = 1.1;
Notional = [10000000 8000000];

USD_Dates = datemnth(Settle,[1 3 6 12*[1 2 3 5 7 10 20 30]]');
USD_Zero = [0.03 0.06 0.08 0.13 0.36 0.76 1.63 2.29 2.88 3.64 3.89]'/100;
Curve_USD = intenvset('StartDate',Settle,'EndDates',USD_Dates,'Rates',USD_Zero);

EUR_Dates = datemnth(Settle,[3 6 12*[1 2 3 5 7 10 20 30]]');
EUR_Zero = [0.017 0.033 0.088 .27 .512 1.056 1.573 2.183 2.898 2.797]'/100;
Curve_EUR = intenvset('StartDate',Settle,'EndDates',EUR_Dates,'Rates',EUR_Zero);

Price = swapbyzero([Curve_USD Curve_EUR], ...
    LegRate, Settle, Maturity,'LegType',LegType,'LegReset',LegReset,'Principal',Notional,...
    'FXRate',[1 FXRate],'ExchangeInitialPrincipal',false)

Price = 1.2002e+06

```

## Input Arguments

### RateSpec — Interest-rate structure

structure

Interest-rate structure, specified using `intenvset` to create a `RateSpec`.

`RateSpec` can also be a 1-by-2 input variable of `RateSpecs`, with the second `RateSpec` structure containing one or more discount curves for the paying leg. If only one `RateSpec` structure is specified, then this `RateSpec` is used to discount both legs.

Data Types: `struct`

### LegRate — Leg rate

matrix

Leg rate, specified as a NINST-by-2 matrix, with each row defined as one of the following:

- [CouponRate Spread] (fixed-float)
- [Spread CouponRate] (float-fixed)
- [CouponRate CouponRate] (fixed-fixed)
- [Spread Spread] (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

### Settle — Settlement date

serial date number | character vector | cell array of character vectors

Settlement date, specified either as a scalar or NINST-by-1 vector of serial date numbers or date character vectors of the same value which represent the settlement date for each swap. **Settle** must be earlier than **Maturity**.

Data Types: char | cell | double

### Maturity — Maturity date

serial date number | character vector | cell array of character vectors

Maturity date, specified as a NINST-by-1 vector of serial date numbers or date character vectors representing the maturity date for each swap.

Data Types: char | cell | double

### Name-Value Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

```
Example: [Price, SwapRate, AI, RecCF, RecCFDates, PayCF, PayCFDates] =
swapbyzero(RateSpec, LegRate, Settle,
Maturity, 'LegType', LegType, 'LatestFloatingRate', LatestFloatingRate, 'AdjustCashFlowsBasis', true,
'BusinessDayConvention', 'modifiedfollow')
```

### Vanilla Swaps, Amortizing Swaps, Forward Swaps

#### LegReset — Reset frequency per year for each swap

[1 1] (default) | vector

Reset frequency per year for each swap, specified as the comma-separated pair consisting of 'LegReset' and a NINST-by-2 vector.

Data Types: double

#### Basis — Day-count basis of instrument

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 array (or NINST-by-2 if **Basis** is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Principal — Notional principal amounts or principal value schedules**

100 (default) | vector or cell array

Notional principal amounts or principal value schedules, specified as the comma-separated pair consisting of 'Principal' and a vector or cell array.

Principal accepts a NINST-by-1 vector or NINST-by-1 cell array (or NINST-by-2 if Principal is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a NumDates-by-2 array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: cell | double

### **LegType — Leg type**

[1 0] for each instrument (default) | matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float)

Leg type, specified as the comma-separated pair consisting of 'LegType' and a NINST-by-2 matrix with values [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float). Each row represents an instrument. Each column indicates if the corresponding leg is fixed (1) or floating (0). This matrix defines the interpretation of the values entered in LegRate. LegType allows [1 1] (fixed-fixed), [1 0] (fixed-float), [0 1] (float-fixed), or [0 0] (float-float) swaps

Data Types: double

### **EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 (or NINST-by-2 if EndMonthRule is different for each leg).

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

### **AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count**

false (default) | value of 0 (false) or 1 (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a NINST-by-1 (or NINST-by-2 if AdjustCashFlowsBasis is different for each leg) of logicals with values of 0 (false) or 1 (true).

Data Types: `logical`

### **BusinessDayConvention — Business day conventions**

`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or a N-by-1 (or NINST-by-2 if BusinessDayConvention is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

### **Holidays — Holidays used in computing business days**

if not specified, the default is to use `holidays.m` (default) | MATLAB date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and MATLAB date numbers using a NHolidays-by-1 vector.

Data Types: `double`

### **StartDate — Dates when swaps actually start**

If not specified, date is `Settle` (default) | serial date number | character vector | cell array of character vectors

Dates when the swaps actually start, specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector of serial date numbers, character vectors, or cell array of character vectors.

Data Types: `char` | `cell` | `double`

### **LatestFloatingRate — Rate for the next floating payment**

If not specified, then `RateSpec` must contain this information (default) | scalar numeric

Rate for the next floating payment, set at the last reset date, specified as the comma-separated pair consisting of 'LatestFloatingRate' and a scalar numeric value.

`LatestFloatingRate` accepts a `Rate` for the next floating payment, set at the last reset date. `LatestFloatingRate` is a NINST-by-1 (or NINST-by-2 if `LatestFloatingRate` is different for each leg).

Data Types: `double`

### **ProjectionCurve — Rate curve used in generating cash flows for the floating leg of the swap**

if `ProjectionCurve` is not specified, then `RateSpec` is used both for discounting and generating cash flows for the floating leg (default) | `RateSpec` or vector

Rate curve used in generating cash flows for the floating leg of the swap, specified as the comma-separated pair consisting of 'ProjectionCurve' and a `RateSpec`.

If specifying a fixed-float or a float-fixed swap, the `ProjectionCurve` rate curve is used in generating cash flows for the floating leg of the swap. This structure must be created using `intenvset`.

If specifying a fixed-fixed or a float-float swap, then `ProjectionCurve` is NINST-by-2 vector because each floating leg could have a different projection curve.

Data Types: `struct`

### **Cross-Currency Swaps**

#### **FXRate — Foreign exchange (FX) rate applied to cash flows**

if not specified, both legs of `swapbyzero` are in same currency (default) | array

Foreign exchange (FX) rate applied to cash flows, specified as the comma-separated pair consisting of 'FXRate' and a NINST-by-2 array of doubles. Since the foreign exchange rate could be applied to either the payer or receiver leg, there are 2 columns in the input array and you must specify which leg has the foreign currency.

Data Types: `double`

#### **ExchangeInitialPrincipal — Flag to indicate if initial Principal is exchanged**

0 (false) (default) | array

Flag to indicate if `InitialPrincipal` is exchanged, specified as the comma-separated pair consisting of 'ExchangeInitialPrincipal' and a NINST-by-1 array of logicals.

Data Types: `logical`

#### **ExchangeMaturityPrincipal — Flag to indicate if Principal exchanged at Maturity**

1 (true) (default) | array

Flag to indicate if `Principal` is exchanged at `Maturity`, specified as the comma-separated pair consisting of 'ExchangeMaturityPrincipal' and a NINST-by-1 array of logicals. While in practice most single currency swaps do not exchange principal at maturity, the default is true to maintain backward compatibility.

Data Types: `logical`

## **Output Arguments**

### **Price — Swap prices**

matrix

Swap prices, returned as the number of instruments (NINST) by number of curves (NUMCURVES) matrix. Each column arises from one of the zero curves. Price output is the dirty price. To compute the clean price, subtract the accrued interest (AI) from the dirty price.

**SwapRate — Rates applicable to fixed leg**

matrix

Rates applicable to the fixed leg, returned as a NINST-by-NUMCURVES matrix of rates applicable to the fixed leg such that the swaps' values are zero at time 0. This rate is used in calculating the swaps' prices when the rate specified for the fixed leg in LegRate is NaN. The SwapRate output is padded with NaN for those instruments in which CouponRate is not set to NaN.

**AI — Accrued interest**

matrix

Accrued interest, returned as a NINST-by-NUMCURVES matrix.

**RecCF — Cash flows for receiving leg**

matrix

Cash flows for the receiving leg, returned as a NINST-by-NUMCURVES matrix.

---

**Note** If there is more than one curve specified in the RateSpec input, then the first NCURVES row corresponds to the first swap, the second NCURVES row correspond to the second swap, and so on.

---

**RecCFDates — Payment dates for receiving leg**

matrix

Payment dates for the receiving leg, returned as an NINST-by-NUMCURVES matrix.

**PayCF — Cash flows for paying leg**

matrix

Cash flows for the paying leg, returned as an NINST-by-NUMCURVES matrix.

**PayCFDates — Payment dates for paying leg**

matrix

Payment dates for the paying leg, returned as an NINST-by-NUMCURVES matrix.

## More About

**Amortizing Swap**

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

**Forward Swap**

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

**Cross-currency Swap**

Swaps where the payment legs of the swap are denominated in different currencies.

One difference between cross-currency swaps and standard swaps is that an exchange of principal may occur at the beginning and/or end of the swap. The exchange of initial principal will only come into play in pricing a cross-currency swap at inception (in other words, pricing an existing cross-currency swap will occur after this cash flow has happened). Furthermore, these exchanges of principal typically do not affect the value of the swap (since the principal values of the two legs are chosen based on the currency exchange rate) but affect the cash flows for each leg.

## Introduced before R2006a

## swaptionbybdt

Price swaption from Black-Derman-Toy interest-rate tree

### Syntax

```
[Price,PriceTree] = swaptionbybdt(BDTree,OptSpec,Strike,ExerciseDates,
Spread,Settle,Maturity)
[Price,PriceTree] = swaptionbybdt( ____,Name,Value)
```

### Description

[Price,PriceTree] = swaptionbybdt(BDTree,OptSpec,Strike,ExerciseDates, Spread,Settle,Maturity) prices swaption using a Black-Derman-Toy tree.

[Price,PriceTree] = swaptionbybdt( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price a 5-Year Call Swaption Using a BDT Interest-Rate Tree

This example shows how to price a 5-year call swaption using a BDT interest-rate tree. Assume that interest rate and volatility are fixed at 6% and 20% annually between the valuation date of the tree until its maturity. Build a tree with the following data.

```
Rates = 0.06 * ones (10,1);
StartDates = ['jan-1-2007';'jan-1-2008';'jan-1-2009';'jan-1-2010';'jan-1-2011';...
'jan-1-2012';'jan-1-2013';'jan-1-2014';'jan-1-2015';'jan-1-2016'];

EndDates =['jan-1-2008';'jan-1-2009';'jan-1-2010';'jan-1-2011';'jan-1-2012';...
'jan-1-2013';'jan-1-2014';'jan-1-2015';'jan-1-2016';'jan-1-2017'];
ValuationDate = 'jan-1-2007';
Compounding = 1;

% define the RateSpec
RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates', EndDates, ...
'Compounding', Compounding);

% use VolSpec to compute interest-rate volatility
Volatility = 0.20 * ones (10,1); VolSpec = bdtvolspec(ValuationDate,...
EndDates, Volatility);

% use TimeSpec to specify the structure of the time layout for a BDT tree
TimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);

% build the BDT tree
BDTree = bdttree(VolSpec, RateSpec, TimeSpec);

% use the following swaption arguments
ExerciseDates = 'jan-1-2012';
```

```

SwapSettlement = ExerciseDates;
SwapMaturity    = 'jan-1-2015';
Spread = 0;
SwapReset = 1;
Principal = 100;
OptSpec = 'call';
Strike=.062;
Basis=1;

% price the swaption
[Price, PriceTree] = swaptionbybdt(BDTTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity, 'SwapReset', SwapReset, ...
'Basis', Basis, 'Principal', Principal)

Price = 2.0592

PriceTree = struct with fields:
    FinObj: 'BDTPriceTree'
    tObs: [0 1 2 3 4 5 6 7 8 9 10]
    PTree: {1x11 cell}

```

### Price a 5-Year Call Swaption with Receiving and Paying Legs Using a BDT Interest-Rate Tree

This example shows how to price a 5-year call swaption with receiving and paying legs using a BDT interest-rate tree. Assume that interest rate and volatility are fixed at 6% and 20% annually between the valuation date of the tree until its maturity. Build a tree with the following data.

```

Rates = 0.06 * ones (10,1);
StartDates = ['jan-1-2007'; 'jan-1-2008'; 'jan-1-2009'; 'jan-1-2010'; 'jan-1-2011'; ...
'jan-1-2012'; 'jan-1-2013'; 'jan-1-2014'; 'jan-1-2015'; 'jan-1-2016'];

EndDates = ['jan-1-2008'; 'jan-1-2009'; 'jan-1-2010'; 'jan-1-2011'; 'jan-1-2012'; ...
'jan-1-2013'; 'jan-1-2014'; 'jan-1-2015'; 'jan-1-2016'; 'jan-1-2017'];
ValuationDate = 'jan-1-2007';
Compounding = 1;

```

#### Define the RateSpec.

```

RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates', EndDates, ...
'Compounding', Compounding)

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [10x1 double]
    Rates: [10x1 double]
    EndTimes: [10x1 double]
    StartTimes: [10x1 double]
    EndDates: [10x1 double]
    StartDates: [10x1 double]
    ValuationDate: 733043
    Basis: 0
    EndMonthRule: 1

```

**Use VolSpec to compute interest-rate volatility.**

```
Volatility = 0.20 * ones (10,1);
VolSpec = bdtvolspec(ValuationDate,EndDates, Volatility);
```

**Use TimeSpec to specify the structure of the time layout for a BDT tree.**

```
TimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
```

**Build the BDT tree.**

```
BDTTree = bdttree(VolSpec, RateSpec, TimeSpec)
```

```
BDTTree = struct with fields:
    FinObj: 'BDTFwdTree'
    VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 4 5 6 7 8 9]
        dObs: [1x10 double]
        TFwd: {1x10 cell}
        CFlowT: {1x10 cell}
        FwdTree: {1x10 cell}
```

**Define the swaption arguments.**

```
ExerciseDates = 'jan-1-2012';
SwapSettlement = ExerciseDates;
SwapMaturity = 'jan-1-2015';
Spread = 0;
SwapReset = [1 1]; % 1st column represents receiving leg, 2nd column represents paying leg
Principal = 100;
OptSpec = 'call';
Strike=.062;
Basis= [2 4]; % 1st column represents receiving leg, 2nd column represents paying leg
```

**Price the swaption.**

```
[Price, PriceTree] = swaptionbybdt(BDTTree, OptSpec, Strike, ExerciseDates, ...
    Spread, SwapSettlement, SwapMaturity, 'SwapReset', SwapReset, ...
    'Basis', Basis, 'Principal', Principal)
```

```
Price = 2.0592
```

```
PriceTree = struct with fields:
    FinObj: 'BDTPriceTree'
    tObs: [0 1 2 3 4 5 6 7 8 9 10]
    PTree: {1x11 cell}
```

**Input Arguments****BDTTree — Interest-rate tree structure**

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: struct

**OptSpec — Definition of option**

character vector with values 'call' or 'put' | cell array of character vector with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors. For more information, see “More About” on page 11-1691.

Data Types: char | cell

**Strike — Strike swap rate values**

decimal

Strike swap rate values, specified as a NINST-by-1 vector.

Data Types: double

**ExerciseDates — Exercise dates for swaption**

serial date number | date character vector | cell array of date character vectors

Exercise dates for the swaption, specified as a NINST-by-1 vector or NINST-by-2 using serial date numbers or date character vectors, depending on the option type.

- For a European option, ExerciseDates are a NINST-by-1 vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one ExerciseDate on the option expiry date.
- For an American option, ExerciseDates are a NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is NINST-by-1, the option can be exercised between the ValuationDate of the tree and the single listed ExerciseDate.

Data Types: double | char | cell

**Spread — Number of basis points over reference rate**

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: double

**Settle — Settlement date**

serial date number | date character vector | cell array of date character vectors

Settlement date (representing the settle date for each swap), specified as a NINST-by-1 vector of serial date numbers or a date character vectors. The Settle date for every swaption is set to the ValuationDate of the BDT tree. The swap argument Settle is ignored. The underlying swap starts at the maturity of the swaption.

Data Types: double | char

**Maturity — Maturity date for swap**

serial date number | date character vector | cell array of date character vectors

Maturity date for each swap, specified as a NINST-by-1 vector of dates using serial date numbers or date character vectors.

Data Types: double | char | cell

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Price, PriceTree] = swaptionbybdt(BDTree, OptSpec, ExerciseDates, Spread, Settle, Maturity, 'SwapReset', 4, 'Basis', 5, 'Principal', 1000 0)`

### AmericanOpt — Option type

0 (European) (default) | integer with values 0 or 1

(Optional) Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST-by-1` positive integer flags with values:

- 0 — European
- 1 — American

Data Types: `double`

### SwapReset — Reset frequency per year for underlying swap

1 (default) | numeric

Reset frequency per year for the underlying swap, specified as the comma-separated pair consisting of `'SwapReset'` and a `NINST-by-1` vector or `NINST-by-2` matrix representing the reset frequency per year for each leg. If `SwapReset` is `NINST-by-2`, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

### Basis — Day-count basis of instrument

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate tree for each instrument, specified as the comma-separated pair consisting of `'Basis'` and a `NINST-by-1` vector or `NINST-by-2` matrix representing the basis for each leg. If `Basis` is `NINST-by-2`, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **Principal — Notional principal amount**

100 (default) | `numeric`

Notional principal amount, specified as the comma-separated pair consisting of 'Principal' and a NINST-by-1 vector.

Data Types: `double`

### **Options — Derivatives pricing options structure**

`structure`

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

## **Output Arguments**

### **Price — Expected prices of swaptions at time 0**

`vector`

Expected prices of the swaptions at time 0, returned as a NINST-by-1 vector.

### **PriceTree — Tree structure of instrument prices**

`structure`

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

## **More About**

### **Call Swaption**

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

### **Put Swaption**

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

# swaptionbybk

Price swaption from Black-Karasinski interest-rate tree

## Syntax

```
[Price,PriceTree] = swaptionbybk(BKTree,OptSpec,Strike,ExerciseDates,Spread,
Settle,Maturity)
[Price,PriceTree] = swaptionbybk( ____,Name,Value)
```

## Description

[Price,PriceTree] = swaptionbybk(BKTree,OptSpec,Strike,ExerciseDates,Spread,Settle,Maturity) prices swaption using a Black-Karasinski tree.

[Price,PriceTree] = swaptionbybk( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Price a 4-Year Call and Put Swaption Using a BK Interest-Rate Tree

This example shows how to price a 4-year call and put swaption using a BK interest-rate tree, assuming the interest rate is fixed at 7% annually.

```
Rates = 0.07 * ones(10,1);
Compounding = 2;
StartDates = ['jan-1-2007';'jul-1-2007';'jan-1-2008';'jul-1-2008';'jan-1-2009'; ...
'jul-1-2009'; 'jan-1-2010'; 'jul-1-2010';'jan-1-2011';'jul-1-2011'];
EndDates = ['jul-1-2007';'jan-1-2008';'jul-1-2008';'jan-1-2009';'jul-1-2009'; ...
'jan-1-2010'; 'jul-1-2010';'jan-1-2011';'jul-1-2011';'jan-1-2012'];
ValuationDate = 'jan-1-2007';

% define the RateSpec

RateSpec = intenvset('Rates',Rates, 'StartDates', StartDates, 'EndDates', EndDates,...
'Compounding', Compounding);

% use BKVolSpec to compute the interest-rate volatility
Volatility = 0.10*ones(10,1);
AlphaCurve = 0.05*ones(10,1);
AlphaDates = EndDates;
BKVolSpec = bkvolspec(ValuationDate, EndDates, Volatility, AlphaDates, AlphaCurve);

% use BKTimeSpec to specify the structure of the time layout for the BK interest-rate tree
BKTimeSpec = bktimespec(ValuationDate, EndDates, Compounding);

% build the BK tree
BKTree = bktree(BKVolSpec, RateSpec, BKTimeSpec);

% use the following arguments for a 1-year swap and 4-year swaption
ExerciseDates = 'jan-1-2011';
```

```

SwapSettlement = ExerciseDates;
SwapMaturity    = 'jan-1-2012';
Spread = 0;
SwapReset = 2 ;
Principal = 100;
OptSpec = {'call' ;'put'};
Strike= [ 0.07 ; 0.0725];
Basis=1;

% price the swaption
PriceSwaption = swaptionbybk(BKTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity, 'SwapReset', SwapReset, 'Basis', Basis, ...
'Principal', Principal)

PriceSwaption = 2x1

    0.3634
    0.4798

```

### Price a 4-Year Call and Put Swaption with Receiving and Paying Legs Using a BK Interest-Rate Tree

This example shows how to price a 4-year call and put swaption with receiving and paying legs using a BK interest-rate tree, assuming the interest rate is fixed at 7% annually. Build a tree with the following data.

```

Rates =0.07 * ones (10,1);
Compounding = 2;
StartDates = ['jan-1-2007';'jul-1-2007';'jan-1-2008';'jul-1-2008';'jan-1-2009'; ...
'jul-1-2009'; 'jan-1-2010'; 'jul-1-2010';'jan-1-2011';'jul-1-2011'];
EndDates =['jul-1-2007';'jan-1-2008';'jul-1-2008';'jan-1-2009';'jul-1-2009'; ...
'jan-1-2010'; 'jul-1-2010';'jan-1-2011';'jul-1-2011';'jan-1-2012'];
ValuationDate = 'jan-1-2007';

```

Define the RateSpec.

```

RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates', EndDates,...
'Compounding', Compounding)

```

```

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: [10x1 double]
    Rates: [10x1 double]
    EndTimes: [10x1 double]
    StartTimes: [10x1 double]
    EndDates: [10x1 double]
    StartDates: [10x1 double]
    ValuationDate: 733043
    Basis: 0
    EndMonthRule: 1

```

Use BKVolSpec to compute interest-rate volatility.

```

Volatility = 0.10*ones(10,1);
AlphaCurve = 0.05*ones(10,1);
AlphaDates = EndDates;
BKVolspec = bkvolspec(ValuationDate, EndDates, Volatility, AlphaDates, AlphaCurve);

```

Use `BKTimeSpec` to specify the structure of the time layout for a BK tree.

```
BKTimeSpec = bktimespec(ValuationDate, EndDates, Compounding);
```

Build the BK tree.

```
BKTree = bktree(BKVolspec, RateSpec, BKTimeSpec);
```

Define the arguments for a 1-year swap and 4-year swaption.

```

ExerciseDates = 'jan-1-2011';
SwapSettlement = ExerciseDates;
SwapMaturity   = 'jan-1-2012';
Spread = 0;
SwapReset = [2 2]; % 1st column represents swaption receiving leg, 2nd column represents swaption
Principal = 100;
OptSpec = {'call' ;'put'};
Strike= [ 0.07 ; 0.0725];
Basis= [1 3]; % 1st column represents swaption receiving leg, 2nd column represents swaption pay

```

Price the swaption.

```

PriceSwaption = swaptionbybk(BKTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity, 'SwapReset', SwapReset, 'Basis', Basis, ...
'Principal', Principal)

```

```
PriceSwaption = 2×1
```

```

    0.3634
    0.4798

```

## Input Arguments

### **BKTree** — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

### **OptSpec** — Definition of option

character vector with values 'call' or 'put' | cell array of character vector with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors. For more information, see “More About” on page 11-1698.

Data Types: `char` | `cell`

### **Strike** — Strike swap rate values

decimal

Strike swap rate values, specified as a NINST-by-1 vector.

Data Types: `double`

### **ExerciseDates — Exercise dates for swaption**

serial date number | date character vector | cell array of date character vectors

Exercise dates for the swaption, specified as a NINST-by-1 vector or NINST-by-2 using serial date numbers or date character vectors, depending on the option type.

- For a European option, `ExerciseDates` are a NINST-by-1 vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one `ExerciseDate` on the option expiry date.
- For an American option, `ExerciseDates` are a NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is NINST-by-1, the option can be exercised between the `ValuationDate` of the tree and the single listed `ExerciseDate`.

Data Types: `double` | `char` | `cell`

### **Spread — Number of basis points over reference rate**

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: `double`

### **Settle — Settlement date**

serial date number | date character vector | cell array of date character vectors

Settlement date (representing the settle date for each swap), specified as a NINST-by-1 vector of serial date numbers or date character vectors. The `Settle` date for every swaption is set to the `ValuationDate` of the BK tree. The swap argument `Settle` is ignored. The underlying swap starts at the maturity of the swaption.

Data Types: `double` | `char`

### **Maturity — Maturity date for swap**

serial date number | date character vector | cell array of date character vectors

Maturity date for each swap, specified as a NINST-by-1 vector of dates using serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Price, PriceTree] = swaptionbybk(BKTree, OptSpec, ExerciseDates, Spread, Settle, Maturity, 'SwapReset', 4, 'Basis', 5, 'Principal', 10000)`

**AmericanOpt — Option type**

0 (European) (default) | integer with values 0 or 1

(Optional) Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European
- 1 — American

Data Types: double

**SwapReset — Reset frequency per year for underlying swap**

1 (default) | numeric

Reset frequency per year for the underlying swap, specified as the comma-separated pair consisting of 'SwapReset' and a NINST-by-1 vector or NINST-by-2 matrix representing the reset frequency per year for each leg. If SwapReset is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

**Basis — Day-count basis of instrument**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate tree for each instrument, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector or NINST-by-2 matrix representing the basis for each leg. If Basis is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**Principal — Notional principal amount**

100 (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of 'Principal' and a NINST-by-1 vector.

Data Types: `double`

### **Options — Derivatives pricing options structure** structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

## **Output Arguments**

### **Price — Expected prices of swaptions at time 0** vector

Expected prices of the swaptions at time 0, returned as a NINST-by-1 vector.

### **PriceTree — Tree structure of instrument prices** structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

## **More About**

### **Call Swaption**

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

### **Put Swaption**

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

## swaptionbycir

Price swaption from Cox-Ingersoll-Ross interest-rate tree

### Syntax

```
[Price,PriceTree] = swaptionbycir(CIRTree,OptSpec,Strike,ExerciseDates,
Spread,Settle,Maturity)
[Price,PriceTree] = swaptionbycir( ____,Name,Value)
```

### Description

[Price,PriceTree] = swaptionbycir(CIRTree,OptSpec,Strike,ExerciseDates, Spread,Settle,Maturity) prices swaption with a Cox-Ingersoll-Ross (CIR) tree using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

[Price,PriceTree] = swaptionbycir( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price a Swaption Using a CIR Interest-Rate Tree

Define a 3-year put swaption.

```
Rates = 0.075 * ones (10,1);
Compounding = 2;
StartDates = ['Jan-1-2017';'Jul-1-2017';'Jan-1-2018';'Jul-1-2018';'Jan-1-2019';...
'Jul-1-2019';'Jan-1-2020';'Jul-1-2020';'Jan-1-2021';'Jul-1-2021'];
EndDates = ['Jul-1-2017';'Jan-1-2018';'Jul-1-2018';'Jan-1-2019';'Jul-1-2019';...
'Jan-1-2020';'Jul-1-2020';'Jan-1-2021';'Jul-1-2021';'Jan-1-2022'];
ValuationDate = 'Jan-1-2017';
```

Create a RateSpec using the intenvset function.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates', EndDates);
```

Create a CIR tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Maturity = '01-jan-2023';
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);
```

```
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
    FinObj: 'CIRFwdTree'
    VolSpec: [1x1 struct]
```

```

TimeSpec: [1x1 struct]
RateSpec: [1x1 struct]
    tObs: [0 0.6000 1.2000 1.8000 2.4000 3 3.6000 4.2000 4.8000 5.4000]
    dObs: [1x10 double]
FwdTree: {1x10 cell}
Connect: {1x9 cell}
Probs: {1x9 cell}

```

Use the following arguments for a 1-year swap and a 3-year swaption.

```

ExerciseDates = 'Jan-1-2020';
SwapSettlement = ExerciseDates;
SwapMaturity = 'Jan-1-2022';
Spread = 0;
SwapReset = 2 ;
Principal = 100;
OptSpec = 'put';
Strike = 0.04;
Basis = 1;

```

Price the swaption.

```

[Price,PriceTree] = swaptionbycir(CIRT,OptSpec,Strike,ExerciseDates,Spread,SwapSettlement,SwapMaturity,
'Basis',Basis,'Principal',Principal)

```

```
Price = 3.1537
```

```

PriceTree = struct with fields:
    FinObj: 'CIRPriceTree'
    PTree: {1x11 cell}
    tObs: [0 0.6000 1.2000 1.8000 2.4000 3 3.6000 4.2000 4.8000 5.4000 6]
    Connect: {1x9 cell}
    Probs: {1x9 cell}

```

## Input Arguments

### CIRTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with values 'call' or 'put' | cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors or string arrays. For more information, see “More About” on page 11-1698.

Data Types: `char` | `cell` | `string`

### Strike — Strike swap rate values

decimal

Strike swap rate values, specified as a NINST-by-1 vector.

Data Types: `double`

### **ExerciseDates — Exercise dates for swaption**

serial date number | date character vector | cell array of date character vectors | string array | `datetime`

Exercise dates for the swaption, specified as a NINST-by-1 vector or NINST-by-2 using serial date numbers, date character vectors, string arrays, or `datetime` arrays depending on the option type.

- For a European option, `ExerciseDates` are a NINST-by-1 vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one `ExerciseDate` on the option expiry date.
- For an American option, `ExerciseDates` are a NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is NINST-by-1, the option can be exercised between the `ValuationDate` of the tree and the single listed `ExerciseDate`.

Data Types: `double` | `char` | `cell` | `string` | `datetime`

### **Spread — Number of basis points over reference rate**

`numeric`

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: `double`

### **Settle — Settlement date**

serial date number | date character vector | cell array of date character vectors | string array | `datetime`

Settlement date (representing the settle date for each swap), specified as a NINST-by-1 vector of serial date numbers, date character vectors, string arrays, or `datetime` arrays. The `Settle` date for every swaption is set to the `ValuationDate` of the CIR tree. The swap argument `Settle` is ignored. The underlying swap starts at the maturity of the swaption.

Data Types: `double` | `char` | `string` | `datetime`

### **Maturity — Maturity date for swap**

serial date number | date character vector | cell array of date character vectors | string array | `datetime`

Maturity date for each swap, specified as a NINST-by-1 vector of dates using serial date numbers, date character vectors, string arrays, or `datetime` arrays.

Data Types: `double` | `char` | `cell` | `string` | `datetime`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: [Price,PriceTree] = swaptionbycir(CIRTree,OptSpec, ExerciseDates,Spread,Settle,Maturity,'SwapReset',4,'Basis',5,'Principal',1000 0)

### **AmericanOpt — Option type**

0 (European) (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European
- 1 — American

Data Types: double

### **SwapReset — Reset frequency per year for underlying swap**

1 (default) | numeric

Reset frequency per year for the underlying swap, specified as the comma-separated pair consisting of 'SwapReset' and a NINST-by-1 vector or NINST-by-2 matrix representing the reset frequency per year for each leg. If SwapReset is NINST-by-2, the first column represents the receiving leg, and the second column represents the paying leg.

Data Types: double

### **Basis — Day-count basis of instrument**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward-rate tree for each instrument, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector or NINST-by-2 matrix representing the basis for each leg. If Basis is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**Principal — Notional principal amount**

100 (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of 'Principal' and a NINST-by-1 vector.

Data Types: double

**Output Arguments****Price — Expected prices of swaptions at time 0**

vector

Expected prices of the swaptions at time 0, returned as a NINST-by-1 vector.

**PriceTree — Tree structure of instrument prices**

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

**More About****Call Swaption**

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

**Put Swaption**

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

## swaptionbyblk

Price European swaption instrument using Black model

### Syntax

```
Price = swaptionbyblk(RateSpec, OptSpec, Strike, Settle, ExerciseDates, Maturity,
Volatility)
Price = swaptionbyblk( ____, Name, Value)
```

### Description

Price = swaptionbyblk(RateSpec, OptSpec, Strike, Settle, ExerciseDates, Maturity, Volatility) prices swaptions using the Black option pricing model.

Price = swaptionbyblk( \_\_\_\_, Name, Value) adds optional name-value pair arguments.

### Examples

#### Price a European Swaption Using the Black Model Where the Yield Curve is Flat at 6%

Price a European swaption that gives the holder the right to enter in five years into a three-year paying swap where a fixed-rate of 6.2% is paid and floating is received. Assume that the yield curve is flat at 6% per annum with continuous compounding, the volatility of the swap rate is 20%, the principal is \$100, and payments are exchanged semiannually.

Create the RateSpec.

```
Rate = 0.06;
Compounding = -1;
ValuationDate = 'Jan-1-2010';
EndDates = 'Jan-1-2020';
Basis = 1;
```

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, ...
'EndDates', EndDates, 'Rates', Rate, 'Compounding', Compounding, 'Basis', Basis);
```

Price the swaption using the Black model.

```
Settle = 'Jan-1-2011';
ExerciseDates = 'Jan-1-2016';
Maturity = 'Jan-1-2019';
Reset = 2;
Principal = 100;
Strike = 0.062;
Volatility = 0.2;
OptSpec = 'call';
```

```
Price = swaptionbyblk(RateSpec, OptSpec, Strike, Settle, ExerciseDates, Maturity, ...
Volatility, 'Reset', Reset, 'Principal', Principal, 'Basis', Basis)
```

```
Price = 2.0710
```

### Price a European Swaption with Receiving and Paying Legs Using the Black Model Where the Yield Curve is 6%

This example shows Price a European swaption with receiving and paying legs that gives the holder the right to enter in five years into a three-year paying swap where a fixed-rate of 6.2% is paid and floating is received. Assume that the yield curve is flat at 6% per annum with continuous compounding, the volatility of the swap rate is 20%, the principal is \$100, and payments are exchanged semiannually.

```
Rate = 0.06;
Compounding = -1;
ValuationDate = 'Jan-1-2010';
EndDates = 'Jan-1-2020';
Basis = 1;
```

#### Define the RateSpec.

```
RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',ValuationDate, ...
'EndDates',EndDates,'Rates',Rate,'Compounding',Compounding,'Basis',Basis);
```

#### Define the swaption arguments.

```
Settle = 'Jan-1-2011';
ExerciseDates = 'Jan-1-2016';
Maturity = 'Jan-1-2019';
Reset = [2 4]; % 1st column represents receiving leg, 2nd column represents paying leg
Principal = 100;
Strike = 0.062;
Volatility = 0.2;
OptSpec = 'call';
Basis = [1 3]; % 1st column represents receiving leg, 2nd column represents paying leg
```

#### Price the swaption.

```
Price= swaptionbyblk(RateSpec,OptSpec,Strike,Settle,ExerciseDates,Maturity,Volatility, ...
'Reset',Reset,'Principal',Principal,'Basis',Basis)
```

```
Price = 1.6494
```

### Price a European Swaption Using the Black Model Where the Yield Curve Is Incrementally Increasing

Price a European swaption that gives the holder the right to enter into a 5-year receiving swap in a year, where a fixed rate of 3% is received and floating is paid. Assume that the 1-year, 2-year, 3-year, 4-year and 5- year zero rates are 3%, 3.4%, 3.7%, 3.9% and 4% with continuous compounding. The swap rate volatility is 21%, the principal is \$1000, and payments are exchanged semiannually.

Create the RateSpec.

```
ValuationDate = 'Jan-1-2010';
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
Rates = [0.03; 0.034 ; 0.037; 0.039; 0.04;];
Compounding = -1;
```

```

Basis = 1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis)

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: -1
    Disc: [5x1 double]
    Rates: [5x1 double]
    EndTimes: [5x1 double]
    StartTimes: [5x1 double]
    EndDates: [5x1 double]
    StartDates: 734139
    ValuationDate: 734139
    Basis: 1
    EndMonthRule: 1

```

Price the swaption using the Black model.

```

Settle = 'Jan-1-2011';
ExerciseDates = 'Jan-1-2012';
Maturity = 'Jan-1-2017';
Strike = 0.03;
Volatility = 0.21;
Principal = 1000;
Reset = 2;
OptSpec = 'put';

Price = swaptionbyblk(RateSpec, OptSpec, Strike, Settle, ExerciseDates, ...
Maturity, Volatility, 'Basis', Basis, 'Reset', Reset, 'Principal', Principal)

Price = 0.5771

```

### Price a Swaption Using a Different Curve to Generate the Future Forward Rates

Define the OIS and Libor curves.

```

Settle = datenum('15-Mar-2013');
CurveDates = daysadd(Settle, 360*[1/12 2/12 3/12 6/12 1 2 3 4 5 7 10], 1);
OISRates = [.0018 .0019 .0021 .0023 .0031 .006 .011 .017 .021 .026 .03]';
LiborRates = [.0045 .0047 .005 .0055 .0075 .0109 .0162 .0216 .0262 .0309 .0348]';

```

Create an associated RateSpec for the OIS and Libor curves.

```

OISCurve = intenvset('Rates', OISRates, 'StartDate', Settle, 'EndDates', CurveDates, 'Compounding', 2, 'Basis', Basis);
LiborCurve = intenvset('Rates', LiborRates, 'StartDate', Settle, 'EndDates', CurveDates, 'Compounding', 2, 'Basis', Basis);

```

Define the swaption instruments.

```

ExerciseDate = '15-Mar-2018';
Maturity = {'15-Mar-2020'; '15-Mar-2023'};
OptSpec = 'call';
Strike = 0.04;
BlackVol = 0.2;

```

Price the swaption instruments using the term structure OISCurve both for discounting the cash flows and generating the future forward rates.

```
Price = swaptionbyblk(OISCurve, OptSpec, Strike, Settle, ExerciseDate, Maturity, BlackVol, 'Reset
```

```
Price = 2x1
```

```
1.0956
2.6944
```

Price the swaption instruments using the term structure LiborCurve to generate the future forward rates. The term structure OISCurve is used for discounting the cash flows.

```
PriceLC = swaptionbyblk(OISCurve, OptSpec, Strike, Settle, ExerciseDate, Maturity, BlackVol, 'Pro
```

```
PriceLC = 2x1
```

```
1.5346
3.8142
```

### Price a Swaption Using the Shifted Black Model

Create the RateSpec.

```
ValuationDate = 'Jan-1-2016';
EndDates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
Rates = [-0.02; 0.024 ; 0.047; 0.090; 0.12;]/100;
Compounding = 1;
Basis = 1;
```

```
RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',ValuationDate, ...
'EndDates',EndDates,'Rates',Rates,'Compounding',Compounding,'Basis',Basis)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [5x1 double]
    Rates: [5x1 double]
    EndTimes: [5x1 double]
    StartTimes: [5x1 double]
    EndDates: [5x1 double]
    StartDates: 736330
    ValuationDate: 736330
    Basis: 1
    EndMonthRule: 1
```

Price the swaption with a negative strike using the Shifted Black model.

```
Settle = 'Jan-1-2016';
ExerciseDates = 'Jan-1-2017';
Maturity = 'Jan-1-2020';
Strike = -0.003; % Set -0.3 percent strike.
ShiftedBlackVolatility = 0.31;
```

```

Principal = 1000;
Reset = 1;
OptSpec = 'call';
Shift = 0.008; % Set 0.8 percent shift.

Price = swaptionbyblk(RateSpec,OptSpec,Strike,Settle,ExerciseDates, ...
Maturity,ShiftedBlackVolatility,'Basis',Basis,'Reset',Reset,...
'Principal',Principal,'Shift',Shift)

Price = 12.8301

```

### Price Swaptions Using the Shifted Black Model with a Vector of Shifts

Create the RateSpec.

```

ValuationDate = 'Jan-1-2016';
EndDates = {'Jan-1-2017';'Jan-1-2018';'Jan-1-2019';'Jan-1-2020';'Jan-1-2021'};
Rates = [-0.02; 0.024 ; 0.047; 0.090; 0.12;]/100;
Compounding = 1;
Basis = 1;

RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',ValuationDate, ...
'EndDates',EndDates,'Rates',Rates,'Compounding',Compounding,'Basis',Basis)

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 1
    Disc: [5x1 double]
    Rates: [5x1 double]
    EndTimes: [5x1 double]
    StartTimes: [5x1 double]
    EndDates: [5x1 double]
    StartDates: 736330
    ValuationDate: 736330
    Basis: 1
    EndMonthRule: 1

```

Price the swaptions with using the Shifted Black model.

```

Settle = 'Jan-1-2016';
ExerciseDates = 'Jan-1-2017';
Maturities = {'Jan-1-2018';'Jan-1-2019';'Jan-1-2020'};
Strikes = [-0.0034;-0.0032;-0.003];
ShiftedBlackVolatilities = [0.33;0.32;0.31]; % A vector of volatilities.
Principal = 1000;
Reset = 1;
OptSpec = 'call';
Shifts = [0.0085;0.0082;0.008]; % A vector of shifts.

Prices = swaptionbyblk(RateSpec,OptSpec,Strikes,Settle,ExerciseDates, ...
Maturities,ShiftedBlackVolatilities,'Basis',Basis,'Reset',Reset, ...
'Principal',Principal,'Shift',Shifts)

Prices = 3x1

```

4.1117  
8.0577  
12.8301

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

If the paying leg is different than the receiving leg, the `RateSpec` can be a NINST-by-2 input variable of `RateSpecs`, with the second input being the discount curve for the paying leg. If only one curve is specified, then it is used to discount both legs.

Data Types: `struct`

### OptSpec — Definition of option

character vector with values 'call' or 'put' | cell array of character vector with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors.

A 'call' swaption, or Payer swaption, allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

A 'put' swaption, or Receiver swaption, allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Data Types: `char` | `cell`

### Strike — Strike swap rate values

decimal

Strike swap rate values, specified as a NINST-by-1 vector of decimal values.

Data Types: `double`

### Settle — Settlement date

serial date number | date character vector | cell array of date character vectors

Settlement date (representing the settle date for each swaption), specified as a NINST-by-1 vector of serial date numbers or date character vectors. `Settle` must not be later than `ExerciseDates`.

The `Settle` date input for `swaptionbyblk` is the valuation date on which the swaption (an option to enter into a swap) is priced. The swaption buyer pays this price on this date to hold the swaption.

Data Types: `double` | `char`

### ExerciseDates — Dates on which swaption expires and underlying swap starts

serial date number | date character vector | cell array of date character vectors

Dates, specified as serial date numbers or date character vectors, on which the swaption expires and the underlying swap starts. The swaption holder can choose to enter into the swap on this date if the situation is favorable.

For a European option, `ExerciseDates` are a NINST-by-1 vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one `ExerciseDate` on the option expiry date.

Data Types: `double` | `char` | `cell`

### **Maturity – Maturity date for each forward swap**

serial date number | date character vector | cell array of date character vectors

Maturity date for each forward swap, specified as a NINST-by-1 vector of dates using serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### **Volatility – Annual volatilities values**

numeric

Annual volatilities values, specified as a NINST-by-1 vector of numeric values.

Data Types: `double`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Price = swaptionbyblk(OISCurve, OptSpec, Strike, Settle, ExerciseDate, Maturity, BlackVol, 'Reset', 1, 'Shift', .5)`

### **Basis – Day-count basis of instrument**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a NINST-by-1 vector or NINST-by-2 matrix representing the basis for each leg. If `Basis` is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg. Default is 0 (actual/actual).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **Principal — Notional principal amount**

100 (default) | `numeric`

Notional principal amount, specified as the comma-separated pair consisting of 'Principal' and a NINST-by-1 vector.

Data Types: `double`

### **Reset — Reset frequency per year for underlying forward swap**

1 (default) | `numeric`

Reset frequency per year for the underlying forward swap, specified as the comma-separated pair consisting of 'Reset' and a NINST-by-1 vector or NINST-by-2 matrix representing the reset frequency per year for each leg. If Reset is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

### **ProjectionCurve — Rate curve used in generating future forward rates**

if `ProjectionCurve` is not specified, then `RateSpec` is used both for discounting cash flows and projecting future forward rates (default) | `structure`

The rate curve to be used in generating the future forward rates, specified as the comma-separated pair consisting of 'ProjectionCurve' and a structure created using `intenvset`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `struct`

### **Shift — Shift in decimals for shifted Black model**

0 (no shift) (default) | `positive decimal`

Shift in decimals for the shifted Black model, specified as the comma-separated pair consisting of 'Shift' and a scalar or NINST-by-1 vector of rate shifts in positive decimals. Set this parameter to a positive rate shift in decimals to add a positive shift to the forward swap rate and strike, which effectively sets a negative lower bound for the forward swap rate and strike. For example, a Shift of 0.01 is equal to a 1% shift.

Data Types: `double`

## **Output Arguments**

### **Price — Prices for swaptions at time 0**

`vector`

Prices for the swaptions at time 0, returned as a NINST-by-1 vector of prices.

## More About

### Forward Swap

A forward swap is a swap that starts at a future date.

### Shifted Black

The Shifted Black model is essentially the same as the Black's model, except that it models the movements of  $(F + Shift)$  as the underlying asset, instead of  $F$  (which is the forward swap rate in the case of swaptions).

This model allows negative rates, with a fixed negative lower bound defined by the amount of shift; that is, the zero lower bound of Black's model has been shifted.

## Algorithms

### Black Model

$$dF = \sigma_{Black} F dw$$

$$call = e^{-vT} [FN(d_1) - KN(d_2)]$$

$$put = e^{-vT} [KN(-d_2) - FN(-d_1)]$$

$$d_1 = \frac{\ln\left(\frac{F}{K}\right) + \left(\frac{\sigma_B^2}{2}\right)T}{\sigma_B \sqrt{T}}, \quad d_2 = d_1 - \sigma_B \sqrt{T}$$

$$\sigma_B = \sigma_{Black}$$

Where  $F$  is the forward value and  $K$  is the strike.

### Shifted Black Model

$$dF = \sigma_{Shifted\_Black} (F + Shift) dw$$

$$call = e^{-vT} [(F + Shift)N(d_{s1}) - (K + Shift)N(d_{s2})]$$

$$put = e^{-vT} [(K + Shift)N(-d_{s2}) - (F + Shift)N(-d_{s1})]$$

$$d_{s1} = \frac{\ln\left(\frac{F + Shift}{K + Shift}\right) + \left(\frac{\sigma_{sB}^2}{2}\right)T}{\sigma_{sB} \sqrt{T}}, \quad d_{s2} = d_{s1} - \sigma_{sB} \sqrt{T}$$

$$\sigma_{sB} = \sigma_{Shifted\_Black}$$

Where  $F+Shift$  is the forward value and  $K+Shift$  is the strike for the shifted version.

## swaptionbyhjm

Price swaption from Heath-Jarrow-Morton interest-rate tree

### Syntax

```
[Price,PriceTree] = swaptionbyhjm(HJMTree,OptSpec,Strike,ExerciseDates,
Spread,Settle,Maturity)
[Price,PriceTree] = swaptionbyhjm( ____,Name,Value)
```

### Description

[Price,PriceTree] = swaptionbyhjm(HJMTree,OptSpec,Strike,ExerciseDates, Spread,Settle,Maturity) prices swaption using a Heath-Jarrow-Morton tree.

[Price,PriceTree] = swaptionbyhjm( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price a 1-Year Call Swaption Using an HJM Interest-Rate Tree

This example shows how to price a 1-year call swaption using an HJM interest-rate tree. Assume that interest rate is fixed at 5% annually between the valuation date of the tree until its maturity. Build a tree with the following data.

```
Rates = [ 0.05;0.05;0.05;0.05];
StartDates = 'jan-1-2007';
EndDates =['jan-1-2008';'jan-1-2009';'jan-1-2010';'jan-1-2011'];
ValuationDate = StartDates;
Compounding = 1;

% define the RateSpec
RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates',...
EndDates, 'Compounding', Compounding);

% use VolSpec to compute the interest-rate volatility
VolSpec=hjmvolspec('Constant',0.01);

% use TimeSpec to specify the structure of the time layout for the HJM interest-rate tree
TimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding);

% build the HJM tree
HJMTree = hjmtree(VolSpec, RateSpec, TimeSpec);

% use the following swaption arguments
ExerciseDates = '01-Jan-2008';
SwapSettlement = ExerciseDates;
SwapMaturity = 'jan-1-2010';
Spread = [0];
SwapReset = 1;
```

```

Basis = 1;
Principal = 100;
OptSpec = 'call';
Strike=0.05;

% price the swaption

[Price, PriceTree] = swaptionbyhjm(HJMTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity, 'SwapReset', SwapReset, ...
'Basis', Basis, 'Principal', Principal)

Price = 0.9296

PriceTree = struct with fields:
    FinObj: 'HJMPriceTree'
    tObs: [5x1 double]
    PBush: {1x5 cell}

```

### Price a 1-Year Call Swaption with Receiving and Paying Legs Using an HJM Interest-Rate Tree

This example shows how to price a 1-year call swaption with receiving and paying legs using an HJM interest-rate tree. Assume that interest rate is fixed at 5% annually between the valuation date of the tree until its maturity. Build a tree with the following data.

```

Rates = [ 0.05;0.05;0.05;0.05];
StartDates = 'jan-1-2007';
EndDates =['jan-1-2008';'jan-1-2009';'jan-1-2010';'jan-1-2011'];
ValuationDate = StartDates;
Compounding = 1;

```

Define the RateSpec.

```

RateSpec = intenvset('Rates',Rates, 'StartDates',StartDates, 'EndDates',...
EndDates, 'Compounding',Compounding);

```

Use VolSpec to compute the interest-rate volatility.

```

VolSpec=hjmvolspec('Constant',0.01);

```

Use TimeSpec to specify the structure of the time layout for the HJM interest-rate tree.

```

TimeSpec = hjmtimespec(ValuationDate,EndDates,Compounding);

```

Build the HJM tree.

```

HJMTree = hjmtree(VolSpec,RateSpec,TimeSpec);

```

Use the following swaption arguments

```

ExerciseDates = '01-Jan-2008';
SwapSettlement = ExerciseDates;
SwapMaturity = 'jan-1-2010';
Spread = [0];
SwapReset = [1 1]; % 1st column represents receiving leg, 2nd column represents paying leg

```

```
Basis = [1 3];      % 1st column represents receiving leg, 2nd column represents paying leg
Principal = 100;
OptSpec = 'call';
Strike=0.05;
```

Price the swaption.

```
[Price, PriceTree] = swaptionbyhjm(HJMTree,OptSpec,Strike,ExerciseDates, ...
Spread,SwapSettlement,SwapMaturity,'SwapReset',SwapReset, ...
'Basis',Basis,'Principal',Principal)
```

```
Price = 0.9296
```

```
PriceTree = struct with fields:
    FinObj: 'HJMPriceTree'
    tObs: [5x1 double]
    PBush: {1x5 cell}
```

## Input Arguments

### HJMTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjm tree`.

Data Types: `struct`

### OptSpec — Definition of option

character vector with values 'call' or 'put' | cell array of character vector with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors. For more information, see “More About” on page 11-1721.

Data Types: `char` | `cell`

### Strike — Strike swap rate values

decimal

Strike swap rate values, specified as a NINST-by-1 vector.

Data Types: `double`

### ExerciseDates — Exercise dates for swaption

serial date number | date character vector | cell array of date character vectors

Exercise dates for the swaption, specified as a NINST-by-1 vector or NINST-by-2 using serial date numbers or date character vectors, depending on the option type.

- For a European option, `ExerciseDates` are a NINST-by-1 vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one `ExerciseDate` on the option expiry date.
- For an American option, `ExerciseDates` are a NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if `ExerciseDates` is NINST-by-1,

the option can be exercised between the `ValuationDate` of the tree and the single listed `ExerciseDate`.

Data Types: `double` | `char` | `cell`

### **Spread — Number of basis points over reference rate**

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: `double`

### **Settle — Settlement date**

serial date number | date character vector | cell array of date character vectors

Settlement date (representing the settle date for each swap), specified as a NINST-by-1 vector of serial date numbers or date character vectors. The `Settle` date for every swaption is set to the `ValuationDate` of the HJM tree. The swap argument `Settle` is ignored. The underlying swap starts at the maturity of the swaption.

Data Types: `double` | `char`

### **Maturity — Maturity date for swap**

serial date number | date character vector | cell array of date character vectors

Maturity date for each swap, specified as a NINST-by-1 vector of dates using serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Price, PriceTree] = swaptionbyhjm(HJMTree, OptSpec, ExerciseDates, Spread, Settle, Maturity, 'SwapReset', 4, 'Basis', 5, 'Principal', 1000 0)`

### **AmericanOpt — Option type**

0 (European) (default) | integer with values 0 or 1

(Optional) Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and NINST-by-1 positive integer flags with values:

- 0 — European
- 1 — American

Data Types: `double`

### **SwapReset — Reset frequency per year for underlying swap**

1 (default) | numeric

Reset frequency per year for the underlying swap, specified as the comma-separated pair consisting of `'SwapReset'` and a NINST-by-1 vector or NINST-by-2 matrix representing the reset frequency per

year for each leg. If `SwapReset` is `NINST-by-2`, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

### **Basis — Day-count basis of instrument**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate tree for each instrument, specified as the comma-separated pair consisting of 'Basis' and a `NINST-by-1` vector or `NINST-by-2` matrix representing the basis for each leg. If `Basis` is `NINST-by-2`, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **Principal — Notional principal amount**

100 (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of 'Principal' and a `NINST-by-1` vector.

Data Types: `double`

### **Options — Derivatives pricing options structure**

structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

## Output Arguments

### Price — Expected prices of swaptions at time 0

vector

Expected prices of the swaptions at time 0, returned as a NINST-by-1 vector.

### PriceTree — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

## More About

### Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

### Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

## swaptionbyhw

Price swaption from Hull-White interest-rate tree

### Syntax

```
[Price,PriceTree] = swaptionbyhw(HWTree,OptSpec,Strike,ExerciseDates,Spread,
Settle,Maturity)
[Price,PriceTree] = swaptionbyhw( ____,Name,Value)
```

### Description

[Price,PriceTree] = swaptionbyhw(HWTree,OptSpec,Strike,ExerciseDates,Spread,Settle,Maturity) prices swaption using a Hull-White tree.

[Price,PriceTree] = swaptionbyhw( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price a 3-Year Put Swaption Using an HW Interest-Rate Tree

This example shows how to price a 3-year put swaption using an HW interest-rate tree with the following data.

```
Rates = 0.075 * ones (10,1);
Compounding = 2;
StartDates = ['jan-1-2007';'jul-1-2007';'jan-1-2008';'jul-1-2008';'jan-1-2009';...
'jul-1-2009';'jan-1-2010'; 'jul-1-2010';'jan-1-2011';'jul-1-2011'];
EndDates = ['jul-1-2007';'jan-1-2008';'jul-1-2008';'jan-1-2009';'jul-1-2009';...
'jan-1-2010';'jul-1-2010';'jan-1-2011';'jul-1-2011';'jan-1-2012'];
ValuationDate = 'jan-1-2007';

% define the RatesSpec
RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates',...
EndDates, 'Compounding', Compounding);

% use HWVolSpec to compute the interest-rate volatility
Volatility = 0.05*ones(10,1);
AlphaCurve = 0.01*ones(10,1);
AlphaDates = EndDates;
HWVolSpec = hwwolspec(ValuationDate, EndDates, Volatility, AlphaDates, AlphaCurve);

% use HWTimeSpec to specify the structure of the time layout for an HW interest-rate tree
HWTimeSpec = hwtimespec(ValuationDate, EndDates, Compounding);

% build the HW tree
HWTree = hwtree(HWVolSpec, RateSpec, HWTimeSpec);

% use the following arguments for a 1-year swap and 3-year swaption
ExerciseDates = 'jan-1-2010';
SwapSettlement = ExerciseDates;
```

```

SwapMaturity = 'jan-1-2012';
Spread = 0;
SwapReset = 2 ;
Principal = 100;
OptSpec = 'put';
Strike= 0.04;
Basis=1;

% price the swaption
PriceSwaption = swaptionbyhw(HWTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity, 'SwapReset', SwapReset, ...
'Basis', Basis, 'Principal', Principal)

PriceSwaption = 2.9201

```

### Price a 3-Year Put Swaption with Receiving and Paying Legs Using an HW Interest-Rate Tree

This example shows how to price a 3-year put swaption with receiving and paying legs using an HW interest-rate tree with the following data.

```

Rates =0.075 * ones (10,1);
Compounding = 2;
StartDates = ['jan-1-2007'; 'jul-1-2007'; 'jan-1-2008'; 'jul-1-2008'; 'jan-1-2009'; ...
'jul-1-2009'; 'jan-1-2010'; 'jul-1-2010'; 'jan-1-2011'; 'jul-1-2011'];
EndDates = ['jul-1-2007'; 'jan-1-2008'; 'jul-1-2008'; 'jan-1-2009'; 'jul-1-2009'; ...
'jan-1-2010'; 'jul-1-2010'; 'jan-1-2011'; 'jul-1-2011'; 'jan-1-2012'];
ValuationDate = 'jan-1-2007';

```

Define the RatesSpec.

```

RateSpec = intenvset('Rates', Rates, 'StartDates', StartDates, 'EndDates', ...
EndDates, 'Compounding', Compounding);

```

Use HWVolSpec to compute the interest-rate volatility.

```

Volatility = 0.05*ones(10,1);
AlphaCurve = 0.01*ones(10,1);
AlphaDates = EndDates;
HWVolSpec = hwwolspec(ValuationDate, EndDates, Volatility, AlphaDates, AlphaCurve);

```

Use HWTimeSpec to specify the structure of the time layout for an HW interest-rate tree.

```

HWTimeSpec = hwtimespec(ValuationDate, EndDates, Compounding);

```

Build the HW tree.

```

HWTree = hwtree(HWVolSpec, RateSpec, HWTimeSpec);

```

Use the following arguments for a 1-year swap and 3-year swaption

```

ExerciseDates = 'jan-1-2010';
SwapSettlement = ExerciseDates;
SwapMaturity = 'jan-1-2012';
Spread = 0;
SwapReset = [2 2]; % 1st column represents receiving leg, 2nd column represents paying leg
Principal = 100;

```

```

OptSpec = 'put';
Strike= 0.04;
Basis= [1 3]; % 1st column represents receiving leg, 2nd column represents paying leg

```

Price the swaption.

```

PriceSwaption = swaptionbyhw(HWTree, OptSpec, Strike, ExerciseDates, ...
Spread, SwapSettlement, SwapMaturity, 'SwapReset', SwapReset, ...
'Basis', Basis, 'Principal', Principal)

```

```
PriceSwaption = 2.9201
```

## Input Arguments

### **HWTree — Interest-rate tree structure**

structure

Interest-rate tree structure, specified by using hwtree.

Data Types: struct

### **OptSpec — Definition of option**

character vector with values 'call' or 'put' | cell array of character vector with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors. For more information, see “More About” on page 11-1727.

Data Types: char | cell

### **Strike — Strike swap rate values**

decimal

Strike swap rate values, specified as a NINST-by-1 vector.

Data Types: double

### **ExerciseDates — Exercise dates for swaption**

serial date number | date character vector | cell array of date character vectors

Exercise dates for the swaption, specified as a NINST-by-1 vector or NINST-by-2 using serial date numbers or date character vectors, depending on the option type.

- For a European option, ExerciseDates are a NINST-by-1 vector of exercise dates. Each row is the schedule for one option. When using a European option, there is only one ExerciseDate on the option expiry date.
- For an American option, ExerciseDates are a NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is NINST-by-1, the option can be exercised between the ValuationDate of the tree and the single listed ExerciseDate.

Data Types: double | char | cell

### **Spread — Number of basis points over reference rate**

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: double

### **Settle — Settlement date**

serial date number | date character vector | cell array of date character vectors

Settlement date (representing the settle date for each swap), specified as a NINST-by-1 vector of serial date numbers or date character vectors. The `Settle` date for every swaption is set to the `ValuationDate` of the HW tree. The swap argument `Settle` is ignored. The underlying swap starts at the maturity of the swaption.

Data Types: double | char

### **Maturity — Maturity date for swap**

serial date number | date character vector | cell array of date character vectors

Maturity date for each swap, specified as a NINST-by-1 vector of dates using serial date numbers or date character vectors.

Data Types: double | char | cell

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Price, PriceTree] = swaptionbyhw(HWTree, OptSpec, ExerciseDates, Spread, Settle, Maturity, 'SwapReset', 4, 'Basis', 5, 'Principal', 10000)`

### **AmericanOpt — Option type**

0 (European) (default) | integer with values 0 or 1

(Optional) Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and NINST-by-1 positive integer flags with values:

- 0 — European
- 1 — American

Data Types: double

### **SwapReset — Reset frequency per year for underlying swap**

1 (default) | numeric

Reset frequency per year for the underlying swap, specified as the comma-separated pair consisting of `'SwapReset'` and a NINST-by-1 vector or NINST-by-2 matrix representing the reset frequency per year for each leg. If `SwapReset` is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

### **Basis — Day-count basis of instrument**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate tree for each instrument, specified as the comma-separated pair consisting of `'Basis'` and a NINST-by-1 vector or

NINST-by-2 matrix representing the basis for each leg. If `Basis` is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **Principal — Notional principal amount**

100 (default) | `numeric`

Notional principal amount, specified as the comma-separated pair consisting of 'Principal' and a NINST-by-1 vector.

Data Types: `double`

### **Options — Derivatives pricing options structure**

`structure`

Derivatives pricing options structure, specified as the comma-separated pair consisting of 'Options' and a structure obtained from using `derivset`.

Data Types: `struct`

## **Output Arguments**

### **Price — Expected prices of swaptions at time 0**

`vector`

Expected prices of the swaptions at time 0, returned as a NINST-by-1 vector.

### **PriceTree — Tree structure of instrument prices**

`structure`

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of swaption instrument prices and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

## More About

### Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

### Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

## swaptionbylg2f

Price European swaption using Linear Gaussian two-factor model

### Syntax

```
Price = swaptionbylg2f(ZeroCurve,a,b,sigma,eta,rho,Strike,ExerciseDate,
Maturity)
Price = swaptionbylg2f(____,Name,Value)
```

### Description

Price = swaptionbylg2f(ZeroCurve,a,b,sigma,eta,rho,Strike,ExerciseDate, Maturity) returns the European swaption price for a two-factor additive Gaussian interest-rate model.

Price = swaptionbylg2f(\_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price a European Swaption Using a Linear Gaussian Two-Factor Model

Define the ZeroCurve, a, b, sigma, eta, and rho parameters to compute the price of the swaption.

```
Settle = datenum('15-Dec-2007');

ZeroTimes = [3/12 6/12 1 5 7 10 20 30]';
ZeroRates = [0.033 0.034 0.035 0.040 0.042 0.044 0.048 0.0475]';
CurveDates = daysadd(Settle,360*ZeroTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

a = .07;
b = .5;
sigma = .01;
eta = .006;
rho = -.7;

Reset = 1;
ExerciseDate = daysadd(Settle,360*5,1);
Maturity = daysadd(ExerciseDate,360*[3;4],1);
Strike = .05;

Price = swaptionbylg2f(irdc,a,b,sigma,eta,rho,Strike,ExerciseDate,Maturity,'Reset',Reset)

Price = 2×1

    1.1869
    1.5590
```

## Input Arguments

### **ZeroCurve — Zero-curve for Linear Gaussian two-factor model**

structure

Zero-curve for the Linear Gaussian two-factor model, specified using `IRDataCurve` or `RateSpec`.

Data Types: `struct`

### **a — Mean reversion for first factor for Linear Gaussian two-factor model**

scalar

Mean reversion for first factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `single` | `double`

### **b — Mean reversion for second factor for Linear Gaussian two-factor model**

scalar

Mean reversion for second factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `single` | `double`

### **sigma — Volatility for first factor for Linear Gaussian two-factor model**

scalar

Volatility for first factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `single` | `double`

### **eta — Volatility for second factor for Linear Gaussian two-factor model**

scalar

Volatility for second factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `single` | `double`

### **rho — Scalar correlation of the factors**

scalar

Scalar correlation of the factors, specified as a scalar.

Data Types: `single` | `double`

### **Strike — Swaption strike price**

nonnegative integer | vector of nonnegative integers

Swaption strike price, specified as a nonnegative integer using a `NumSwaptions-by-1` vector.

Data Types: `single` | `double`

### **ExerciseDate — Swaption exercise dates**

vector of serial date numbers | character vector of dates

Swaption exercise dates, specified as a `NumSwaptions-by-1` vector of serial date numbers or date character vectors.

Data Types: `single` | `double` | `char` | `cell`

**Maturity — Underlying swap maturity date**

vector of serial date numbers | character vector of dates

Underlying swap maturity date, specified using a NumSwaptions-by-1 vector of serial date numbers or date character vectors.

Data Types: single | double | char | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: Price =  
 swaptionbylg2f(irdc,a,b,sigma,eta,rho,Strike,ExerciseDate,Maturity,'Reset',1,  
 'Notional',100,'OptSpec','call')

**Reset — Frequency of swaption payments per year**

2 (default) | positive integer from the set[1,2,3,4,6,12] | vector of positive integers from the set [1,2,3,4,6,12]

Frequency of swaption payments per year, specified as the comma-separated pair consisting of 'Reset' and positive integers for the values 1,2,4,6,12 in a NumSwaptions-by-1 vector.

Data Types: single | double

**Notional — Notional value of swaption**

100 (default) | nonnegative integer | vector of nonnegative integers

Notional value of swaption, specified as the comma-separated pair consisting of 'Notional' and a nonnegative integer using a NumSwaptions-by-1 vector of notional amounts.

Data Types: single | double

**OptSpec — Option specification for the swaption**

'call' (default) | character vector with value of 'call' or 'put' | cell array of character vectors with values of 'call' or 'put'

Option specification for the swaption, specified as the comma-separated pair consisting of 'OptSpec' and a character vector or a NumSwaptions-by-1 cell array of character vectors with a value of 'call' or 'put'.

A 'call' swaption or Payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

A 'put' swaption or Receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Data Types: char | cell

**Output Arguments****Price — Swaption price**

scalar | vector

Swaption price, returned as a scalar or an NumSwaptions-by-1 vector.

## More About

### Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

### Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

## Algorithms

The following defines the swaption price for a two-factor additive Gaussian interest-rate model, given the ZeroCurve, a, b, sigma, eta, and rho parameters:

$$r(t) = x(t) + y(t) + \phi(t)$$

$$dx(t) = -ax(t)dt + \sigma dW_1(t), \quad x(0) = 0$$

$$dy(t) = -by(t)dt + \eta dW_2(t), \quad y(0) = 0$$

where  $dW_1(t)dW_2(t) = \rho dt$  is a two-dimensional Brownian motion with correlation  $\rho$  and  $\phi$  is a function chosen to match the initial zero curve.

## swaptionbynormal

Price swaptions using Normal or Bachelier option pricing model

### Syntax

```
Price = swaptionbynormal(RateSpec,OptSpec,Strike,Settle,ExerciseDates,
Maturity,Volatility)
Price = swaptionbynormal( ____,Name,Value)
```

### Description

Price = swaptionbynormal(RateSpec,OptSpec,Strike,Settle,ExerciseDates, Maturity,Volatility) prices swaptions using the Normal or Bachelier option pricing model.

Price = swaptionbynormal( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Price a Swaption Using the Normal Model

Define the zero curve, and create a RateSpec.

```
Settle = datenum('20-Jan-2016');
ZeroTimes = [.5 1 2 3 4 5 7 10 20 30]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = datemnth(Settle,12*ZeroTimes);
RateSpec = intenvset('StartDate',Settle,'EndDates',ZeroDates,'Rates',ZeroRates)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: [10x1 double]
    Rates: [10x1 double]
    EndTimes: [10x1 double]
    StartTimes: [10x1 double]
    EndDates: [10x1 double]
    StartDates: 736349
    ValuationDate: 736349
    Basis: 0
    EndMonthRule: 1
```

Define the swaption.

```
ExerciseDate = datenum('20-Jan-2021');
Maturity = datenum('20-Jan-2026');
OptSpec = 'call';
LegReset = [1 1];
```

Compute the par swap rate.

```
[~,ParSwapRate] = swapyzero(RateSpec,[NaN 0],Settle,Maturity,'LegReset',LegReset)
```

```

ParSwapRate = 0.0216

Strike = ParSwapRate;
BlackVol = .3;
NormalVol = BlackVol*ParSwapRate;

Price with Black volatility.

Price = swaptionbyblk(RateSpec,OptSpec,Strike,Settle,ExerciseDate,Maturity,BlackVol)

Price = 5.9756

Price with Normal volatility.

Price_Normal = swaptionbynormal(RateSpec,OptSpec,Strike,Settle,ExerciseDate,Maturity,NormalVol)

Price_Normal = 5.5537

```

### Price a Swaption with a Receiving and Paying Leg Using the Normal Model

Create a RateSpec.

```

Rate = 0.06;
Compounding = -1;
ValuationDate = 'Jan-1-2010';
EndDates = 'Jan-1-2020';
Basis = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, ...
'EndDates', EndDates, 'Rates', Rate, 'Compounding', Compounding, 'Basis', Basis);

```

Define the swaption.

```

ExerciseDate = datenum('20-Jan-2021');
Maturity = datenum('20-Jan-2026');
Settle = 'Jan-1-2010';
OptSpec = 'call';
Strike = .09;
NormalVol = .03;
Reset = [1 4]; % 1st column represents receiving leg, 2nd column represents paying leg
Basis = [1 7]; % 1st column represents receiving leg, 2nd column represents paying leg

```

Price with Normal volatility.

```

Price_Normal = swaptionbynormal(RateSpec,OptSpec,Strike,Settle,ExerciseDate,Maturity,NormalVol, 'B')

Price_Normal = 5.9084

```

### Price a Swaption Using swaptionbynormal and Compare to swaptionbyblk

Define the RateSpec.

```

Settle = datenum('20-Jan-2016');
ZeroTimes = [.5 1 2 3 4 5 7 10 20 30]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';

```

```

ZeroDates = datemnth(Settle,12*ZeroTimes);
RateSpec = intenvset('StartDate',Settle,'EndDates',ZeroDates,'Rates',ZeroRates)

RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: [10x1 double]
    Rates: [10x1 double]
    EndTimes: [10x1 double]
    StartTimes: [10x1 double]
    EndDates: [10x1 double]
    StartDates: 736349
    ValuationDate: 736349
    Basis: 0
    EndMonthRule: 1

```

Define the swaption instrument and price with `swaptionbyblk`.

```

ExerciseDate = datenum('20-Jan-2021');
Maturity = datenum('20-Jan-2026');
OptSpec = 'call';

[~,ParSwapRate] = swapyzero(RateSpec,[NaN 0],Settle,Maturity,'StartDate',ExerciseDate)

ParSwapRate = 0.0326

Strike = ParSwapRate;
BlackVol = .3;
NormalVol = BlackVol*ParSwapRate;

Price = swaptionbyblk(RateSpec,OptSpec,Strike,Settle,ExerciseDate,Maturity,BlackVol)

Price = 3.6908

```

Price the swaption instrument using `swaptionbynormal`.

```

Price_Normal = swaptionbynormal(RateSpec,OptSpec,Strike,Settle,ExerciseDate,Maturity,NormalVol)

Price_Normal = 3.7602

```

Price the swaption instrument using `swaptionbynormal` for a negative strike.

```

Price_Normal = swaptionbynormal(RateSpec,OptSpec,-.005,Settle,ExerciseDate,Maturity,NormalVol)

Price_Normal = 16.3674

```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

If the discount curve for the paying leg is different than the receiving leg, `RateSpec` can be a `NINST-by-2` input variable of `RateSpecs`, with the second input being the discount curve for the paying leg. If only one curve is specified, then it is used to discount both legs.

Data Types: struct

### **OptSpec — Definition of option**

character vector with values 'call' or 'put' | cell array of character vector with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors.

A 'call' swaption, or Payer swaption, allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

A 'put' swaption, or Receiver swaption, allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

Data Types: char | cell

### **Strike — Strike swap rate values**

decimal

Strike swap rate values, specified as a NINST-by-1 vector of decimal values.

Data Types: double

### **Settle — Settlement date**

serial date number | date character vector | cell array of date character vectors | datetime object | string object

Settlement date (representing the settle date for each swaption), specified as a NINST-by-1 vector of serial date numbers, or cell array of date character vectors, datetime objects, or string objects. **Settle** must not be later than **ExerciseDates**.

The **Settle** date input for **swaptionbynormal** is the valuation date on which the swaption (an option to enter into a swap) is priced. The swaption buyer pays this price on this date to hold the swaption.

Data Types: double | char | cell | datetime | string

### **ExerciseDates — Dates on which swaption expires and underlying swap starts**

serial date number | date character vector | cell array of date character vectors | datetime object

Dates on which the swaption expires and the underlying swap starts, specified as a NINST-by-1 vector of serial date numbers, or cell array of date character vectors, datetime objects, or string objects. There is only one **ExerciseDate** on the option expiry date. This is also the **StartDate** of the underlying forward swap.

Data Types: double | char | cell | datetime | string

### **Maturity — Maturity date for each forward swap**

serial date number | date character vector | cell array of date character vectors | datetime object

Maturity date for each forward swap, specified as a NINST-by-1 vector of dates using serial date numbers, cell array of date character vectors, datetime objects, or string objects.

Data Types: double | char | cell | datetime | string

### **Volatility — Volatilities values**

numeric

Volatilities values (for normal volatility), specified as a NINST-by-1 vector of numeric values.

For more information on the Normal model, see “Work with Negative Interest Rates” on page 2-17.

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1, Value1, . . . , NameN, ValueN**.

Example: `Price =`

```
swaptionbynormal(0ISCurve, OptSpec, Strike, Settle, ExerciseDate, Maturity, NormalVol, 'Reset', 4)
```

### Reset — Reset frequency per year for underlying forward swap

1 (default) | numeric

Reset frequency per year for the underlying forward swap, specified as the comma-separated pair consisting of 'Reset' and a NINST-by-1 vector or NINST-by-2 matrix representing the reset frequency per year for each leg. If **Reset** is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

### Basis — Day-count basis of instrument

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis of the instrument representing the basis used when annualizing the input term structure, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector or NINST-by-2 matrix representing the basis for each leg. If **Basis** is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Principal — Notional principal amount**

100 (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of 'Principal' and a NINST-by-1 vector.

Data Types: double

### **ProjectionCurve — Rate curve used in projecting future cash flows**

if ProjectionCurve is not specified, then RateSpec is used both for discounting cash flows and projecting future cash flows (default) | structure

The rate curve to be used in projecting the future cash flows, specified as the comma-separated pair consisting of 'ProjectionCurve' and a rate curve structure. This structure must be created using `intenvset`. Use this optional input if the forward curve is different from the discount curve.

Data Types: struct

## **Output Arguments**

### **Price — Prices for swaptions at time 0**

vector

Prices for the swaptions at time 0, returned as a NINST-by-1 vector of prices.

## **More About**

### **Call Swaption**

A Call swaption or Payer swaption allows the option buyer to enter into an interest rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

### **Put Swaption**

A Put swaption or Receiver swaption allows the option buyer to enter into an interest rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

## time2date

Dates from time and frequency

### Syntax

Dates = time2date(Settle,Times,Compounding,Basis,EndMonthRule)

### Arguments

Settle	Settlement date. A vector of serial date numbers or date character vectors.
Times	Vector of times corresponding to the compounding value. Times must be equal to or greater than 0.
Compounding	<p>(Optional) Scalar value representing the rate at which the input zero rates were compounded when annualized. Default = 2. This argument determines the formula for the discount factors:</p> <p>Compounding = 1, 2, 3, 4, 6, 12 = F</p> <p><math>Disc = (1 + Z/F)^{-T}</math>, where F is the compounding frequency, Z is the zero rate, and T is the time in periodic units; for example, T = F is 1 year.</p> <p>Compounding = 365</p> <p><math>Disc = (1 + Z/F)^{-T}</math>, where F is the number of days in the basis year and T is a number of days elapsed computed by basis.</p> <p>Compounding = -1</p> <p><math>Disc = \exp(-T*Z)</math>, where T is time in years.</p>

Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
EndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>

## Description

`Dates = time2date(Settle, Times, Compounding, Basis, EndMonthRule)` computes dates corresponding to compounded rate quotes between `Settle` and time factors.

---

**Note** To obtain accurate results from this function, the `Basis` and `Dates` arguments must be consistent. If the `Dates` argument contains months that have 31 days, `Basis` must be one of the values that allow months to contain more than 30 days; for example, `Basis = 0, 3, or 7`.

---

The `time2date` function is the inverse of `date2time`.

## Examples

Show that `date2time` and `time2date` are the inverse of each other. First compute the time factors using `date2time`.

```
Settle = '1-Sep-2002';
Dates = datenum(['31-Aug-2005'; '28-Feb-2006'; '15-Jun-2006';
                '31-Dec-2006']);
Compounding = 2;
Basis = 0;
EndMonthRule = 1;
```

```
Times = date2time(Settle, Dates, Compounding, Basis,...  
                EndMonthRule)
```

```
Times =
```

```
5.9945  
6.9945  
7.5738  
8.6576
```

Now use the calculated Times in `time2date` and compare the calculated dates with the original set.

```
Dates_calc = time2date(Settle, Times, Compounding, Basis,...  
                    EndMonthRule)
```

```
Dates_calc =
```

```
732555  
732736  
732843  
733042
```

```
datestr(Dates_calc)
```

```
ans =
```

```
31-Aug-2005  
28-Feb-2006  
15-Jun-2006  
31-Dec-2006
```

# treepath

Entries from node of recombining binomial tree

## Syntax

Values = treepath(Tree,BranchList)

## Arguments

Tree	Recombining binomial tree.
BranchList	Number of paths (NUMPATHS) by path length (PATHLENGTH) matrix containing the sequence of branchings.

## Description

Values = treepath(Tree,BranchList) extracts entries of a node of a recombining binomial tree. The node path is described by the sequence of branchings taken, starting at the root. The top branch is number one, the second-to-top is two, and so on. Set the branch sequence to zero to obtain the entries at the root node.

Values is a number of values (NUMVALS)-by-NUMPATHS matrix containing the retrieved entries of a recombining tree.

## Examples

Create a BDT tree by loading the example file.

```
load deriv.mat;
```

Then

```
FwdRates = treepath(BDTree.FwdTree, [1 2 1])
```

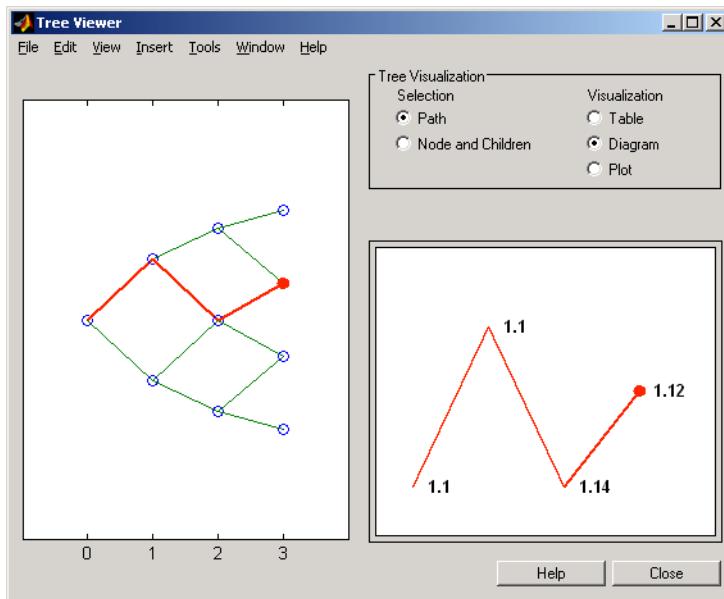

returns the rates at the tree nodes located by taking the up branch, then the down branch, and finally the up branch again.

```
FwdRates =
```

```
    1.1000
    1.0979
    1.1377
    1.1183
```

You can visualize this with the treeviewer function.

```
treeviewer(BDTree)
```

# treeshape

Shape of recombining binomial tree

## Syntax

```
[NumLevels,NumPos,IsPriceTree] = treeshape(Tree)
```

## Arguments

Tree	Recombining binomial tree.
------	----------------------------

## Description

`[NumLevels,NumPos,IsPriceTree] = treeshape(Tree)` returns information on a recombining binomial tree's shape.

`NumLevels` is the number of time levels of the tree.

`NumPos` is a 1-by-`NUMLEVELS` vector containing the length of the state vectors in each level.

`IsPriceTree` is a Boolean determining if a final horizontal branch is present in the tree.

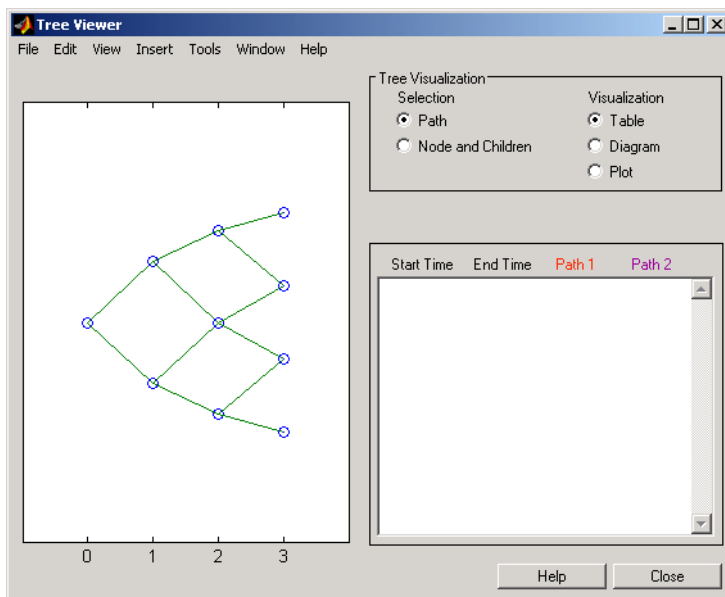

## Examples

Create a BDT tree by loading the example file.

```
load deriv.mat;
```

With `treeviewer` you can see the general shape of the BDT interest-rate tree.

```
treeviewer(BDTree)
```

With this tree

```
[NumLevels, NumPos, IsPriceTree] = treeshape(BDTree.FwdTree)
```

returns

```
NumLevels =  
    4
```

```
NumPos     =  
    1     1     1     1
```

```
IsPriceTree =  
    0
```

# treeviewer

Tree information

## Syntax

```
treeviewer(Tree)
treeviewer(PriceTree,InstSet)
treeviewer(CFTree,InstSet)
```

## Description

`treeviewer(Tree)` displays an interest rate tree, stock price tree, or money-market tree.

`treeviewer(PriceTree,InstSet)` displays a tree of instrument prices.

If you provide the name of an instrument set (`InstSet`) and you have named the instruments using the field `Name`, the `treeviewer` display identifies the instrument being displayed with its name. (See Example 3 on page 11-1748 for a description.) If you do not provide the optional `InstSet` input argument, the instruments are identified by their sequence number in the instrument set. (See Example 6 on page 11-1751 for a description.)

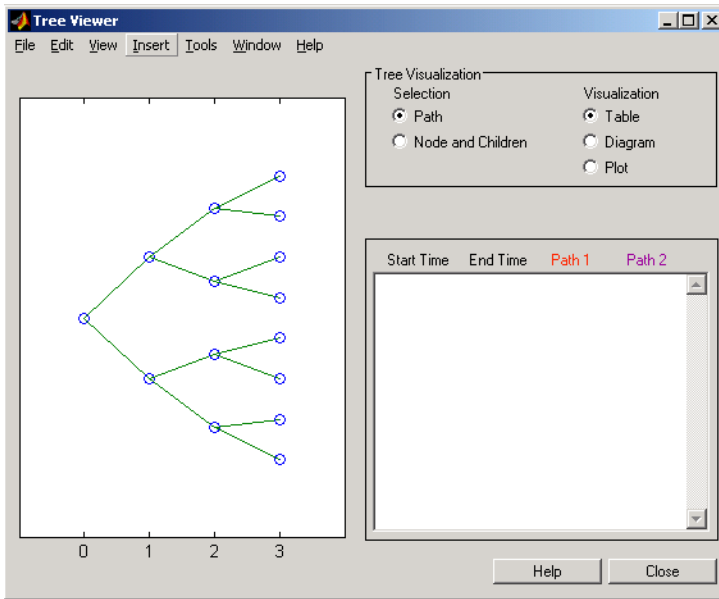

`treeviewer(CFTree,InstSet)` displays a cash flow tree that has been created with `swapbybdt` or `swapbyhjm`. If you provide the name of an instrument set (`InstSet`) containing cash flow names, the `treeviewer` display identifies the instrument being displayed with its name. (See Example 3 on page 11-1748 for a description.) If the optional `InstSet` argument is not present, the instruments are identified by their sequence number in the instrument set. See Example 6 on page 11-1751 for a description.)

## Examples

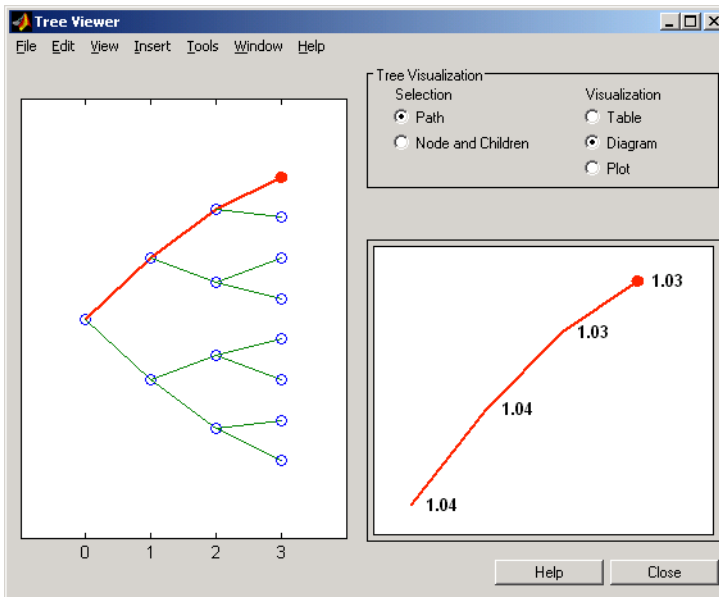

### Display an HJM Interest-Rate Tree

```
load deriv.mat
treeviewer(HJMTree)
```

The `treeviewer` function displays the structure of an HJM tree in the left pane. The tree visualization in the right pane is blank.

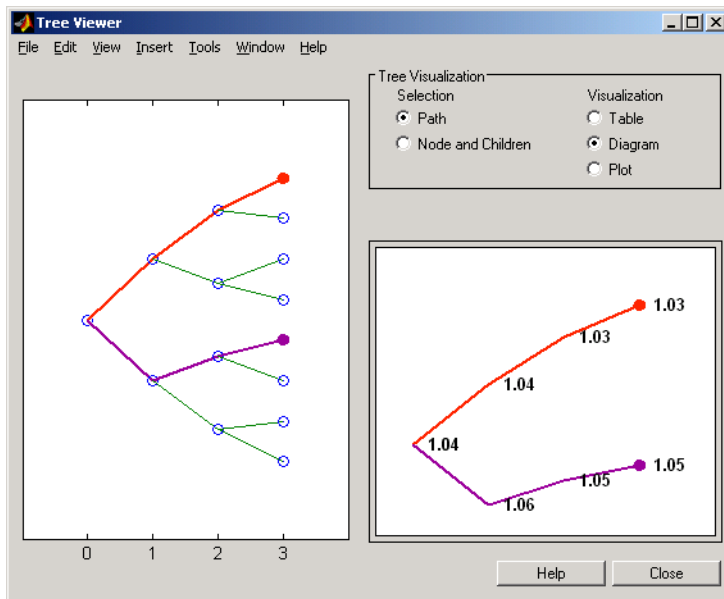

To visualize the actual interest-rate tree, go to the **Tree Visualization** pane and click **Path** (the default) and **Diagram**. Now, select the first path by clicking the last node ( $t = 3$ ) of the upper branch.

The entire upper path is highlighted in red.

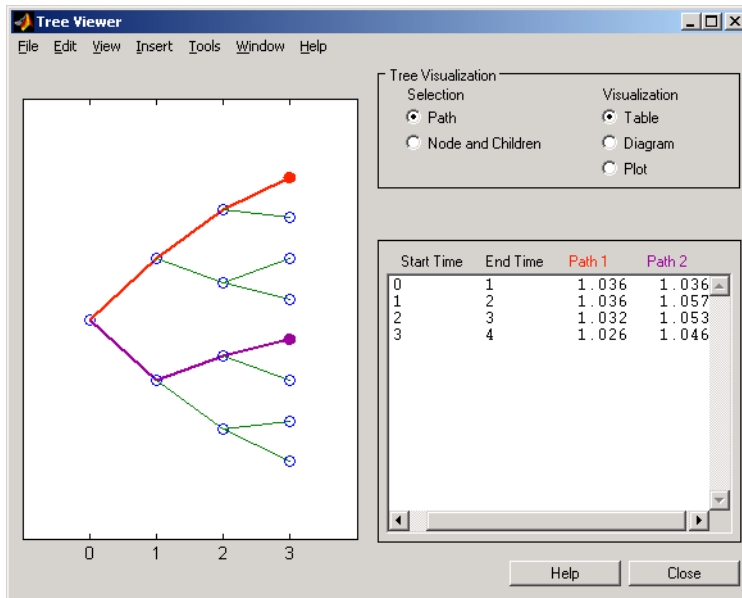

To complete the process, select a second path by clicking the last node ( $t = 3$ ) of another branch. The second path is highlighted in purple. The final display looks like this.

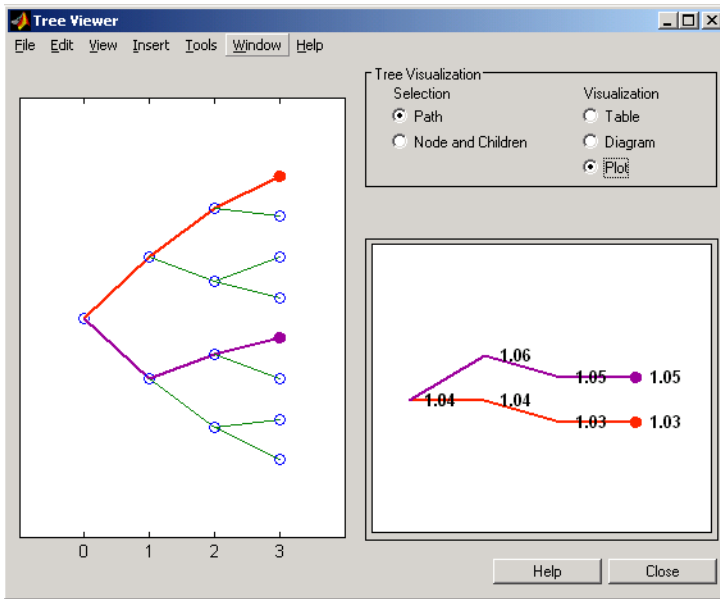

### Alternative Forms of Display

The **Tree Visualization** pane allows you to select alternative ways to display tree data. For example, if you select **Path** and **Table** as your visualization choices, the final display above instead appears in tabular form.

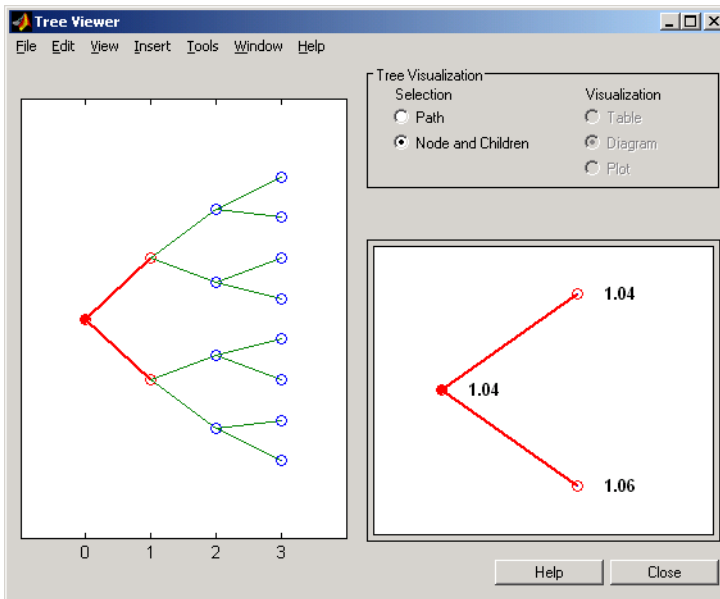

To see a plot of interest rates along the chosen branches, click **Path** and **Plot** in the **Tree Visualization** pane.

With **Plot** selected, rising interest rates are shown on the upper branch and declining interest rates on the lower.

Finally, if you clicked **Node and Children** under **Tree Visualization**, you restrict the data displayed to just the selected parent node and its children.

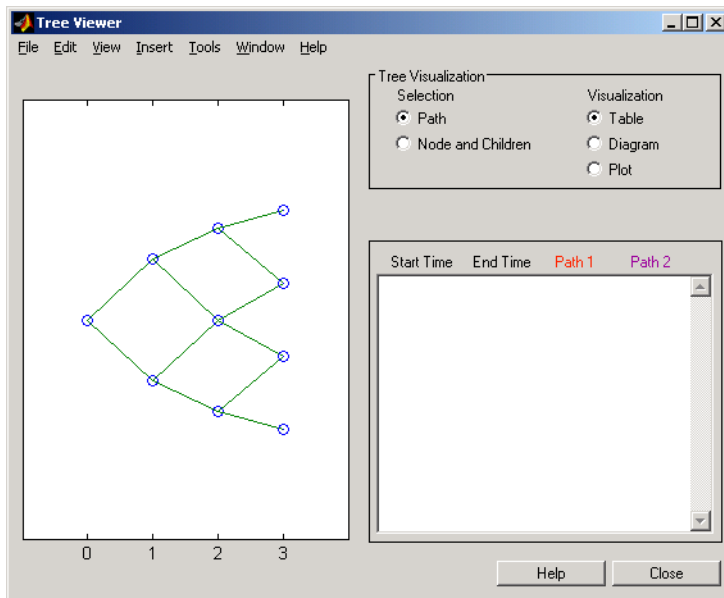

With **Node and Children** selected, the choices under **Visualization** are unavailable.

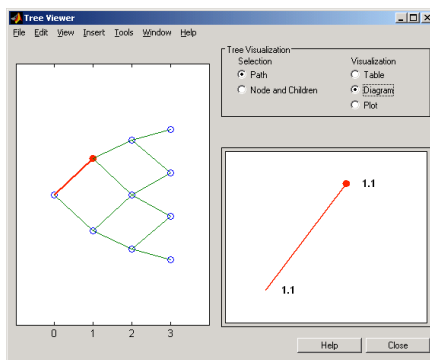

### Display a BDT Interest-Rate Tree

```
load deriv.mat
treeviewer(BDTTree)
```

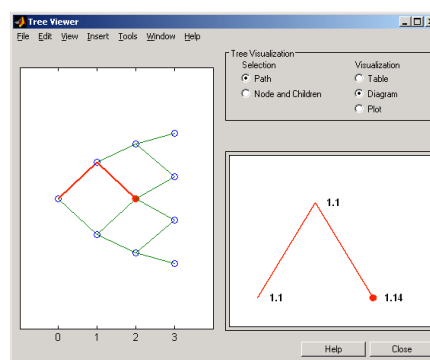

The `treeviewer` function displays the structure of a BDT tree in the left pane. The tree visualization in the right pane is blank.

To visualize the actual interest-rate tree, go to the **Tree Visualization** pane and click **Path** (the default) and **Diagram**. Now, select the first path by clicking the first node of the up branch ( $t = 1$ ). Continue by clicking the down branch at the next node ( $t = 2$ ). The two figures below show the treeviewer path diagrams for these selections.

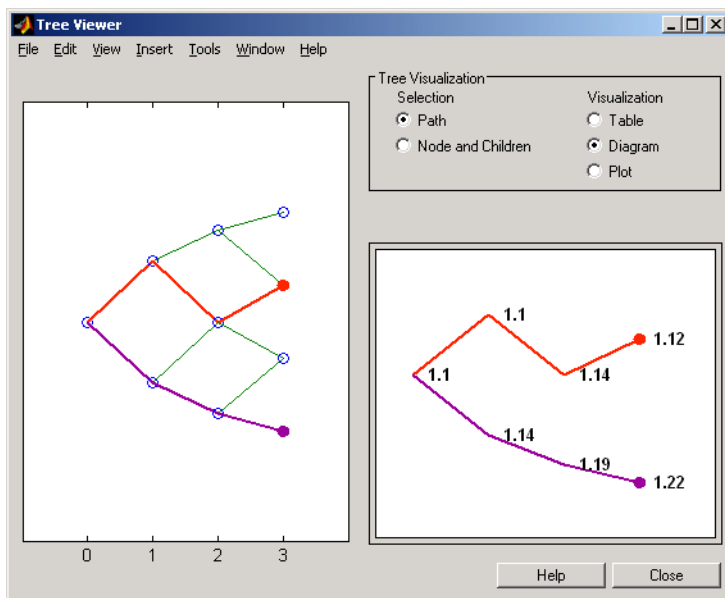

$t = 1$

$t = 2$

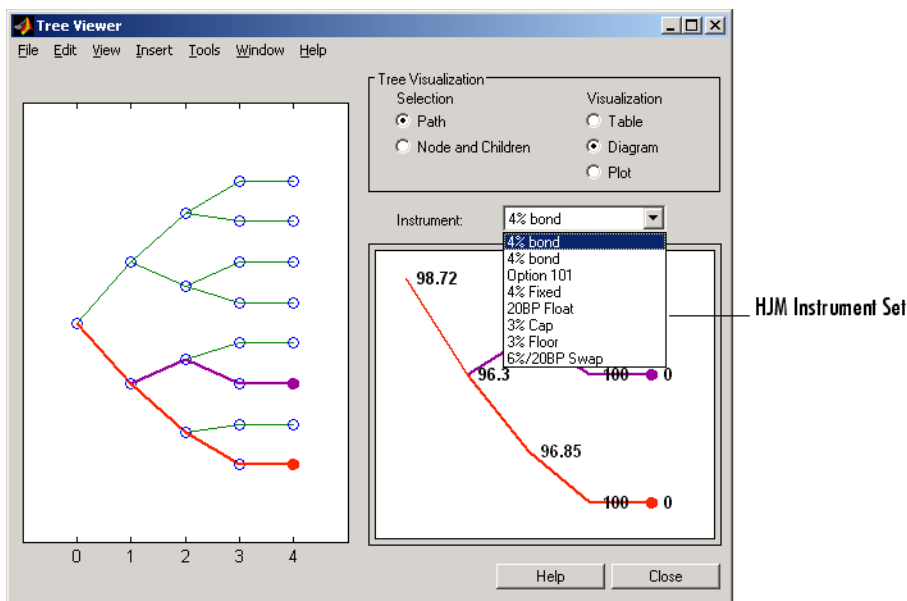

Continue clicking all nodes in succession until you reach the end of the branch. The entire path you have selected is highlighted in red.

Select a second path by clicking the first node of the lower branch ( $t = 1$ ). Continue clicking lower nodes as you did on the first branch. The second branch is highlighted in purple. The final display looks like this.

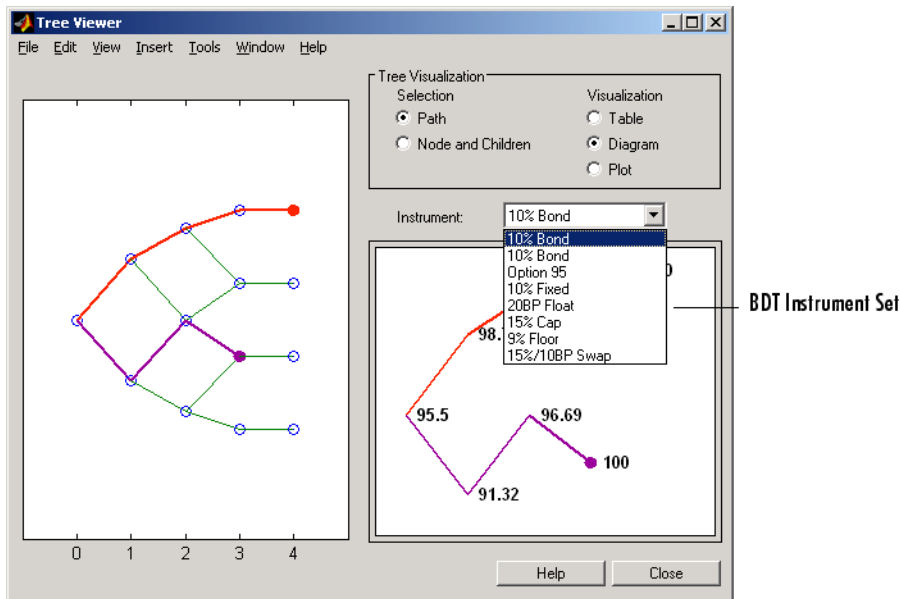

### Display an HJM Price Tree for Named Instruments

```
load deriv.mat
[Price, PriceTree] = hjmprice(HJMTree, HJMInstSet);
treeviewer(PriceTree, HJMInstSet)
```

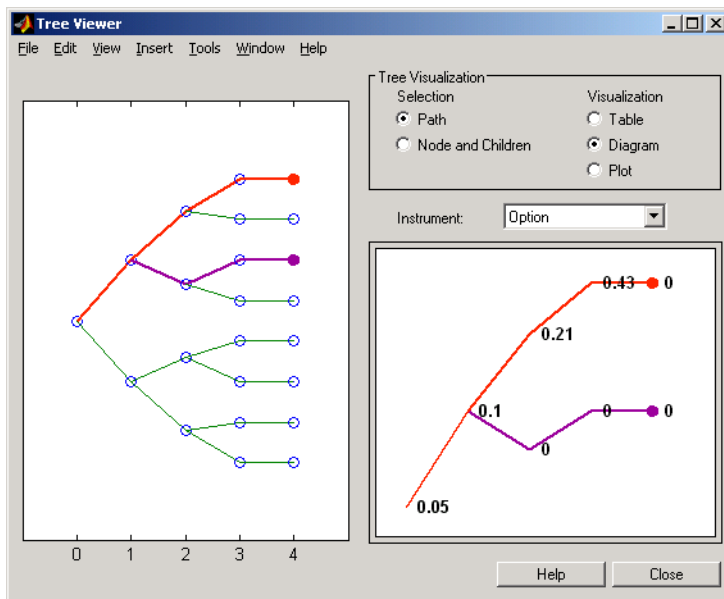

### Display a BDT Price Tree for Named Instruments

```
load deriv.mat
[Price, PriceTree] = bdtprice(BDTree, BDTInstSet);
treeviewer(PriceTree, BDTInstSet)
```

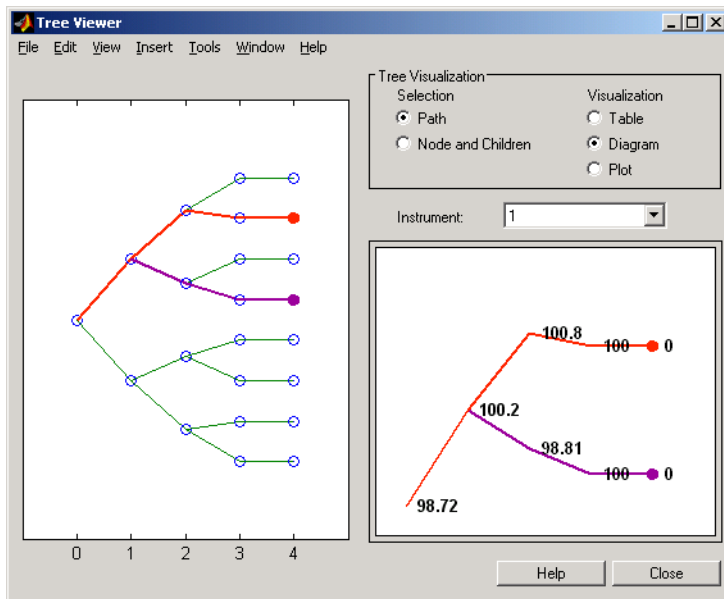

### Display an HJM Price Tree with Renamed Instruments

```
load deriv.mat
[Price, PriceTree] = hjmprice(HJMTree, HJMInstSet);
Names = {'Bond1', 'Bond2', 'Option', 'Fixed', 'Float', 'Cap', ...
'Floor', 'Swap'};
treeviewer(PriceTree, Names)
```

### Display an HJM Price Tree Using Default Instrument Names (Numbers)

```
load deriv.mat
[Price, PriceTree] = hjmprice(HJMTree, HJMInstSet);
treeviewer(PriceTree)
```

## Input Arguments

### Tree — Interest-rate tree, stock price tree, or money-market tree

[interest-rate tree structure](#) | [stock price tree structure](#) | [money-market tree structure](#)

Interest-rate tree, stock price tree, or money-market tree, specified using the associated tree function.

*Interest-rate trees:*

- Black-Derman-Toy (BDTree) obtained from `bdttree`
- Black-Karasinski (BKTree) obtained from `bktree`
- Heath-Jarrow-Morton (HJMTree) obtained from `hjmtree`
- Hull-White (HWTtree) obtained from `hwtree`
- Cox-Ingersoll-Ross (CIRTtree) obtained from `cirtree`

*Money market trees:*

- Black-Derman-Toy (BDTMMktTree) obtained from `mmktbybdt` for a money-market tree from a BDT interest-rate tree.
- Heath-Jarrow-Morton (HJMMMktTree) obtained from `mmktbyhjm` for a money-market tree from an HJM interest-rate tree.

---

**Note** Money market trees cannot be created from BK or HW interest-rate trees.

---

*Stock price trees:*

- Cox-Ross-Rubinstein (CRRTree) obtained from `crmtree`
- Implied Trinomial tree (ITTTree) obtained from `itttree`
- Standard Trinomial tree (STTTree) obtained from `stttree`

- Leisen-Reimer stock tree (LRTree) obtained from `lrtree`
- Equal probabilities (EQPTree) obtained from `eqptree`

*Cash flow trees:*

- Black-Derman-Toy (BDTCFTree) obtained as output from the swap function `swapbybdt`
- Heath-Jarrow-Morton (HJMCFTree) obtained as output from the swap function `swapbyhjm`

---

**Note** For the function `swapbybdt`, which uses a recombining binomial tree, this structure contains only NaNs because cash flows cannot be accurately calculated at every tree node for floating-rate notes.

---

Data Types: `struct`

### PriceTree — Tree structure of instrument prices

structure

Tree structure of instrument prices, specified as:

- Black-Derman-Toy (BDTPriceTree) obtained from the portfolio function `bdtpprice` or the individual functions, such as `bondbybdt`, `capbybdt`, and so on.
- Black-Karasinski (BKPriceTree) obtained from the portfolio function `bkprice` or the individual functions, such as `bondbybk`, `capbybk`, and so on.
- Cox-Ingersoll-Ross (CIRPriceTree) obtained from the portfolio function `cirprice` or the individual functions, such as `bondbycir`, `capbycir`, and so on.
- Heath-Jarrow-Morton (HJMPriceTree) obtained from the portfolio function `hjmprice` or the individual functions, such as `bondbyhjm`, `capbyhjm`, and so on.
- Hull-White (HWPriceTree) obtained from the portfolio function `hwprice` or the individual functions, such as `bondbyhw`, `capbyhw`, and so on.
- Leisen-Reimer (LRPriceTree) obtained from the individual function `optstockbylr`.
- Cox-Ross-Rubinstein (CRRPriceTree) obtained from the portfolio function `crrprice` or the individual functions, such as `asianbycrr`, `barrierbycrr`, and so on.
- Equal probabilities (EQPPriceTree) obtained from the portfolio function `eqpprice` or the individual functions, such as `asianbyeqp`, `barrierbyeqp`, and so on.
- Implied Trinomial tree (ITTPriceTree) obtained from the portfolio function `ittprice` or the individual functions, such as `asianbyitt`, `barrierbyitt`, and so on.
- Standard trinomial tree (STTPriceTree) obtained from the portfolio function `sttprice` or the individual functions, such as `asianbystt`, `barrierbystt`, and so on.

Data Types: `struct`

### CFTree — Tree of swap cash flows

structure

CFTree is a tree of swap cash flows, specified when you create cash flow trees by executing the Black-Derman-Toy (obtained as output from the swap function `swapbybdt`) and Heath-Jarrow-Morton (`swapbyhjm`) swap functions. (Black-Derman-Toy cash flow trees contain only NaNs.)

Data Types: `struct`

**InstSet — Variable containing a collection of instruments whose prices or cash flows are contained in a tree**

structure

(Optional) Variable containing a collection of instruments whose prices or cash flows are contained in a tree, specified using `instadd`. To display the names of the instruments, the field `Name` should exist in `InstSet`. If `InstSet` is not passed, `treeviewer` uses default instruments names (numbers) when displaying prices or cash flows.

Data Types: `struct`**More About****Treeviewer Conventions**

`treeviewer` price tree diagrams follow the convention that increasing prices appear on the upper branch of a tree and, so, decreasing prices appear on the lower branch.

Conversely, for interest rate displays, *decreasing* interest rates appear on the upper branch (prices are rising) and *increasing* interest rates on the lower branch (prices are falling).

**Using Treeviewer**

`treeviewer` provides an interactive display of prices or interest rates.

The `treeviewer` display is activated by clicking the nodes along the price or interest rate path shown in the left pane when the function is called.

- For HJM trees, you select the endpoints of the path, and `treeviewer` displays all data from beginning to end.
- With recombining trees, such as BDT, BK, HW, and CIR you must click *each* node in succession from the beginning ( $t = 1$ ) to the last node ( $t = n$ ). Do not include the *root node*, the node at  $t = 0$ . If you do not click the nodes in the proper order, you are reminded with the message

Parent of selected node must be selected.

---

**Note** The **Help** button is not available for `treeviewer` in MATLAB Online.

---

# trintreepath

Entries from node of recombining trinomial tree

## Syntax

Values = trintreepath(TrinTree,BranchList)

## Arguments

TrinTree	Recombining price or interest-rate trinomial tree.
BranchList	Number of paths (NUMPATHS) by path length (PATHLENGTH) matrix containing the sequence of branchings.

## Description

Values = trintreepath(TrinTree,BranchList) extracts entries of a node of a recombining trinomial tree. The node path is described by the sequence of branchings taken, starting at the root. The top branch is number 1, the middle branch is 2, and the bottom branch is 3. Set the branch sequence to 0 to obtain the entries at the root node.

Values is a number of values (NUMVALS)-by-NUMPATHS matrix containing the retrieved entries of a recombining tree.

## Examples

Create a Hull-White tree by loading the example file.

```
load deriv.mat;
```

Then, for example

```
FwdRates = trintreepath(HWTree, [1 2 3])
```

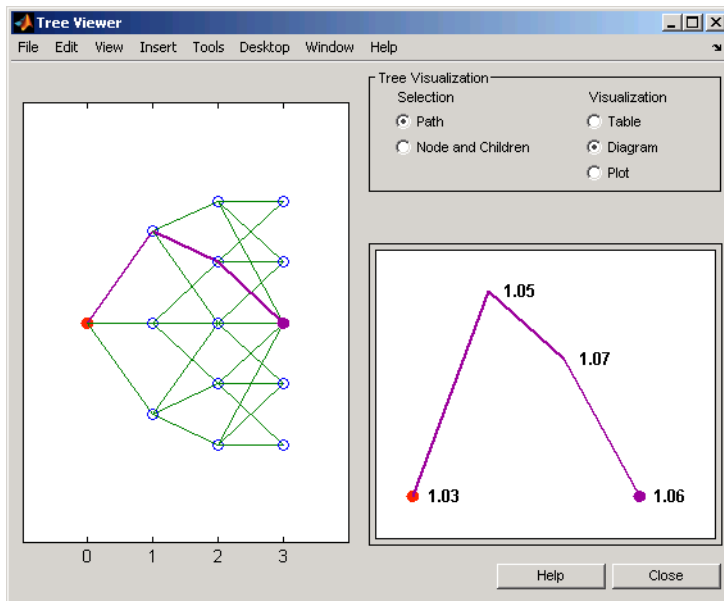

returns the rates at the tree nodes located by starting at 0, taking the up branch at the first node, the middle branch at the second node, and finally the bottom branch at the third node.

```
FwdRates =
```

```
    1.0279
    1.0528
    1.0652
    1.0591
```

You can visualize this with the treeviewer function.

```
treeviewer(HWTree)
```

# trintreeshape

Shape of recombining trinomial tree

## Syntax

```
[NumLevels, NumPos, NumStates] = trintreeshape(TrinTree)
```

## Arguments

TrinTree	Recombining price or interest-rate trinomial tree.
----------	--

## Description

`[NumLevels, NumPos, NumStates] = trintreeshape(TrinTree)` returns information on a recombining trinomial tree's shape.

`NumLevels` is the number of time levels of the tree.

`NumPos` is a 1-by-`NUMLEVELS` vector containing the length of the state vectors in each level.

`NumStates` is a 1-by-`NUMLEVELS` vector containing the number of state vectors in each level.

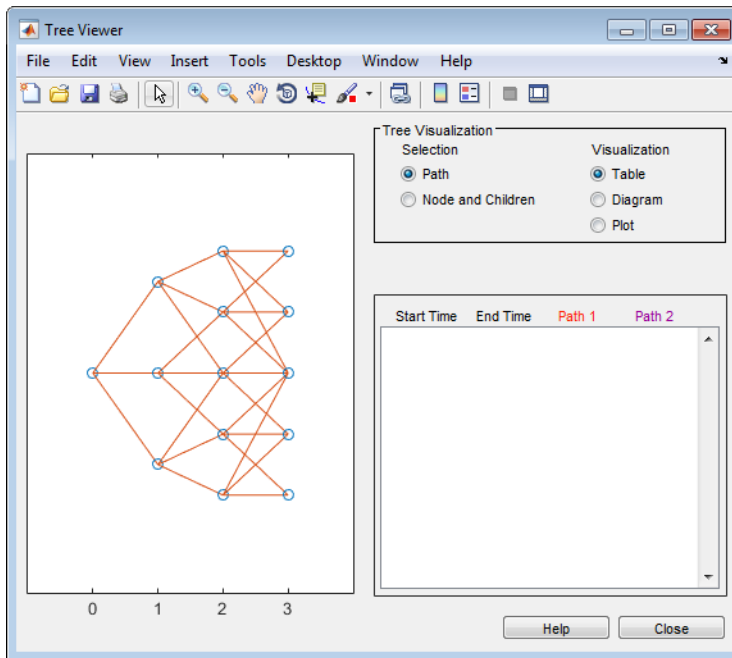

## Examples

Create a Hull-White tree by loading the example file.

```
load deriv.mat;
```

With `treeviewer` you can see the general shape of the HW interest-rate tree.

```
treeviewer(HWTree)
```

With this tree

```
[NumLevels, NumPos, NumStates] = trintreeshape(HWTtree)
```

returns

```
NumLevels =
    4
```

```
NumPos =
    1    1    1    1
```

```
NumStates =
    1    3    5    5
```

# agencyoas

Determine option-adjusted spread of callable bond using Agency OAS model

## Syntax

```
OAS = agencyoas(ZeroData,Price,CouponRate,Settle,Maturity,Vol,CallDate)
OAS = agencyoas( ____,Name,Value)
```

## Description

OAS = agencyoas(ZeroData,Price,CouponRate,Settle,Maturity,Vol,CallDate) computes OAS of a callable bond given price using the Agency OAS model.

OAS = agencyoas( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Agency OAS Value

This example shows how to compute the agency OAS value.

```
Settle = datenum('20-Jan-2010');
ZeroRates = [.07 .164 .253 1.002 1.732 2.226 2.605 3.316 ...
3.474 4.188 4.902]'/100;
ZeroDates = daysadd(Settle,360* [.25 .5 1 2 3 4 5 7 10 20 30],1);
ZeroData = [ZeroDates ZeroRates];

Maturity = datenum('30-Dec-2013');
CouponRate = .022;
Price = 99.155;
Vol = .5117;
CallDate = datenum('30-Dec-2010');
OAS = agencyoas(ZeroData, Price, CouponRate, Settle, Maturity, Vol, CallDate)

OAS = 8.5837
```

## Input Arguments

### ZeroData — Zero curve

matrix

Zero curve, specified as an numRates-by-2 matrix where the first column is zero dates and the second column is the accompanying zero rates.

Data Types: double

### Price — Prices

vector

Prices specified as an numBonds-by-1 vector.

Data Types: double

**CouponRate — Coupon rates**

vector in decimals

Coupon rates, specified as an numBonds-by-1 vector in decimals.

Data Types: double

**Settle — Settlement date**

serial date number

Settlement date, specified as a scalar serial date number.

---

**Note** The `Settle` date must be an identical settlement date for all the bonds and the zero curve.

---

Data Types: double

**Maturity — Maturity date**

serial date number

Maturity date, specified as a numBonds-by-1 vector.

Data Types: double

**Vol — Volatilities**

vector in decimals

Volatilities specified as a scalar or an numBonds-by-1 vector in decimals. `Vol` is the volatility of interest rates corresponding to the time of the `CallDate`.

Data Types: double

**CallDate — Call dates**

vector

Call dates, specified as an numBonds-by-1 vector.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `OAS =`

```
agencyoas(ZeroData, Price, CouponRate, Settle, Maturity, Vol, CallDate, 'Basis', 7, 'Face', 1000)
```

**Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a N-by-1 vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

#### **CurveBasis – Curve basis**

0 (actual/actual) (default) | integer from 0 to 13

Curve basis, specified as the comma-separated pair consisting of 'CurveBasis' and a N-by-1 vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

#### **CurveCompounding – Compounding frequency of the zero curve**

2 (semiannual) (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'CurveCompounding' and a N-by-1 vector using the supported values: -1, 0, 1, 2, 3, 4, 6, and 12.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a N-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

**Face — face value of bond**

100 (default) | vector

Face value of bond, specified as the comma-separated pair consisting of 'Face' and an N-by-1 vector of numeric values.

Data Types: double

**FirstCouponDate — Irregular first coupon date**

if you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs (default) | serial date number

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using a serial date numbers.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Data Types: double

**InterpMethod — Interpolation method**

'linear' (default) | 'cubic', 'pchip'

Interpolation method, specified as the comma-separated pair consisting of 'InterpMethod' and a N-by-1 vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: char

**IssueDate — Bond issue date**

if you do not specify an IssueDate, the cash flow payment dates are determined from other inputs (default) | serial date number

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a N-by-1 vector using serial date numbers.

Data Types: double

**LastCouponDate — Irregular last coupon date**

serial date number

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a N-by-1 vector using serial date numbers

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Data Types: `double`

### **Period — Coupons per year**

2 per year (default) | `vector`

Coupons per year, specified as the comma-separated pair consisting of 'Period' and an N-by-1 vector. Values for Period are 0, 1, 2, 3, 4, 6, and 12.

Data Types: `double`

### **StartDate — Forward starting date of payments**

Settle date (default) | `serial date number`

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a N-by-1 vector using serial date numbers.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Data Types: `double`

## **Output Arguments**

### **OAS — Option-adjusted spreads**

`matrix`

Option-adjusted spreads, returned as an `numBonds-by-1` matrix.

## **More About**

### **Agency OAS Model**

The BMA European Callable Securities Formula provides a standard methodology for computing price and option-adjusted spread for European Callable Securities (ECS).

## agencyprice

Price callable bond using Agency OAS model

### Syntax

```
Price = agencyprice(ZeroData,OAS,CouponRate,Settle,Maturity,Vol,CallDate)
Price = agencyprice( ____,Name,Value)
```

### Description

Price = agencyprice(ZeroData,OAS,CouponRate,Settle,Maturity,Vol,CallDate) computes the price for a callable bond, given OAS, using the Agency OAS model.

Price = agencyprice( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Agency Price

This example shows how to compute the agency Price.

```
Settle = datenum('20-Jan-2010');
ZeroRates = [.07 .164 .253 1.002 1.732 2.226 2.605 3.316 ...
3.474 4.188 4.902]'/100;
ZeroDates = daysadd(Settle,360* [.25 .5 1 2 3 4 5 7 10 20 30],1);
ZeroData = [ZeroDates ZeroRates];

Maturity = datenum('30-Dec-2013');
CouponRate = .022;
OAS = 6.53/10000;
Vol = .5117;
CallDate = datenum('30-Dec-2010');
Price = agencyprice(ZeroData, OAS, CouponRate, Settle, Maturity, Vol, CallDate)

Price = 99.4212
```

### Input Arguments

#### ZeroData — Zero curve

matrix

Zero curve, specified as an numRates-by-2 matrix where the first column is zero dates and the second column is the accompanying zero rates.

Data Types: double

#### OAS — Option-adjusted spreads

vector in decimals

Option-adjusted spreads, specified as an `numBonds-by-1` vector expressed as a decimal (that is, 50 basis points is entered as `.005`).

Data Types: `double`

### **CouponRate — Coupon rates**

vector in decimals

Coupon rates, specified as an `numBonds-by-1` vector in decimals.

Data Types: `double`

### **Settle — Settlement date**

serial date number

Settlement date, specified as a scalar serial date number.

---

**Note** The `Settle` date must be an identical settlement date for all the bonds and the zero curve.

---

Data Types: `double`

### **Maturity — Maturity date**

serial date number

Maturity date, specified as a `numBonds-by-1` vector.

Data Types: `double`

### **Vol — Volatilities**

vector in decimals

Volatilities specified as a scalar or an `numBonds-by-1` vector in decimals. `Vol` is the volatility of interest rates corresponding to the time of the `CallDate`.

Data Types: `double`

### **CallDate — Call dates**

vector

Call dates, specified as an `numBonds-by-1` vector.

Data Types: `double`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Price =`

```
agencyprice(ZeroData, OAS, CouponRate, Settle, Maturity, Vol, CallDate, 'Basis', 7, 'Face', 1000)
```

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a N-by-1 vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **CurveBasis – Curve basis**

0 (actual/actual) (default) | integer from 0 to 13

Curve basis, specified as the comma-separated pair consisting of 'CurveBasis' and a N-by-1 vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**CurveCompounding — Compounding frequency of the zero curve**

2 (semiannual) (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'CurveCompounding' and a N-by-1 vector using the supported values: -1, 0, 1, 2, 3, 4, 6, and 12.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a N-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

**Face — face value of bond**

100 (default) | vector

Face value of bond, specified as the comma-separated pair consisting of 'Face' and an N-by-1 vector of numeric values.

Data Types: double

**FirstCouponDate — Irregular first coupon date**

if you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs (default) | serial date number

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using a serial date numbers.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Data Types: double

**InterpMethod — Interpolation method**

'linear' (default) | 'cubic', 'pchip'

Interpolation method, specified as the comma-separated pair consisting of 'InterpMethod' and a N-by-1 vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: char

**IssueDate — Bond issue date**

if you do not specify an IssueDate, the cash flow payment dates are determined from other inputs (default) | serial date number

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a N-by-1 vector using serial date numbers.

Data Types: double

**LastCouponDate — Irregular last coupon date**

serial date number

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a N-by-1 vector using serial date numbers

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Data Types: double

### **Period – Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and an N-by-1 vector. Values for Period are 0, 1, 2, 3, 4, 6, and 12.

Data Types: double

### **StartDate – Forward starting date of payments**

Settle date (default) | serial date number

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a N-by-1 vector using serial date numbers.

If you do not specify StartDate, the effective start date is the Settle date.

Data Types: double

## **Output Arguments**

### **Price – Prices**

matrix

Prices returned as an numBonds-by-1 matrix.

## bkcall

Price European call option on bonds using Black model

### Syntax

CallPrice = bkcall(Strike,ZeroData,Sigma,BondData,Settle,Expiry,Period,Basis,EndMonthRule,Interp)

### Arguments

Strike	Scalar or number of options (NOPT)-by-1 vector of strike prices.
ZeroData	Two-column (optionally three-column) matrix containing zero (spot) rate information used to discount future cash flows. <ul style="list-style-type: none"> <li>Column 1: Serial maturity date associated with the zero rate in the second column.</li> <li>Column 2: Annualized zero rates, in decimal form, appropriate for discounting cash flows occurring on the date specified in the first column. All dates must occur after <b>Settle</b> (dates must correspond to future investment horizons) and must be in ascending order.</li> <li>Column 3 (optional): Annual compounding frequency. Values are 1 (annual), 2 (semiannual, default), 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).</li> </ul>
Sigma	Scalar or NOPT-by-1 vector of annualized price volatilities required by Black's model.
BondData	Row vector with three (optionally four) columns or NOPT-by-3 (optionally NOPT-by-4) matrix specifying characteristics of underlying bonds in the form:  [CleanPrice CouponRate Maturity Face]  CleanPrice is the price excluding accrued interest.  CouponRate is the decimal coupon rate.  Maturity is the bond maturity date in serial date number format.  Face is the face value of the bond. If unspecified, the face value is assumed to be 100.
Settle	Settlement date of the options, specified as a serial date number or date character vector. <b>Settle</b> also represents the starting reference date for the input zero curve.
Expiry	Scalar or NOPT-by-1 vector of option maturity dates, specified as a serial date number or date character vector.

Period	(Optional) Number of coupons per year for the underlying bond. Default = 2 (semiannual). Supported values are 0, 1, 2, 3, 4, 6, and 12.
Basis	<p>(Optional) Day-count basis of the bond. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
EndMonthRule	(Optional) End-of-month rule. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
InterpMethod	(Optional) Scalar integer zero curve interpolation method. For cash flows that do not fall on a date found in the <b>ZeroData</b> spot curve, indicates the method used to interpolate the appropriate zero discount rate. Available methods are (0) nearest, (1) linear, and (2) cubic. Default = 1. See <b>interp1</b> for more information.
StrikeConvention	<p>(Optional) Scalar or NOPT-by-1 vector of option contract strike price conventions.</p> <p><b>StrikeConvention = 0</b> (default) defines the strike price as the cash (dirty) price paid for the underlying bond.</p> <p><b>StrikeConvention = 1</b> defines the strike price as the quoted (clean) price paid for the underlying bond. When evaluating Black's model, the accrued interest of the bond at option expiration is added to the input strike price.</p>

## Description

CallPrice = `bkcall(Strike, ZeroData, Sigma, BondData, Settle, Expiry, Period, Basis, EndMonthRule, InterpMethod, StrikeConvention)` using Black's model, derives an NOPT-by-1 vector of prices of European call options on bonds.

If cash flows occur beyond the dates spanned by `ZeroData`, the input zero curve, the appropriate zero rate for discounting such cash flows is obtained by extrapolating the nearest rate on the curve (that is, if a cash flow occurs before the first or after the last date on the input zero curve, a flat curve is assumed).

In addition, you can use the Financial Instruments Toolbox method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `bkcall`. For more information, see “Converting an `IRDataCurve` or `IRFunctionCurve` Object” on page 9-33.

## Examples

### Price a European Call Option On Bonds Using the Black Model

This example shows how to price a European call option on bonds using the Black model. Consider a European call option on a bond maturing in 9.75 years. The underlying bond has a clean price of \$935, a face value of \$1000, and pays 10% semiannual coupons. Since the bond matures in 9.75 years, a \$50 coupon will be paid in 3 months and again in 9 months. Also, assume that the annualized volatility of the forward bond price is 9%. Furthermore, suppose the option expires in 10 months and has a strike price of \$1000, and that the annualized continuously compounded risk-free discount rates for maturities of 3, 9, and 10 months are 9%, 9.5%, and 10%, respectively.

```
% specify the option information
Settle      = '15-Mar-2004';
Expiry      = '15-Jan-2005'; % 10 months from settlement
Strike      = 1000;
Sigma       = 0.09;
Convention  = [0 1]';

% specify the interest-rate environment
ZeroData    = [datenum('15-Jun-2004') 0.09 -1; % 3 months
               datenum('15-Dec-2004') 0.095 -1; % 9 months
               datenum(Expiry)        0.10 -1]; % 10 months

% specify the bond information
CleanPrice  = 935;
CouponRate  = 0.1;
Maturity    = '15-Dec-2013'; % 9.75 years from settlement
Face       = 1000;
BondData    = [CleanPrice CouponRate datenum(Maturity) Face];
Period     = 2;
Basis      = 1;

% call Black's model
CallPrices = bkcall(Strike, ZeroData, Sigma, BondData, Settle, ...
                   Expiry, Period, Basis, [], [], Convention)
```

```
CallPrices = 2x1
```

```
9.4873
```

```
7.9686
```

When the strike price is the dirty price (`Convention = 0`), the call option value is \$9.49. When the strike price is the clean price (`Convention = 1`), the call option value is \$7.97.

## bkcaplet

Price interest-rate caplet using Black model

---

**Note** `bkcaplet` has been removed. Use `capbyblk` instead.

---

### Syntax

`CapPrices = bkcaplet(CapData, FwdRates, ZeroPrice, Settle, StartDate, EndDate, Sigma)`

### Arguments

CapData	<p>Number of caps (NCAP)-by-2 matrix containing cap rates and bases: [CapRates Basis].</p> <p>Values for bases are:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
FwdRates	Scalar or NCAP-by-1 vector containing forward rates in decimal. <code>FwdRates</code> accrue on the same basis as <code>CapRates</code> .
ZeroPrice	Scalar or NCAP-by-1 vector containing zero coupon prices with maturities corresponding to those of each cap in <code>CapData</code> , per \$100 nominal value.
Settle	Scalar or NCAP-by-1 vector of identical elements containing settlement date of caplets.
StartDate	Scalar or NCAP-by-1 vector containing start dates of the caplets.
EndDate	Scalar or NCAP-by-1 vector containing maturity dates of caplets.

Sigma	Scalar or NCAP-by-1 vector containing volatility of forward rates in decimal, corresponding to each caplet.
-------	---

## Description

CapPrices =  
**bkcaplet**(CapData, FwdRates, ZeroPrice, Settle, StartDate, EndDate, Sigma) computes the prices of interest-rate caplets for every \$100 face value of principal.

## Examples

### Compute the Price of Interest-Rate Caplets for Every \$100 Face Value of Principal

This example shows how to compute the price of interest-rate caplets for every \$100 face value of principal. Given a notional amount of \$1,000,000, compute the value of a caplet on October 15, 2002 that starts on October 15, 2003 and ends on January 15, 2004.

```
CapData = [0.08, 1];
FwdRates = 0.07;
ZeroPrice = 100*exp(-0.065*1.25);
Settle = datenum('15-Oct-2002');
BeginDates = datenum('15-Oct-2003');
EndDates = datenum('15-Jan-2004');
Sigma = 0.20;

% because the caplet is $100 notional, divide $1,000,000 by $100
Notional = 1000000/100;

CapPrice = Notional*bkcaplet(CapData, FwdRates, ZeroPrice, ...
Settle, BeginDates, EndDates, Sigma)

Error using bkcaplet (line 117)
BKCAPLET has been removed. Use CAPBYBLK instead.
```

## bkfloorlet

Price interest-rate floorlet using Black model

---

**Note** `bkfloorlet` has been removed. Use `floorbyblk` instead.

---

### Syntax

FloorPrices = `bkfloorlet`(FloorData, FwdRates, ZeroPrice, Settle, StartDate, EndDate, Sigma)

### Arguments

FloorData	<p>Number of floors (NFLR)-by-2 matrix containing floor rates and bases: [FloorRate Basis].</p> <p>Values for bases are:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
FwdRates	Scalar or NFLR-by-1 vector containing forward rates in decimal. FwdRates accrue on the same basis as FloorRates.
ZeroPrice	Scalar or NFLR-by-1 vector containing zero coupon prices with maturities corresponding to those of each floor in FloorData, per \$100 nominal value.
Settle	Scalar or NFLR-by-1 vector of identical elements containing settlement date of floorlets.
StartDate	Scalar or NFLR-by-1 vector containing start dates of the floorlets.
EndDate	Scalar or NFLR-by-1 vector containing maturity dates of floorlets.

Sigma	Scalar or NFLR-by-1 vector containing volatility of forward rates in decimal, corresponding to each floorlet.
-------	---

## Description

FloorPrices =  
**bkfloorlet**(FloorData, FwdRates, ZeroPrice, Settle, StartDate, EndDate, Sigma)  
 computes the prices of interest-rate floorlets for every \$100 of notional value.

## Examples

### Price an Interest-Rate Floorlet For Every \$100 of Notional Value Using the Black Model

This example shows how to price an interest-rate floorlet for every \$100 of notional value using the Black model. Given a notional amount of \$1,000,000, compute the value of a floorlet on October 15, 2002 that starts on October 15, 2003 and ends on January 15, 2004.

```
FloorData = [0.08, 1];
FwdRates = 0.07;
ZeroPrice = 100*exp(-0.065*1.25);
Settle = datenum('15-Oct-2002');
BeginDates = datenum('15-Oct-2003');
EndDates = datenum('15-Jan-2004');
Sigma = 0.20;

% because floorlet is $100 notional, divide $1,000,000 by $100
Notional = 1000000/100;
```

```
FloorPrice = Notional*bkfloorlet(FloorData, FwdRates, ...
ZeroPrice, Settle, BeginDates, EndDates, Sigma)
```

```
Error using bkfloorlet (line 115)
BKFLOORLET has been removed. Use FLOORBYBLK instead.
```

## bkput

Price European put option on bonds using Black model

### Syntax

PutPrice = bkput(Strike, ZeroData, Sigma, BondData, Settle, Expiry, Period, Basis, EndMonthRule, InterpMe

### Arguments

Strike	Scalar or number of options (NOPT)-by-1 vector of strike prices.
ZeroData	Two-column (optionally three-column) matrix containing zero (spot) rate information used to discount future cash flows. <ul style="list-style-type: none"> <li>Column 1: Serial maturity date associated with the zero rate in the second column.</li> <li>Column 2: Annualized zero rates, in decimal form, appropriate for discounting cash flows occurring on the date specified in the first column. All dates must occur after <code>Settle</code> (dates must correspond to future investment horizons) and must be in ascending order.</li> <li>Column 3 (optional): Annual compounding frequency. Values are 1 (annual), 2 (semiannual, default), 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).</li> </ul>
Sigma	Scalar or NOPT-by-1 vector of annualized price volatilities required by Black's model.
BondData	Row vector with three (optionally four) columns or NOPT-by-3 (optionally NOPT-by-4) matrix specifying characteristics of underlying bonds in the form [CleanPrice CouponRate Maturity Face] where: <ul style="list-style-type: none"> <li>CleanPrice is the price excluding accrued interest.</li> <li>CouponRate is the decimal coupon rate.</li> <li>Maturity is the bond maturity date in serial date number format.</li> <li>Face is the face value of the bond. If unspecified, the face value is assumed to be 100.</li> </ul>
Settle	Settlement date of the options, specified using a serial date number or date character vector. <code>Settle</code> also represents the starting reference date for the input zero curve.
Expiry	Scalar or NOPT-by-1 vector of option maturity dates, specified using a serial date number or date character vector.
Period	(Optional) Number of coupons per year for the underlying bond. Default = 2 (semiannual). Supported values are 0, 1, 2, 3, 4, 6, and 12.

Basis	<p>(Optional) Day-count basis of the bond. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
EndMonthRule	<p>(Optional) End-of-month rule. This rule applies only when <code>Maturity</code> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
InterpMethod	<p>(Optional) Scalar integer zero curve interpolation method. For cash flows that do not fall on a date found in the <code>ZeroData</code> spot curve, indicates the method used to interpolate the appropriate zero discount rate. Available methods are (0) nearest, (1) linear, and (2) cubic. Default = 1. See <code>interp1</code> for more information.</p>
StrikeConvention	<p>(Optional) Scalar or NOPT-by-1 vector of option contract strike price conventions.</p> <p><code>StrikeConvention = 0</code> (default) defines the strike price as the cash (dirty) price paid for the underlying bond.</p> <p><code>StrikeConvention = 1</code> defines the strike price as the quoted (clean) price paid for the underlying bond. The accrued interest of the bond at option expiration is added to the input strike price when evaluating Black's model.</p>

## Description

`PutPrice = bkput(Strike, ZeroData, Sigma, BondData, Settle, Expiry, Period, Basis, EndMonthRule, InterpMethod, StrikeConvention)` using Black's model, derives an NOPT-by-1 vector of prices of European put options on bonds.

If cash flows occur beyond the dates spanned by `ZeroData`, the input zero curve, the appropriate zero rate for discounting such cash flows is obtained by extrapolating the nearest rate on the curve (that is, if a cash flow occurs before the first or after the last date on the input zero curve, a flat curve is assumed).

In addition, you can use the Financial Instruments Toolbox method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `bkput`. For more information, see “Converting an `IRDataCurve` or `IRFunctionCurve` Object” on page 9-33.

## Examples

### Price European Put Options On Bonds Using the Black Model

This example shows how to price European put options on bonds using the Black model. Consider a European put option on a bond maturing in 10 years. The underlying bond has a clean price of \$122.82, a face value of \$100, and pays 8% semiannual coupons. Also, assume that the annualized volatility of the forward bond yield is 20%. Furthermore, suppose the option expires in 2.25 years and has a strike price of \$115, and that the annualized continuously compounded risk free zero (spot) curve is flat at 5%. For a hypothetical settlement date of March 15, 2004, the following code illustrates the use of Black's model to duplicate the put prices in Example 22.2 of the Hull reference. In particular, it illustrates how to convert a broker's yield volatility to a price volatility suitable for Black's model.

```
% Specify the option information.
Settle      = '15-Mar-2004';
Expiry      = '15-Jun-2006'; % 2.25 years from settlement
Strike      = 115;
YieldSigma  = 0.2;
Convention  = [0; 1];

% Specify the interest-rate environment. Since the
% zero curve is flat, interpolation into the curve always returns
% 0.05. Thus, the following curve is not unique to the solution.
ZeroData    = [datenum('15-Jun-2004') 0.05 -1;
               datenum('15-Dec-2004') 0.05 -1;
               datenum(Expiry)        0.05 -1];

% Specify the bond information.
CleanPrice  = 122.82;
CouponRate  = 0.08;
Maturity    = '15-Mar-2014'; % 10 years from settlement
Face        = 100;
BondData    = [CleanPrice CouponRate datenum(Maturity) Face];
Period      = 2; % semiannual coupons
Basis       = 1; % 30/360 day-count basis

% Convert a broker's yield volatility quote to a price volatility
% required by Black's model. To duplicate Example 22.2 in Hull,
% first compute the periodic (semiannual) yield to maturity from
% the clean bond price.
Yield = bndyield(CleanPrice, CouponRate, Settle, Maturity,...
Period, Basis);
```

```

% Compute the duration of the bond at option expiration. Most
% fixed-income sensitivity analyses use the modified duration
% statistic to examine the impact of small changes in periodic
% yields on bond prices. However, Hull's example operates in
% continuous time (annualized instantaneous volatilities and
% continuously compounded zero yields for discounting coupons).
% To duplicate Hull's results, use the second output of BNDURY,
% the Macaulay duration.
[Modified, Macaulay] = bndury(Yield, CouponRate, Expiry,...
Maturity, Period, Basis);

% Convert the yield-to-maturity from a periodic to a
% continuous yield.
Yield = Period .* log(1 + Yield./Period);

% Convert the yield volatility to a price volatility via
% Hull's Equation 22.6 (page 514).
PriceSigma = Macaulay .* Yield .* YieldSigma;

% Finally, call Black's model.
PutPrices = bkput(Strike, ZeroData, PriceSigma, BondData,...
Settle, Expiry, Period, Basis, [], [], Convention)

PutPrices = 2x1

    1.7838
    2.4071

```

When the strike price is the dirty price (Convention = 0), the call option value is \$1.78. When the strike price is the clean price (Convention = 1), the call option value is \$2.41.

## bndfutimprepo

Implied repo rates for bond future given price

### Syntax

```
ImpRepo = bndfutimprepo(Price,FutSettle,FutPrice,Delivery,ConvFactor,  
CouponRate,Maturity)  
ImpRepo = bndfutimprepo( ____,Name,Value)
```

### Description

`ImpRepo = bndfutimprepo(Price,FutSettle,FutPrice,Delivery,ConvFactor,CouponRate,Maturity)` computes the implied repo rate for a bond future given the price of a bond, the bond properties, the price of the bond future, and the bond conversion factor. The default behavior is that the coupon reinvestment rate matches the repo rate. However, you can specify a separate reinvestment rate using optional inputs.

`ImpRepo = bndfutimprepo( ____,Name,Value)` specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Repo Rate For a Bond Future

This example shows how to compute the repo rate for a bond future using the following data.

```
bndfutimprepo(129,98,'9/21/2000','12/29/2000',1.3136,.0875,'8/15/2020')  
ans = 0.0584
```

### Input Arguments

#### Price — Bond prices

vector

Bond prices, specified as an `numBonds-by-1` vector in decimals.

Data Types: `double`

#### FutPrice — Future prices

vector

Future prices, specified as an `numBonds-by-1` vector.

Data Types: `double` | `cell`

#### FutSettle — Future settlement dates

vector

Future settlement dates, specified as an numBonds-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

### **Delivery — Future delivery dates**

vector

Future delivery dates, specified as an numBonds-by-1 vector.

Data Types: double | cell

### **ConvFactor — Bond conversion factors**

vector

Bond conversion factors, specified as an numBonds-by-1 vector. For more information, see `convfactor`.

Data Types: double

### **CouponRate — Coupon rates**

vector

Coupon rates, specified as an numBonds-by-1 vector of numeric decimals.

Data Types: double

### **Maturity — Maturity dates**

vector

Maturity dates, specified as an numBonds-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `ImpRepo =`

```
bndfutimprepo(Price, FutPrice, FutSettle, Delivery, ConvFactor, CouponRate, Maturity, 'Basis', 5, 'Face', 1000, 'Period', 4)
```

### **Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **EndMonthRule — End-of-month rule flag for generating floorlet dates**

1 (in effect) (default) | scalar of nonnegative integer [0, 1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar with a nonnegative integer [0, 1].

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

### **Face — Face value of the bond**

100 (default) | scalar numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar numeric. Face has no impact on key rate duration.

Data Types: `double`

### **FirstCouponDate — Irregular first coupon date**

if you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar date using a serial date number or a date character vector.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure.

Data Types: `double` | `char`

### **IssueDate — Bond issue date**

if you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar date using a serial date number or a date character vector.

Data Types: `double` | `char`

**LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar date using a serial date number or a date character vector.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Data Types: double | char

**Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a scalar integer. Values for Period are 0, 1, 2, 3, 4, 6, and 12.

Data Types: double

**ReinvestBasis — Day count basis for reinvestment rate**

identical to RepoBasis (default) | integer from 0 to 13

Day count basis for the reinvestment rate, specified as the comma-separated pair consisting of 'ReinvestBasis' and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**ReinvestRate — Underlying bond annual coupon**

scalar decimal numeric

Underlying bond annual coupon, specified as the comma-separated pair consisting of 'ReinvestRate' and a scalar decimal numeric.

Data Types: double

**RepoBasis — Day count basis for repo rate**

2 (actual/360) (default) | integer from 0 to 13

Day count basis for repo rate, specified as the comma-separated pair consisting of 'RepoBasis' and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**StartDate — Forward starting date of payments**

Settle date (default) | serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a scalar date using a serial date number or a date character vector.

Data Types: double

**Output Arguments****ImpRepo — Implied repo rate**

vector

Implied repo rate, or the repo rate that would produce the price input, returned as numBonds-by-1 vector.

## bndfutprice

Price bond future given repo rates

### Syntax

```
[FutPrice,AccrInt] = bndfutprice(RepoRatePrice,FutSettle,Delivery,ConvFactor,  
CouponRate,Maturity)  
[FutPrice,AccrInt] = bndfutprice( ____,Name,Value)
```

### Description

[FutPrice,AccrInt] = bndfutprice(RepoRatePrice,FutSettle,Delivery,ConvFactor,CouponRate,Maturity) computes the price of a bond futures contract for one or more bonds given a repo rate, and bond properties, including the bond conversion factor. The default behavior is that the coupon reinvestment rate matches the repo rate. However, you can specify a separate reinvestment rate using optional arguments.

[FutPrice,AccrInt] = bndfutprice( \_\_\_\_,Name,Value) specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Price For a Bond Future

This example shows how to compute the price for a bond future using the following data.

```
bndfutprice(.064, 129, '9/21/2000', '12/29/2000', 1.3136, .0875, '8/15/2020')  
ans = 98.1516
```

### Input Arguments

#### RepoRate — Repo rates

vector

Repo rates, specified as an numBonds-by-1 vector in decimals.

Data Types: double

#### Price — Bond prices

vector

Bond prices, specified as an numBonds-by-1 vector in decimals.

Data Types: double

#### FutSettle — Future settlement date

scalar

Future settlement date, specified as scalar date using a serial date number or a date character vectors.

Data Types: `double` | `char`

### **Delivery – Future delivery dates**

vector

Future delivery dates, specified as an `numBonds-by-1` vector.

Data Types: `double` | `cell`

### **ConvFactor – Bond conversion factors**

vector

Bond conversion factors, specified as an `numBonds-by-1` vector. For more information, see `convfactor`.

Data Types: `double`

### **CouponRate – Coupon rates**

vector

Coupon rates, specified as an `numBonds-by-1` vector of numeric decimals.

Data Types: `double`

### **Maturity – Maturity dates**

vector

Maturity dates, specified as an `numBonds-by-1` vector of serial date numbers or a cell array of character vectors.

Data Types: `double` | `cell`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[FutPrice, AccrInt] =`

```
bndfutprice(RepoRate, Price, FutSettle, Delivery, ConvFactor, CouponRate, Maturity,
' Basis', 5, 'Face', 1000, 'Period', 4)
```

### **Basis – Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **EndMonthRule — End-of-month rule flag for generating floorlet dates**

1 (in effect) (default) | scalar of nonnegative integer [0, 1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar with a nonnegative integer [0, 1].

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

### **IssueDate — Bond issue date**

if you do not specify an IssueDate, the cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar date using a serial date number or a date character vector.

Data Types: `double` | `char`

### **Face — Face value of the bond**

100 (default) | scalar numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar numeric. Face has no impact on key rate duration.

Data Types: `double`

### **FirstCouponDate — Irregular first coupon date**

if you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar date using a serial date number or a date character vector.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Data Types: `double` | `char`

**LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar date using a serial date number or a date character vector.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Data Types: double | char

**Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a scalar integer. Values for Period are 0, 1, 2, 3, 4, 6, and 12.

Data Types: double

**ReinvestBasis — Day count basis for reinvestment rate**

identical to RepoBasis (default) | integer from 0 to 13

Day count basis for the reinvestment rate, specified as the comma-separated pair consisting of 'ReinvestBasis' and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-129.

Data Types: double

**ReinvestRate — Underlying bond annual coupon**

scalar decimal numeric

Underlying bond annual coupon, specified as the comma-separated pair consisting of 'ReinvestRate' and a scalar decimal numeric.

Data Types: double

**RepoBasis — Day count basis for repo rate**

2 (actual/360) (default) | integer from 0 to 13

Day count basis for repo rate, specified as the comma-separated pair consisting of 'RepoBasis' and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**StartDate — Forward starting date of payments**

Settle date (default) | serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a scalar date using a serial date number or a date character vector.

Data Types: double

**Output Arguments****FutPrice — Quoted futures price, per \$100 notional**

vector

Quoted futures price, per \$100 notional, returned as numBonds-by-1 vector.

**AccrInt — Accrued interest due at delivery date, per \$100 notional**

vector

Accrued interest due at delivery date, per \$100 notional, returned as numBonds-by-1 vector.

## bootstrap

Bootstrap interest-rate curve from market data

### Class

@IRDataCurve on page A-7

### Syntax

```
Dcurve = IRDataCurve.bootstrap(Type,Settle,InstrumentTypes,Instruments)
```

```
Dcurve = IRDataCurve.bootstrap(Type,Settle,InstrumentTypes,Instruments,'Parameter1',Value1,'Parameter2',Value2)
```

### Arguments

Type	Type of interest-rate curve. Type refers to the type of data in the curve that is bootstrapped from the market instruments. Acceptable values are: <code>discount</code> , <code>forward</code> , or <code>zero</code> .  When using the <code>bootstrap</code> method, the choice of the <code>Type</code> parameter can impact the curve construction because it will affect the type of data that will be interpolated on (that is, forward rates, zero rates or discount factors) during the bootstrapping process. So curves that are bootstrapped using different <code>Type</code> parameters undergo different bootstrapping algorithms with different interpolation methods, and they can sometimes produce different results when using the “get” methods (for example, <code>getForwardRates</code> ).
Settle	Scalar or column vector of settlement dates.
InstrumentTypes	N-by-1 cell array (where N is the number of instruments) indicating what kind of instrument is in the <code>Instruments</code> matrix. Acceptable values are <code>deposit</code> , <code>futures</code> , <code>swap</code> , <code>bond</code> , and <code>fra</code> .

Instruments	<p>N-by-3 data matrix for Instruments where the first column is <code>Settle</code> date, the second column is <code>Maturity</code>, and the third column is the market quote (dates must be MATLAB date numbers). The market quote represents the following for each instrument:</p> <ul style="list-style-type: none"> <li>• <code>deposit</code>: rate</li> <li>• <code>futures</code>: price (e.g., 9628.54)</li> <li>• <code>swap</code>: rate</li> <li>• <code>bond</code>: clean price</li> <li>• <code>fra</code>: forward rate</li> </ul> <hr/> <p><b>Note</b> Instruments input for <code>fra</code> and for <code>futures</code> are different. Specifically, the forward rate underlying a <code>fra</code> starts on the start date (column 1 of Instruments) and ends on the end date (column 2 of Instruments). While the forward rate underlying a <code>futures</code> contract starts on the maturity date of the <code>futures</code> contract and ends on a date <math>n</math> months after the <code>futures</code> maturity, where <math>n</math> is the periodicity of the <code>futures</code> contract.</p>
Compounding	<p>(Optional) Scalar that sets the compounding frequency per year for an <code>IRDataCurve</code> object:</p> <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 0 = Simple interest (no compounding) for “zero” and “discount” curve types only, not supported for “forward” curves</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding (default)</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>

Basis	<p>(Optional) Day-count basis of the interest-rate curve. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
InterpMethod	<p>(Optional) Values are:</p> <ul style="list-style-type: none"> <li>• 'linear' — Linear interpolation (default).</li> <li>• 'constant' — Piecewise constant interpolation.</li> <li>• 'pchip' — Piecewise cubic Hermite interpolation.</li> <li>• 'spline' — Cubic spline interpolation.</li> </ul>
IRBootstrapOptionsObj	(Optional) An IRBootstrapOptions object.
DiscountCurve	(Optional) RateSpec for a curve used to discount the cash flows.

## Instrument Parameters

For each bond Instrument, you can specify the following additional instrument parameters as parameter/value pairs. For example, InstrumentBasis distinguishes a bond instrument's Basis value from the curve's Basis value. For instruments of type deposit, futures, or swap the Basis and Compounding values must be identical for each instance of the instrument.

InstrumentCouponRate	(Optional) Decimal number indicating the annual percentage rate used to determine the coupons payable on an instrument.
InstrumentPeriod	(Optional) Coupons per year of the instrument. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.

InstrumentBasis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
InstrumentEndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that an instrument's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that an instrument's coupon payment date is always the last actual day of the month.</p>
InstrumentIssueDate	<p>(Optional) Date when an instrument was issued.</p>
InstrumentFirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentLastCouponDate	<p>(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b>, a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b>, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentFace	<p>(Optional) Face or par value. Default = 100.</p>

**Note** When using **Instrument** parameter/value pairs, you can specify simple interest for an **Instrument** by specifying the **InstrumentPeriod** value as 0. If **InstrumentBasis** and **InstrumentPeriod** are not specified for an **Instrument**, the following default values are used:

- deposit instrument uses InstrumentBasis as 2 (act/360) and InstrumentPeriod is 0 (simple interest).
- futures instrument uses InstrumentBasis as 2 (act/360) and InstrumentPeriod is 4 (quarterly).
- swap instrument uses InstrumentBasis as 2 (act/360) and InstrumentPeriod is 2.
- bond instrument uses InstrumentBasis as 0 (act/act) and InstrumentPeriod is 2.
- FRA instrument uses InstrumentBasis as 2 (act/360) and InstrumentPeriod is 4 (quarterly).

## Description

Dcurve = IRDataCurve.bootstrap(Type, Settle, InstrumentTypes, Instruments, 'Parameter1', Value1, 'Parameter2', Value2, ...) bootstraps an interest-rate curve from market data. The dates of the bootstrapped curve correspond to the maturity dates of the input instruments. You must enter the optional arguments for Basis, Compounding, Interpmethod, IRBootstrapOptionsObj, and DiscountCurve as parameter/value pairs.

## Examples

### Use the bootstrap Method to Create an IRDataCurve Object

In this bootstrapping example, InstrumentTypes, Instruments, and a Settle date are defined:

```
InstrumentTypes = {'Deposit';'Deposit';...
'Futures';'Futures';'Futures';'Futures';'Futures';'Futures';...
'Swap';'Swap';'Swap';'Swap'};

Instruments = [datenum('08/10/2007'),datenum('09/17/2007'),.0532000; ...
datenum('08/10/2007'),datenum('11/17/2007'),.0535866; ...
datenum('08/08/2007'),datenum('19-Dec-2007'),9485; ...
datenum('08/08/2007'),datenum('19-Mar-2008'),9502; ...
datenum('08/08/2007'),datenum('18-Jun-2008'),9509.5; ...
datenum('08/08/2007'),datenum('17-Sep-2008'),9509; ...
datenum('08/08/2007'),datenum('17-Dec-2008'),9505.5; ...
datenum('08/08/2007'),datenum('18-Mar-2009'),9501; ...
datenum('08/08/2007'),datenum('08/08/2014'),.0530; ...
datenum('08/08/2007'),datenum('08/08/2019'),.0551; ...
datenum('08/08/2007'),datenum('08/08/2027'),.0565; ...
datenum('08/08/2007'),datenum('08/08/2037'),.0566];
```

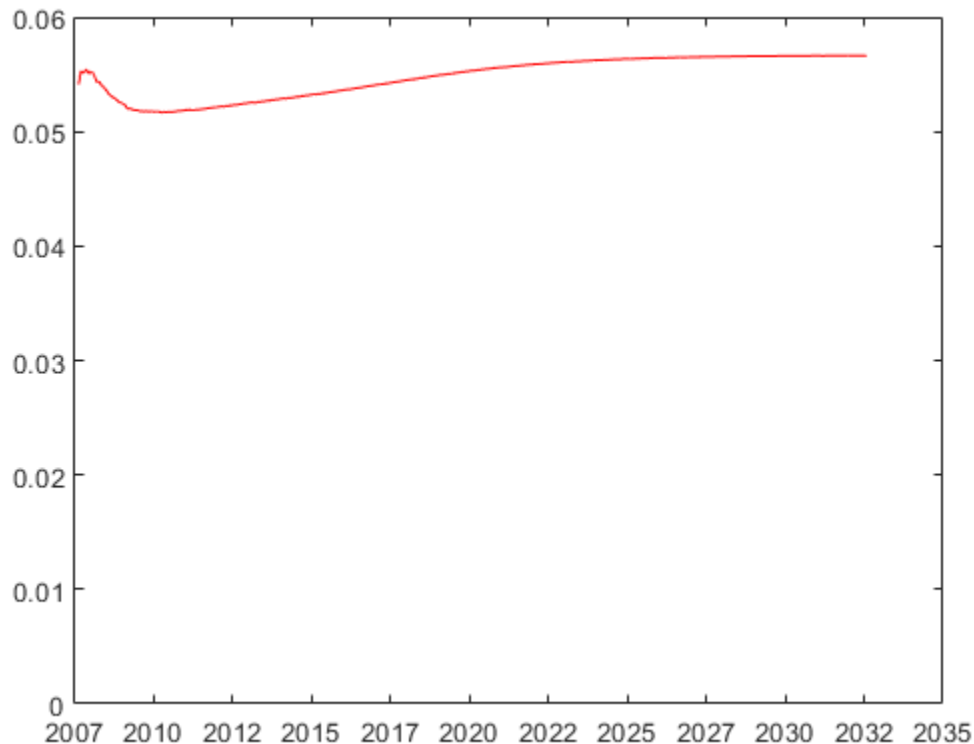

```
CurveSettle = datenum('08/10/2007');
```

Use the bootstrap method to create an IRDataCurve object.

```
bootModel = IRDataCurve.bootstrap('Forward', CurveSettle, ...
InstrumentTypes, Instruments,'InterpMethod','pchip');
```

To create the plot for the bootstrapped market data:

```
PlottingDates = (datenum('08/11/2007'):30:CurveSettle+365*25)';
plot(PlottingDates, getParYields(bootModel, PlottingDates),'r')
ylim([0 .06])
datetick
```

### Use the bootstrap Method to Create an IRDataCurve Object That Includes Bonds

In this bootstrapping example, InstrumentTypes, Instruments, and a Settle date are defined:

```
CurveSettle = datenum('8-Mar-2010');
```

```
InstrumentTypes = {'Deposit'; 'Deposit'; 'Deposit'; 'Deposit'; ...  
                  'Futures'; 'Futures'; 'Futures'; 'Futures'; 'Swap'; 'Swap'; 'Bond'; 'Bond'};
```

```
Instruments = [datenum('8-Mar-2010'), datenum('8-Apr-2010'), .003; ...  
              datenum('8-Mar-2010'), datenum('8-Jun-2010'), .005; ...  
              datenum('8-Mar-2010'), datenum('8-Sep-2010'), .007; ...  
              datenum('8-Mar-2010'), datenum('8-Mar-2011'), .009; ...  
              datenum('8-Mar-2010'), datenum('18-Jun-2011'), 9840; ...  
              datenum('8-Mar-2010'), datenum('17-Sep-2011'), 9820; ...  
              datenum('8-Mar-2010'), datenum('17-Dec-2011'), 9810; ...  
              datenum('8-Mar-2010'), datenum('18-Mar-2012'), 9800; ...  
              datenum('8-Mar-2010'), datenum('8-Mar-2015'), .025; ...  
              datenum('8-Mar-2010'), datenum('8-Mar-2020'), .035; ...  
              datenum('8-Mar-2010'), datenum('8-Mar-2030'), 99; ...  
              datenum('8-Mar-2010'), datenum('8-Mar-2040'), 101];
```

When bonds are used, InstrumentCouponRate must be specified:

```
InstrumentCouponRate = [zeros(10,1); .045; .05];
```

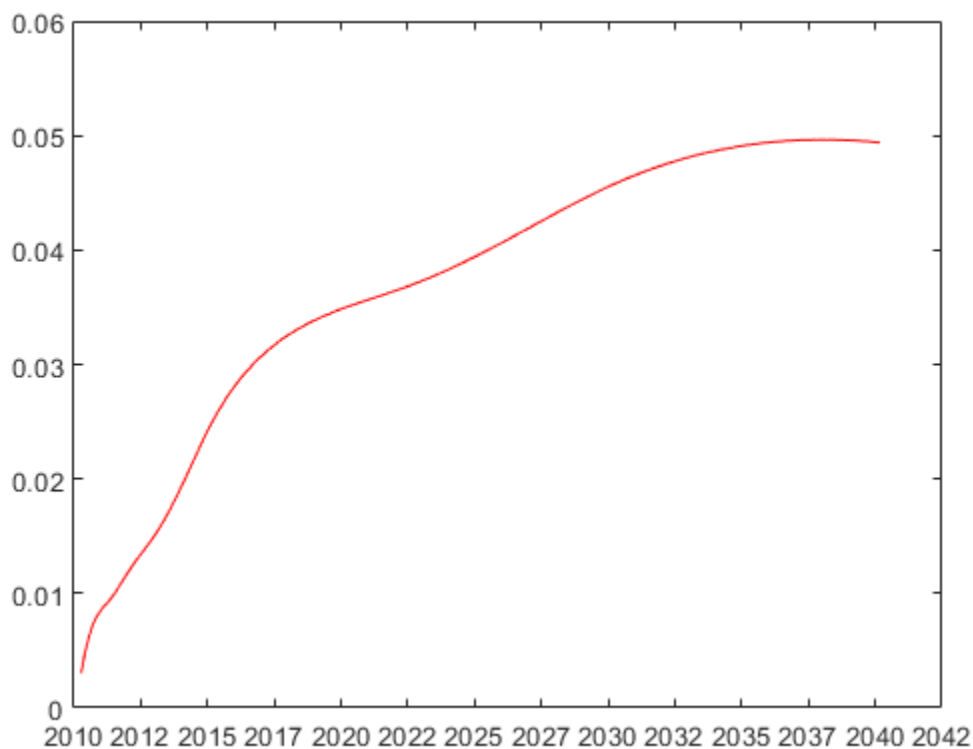

Note, for parameters that are only applicable to bonds (`InstrumentFirstCouponDate`, `InstrumentLastCouponDate`, `InstrumentIssueDate`, `InstrumentFace`) the entries for non-bond instruments (deposits and futures) are ignored.

Use the `bootstrap` method to create an `IRDataCurve` object.

```
bootModel = IRDataCurve.bootstrap('Forward', CurveSettle, ...
InstrumentTypes, Instruments, 'InterpMethod', 'pchip', ...
'InstrumentCouponRate', InstrumentCouponRate);
```

Create the plot for the bootstrapped market data.

```
PlottingDates = datemnth(CurveSettle, 1:30*12);
plot(PlottingDates, getParYields(bootModel, PlottingDates), 'r')
ylim([0 .06])
datetick
```

### Use `IRBootstrapOptionsObj` with `bootstrap` for Negative Zero Interest-Rates

Use the `IRBootstrapOptionsObj` optional argument with the `bootstrap` method to allow for negative zero rates when solving for the swap zero points.

```
Settle = datenum('15-Mar-2015');
InstrumentTypes = {'Deposit'; 'Deposit'; 'Swap'; 'Swap'; 'Swap'; 'Swap'};
```

```

Instruments = [Settle,datenum('15-Jun-2015'),.001; ...
Settle,datenum('15-Dec-2015'),.0005; ...
Settle,datenum('15-Mar-2016'),-.001; ...
Settle,datenum('15-Mar-2017'),-0.0005; ...
Settle,datenum('15-Mar-2018'),.0017; ...
Settle,datenum('15-Mar-2020'),.0019];

irbo = IRBootstrapOptions('LowerBound',-1);

bootModel = IRDataCurve.bootstrap('zero', Settle, InstrumentTypes,...
    Instruments,'IRBootstrapOptions',irbo);

bootModel.getZeroRates(datemnth(Settle,1:60))

ans = 60x1

    0.0012
    0.0011
    0.0010
    0.0009
    0.0008
    0.0008
    0.0007
    0.0006
    0.0005
   -0.0000
    :

```

Note that optional argument for `LowerBound` is set to `-1` for negative zero rates when solving the swap zero points.

## Introduced in R2008b

## **cdsoptprice**

Price payer and receiver credit default swap options

### **Syntax**

```
[Payer,Receiver] =  
cdsoptprice(ZeroData,ProbData,Settle,OptionMaturity,CDSMaturity,Strike,Spread  
Vol)  
[Payer,Receiver] =  
cdsoptprice(ZeroData,ProbData,Settle,OptionMaturity,CDSMaturity,Strike,Spread  
Vol,Name,Value)
```

### **Description**

[Payer,Receiver] =  
cdsoptprice(ZeroData,ProbData,Settle,OptionMaturity,CDSMaturity,Strike,Spread  
Vol) computes the price of payer and receiver credit default swap options.

[Payer,Receiver] =  
cdsoptprice(ZeroData,ProbData,Settle,OptionMaturity,CDSMaturity,Strike,Spread  
Vol,Name,Value) computes the price of payer and receiver credit default swap options with  
additional options specified by one or more Name,Value pair arguments.

### **Input Arguments**

#### **ZeroData**

M-by-2 vector of dates and zero rates or an `IRDataCurve` object of zero rates. For more information on an `IRDataCurve` object, see “Creating an `IRDataCurve` Object” on page 9-6.

#### **ProbData**

P-by-2 array of dates and default probabilities.

#### **Settle**

Settlement date is a serial date number or date character vector. `Settle` must be earlier than the maturity date.

#### **OptionMaturity**

N-by-1 vector of serial date numbers or date character vectors containing the option maturity dates.

#### **CDSMaturity**

N-by-1 vector of serial date numbers or date character vectors containing the CDS maturity dates.

#### **Strike**

N-by-1 vector of option strikes expressed in basis points.

**SpreadVol**

N-by-1 vector of annualized credit spread volatilities expressed as a positive decimal number.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1, Value1, . . . , NameN, ValueN**.

---

**Note** Any optional input of size N-by-1 is also acceptable as an array of size 1-by-N, or as a single value applicable to all contracts. Single values are internally expanded to an array of size N-by-1.

---

**AdjustedForwardSpread**

N-by-1 vector of adjusted forward spreads (in basis points) to be used when pricing CDS index options.

**Default:** unadjusted forward spread normally used for single-name CDS options

**Basis**

N-by-1 vector of contract day-count basis:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

**Default:** 2 (actual/360)

**BusDayConvention**

Business day conventions, specified by a character vector or N-by-1 cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- **actual** — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- **follow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- **modifiedfollow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- **previous** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- **modifiedprevious** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

**Default:** actual

### **Knockout**

N-by-1 vector of Boolean flags. If the credit default swaptions is a knockout, the flag is `True`, otherwise it is `False`.

**Default:** False

### **PayAccruedPremium**

N-by-1 vector of Boolean flags. If accrued premiums are paid upon default, the flag is `True`, otherwise it is `False`.

**Default:** True

### **Period**

N-by-1 vector of the number of premiums per year of the CDS. Allowed values are 1, 2, 3, 4, 6, and 12.

**Default:** 4

### **RecoveryRate**

N-by-1 vector of recovery rates, expressed as a decimal from 0 to 1.

**Default:** 0.4

### **ZeroBasis**

Basis of the zero curve. Choices are identical to `Basis`.

**Default:** 0 (actual/actual)

### **ZeroCompounding**

Compounding frequency of the zero curve. Allowed values are:

- 1 — Annual compounding
- 2 — Semiannual compounding

- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

---

**Note** When `ZeroData` is an `IRDataCurve` object, the arguments `ZeroCompounding` and `ZeroBasis` are implicit in `ZeroData` and are redundant inside this function. In that case, specify these optional arguments when constructing the `IRDataCurve` object before calling this function.

---

**Default:** 2 (Semiannual compounding)

## Output Arguments

### Payer

N-by-1 vector of prices for payer swap options in `Basis` points.

### Receiver

N-by-1 vector of prices for receiver swap options in `Basis` points.

## Examples

### Obtain Payer and Receiver Values for a Credit Default Swap Option

Use `cdsoptprice` to generate Payer and Receiver values for a credit default swap option.

```
Settle = datenum('12-Jun-2012');
OptionMaturity = datenum('20-Sep-2012');
CDSMaturity = datenum('20-Sep-2017');
OptionStrike = 200;
SpreadVolatility = .4;

Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [.5 .75 1.5 1.7 1.9 2.2]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];

Market_Time = [1 2 3 5 7 10]';
Market_Rate = [100 120 145 220 245 270]';
Market_Dates = daysadd(Settle,360*Market_Time,1);
MarketData = [Market_Dates Market_Rate];

ProbData = cdsbootstrap(ZeroData, MarketData, Settle);

[Payer,Receiver] = cdsoptprice(ZeroData, ProbData, Settle,...
OptionMaturity, CDSMaturity, OptionStrike, SpreadVolatility)

Payer = 223.5780
Receiver = 22.7460
```

## More About

### Credit Default Swap Option

A credit default swap (CDS) option, or credit default swaption, is a contract that provides the option holder with the right, but not the obligation, to enter into a credit default swap in the future.

CDS options can either be payer swaptions or receiver swaptions. In a payer swaption, the option holder has the right to enter into a CDS in which they are paying premiums and in a receiver swaption, the option holder is receiving premiums.

### Algorithms

The payer and receiver credit default swap options are computed using the Black's model as described in O'Kane [1]:

$$V_{Pay(Knockout)} = RPV01(t, t_E, T)(F\Phi(d_1) - K\Phi(d_2))$$

$$V_{Rec(Knockout)} = RPV01(t, t_E, T)(K\Phi(-d_2) - F\Phi(-d_1))$$

$$d_1 = \frac{\ln\left(\frac{F}{K}\right) + \frac{1}{2}\sigma^2(t_E - t)}{\sigma\sqrt{t_E - t}}$$

$$d_2 = d_1 - \sigma\sqrt{t_E - t}$$

$$V_{Pay(Non - Knockout)} = V_{Pay(Knockout)} + FEP$$

$$V_{Pay(Non - Knockout)} = V_{Rec(Knockout)}$$

where

$RPV01$  is the risky present value of a basis point (see `cdsrpv01`).

$\Phi$  is the normal cumulative distribution function.

$\sigma$  is the spread volatility.

$t$  is the valuation date.

$t_E$  is the option expiry date.

$T$  is the CDS maturity date.

$F$  is the forward spread (from option expiry to CDS maturity).

$K$  is the strike spread.

$FEP$  is the front-end protection (from option initiation to option expiry).

## cmosched

Generate principal balance schedule for planned amortization class (PAC) or targeted amortization class (TAC) bond

### Syntax

```
[BalanceSchedule,InitialBalance] = cmosched(Principal,Coupon,OriginalTerm,
TermRemaining,PrepaySpeed)
[BalanceSchedule,InitialBalance] = cmosched( ____,TranchePrincipal)
```

### Description

[BalanceSchedule,InitialBalance] = cmosched(Principal,Coupon,OriginalTerm,TermRemaining,PrepaySpeed) generates a principal balance schedule for planned amortization class (PAC) bonds using two bands of Public Securities Association Prepayment Model (PSA) speeds or targeted amortization class (TAC) bonds using a single PSA speed.

[BalanceSchedule,InitialBalance] = cmosched( \_\_\_\_,TranchePrincipal) adds an optional argument for TranchePrincipal.

### Examples

#### Calculate the Principal Balance Schedule for a CMO PAC Bond

Define the mortgage pool under consideration and generate a principal balance schedule for planned amortization class (PAC) bonds using two bands of PSA speeds.

```
Principal = 128687000;
GrossRate = 0.0648;
OriginalTerm = 360;
TermRemaining = 325;
PrepaySpeed = [300 525];
PacPrincipal = 100250000;
```

```
[BalanceSchedule, InitialBalance] ...
= cmosched(Principal, GrossRate, OriginalTerm, TermRemaining, ...
PrepaySpeed, PacPrincipal)
```

```
BalanceSchedule = 1×325
107 ×
```

```
    9.7996    9.5780    9.3602    9.1461    8.9357    8.7289    8.5257    8.3259    8.1296    7.9
```

```
InitialBalance = 100250000
```

## Input Arguments

### **Principal** — Principal of the underlying mortgage pool

numeric

Principal of the underlying mortgage pool, specified as a scalar numeric value.

Data Types: double

### **Coupon** — Coupon rate of the underlying mortgage pool

decimal

Coupon rate of the underlying mortgage pool, specified as a scalar decimal value.

Data Types: double

### **OriginalTerm** — Original term in months of the underlying mortgage pool

numeric

Original term in months of the underlying mortgage pool, specified as a scalar numeric value.

Data Types: double

### **TermRemaining** — Terms remaining in months of the underlying mortgage pool

numeric

Terms remaining in months of the underlying mortgage pool, specified as a scalar numeric value.

Data Types: double

### **PrepaySpeed** — PSA speed

matrix numeric | scalar numeric

PSA speed is specified as follows:

- For planned amortization class (PAC) bonds, PSA speed is specified as a 1-by-2 matrix, where the first element is the lower band and the second element is the upper band.
- For targeted amortization class (TAC) bonds, the PSA speed is specified as a scalar numeric value

Data Types: double

### **TranchePrincipal** — Principal of the scheduled tranche

numeric

(Optional) Principal of the scheduled tranche, specified as a scalar numeric value. If `TranchePrincipal` is unspecified or empty `[]`, the principal of the scheduled tranche is assumed to be the sum of the payment schedule calculated from the PSA prepayment speeds.

Data Types: double

## Output Arguments

### **BalanceSchedule** — Number of terms remaining

matrix

Number of terms remaining, returned as a matrix of size 1-by-`NUMTERMS`, where `NUMTERMS` is the number of terms remaining. Each column contains the scheduled principal balance for the time period corresponding to the column number.

**InitialBalance — Initial principal balance of the scheduled tranche**

scalar

initial principal balance of the scheduled tranche, returned as a scalar numeric value.

**More About****Planned Amortization Class (PAC) Bond**

PAC bonds are a type of CMO bond and are designed to largely eliminate prepayment risk for investors.

They do this by transferring essentially all prepayment risk to other bonds in the CMO that are called support bonds.

**Targeted Amortization Class (TAC) Bond**

TAC bonds are analogous to PAC bonds, but are structured differently.

TAC bonds offer one-sided protection, shielding investors from high prepayment rates up to a specified PSA and do not protect against low prepayment rates.

## cmoschedcf

Generate cash flows for scheduled collateralized mortgage obligation (CMO) using PAC or TAC model

### Syntax

```
[Balance,Principal,Interest] = cmoschedcf(PrincipalPayments,TranchePrincipals
TrancheCoupons,BalanceSchedule)
```

### Description

[Balance,Principal,Interest] = cmoschedcf(PrincipalPayments,TranchePrincipals TrancheCoupons,BalanceSchedule) generates cash flows for a scheduled CMO, such as the planned amortization class (PAC) or targeted amortization class (TAC), given the underlying mortgage pool payments (or payments from another CMO tranche). The output **Balance**, **Principal**, and **Interest** from this function can be used as input into **cmoseqcf** to further divide the PAC, TAC, or support dividing a tranche into sequential tranches.

### Examples

#### Calculate Cash Flows for Each PAC Tranche

Define the mortgage pool under consideration for CMO structuring using **mbscfamounts** or **mbspassthrough**. Calculate the underlying mortgage cash flow, define the PAC schedule and CMO tranches, and calculate the cash flows for each tranche.

```
MortgagePrincipal = 1000000; % underlying mortgage
Coupon = 0.12;
Terms = 6; % months

[PrincipalBalance, MonthlyPayments, SchedPrincipalPayments, ...
InterestPayments, Prepayments] = ...
mbspassthrough(MortgagePrincipal, Coupon, Terms, Terms, 0, []);
PrincipalPayments = SchedPrincipalPayments.' + Prepayments.'

PrincipalPayments = 1x6
105 ×

    1.6255    1.6417    1.6582    1.6747    1.6915    1.7084
```

Calculate the PAC schedule for CMO using **cmosched**.

```
PrepaySpeed = [100 300];
[BalanceSchedule, InitialBalance] ...
= cmosched(MortgagePrincipal, Coupon, Terms, Terms, PrepaySpeed, [])

BalanceSchedule = 1x6
105 ×

    8.3617    6.7180    5.0581    3.3828    1.6955    0
```

```
InitialBalance = 9.9886e+05
```

Define CMO tranches.

```
TranchePrincipals = ...
[InitialBalance; MortgagePrincipal-InitialBalance];
TrancheCoupons = [0.12; 0.12];
```

Calculate cash flows for each tranche.

```
[Balance, Principal, Interest] = ...
cmoschedcf(PrincipalPayments, TranchePrincipals, ...
TrancheCoupons, BalanceSchedule)
```

```
Balance = 2×6
105 ×
```

8.3631	6.7213	5.0632	3.3885	1.6970	0
0.0114	0.0114	0.0114	0.0114	0.0114	0.0000

```
Principal = 2×6
105 ×
```

1.6255	1.6417	1.6582	1.6747	1.6915	1.6970
0	0	0	0	0	0.0114

```
Interest = 2×6
103 ×
```

9.9886	8.3631	6.7213	5.0632	3.3885	1.6970
0.0114	0.0114	0.0114	0.0114	0.0114	0.0114

## Input Arguments

### PrincipalPayments — Number of terms remaining for underlying principal payments

numeric matrix

Number of terms remaining for underlying principal payments, specified as a matrix of size 1-by-NUMTERMS, where NUMTERMS is the number of terms remaining. Each column contains the underlying principal payment for the time period corresponding to the row number. Calculate underlying principal payments using `mbscfamounts` or `mbspassthrough`. The underlying principal payments can also be outputs from other CMO cash flow functions.

Data Types: double

### TranchePrincipals — Initial principal for the scheduled and the support tranche

numeric matrix

Initial principal for the scheduled and the support tranche, specified as a matrix of size 2-by-1.

Data Types: double

### TrancheCoupons — Coupons for the schedule tranche and the support tranche

matrix of coupon values

Coupons for the schedule tranche and the support tranche, specified as a matrix of size 2-by-1 of coupon values. The weighted average coupon for the CMO should not exceed the coupon of the underlying mortgage.

Data Types: double

### **BalanceSchedule — Number of terms remaining for targeted balance**

numeric matrix

Number of terms remaining for targeted balance, specified as a matrix of size 1-by-NUMTERMS, where NUMTERMS is the number of terms remaining. Each element represents the targeted balance schedule for the time period corresponding to that column.

Data Types: double

## **Output Arguments**

### **Balance — Number of terms remaining and principal balances**

matrix

Number of terms remaining and principal balances, returned as a matrix of size 2-by-NUMTERMS, where NUMTERMS is the number of terms remaining. The first row is the principal balances of the scheduled tranche, and the second row is the principal balances of the support tranche at the time period corresponding to the column.

### **Principal — Number of terms remaining and principal payments**

matrix

Number of terms remaining and principal payments, returned as a matrix of size 2-by-NUMTERMS, where NUMTERMS is the number of terms remaining. The first row is the principal payments of the scheduled tranche, and the second row is the principal payments of the support tranche at the time period corresponding to the column.

### **Interest — Number of terms remaining and interest payments**

scalar

Number of terms remaining and interest payments, returned as a matrix of size 2-by-NUMTERMS, where NUMTERMS is the number of terms remaining. The first row is the interest payments of the schedule tranche, and the second row is the interest payments of the support tranche at the time period corresponding to the column.

## **More About**

### **Planned Amortization Class (PAC) Tranches**

In a PAC CMO, there is a main tranche, known as the schedule tranche, and a support tranche.

The main purpose of a schedule tranche is to give investors in the PAC tranche a more certain cash flow.

### **Targeted Amortization Class (TAC) Tranches**

TACs are like PACs, but principal payment is specified for only one prepayment rate.

If prepayment rates are higher or lower, then the principal payment to TAC holders are higher or lower accordingly.

### **Schedule and Support Tranche**

The main purpose of a PAC tranche is to give investors in the PAC tranche a more certain cash flow.

The PAC tranche receives priority for receiving payments of principal and interest that gives investors in the PAC tranche a steadier income. If prepayments differ from what was expected, then the support tranche gets the variable portion of the payments. While income to the support tranche is more variable, it is also higher yielding. Estimates of the yield, average life, and lockout periods of the PAC tranche is more certain.

## cmoseqcf

Generate cash flows for sequential collateralized mortgage obligation (CMO)

### Syntax

```
[Balance,Principal,Interest] = cmoseqcf(PrincipalPayments,TranchePrincipals
TrancheCoupons)
[Balance,Principal,Interest] = cmoseqcf( ____,HasZ)
```

### Description

[Balance,Principal,Interest] = cmoseqcf(PrincipalPayments,TranchePrincipals TrancheCoupons) generates cash flows for a sequential CMO without a Z-bond, given the underlying mortgage pool payments.

[Balance,Principal,Interest] = cmoseqcf( \_\_\_\_,HasZ) generates cash flows for a sequential CMO with a Z-bond, given the underlying mortgage pool payments, by adding an additional optional input for HasZ.

### Examples

#### Calculate Cash Flows for a Sequential Collateralized Mortgage Obligation (CMO)

Define the mortgage pool under consideration for CMO structuring using mbscfamounts or mbspassthrough and calculate the cash flows with an A and B tranche for a sequential CMO.

```
MortgagePrincipal = 1000000;
Coupon = 0.12;
Terms = 6; % months

% Calculate underlying mortgage cash flows
[PrincipalBalance, MonthlyPayments, SchedPrincipalPayments, ...
InterestPayments, Prepayments] = ...
mbspassthrough(MortgagePrincipal, Coupon, Terms, Terms, 0, []);
PrincipalPayments = SchedPrincipalPayments.' + Prepayments.'

PrincipalPayments = 1x6
105 ×

    1.6255    1.6417    1.6582    1.6747    1.6915    1.7084
```

Define CMO tranches, A and B.

```
TranchePrincipals = [500000; 500000];
TrancheCoupons = [0.12; 0.12];
```

Calculate cash flows for each tranche.

```
[Balance, Principal, Interest] = ...
cmoseqcf(PrincipalPayments, TranchePrincipals, TrancheCoupons, false)
```

Balance = 2×6  
10<sup>5</sup> ×

3.3745	1.7328	0.0746	0	0	0
5.0000	5.0000	5.0000	3.3999	1.7084	0.0000

Principal = 2×6  
10<sup>5</sup> ×

1.6255	1.6417	1.6582	0.0746	0	0
0	0	0	1.6001	1.6915	1.7084

Interest = 2×6  
10<sup>3</sup> ×

5.0000	3.3745	1.7328	0.0746	0	0
5.0000	5.0000	5.0000	5.0000	3.3999	1.7084

## Input Arguments

### PrincipalPayments — Number of terms remaining for underlying principal payments

numeric matrix

Number of terms remaining for underlying principal payments, specified as a matrix of size 1-by-`NUMTERMS`, where `NUMTERMS` is the number of terms remaining. Each column contains the underlying principal payment for the time period corresponding to the row number. Calculate underlying principal payments using `mbscfamounts` or `mbspassthrough`. The underlying principal payments can also be outputs from other CMO cash flow functions.

Data Types: double

### TranchePrincipals — Initial principal for each tranche

numeric matrix

Initial principal for each tranche, specified as a matrix of size `NUMTRANCHES`-by-1, where `NUMTRANCHES` is the number of tranches in the sequential CMO. Each element of the matrix represents the initial principal for each tranche. If the sequential CMO includes a Z-bond (`HasZ` is `true`), the last element of this matrix is the principal of the Z-bond.

Data Types: double

### TrancheCoupons — Coupon for each tranche

matrix of coupon values

Coupon for each tranche, specified as a matrix of size `NUMTRANCHES`-by-1, where `NUMTRANCHES` is the number of tranches in the sequential CMO. Each element of the matrix represents the coupon for each tranche. If the sequential CMO includes a Z-bond (`HasZ` is `true`), the last element of this matrix is the coupon of the Z-bond. The weighted average coupon for the CMO should not exceed the coupon of the underlying mortgage.

Data Types: double

**HasZ — Indicates that the sequential CMO contains a Z-bond**

false (default) | true | false

(Optional) Indicates that the sequential CMO contains a Z-bond, specified as a Boolean (`true` or `false`). A value of `true` indicates that the sequential CMO contains a Z-bond, and the last element of `TranchePrincipals` and `TrancheCoupons` is treated as that of the Z-bond. A value of `false` indicates that there is no Z-bond in the sequential CMO, and the last element of `TranchePrincipals` and `TrancheCoupons` is treated as an ordinary tranche.

Data Types: `logical`**Output Arguments****Balance — Principal balance for time period and tranche**

matrix

Principal balance for time period and tranche, returned as a matrix of size `NUMTRANCHES`-by-`NUMTERMS`, where `NUMTRANCHES` is the number of terms remaining and `NUMTRANCHES` is the number of tranches. Each element represents the principal balance at the time period corresponding to the column, and for the tranche corresponding to the row.

**Principal — Principal payments for time period and tranche**

matrix

Principal payments for time period and tranche, returned as a matrix of size `NUMTRANCHES`-by-`NUMTERMS`, where `NUMTRANCHES` is the number of terms remaining and `NUMTRANCHES` is the number of tranches. Each element represents the principal payments made at the time period corresponding to the column, and to the tranche corresponding to the row.

**Interest — Interest payments for time period and tranche**

matrix

Interest payments for time period and tranche, returned as a matrix of size `NUMTRANCHES`-by-`NUMTERMS`, where `NUMTRANCHES` is the number of terms remaining and `NUMTRANCHES` is the number of tranches. Each element represents the interest payments made at the time period corresponding to the column, and to the tranche corresponding to the row.

**More About****Sequential Pay CMO**

A sequential pay CMO involves tranches that pay off principal sequentially.

For example, consider the following case, where all principal from the underlying mortgage pool is repaid on tranche A first, then tranche B, then tranche C. Interest is paid on each tranche as long as the principal for the tranche has not been retired.

**CMO Tranche**

Tranche is a term often used to describe a specific class of bonds within an offering wherein each tranche offers varying degrees of risk to the investor.

## Introduced in R2012a

# convfactor

Bond conversion factors

## Syntax

```
CF = convfactor(RefDate,Maturity,CouponRate)
CF = convfactor( ____,Name,Value)
```

## Description

CF = convfactor(RefDate,Maturity,CouponRate) computes a conversion factor for a bond futures contract.

CF = convfactor( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Conversion Factors For a Bond Futures Contract

This example shows how to calculate CF, given the following RefDate, Maturity, and CouponRate.

```
RefDate = {'1-Dec-2002';
           '1-Mar-2003';
           '1-Jun-2003';
           '1-Sep-2003';
           '1-Dec-2003';
           '1-Sep-2003';
           '1-Dec-2002';
           '1-Jun-2003'};
```

```
Maturity = {'15-Nov-2012';
            '15-Aug-2012';
            '15-Feb-2012';
            '15-Feb-2011';
            '15-Aug-2011';
            '15-Aug-2010';
            '15-Aug-2009';
            '15-Feb-2010'};
```

```
CouponRate = [0.04; 0.04375; 0.04875; 0.05; 0.05; 0.0575; 0.06; 0.065];
```

```
CF = convfactor(RefDate, Maturity, CouponRate)
```

```
CF = 8×1
```

```
0.8539
0.8858
0.9259
0.9418
0.9403
```

```
0.9862
1.0000
1.0266
```

### Compute the Conversion Factor For a German Bond

This example shows how to calculate `cf`, given the following `RefDate`, `Maturity`, and `CouponRate` for a German bond.

```
cf = convfactor('3/10/2009', '1/04/2018', .04, .06, 3)
cf = 0.8659
```

## Input Arguments

### RefDate — Reference dates

serial date number

Reference dates for which conversion factor is computed (usually the first day of delivery months), specified as an N-by-1 vector of serial date numbers.

Data Types: `double`

### Maturity — Maturity date

serial date number

Maturity date, specified as a N-by-1 vector of serial date numbers.

Data Types: `double`

### CouponRate — Annual coupon rates for underlying bond

vector in decimals

Annual coupon rates for underlying bond, specified as an `numBonds`-by-1 vector in decimals.

Data Types: `double`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `CF = convfactor(RefDate, Maturity, CouponRate, 'Convention', 2)`

### Convention — Conversion factor convention

1 US Treasury bond (30-year) and Treasury note (10-year) futures contract (default) | integer from 1 to 5

Conversion factor convention, specified as the comma-separated pair consisting of `'Convention'` and a N-by-1 vector using the following values:

- 1 = US Treasury bond (30-year) and Treasury note (10-year) futures contract
- 2 = US 2-year and 5-year Treasury note futures contract
- 3 = German Bobl, Bund, Buxl, and Schatz
- 4 = UK gilts
- 5 = Japanese Government Bonds (JGBs)

Data Types: double

### **FirstCouponDate — Irregular first coupon date**

serial date number

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a N-by-1 vector using a serial date numbers.

Data Types: double

### **RefYield — Reference semiannual yield**

0.06 (6%) (default) | vector in decimals

Reference semiannual yield, specified as the comma-separated pair consisting of 'RefYield' and an N-by-1 vector in decimals.

Data Types: double

### **StartDate — Forward starting date of payments**

serial date number

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a N-by-1 vector using serial date numbers.

Data Types: double

## **Output Arguments**

### **CF — Conversion factors against the 6% yield par-bond**

vector

Conversion factors against the 6% yield par-bond, returned as an N-by-1 vector.

## **More About**

### **Conversion Factors**

Conversion factors of US Treasury bonds and other government bonds are based on a bond yielding 6%.

Optionally, you can specify other types of bonds and yields using inputs for RefYield and Convention. For US Treasury bonds, verify the output of convfactor by comparing the output against the quotations provided by the Chicago Board of Trade (<https://www.cmegroup.com/company/cbot.html>).

For German bonds, verify the output of convfactor by comparing the output against the quotations provided by Eurex (<https://www.eurexchange.com>).

For UK Gilts, verify the output of `convfactor` by comparing the output against the quotations provided by Euronext (<https://www.euronext.com>).

For Japanese Government Bonds, verify the output of `convfactor` by comparing the output against the quotations provided by the Tokyo Stock Exchange (<https://www.jpx.co.jp/english/>).

## Introduced in R2009b

# fitFunction

Custom fit interest-rate curve object to bond market data

## Class

@IRFunctionCurve on page A-12

## Syntax

CurveObj = IRFunctionCurve.fitFunction(Type,Settle,FunctionHandle,Instruments,IRFitOptionsObj)

CurveObj = IRFunctionCurve.fitFunction(Type,Settle,FunctionHandle,Instruments,IRFitOptionsObj,Name)

## Arguments

Type	Type of interest-rate curve for a bond: <b>zero</b> , <b>forward</b> , or <b>discount</b> .
Settle	Scalar for the <b>Settle</b> date of the curve.
FunctionHandle	Function handle that defines the interest-rate curve. The function handle takes two numeric vectors (time-to-maturity and a vector of function coefficients) and returns one numeric output (interest rate or discount factor). For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.
Instruments	N-by-4 data matrix for <b>Instruments</b> where the first column is <b>Settle</b> date, the second column is <b>Maturity</b> , the third column is the clean price, and the fourth column is a <b>CouponRate</b> for the bond.
IRFitOptionsObj	Object constructed from <b>IRFitOptions</b> .
Compounding	(Optional) Scalar that sets the compounding frequency per year for the <b>IRFunctionCurve</b> object: <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding (default)</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>

<b>Basis</b>	<p>(Optional) Day-count basis of the bond. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
--------------	---

## Instrument Parameters

For each bond `Instrument`, you can specify the following additional instrument parameters as parameter/value pairs. For example, `InstrumentBasis` distinguishes a bond instrument's `Basis` value from the curve's `Basis` value.

<b>InstrumentPeriod</b>	<p>(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.</p>
-------------------------	--

InstrumentBasis	<p>(Optional) Day-count basis of the bond. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
InstrumentEndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
InstrumentIssueDate	<p>(Optional) Date when an instrument was issued.</p>
InstrumentFirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentLastCouponDate	<p>(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b>, a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b>, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentFace	<p>(Optional) Face or par value. Default = 100.</p>

**Note** When using **Instrument** name-value pairs, you can specify simple interest for a bond by specifying the **InstrumentPeriod** value as 0. If **InstrumentBasis** and **InstrumentPeriod** are not specified for a bond, the following default values are used: **Basis** is 0 (act/act) and **Period** is 2.

## Description

CurveObj = IRFunctionCurve.fitFunction(Type, Settle, FunctionHandle, Instruments, IRFitOptionsObj, Name, Value) fits a bond to a custom fitting function. You must enter the optional arguments for Basis and Compounding as comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## Examples

```
Settle = repmat(datenum('30-Apr-2008'),[6 1]);
Maturity = [datenum('07-Mar-2009');datenum('07-Mar-2011');...
datenum('07-Mar-2013');datenum('07-Sep-2016');...
datenum('07-Mar-2025');datenum('07-Mar-2036')];
CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];
Instruments = [Settle Maturity CleanPrice CouponRate];
CurveSettle = datenum('30-Apr-2008');
OptOptions = optimoptions('lsqnonlin','display','iter');
functionHandle = @(t,theta) polyval(theta,t);

CustomModel = IRFunctionCurve.fitFunction('Zero', CurveSettle, ...
functionHandle, Instruments, ...
IRFitOptions([.05 .05 .05], 'FitType','price',...
'OptOptions',OptOptions));
```

Iteration	Func-count	f(x)	Norm of step	First-order optimality	CG-iterations

## fitNelsonSiegel

Fit Nelson-Siegel function to bond market data

---

**Note** `fitNelsonSiegel` for an `IRFunctionCurve` is not recommended. Use `fitNelsonSiegel` with a `parametercurve` object instead. For more information, see `fitNelsonSiegel`.

---

### Class

@IRFunctionCurve on page A-12

### Syntax

`CurveObj = IRFunctionCurve.fitNelsonSiegel(Type,Settle,Instruments)`

`CurveObj = IRFunctionCurve.fitNelsonSiegel(Type,Settle,Instruments,Name,Value)`

### Arguments

Type	Type of interest-rate curve for a bond: zero or forward.
Settle	Scalar for the <code>Settle</code> date of the curve.
Instruments	N-by-4 data matrix for <code>Instruments</code> where the first column is <code>Settle</code> date, the second column is <code>Maturity</code> , the third column is the clean price, and the fourth column is a <code>CouponRate</code> for the bond.
Compounding	(Optional) Scalar that sets the compounding frequency per year for the <code>IRFunctionCurve</code> object: <ul style="list-style-type: none"> <li>-1 = Continuous compounding</li> </ul>

Basis	<p>(Optional) Day-count basis of the interest-rate curve. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
IRFitOptions	<p>(Optional) Object constructed from IRFitOptions. When using IRFitOption, the default FitType is DurationWeightedPrice. Duration weighted price refers to the form of the objective function that needs to be minimized to find the optimal Nelson-Siegel parameters. Specifically, this objective function minimizes using the following three algorithms:</p> <ul style="list-style-type: none"> <li>• The difference between observed and model-predicted yields for each bond, <math>ObsY_i - PredY_i</math></li> <li>• The difference between observed and model-predicted prices for each bond, <math>ObsP_i - PredP_i</math></li> <li>• The difference between observed and model-predicted prices, weighted by the inverse of the duration of each bond <math>(ObsP_i - PredP_i) / D_i</math>. Weighting price by inverse duration converts the pricing errors into yield fitting errors, to a first approximation.</li> </ul>

## Instrument Parameters

For each bond Instrument, you can specify the following additional instrument parameters as name-value pairs. For example, InstrumentBasis distinguishes a bond instrument's Basis value from the curve's Basis value.

InstrumentPeriod	<p>(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.</p>
------------------	--

InstrumentBasis	<p>(Optional) Day-count basis of the bond. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
InstrumentEndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
InstrumentIssueDate	<p>(Optional) Date when an instrument was issued.</p>
InstrumentFirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentLastCouponDate	<p>(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b>, a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b>, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentFace	<p>(Optional) Face or par value. Default = 100.</p>

**Note** When using **Instrument** name-value pairs, you can specify simple for a bond by specifying the **InstrumentPeriod** value as 0. If **InstrumentBasis** and **InstrumentPeriod** are not specified for a bond, the following default values are used: **Basis** is 0 (act/act) and **Period** is 2.

## Description

`CurveObj = IRFunctionCurve.fitNelsonSiegel(Type, Settle, Instruments, Name, Value)` fits a Nelson-Siegel function to market data for a bond. You must enter the optional arguments for `Basis`, `Compounding`, and `IRFitOptions` as comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

After creating a Nelson-Siegel model, you can view the Nelson-Siegel model parameters using:

```
CurveObj.Parameters
```

where the order of parameters is `[Beta0, Beta1, Beta2, tau1]`.

## Examples

### Use the Nelson-Siegel Function to Fit Bond Market Data

This example shows how to use the Nelson-Siegel function to fit bond market data.

```
Settle = repmat(datenum('30-Apr-2008'), [6 1]);
Maturity = [datenum('07-Mar-2009'); datenum('07-Mar-2011'); ...
datenum('07-Mar-2013'); datenum('07-Sep-2016'); ...
datenum('07-Mar-2025'); datenum('07-Mar-2036')];

CleanPrice = [100.1; 100.1; 100.8; 96.6; 103.3; 96.3];
CouponRate = [0.0400; 0.0425; 0.0450; 0.0400; 0.0500; 0.0425];
Instruments = [Settle Maturity CleanPrice CouponRate];
PlottingPoints = datenum('07-Mar-2009'):180:datenum('07-Mar-2036');
Yield = bndyield(CleanPrice, CouponRate, Settle, Maturity);

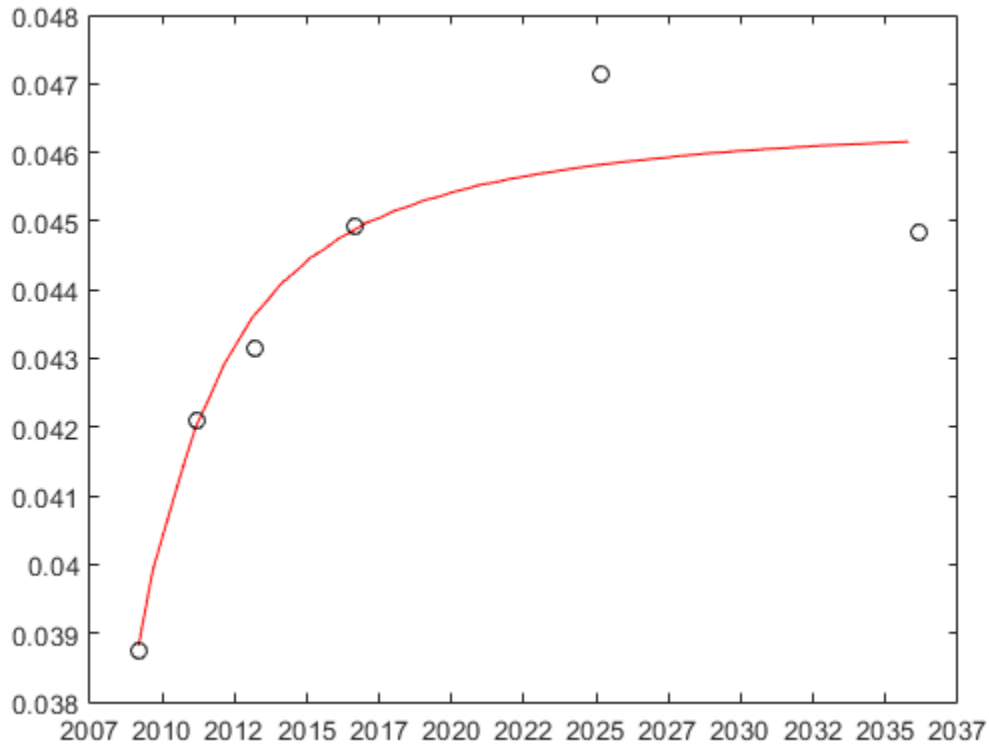

NSModel = IRFunctionCurve.fitNelsonSiegel('Zero', datenum('30-Apr-2008'), Instruments);

NSModel.Parameters

ans = 1x4

    4.6617    -1.0227    -0.3484     1.2386

% create the plot
plot(PlottingPoints, getParYields(NSModel, PlottingPoints), 'r')
hold on
scatter(Maturity, Yield, 'black')
datetick('x')
```

## Algorithms

The Nelson-Siegel model proposes that the instantaneous forward curve can be modeled with the following:

$$f = \beta_0 + \beta_1 e^{-\frac{m}{\tau}} + \beta_2 \frac{m}{\tau} e^{-\frac{m}{\tau}}$$

This can be integrated to derive an equation for the zero curve (see [6] for more information on the equations and the derivation):

$$s = \beta_0 + (\beta_1 + \beta_2) \frac{\tau}{m} (1 - e^{-\frac{m}{\tau}}) - \beta_2 e^{-\frac{m}{\tau}}$$

See [1] for more information.

## fitSmoothingSpline

Fit smoothing spline to bond market data

### Class

@IRFunctionCurve on page A-12

### Syntax

```
CurveObj = IRFunctionCurve.fitSmoothingSpline(Type,Settle,Instruments,Lambdafun)
```

```
CurveObj = IRFunctionCurve.fitSmoothingSpline(Type,Settle,Instruments,Lambdafun,Name,Value)
```

### Arguments

**Note** You must have a license for Curve Fitting Toolbox software to use the `fitSmoothingSpline` method.

Type	Type of interest-rate curve for a bond: Forward, Zero, or Discount.
Settle	Scalar for the <code>Settle</code> date of the curve.
Instruments	N-by-4 data matrix for <code>Instruments</code> where the first column is <code>Settle</code> date, the second column is <code>Maturity</code> , the third column is the clean price, and the fourth column is a <code>CouponRate</code> for the bond.
Lambdafun	Penalty function that takes as its input time and returns a penalty value. Use a function handle to support the penalty function. The function handle for the penalty function which takes one numeric input (time-to-maturity) and returns one numeric output (penalty to be applied to the curvature of the spline). For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.  <b>Note</b> The smoothing spline represents the forward curve. The spline is penalized for curvature by specifying a penalty function. This fit may only be done with a <code>FitType</code> of <code>DurationWeightedPrice</code> .
Knots	(Optional) Vector of knot locations (times-to-maturity); by default, <code>knots</code> is set to be a vector comprised of 0 and the time to maturity of all input instruments. The default is for the spline type to be cubic but you can specify any spline type by explicitly specifying the knots. User-defined knots can be specified using the following command, where <code>k</code> is the order: <code>augknt(knots,k)</code> .

Compounding	<p>(Optional) Scalar that sets the compounding frequency per year for the IRFunctionCurve object:</p> <ul style="list-style-type: none"> <li>• -1 = Continuous compounding (default)</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>
Basis	<p>(Optional) Day-count basis of the interest-rate curve. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>

## Instrument Parameters

For each bond Instrument, you can specify the following additional instrument parameters as name-value pairs. For example, InstrumentBasis distinguishes a bond instrument's Basis value from the curve's Basis value.

InstrumentPeriod	<p>(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.</p>
------------------	--

InstrumentBasis	<p>(Optional) Day-count basis of the bond. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
InstrumentEndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
InstrumentIssueDate	<p>(Optional) Date when an instrument was issued.</p>
InstrumentFirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentLastCouponDate	<p>(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b>, a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b>, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentFace	<p>(Optional) Face or par value. Default = 100.</p>

**Note** When using **Instrument** name-value pairs, you can specify simple interest for a bond by specifying the **InstrumentPeriod** value as 0. If **InstrumentBasis** and **InstrumentPeriod** are not specified for a bond, the following default values are used: **Basis** is 0 (act/act) and **Period** is 2.

## Description

`Fcurve = IRFunctionCurve.fitSmoothingSpline(Type, Settle, Instruments, Lambdafun, Name, Value)` fits a smoothing spline to market data for a bond. You must enter the optional arguments for `Basis`, `Compounding`, and `Knots` as comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## Examples

### Use a Smoothing Spline Function to Fit Market Data For a Bond

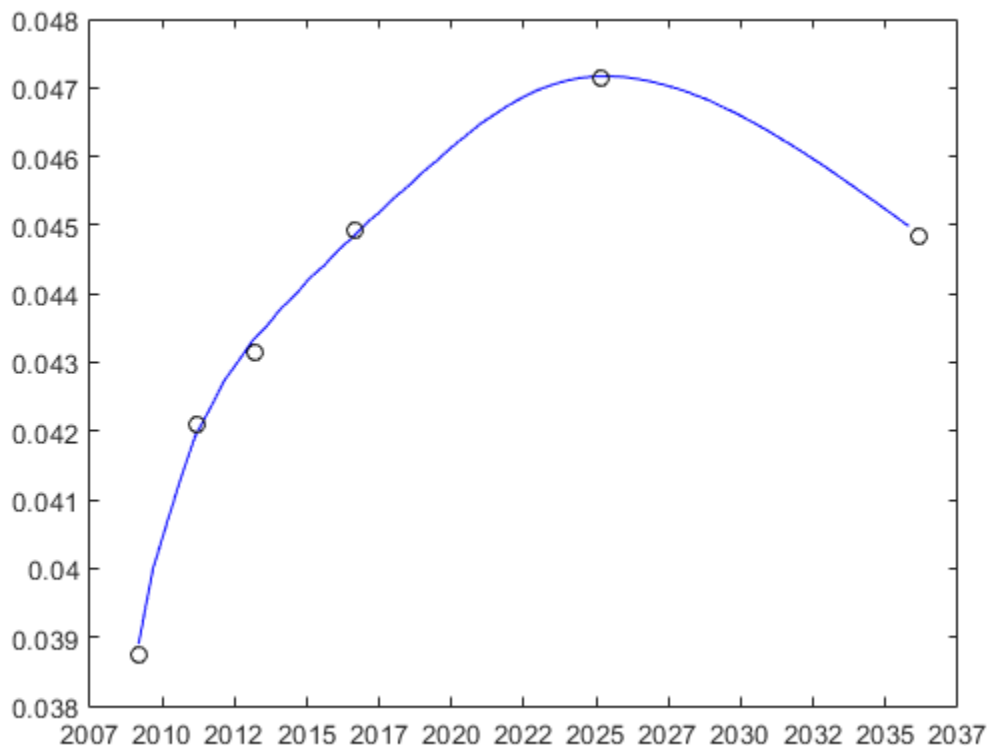

This example shows how to use a smoothing spline function to fit market data for a bond.

```
Settle = repmat(datenum('30-Apr-2008'),[6 1]);
Maturity = [datenum('07-Mar-2009');datenum('07-Mar-2011');...
datenum('07-Mar-2013');datenum('07-Sep-2016');...
datenum('07-Mar-2025');datenum('07-Mar-2036')];

CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];
Instruments = [Settle Maturity CleanPrice CouponRate];
PlottingPoints = datenum('07-Mar-2009'):180:datenum('07-Mar-2036');
Yield = bndyield(CleanPrice,CouponRate,Settle,Maturity);

% use the AUGKNT function to construct the knots for a cubic spline at every 5 years
CustomKnots = augknt(0:5:30,4);
SmoothingModel = IRFunctionCurve.fitSmoothingSpline('Zero',datenum('30-Apr-2008'),...
Instruments,@(t) 1000,'knots', CustomKnots);

% create the plot
plot(PlottingPoints, getParYields(SmoothingModel, PlottingPoints),'b')
hold on
scatter(Maturity,Yield,'black')
datetick('x')
```

### Fitting an IRFunctionCurve Object Using the Smoothing Spline Method With the Penalty Function

Use the `fitSmoothinSpline` method to fit the interest-rate curve and model the `Lambdafun` penalty function. First, load the data.

```
load ukdata20080430
```

Convert the repo rates to be equivalent zero coupon bonds.

```
RepoCouponRate = repmat(0,size(RepoRates));
RepoPrice = bndprice(RepoRates, RepoCouponRate, RepoSettle, RepoMaturity);
```

Aggregate the data.

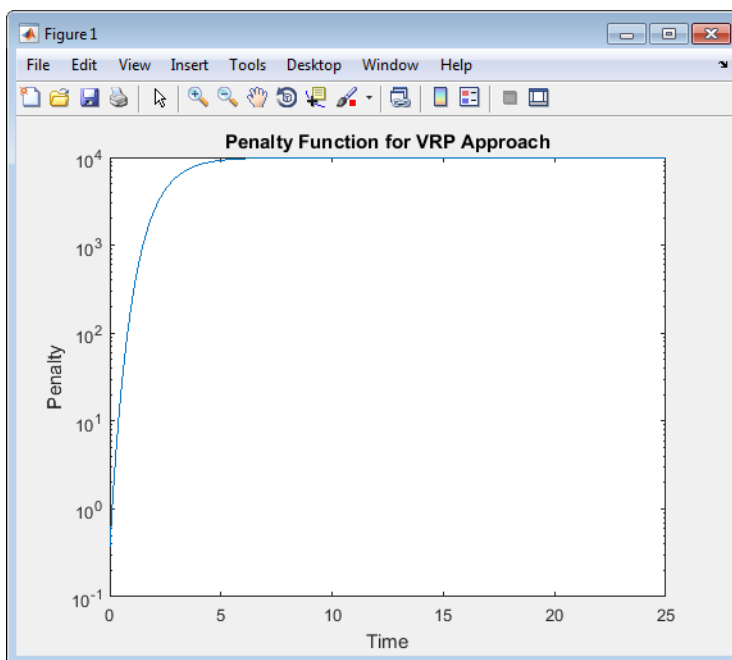

```
Settle = [RepoSettle;BondSettle];
Maturity = [RepoMaturity;BondMaturity];
CleanPrice = [RepoPrice;BondCleanPrice];
CouponRate = [RepoCouponRate;BondCouponRate];
Instruments = [Settle Maturity CleanPrice CouponRate];
InstrumentPeriod = [repmat(0,6,1);repmat(2,31,1)];
CurveSettle = datenum('30-Apr-2008');
```

Choose the parameters for the `Lambdafun` input argument.

```
L = 9.2;
S = -1;
mu = 1;
```

Define the Lambdafun penalty function.

```
lambdafun = @(t) exp(L - (L-S)*exp(-t/mu));
t = 0:.1:25;
y = lambdafun(t);
figure
semilogy(t,y);
title('Penalty Function for VRP Approach')
ylabel('Penalty')
xlabel('Time')
```

Use the fitSmoothingSpline method to fit the interest-rate curve and model the Lambdafun penalty function.

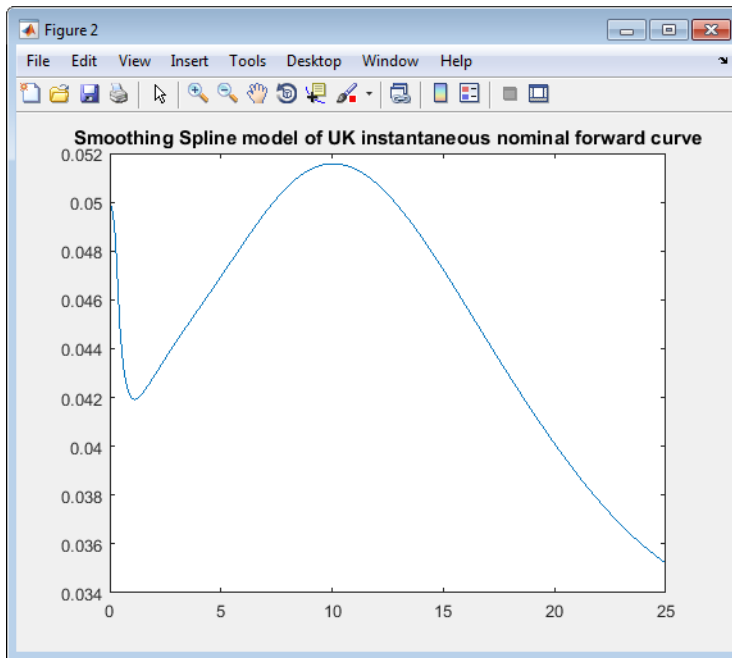

```
VRPModel = IRFunctionCurve.fitSmoothingSpline('Forward',CurveSettle,...
Instruments,lambdafun,'Compounding',-1, 'InstrumentPeriod',InstrumentPeriod)
```

```
VRPModel =
```

```
    Type: Forward
    Settle: 733528 (30-Apr-2008)
    Compounding: -1
    Basis: 0 (actual/actual)
```

Plot the smoothing spline interest-rate curve for the forward rates.

```
PlottingDates = CurveSettle+20:30:CurveSettle+365*25;
TimeToMaturity = yearfrac(CurveSettle,PlottingDates);
VRPForwardRates = getForwardRates(VRPModel, PlottingDates);
figure;plot(TimeToMaturity,VRPForwardRates)
title('Smoothing Spline model of UK instantaneous nominal forward curve')
```

## Algorithms

The term structure can be modeled with a spline — specifically, one way to model the term structure is by representing the forward curve with a cubic spline. To ensure that the spline is sufficiently smooth, a penalty is imposed relating to the curvature (second derivative) of the spline:

$$\sum_{i=1}^N \left[ \frac{P_i - \hat{P}_i(f)}{D_i} \right]^2 + \int_0^M \lambda_t(m) [f''(m)]^2 dm$$

where the first term is the difference between the observed price  $P$  and the predicted price,  $\hat{P}$ , (weighted by the bond's duration,  $D$ ) summed over all bonds in our data set and the second term is the penalty term (where  $\lambda$  is a penalty function and  $f$  is the spline).

See [3], [4], [5] below.

There have been different proposals for the specification of the penalty function  $\lambda$ . One approach, advocated by [4], and currently used by the UK Debt Management Office, is a penalty function of the following form:

$$\log(\lambda(m)) = L - (L - S)e^{-\frac{m}{\tau}}$$

## fitSvensson

Fit Svensson function to bond market data

---

**Note** `fitSvensson` for an `IRFunctionCurve` is not recommended. Use `fitSvensson` with a `parametercurve` object instead. For more information, see `fitSvensson`.

---

### Class

@IRFunctionCurve on page A-12

### Syntax

`CurveObj = IRFunctionCurve.fitSvensson(Type, Settle, Instruments)`

`CurveObj = IRFunctionCurve.fitSvensson(Type, Settle, Instruments, Name, Value)`

### Arguments

Type	Type of interest-rate curve for a bond: zero or forward.
Settle	Scalar for the <code>Settle</code> date of the curve.
Instruments	N-by-4 data matrix for <code>Instruments</code> where the first column is <code>Settle</code> date, the second column is <code>Maturity</code> , the third column is the clean price, and the fourth column is a <code>CouponRate</code> for the bond.
Compounding	(Optional) Scalar that sets the compounding frequency per year for the <code>IRFunctionCurve</code> object: <ul style="list-style-type: none"> <li>-1 = Continuous compounding</li> </ul>

Basis	<p>(Optional) Day-count basis of the interest-rate curve. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
IRFitOptions	(Optional) Object constructed from IRFitOptions.

## Instrument Parameters

For each bond Instrument, you can specify the following additional instrument parameters as name-value pairs. For example, InstrumentBasis distinguishes a bond instrument's Basis value from the curve's Basis value.

InstrumentPeriod	<p>(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.</p>
------------------	--

InstrumentBasis	<p>(Optional) Day-count basis of the bond. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
InstrumentEndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
InstrumentIssueDate	<p>(Optional) Date when an instrument was issued.</p>
InstrumentFirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentLastCouponDate	<p>(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b>, a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b>, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentFace	<p>(Optional) Face or par value. Default = 100.</p>

**Note** When using **Instrument** name-value pairs, you can specify simple interest for a bond by specifying the **InstrumentPeriod** value as 0. If **InstrumentBasis** and **InstrumentPeriod** are not specified for a bond, the following default values are used: **Basis** is 0 (act/act) and **Period** is 2.

## Description

`CurveObj = IRFunctionCurve.fitSvensson(Type, Settle, Instruments, Name, Value)` fits the Svensson function to bond market data. You must enter the optional arguments for `Basis`, `Compounding`, and `IRFitOptions` as comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

After creating a Svensson model, you can view the Svensson model parameters using:

```
CurveObj.Parameters
```

where the order of parameters is `[Beta0, Beta1, Beta2, Beta3, tau1, tau2]`.

## Examples

### Use a Svensson Function to Fit Bond Market Data

This example shows how to use a Svensson function to fit bond market data.

```
Settle = datenum('15-Apr-2014');
Maturity = datemnth(Settle, 12*[1 2 3 5 7 10 20 30]);

CleanPrice = [100.1 100.1 100.2 99.0 101.8 99.2 101.7 100.2]';
CouponRate = [0.0200 0.0275 0.035 0.042 0.0475 0.0525 0.055 0.052]';
Instruments = [repmat(Settle, size(Maturity)) Maturity CleanPrice CouponRate];
PlottingPoints = datemnth(Settle, 1:360);
Yield = bndyield(CleanPrice, CouponRate, Settle, Maturity);

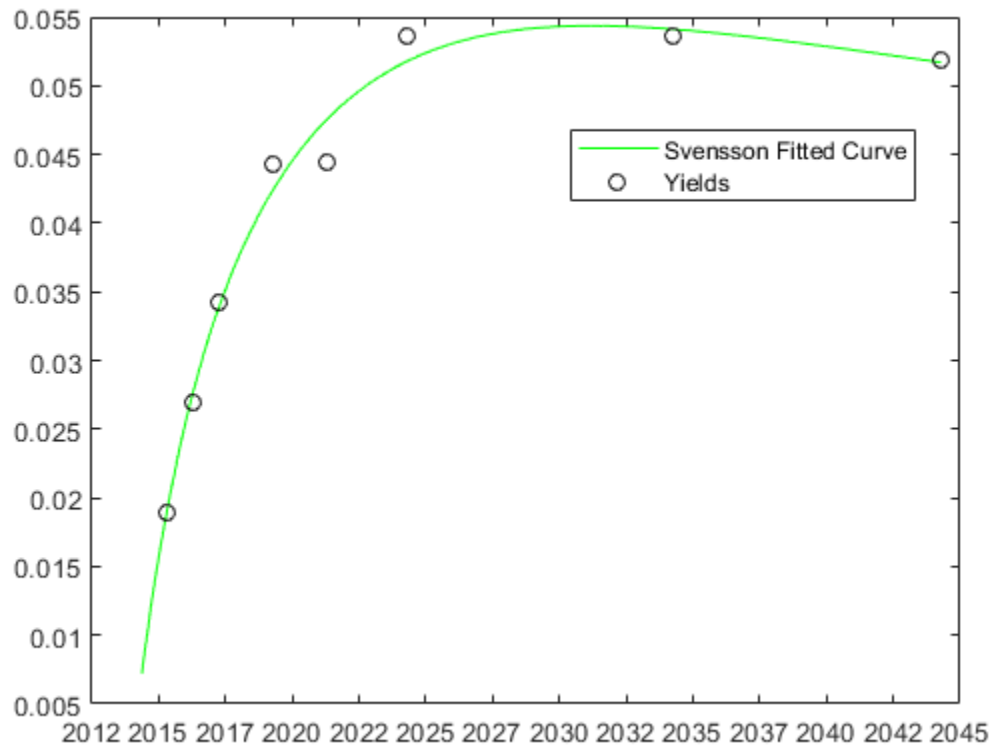

SvenssonModel = IRFunctionCurve.fitSvensson('Zero', Settle, Instruments);

SvenssonModel.Parameters

ans = 1x6

    1.8298    -1.2299    1.6316    12.3890    1.6982    8.9422

% create the plot
plot(PlottingPoints, getParYields(SvenssonModel, PlottingPoints), 'g')
hold on
scatter(Maturity, Yield, 'black')
datetick('x')
legend({'Svensson Fitted Curve', 'Yields'}, 'location', 'best')
```

## Algorithms

A similar model to the Nelson-Siegel is the Svensson model, which adds two additional parameters to account for greater flexibility in the term structure. This model proposes that the forward rate can be modeled with the following form:

$$f = \beta_0 + \beta_1 e^{-\frac{m}{\tau_1}} + \beta_2 e^{-\frac{m}{\tau_1}} \frac{m}{\tau_1} + \beta_3 e^{-\frac{m}{\tau_2}} \frac{m}{\tau_2}$$

As above, this can be integrated to derive an equation for the zero curve:

$$s = \beta_0 + \beta_1 (1 - e^{-\frac{m}{\tau_1}}) \left(-\frac{\tau_1}{m}\right) + \beta_2 \left( (1 - e^{-\frac{m}{\tau_1}}) \frac{\tau_1}{m} - e^{-\frac{m}{\tau_1}} \right) + \beta_3 \left( (1 - e^{-\frac{m}{\tau_2}}) \frac{\tau_2}{m} - e^{-\frac{m}{\tau_2}} \right)$$

## getDiscountFactors

Get discount factors for input dates for IRDataCurve

### Class

@IRDataCurve on page A-7

### Syntax

```
F = getDiscountFactors(CurveObj,InpDates)
```

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRDataCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.

### Description

F = getDiscountFactors(CurveObj, InpDates) returns discount factors for the input dates.

### Examples

#### Get Discount Factors For Input Dates for an IRDataCurve

This example shows how to get discount factors for input dates for an IRDataCurve.

```
CurveSettle = datenum('2-Mar-2016');
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data);
getDiscountFactors(irdc, CurveSettle+30:30:CurveSettle+720)
```

## getForwardRates

Get forward rates for input dates for IRDataCurve

### Class

@IRDataCurve on page A-7

### Syntax

F = getForwardRates(CurveObj, InpDates)

F = getForwardRates(CurveObj, InpDates, Name, Value)

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRDataCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.
Compounding	(Optional) Scalar that sets the compounding frequency per year for forward rates. The default <b>Compounding</b> value is <code>CurveObj.Compounding</code> . Acceptable values are: <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 0 = Simple interest (no compounding)</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>

<b>Basis</b>	<p>(Optional) Day-count basis values for the forward rates:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
--------------	--

## Description

`F = getForwardRates(CurveObj, InpDates, Name, Value)` returns forward rates for the input dates. `getForwardRates` returns discrete forward rates for the intervals input into this method. For example, running the following code:

```
getForwardRates(irdc, {Date1, Date2, Date3})
```

gives three forwards rates and the three tenors are: `[Settle, Date1]`, `[Date1, Date2]`, and `[Date2, Date3]`.

You must enter the optional arguments for `Basis` and `Compounding` as comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

The `getForwardRates` method returns forward rates corresponding to the periodicity of the dates input to `getForwardRates`. For example, where the dates are monthly, monthly forward rates are returned. The first element of the output is the forward rate from the `Settle` to one month, the second element is the forward rate from one month to two months, and so on.

## Examples

### Get Forward Rates For Input Dates for an IRDataCurve

This example shows how to get forward rates for input dates for an `IRDataCurve`.

```
CurveSettle = datenum('2-Mar-2016');
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
```

```
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data);
getForwardRates(irdc, CurveSettle+30:30:CurveSettle+720)
```

```
ans = 24×1
```

```
0.0174
0.0180
0.0187
0.0193
0.0199
0.0205
0.0212
0.0218
0.0224
0.0230
⋮
```

### Use getForwardRates to Compute the Five Year Forward Rate in Five Years Time

Use `getForwardRates` to compute the forward rate from the `Settle` date to 5 years from March 1, 2017 and then the forward rate for the period from 5 years to 10 years from March 1, 2017.

```
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = daysadd(736755,[360 2*360 3*360 5*360 7*360 10*360 20*360 30*360],1);
irdc = IRDataCurve('Zero',today,Dates,Data);
getForwardRates(irdc,datemnth(irdc.Settle,12*[5 10]))
```

```
ans = 2×1
```

```
0.0357
0.0456
```

The first element (.0312) is the forward rate from the `Settle` to 5 years from March 1, 2017. The second rate (0.0458) is the forward rate for the period from 5 years to 10 years from March 1, 2017, in other words, the 5-year forward rate 5 years from March 1, 2017.

### Compute the Six Month Forward Rates in 1 Month, 2 Months and 3 Months

Use the following data to create an `IRDataCurve` object:

```
Data = [0.1 0.30 0.70 1.05 1.45 1.71 2.12 2.43 2.85 3.57]/100;
Settle = datenum('08-Aug-2016'); % Today's date
Dates = datemnth(Settle,[3 6 9 12*[1 2 3 5 7 10 20]]);
irdc = IRDataCurve('Zero',Settle,Dates,Data)
```

```
irdc =
```

```
    Type: Zero
    Settle: 736550 (08-Aug-2016)
    Compounding: 2
    Basis: 0 (actual/actual)
```

```

InterpMethod: linear
  Dates: [10x1 double]
  Data: [10x1 double]

```

Compute the implied 6 month forward rates in 1 month, 2 months, and 3 months from the Settle date.

```

IntervalMonth = 6; % Interval for 6 month forward rates
FwdMonths = [1 2 3]'; % Starting in 1, 2, and 3 months from Settle
N = length(FwdMonths);
FwdRates_6M = zeros(N,1);

for k = 1:N
    FwdDates = datemnth(irdc.Settle, [FwdMonths(k) FwdMonths(k)+IntervalMonth]);
    f = getForwardRates(irdc,FwdDates);
    FwdRates_6M(k) = f(2);
end

```

```
[FwdMonths FwdRates_6M]

## getForwardRates

Get forward rates for input dates for IRFunctionCurve

### Class

@IRFunctionCurve on page A-12

### Syntax

F = getForwardRates(CurveObj, InpDates)

F = getForwardRates(CurveObj, InpDates, Name, Value)

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRFunctionCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.
Compounding	(Optional) Scalar that sets the compounding frequency per year for the forward rates are: <ul style="list-style-type: none"><li>• -1 = Continuous compounding</li><li>• 1 = Annual compounding</li><li>• 2 = Semiannual compounding (default)</li><li>• 3 = Compounding three times per year</li><li>• 4 = Quarterly compounding</li><li>• 6 = Bimonthly compounding</li><li>• 12 = Monthly compounding</li></ul>

<b>Basis</b>	<p>(Optional) Day-count basis for the forward rates:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
--------------	---

## Description

$F = \text{getForwardRates}(\text{CurveObj}, \text{InpDates}, \text{Name}, \text{Value})$  returns forward rates for the input dates. You must enter the optional arguments for **Basis** and **Compounding** as comma-separated pairs of **Name,Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

## Examples

### Get Forward Rates For Input Dates For an IRFunctionCurve

This example shows how to get forward rates for input dates for an IRFunctionCurve.

```
irfc = IRFunctionCurve('Forward',today,@(t) polyval([-0.0001 0.003 0.02],t));
getForwardRates(irfc, today+30:30:today+720)
```

```
ans = 24x1
```

```
0.0202
0.0205
0.0207
0.0210
0.0212
0.0215
0.0217
0.0219
0.0222
0.0224
```

:

### Compute the Implied 2-Year Forward Rates in 1 Year, 2 Years, 5 Years, and 10 Years

This example shows how to compute the implied 2-year forward rates in 1 year, 2 years, 5 years, and 10 years from the `Settle` date by using the `getForwardRates` method.

Use the following data for an `IRFunctionCurve` object that is created when using the `fitSvensson` method.

```
Settle = datenum('15-Apr-2014');
Maturity = datemnth(Settle,12*[1 2 3 5 7 10 20 30]');

CleanPrice = [100.1 100.1 100.2 99.0 101.8 99.2 101.7 100.2]';
CouponRate = [0.0200 0.0275 0.035 0.042 0.0475 0.0525 0.055 0.052]';
Instruments = [repmat(Settle,size(Maturity)) Maturity CleanPrice CouponRate];

SvenssonModel = IRFunctionCurve.fitSvensson('Zero',Settle,Instruments);
```

Compute the implied 2-year forward rates in 1 year, 2 years, 5 years, and 10 years from the `Settle` date.

```
IntervalMonth = 12.*2;           % Interval months for 2-year forward rates
FwdMonths = 12.*[1 2 5 10]';    % Starting in 1, 2, 5, and 10 years from Settle
N = length(FwdMonths);
FwdRates_2Y = zeros(N,1);

for k = 1:N
    FwdDates = datemnth(SvenssonModel.Settle, [FwdMonths(k) FwdMonths(k)+IntervalMonth]);
    f = getForwardRates(SvenssonModel,FwdDates);
    FwdRates_2Y(k) = f(2);
end
```

```
[FwdMonths FwdRates_2Y]
```

```
ans = 4x2
```

```
    12.0000    0.0418
    24.0000    0.0504
    60.0000    0.0620
   120.0000    0.0629
```

## getParYields

Get par yields for input dates for IRDataCurve

### Class

@IRDataCurve on page A-7

### Syntax

F = getParYields(CurveObj, InpDates)

F = getParYields(CurveObj, InpDates, Name, Value)

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRDataCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.
Compounding	(Optional) Scalar that sets the compounding frequency per year for the par yield rates are: <ul style="list-style-type: none"><li>• -1 = Continuous compounding</li><li>• 1 = Annual compounding</li><li>• 2 = Semiannual compounding (default)</li><li>• 3 = Compounding three times per year</li><li>• 4 = Quarterly compounding</li><li>• 6 = Bimonthly compounding</li><li>• 12 = Monthly compounding</li></ul>

<b>Basis</b>	<p>(Optional) Day-count basis values for the par yield rates:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
--------------	--

## Description

`F = getParYields(CurveObj, InpDates, Name, Value)` returns par yields for the input dates. You must enter the optional arguments for `Basis` and `Compounding` as comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## Examples

### Get Par Yields For Input Dates For an IRDataCurve

This example shows how to get par yields for input dates for an `IRDataCurve`.

```
CurveSettle = datenum('2-Mar-2016');
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle, 12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero', CurveSettle, Dates, Data);
getParYields(irdc, CurveSettle+30:30:CurveSettle+720)
```

```
ans = 24x1

```

### **Compute Par Yields From a Curve With Simple Interest Compounding**

This example shows how set the compounding of an IRDataCurve to Zero (simple interest) and then compute par yields from that curve.

```
CurveSettle = datenum('2-Mar-2016');  
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;  
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);  
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data,'Compounding',0);  
SimpleInt = irdc.getParYields(Dates(1), 'Basis', 2, 'Compounding', 1)  
  
SimpleInt = 0.0209
```

## getZeroRates

Get zero rates for input dates for IRDataCurve

### Class

@IRDataCurve on page A-7

### Syntax

F = getZeroRates(CurveObj, InpDates)

F = getZeroRates(CurveObj, InpDates, Name, Value)

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRDataCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.
Compounding	(Optional) Scalar that sets the compounding frequency per year for zero rates. The default Compounding value is CurveObj.Compounding. Acceptable values are: <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 0 = Simple interest (no compounding)</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>

<b>Basis</b>	<p>(Optional) Day-count basis values for zero rates:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>

## IRBootstrapOptions

Construct specific options for bootstrapping interest-rate curve object

### Class

@IRBootstrapOptions on page A-2

### Syntax

```
mybootoptions = IRBootstrapOptions(Name,Value)
```

### Arguments

ConvexityAdjustment	(Optional) Controls the convexity adjustment to interest-rate futures. This can be specified as a function handle that takes one numeric input (time-to-maturity) and returns one numeric output, ConvexityAdjustment. For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.  Alternatively, you can define ConvexityAdjustment as an N-by-1 vector of values, where N is the number of interest-rate futures.  In either case, the ConvexityAdjustment is subtracted from the futures rate.
LowerBound	(Optional) Specifies a lower bound for rates associated with bonds or swaps. LowerBound can be a scalar or N-by-1 vector where N is the number of swaps and bonds. By default, LowerBound is 0.
UpperBound	(Optional) Specifies an upper bound for rates associated with bonds or swaps. UpperBound can be a scalar or N-by-1 vector where N is the number of swaps and bonds. By default, UpperBound is 1. Specify an upper bound that is greater than 1 when bootstrapping a discount curve.

### Description

mybootoptions = IRBootstrapOptions(Name,Value) constructs an IRBootstrapOptionsObj structure. You must enter the optional arguments for ConvexityAdjustment, LowerBound, and UpperBound as comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

The IRBootstrapOptionsObj is used with the bootstrap method.

## Examples

### Create IRBootstrapOptionsObj to Use With the bootstrap Method

Set the ConvexityAdjustment to control interest-rate futures.

```
mybootoptions = IRBootstrapOptions('ConvexityAdjustment', repmat(.005,10,1))
```

```
mybootoptions =
  IRBootstrapOptions with properties:
    ConvexityAdjustment: [10x1 double]
    LowerBound: 0
    UpperBound: 1
```

Use mybootoptions as the optional argument, IRBootstrapOptionsObj, to use with the bootstrap method.

### Create an IRBootstrapOptionsObj to Use With Negative Zero Interest-Rates

Use an IRBootstrapOptionsObj optional argument with the bootstrap method to allow for negative zero rates when solving the swap zero points.

```
Settle = datenum('15-Mar-2015');
InstrumentTypes = {'Deposit'; 'Deposit'; 'Swap'; 'Swap'; 'Swap'; 'Swap'};
```

```
Instruments = [Settle, datenum('15-Jun-2015'), .001; ...
Settle, datenum('15-Dec-2015'), .0005; ...
Settle, datenum('15-Mar-2016'), -.001; ...
Settle, datenum('15-Mar-2017'), -0.0005; ...
Settle, datenum('15-Mar-2018'), .0017; ...
Settle, datenum('15-Mar-2020'), .0019];
```

```
irbo = IRBootstrapOptions('LowerBound', -1);
```

```
bootModel = IRDataCurve.bootstrap('zero', Settle, InstrumentTypes, ...
  Instruments, 'IRBootstrapOptions', irbo);
```

```
bootModel.getZeroRates(datemnth(Settle, 1:60))
```

```
ans = 60x1
```

```
0.0012
0.0011
0.0010
0.0009
0.0008
0.0008
0.0007
0.0006
0.0005
-0.0000
```

⋮

Note that `IRBootstrapOptions` optional argument for `LowerBound` is set to `-1` for negative zero rates when solving the swap zero points.

# IRDataCurve

Construct interest-rate curve object from dates and data

## Class

@IRDataCurve on page A-7

## Syntax

CurveObj = IRDataCurve(Type, Settle, Dates, Data)

CurveObj = IRDataCurve(Type, Settle, Dates, Data, Name, Value)

## Arguments

Type	Type of interest-rate curve. Acceptable values are forward, zero, or discount.
Settle	Scalar for the Settle date of the curve.
Dates	Dates corresponding to rate data.
Data	Interest-rate data for the curve object.
Compounding	<p>(Optional) Scalar that sets the compounding frequency per year for the IRDataCurve object:</p> <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 0 = Simple interest (no compounding) for “zero” and “discount” curve types only, not supported for “forward” curves</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding (default)</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul> <p><b>Note</b> Simple interest can be specified for an instrument by specifying the Compounding value as 0 and is supported for “zero” and “discount” curve types only (not supported for “forward” curves).</p>

Basis	<p>(Optional) Day-count basis of the interest-rate curve. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
InterpMethod	<p>(Optional) Values are:</p> <ul style="list-style-type: none"> <li>• 'linear' — Linear interpolation (default).</li> <li>• 'constant' — Piecewise constant interpolation.</li> <li>• 'pchip' — Piecewise cubic Hermite interpolation.</li> <li>• 'spline' — Cubic spline interpolation.</li> </ul>

## Description

`CurveObj = IRDataCurve(Type,Settle,Dates,Data,Name,Value)` constructs an interest-rate curve with the specified `Dates` and `Data`. You must enter the optional arguments for `Basis`, `Compounding`, and `InterpMethod` as comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alternatively, an `IRDataCurve` object can be bootstrapped from market data using the `bootstrap` method.

After an `IRDataCurve` curve object is constructed, you can use the following methods to determine the forward rates, zero rates, and discount factors. In addition, you can use the `toRateSpec` method to convert the interest-rate curve object to a `RateSpec` structure.

Method	Description
<code>getForwardRates</code>	Returns forward rates for input dates.
<code>getZeroRates</code>	Returns zero rates for input dates.
<code>getDiscountFactors</code>	Returns discount factors for input dates.

Method	Description
getParYields	Returns par yields for input dates.
toRateSpec	Converts to be a RateSpec object; this structure is identical to the RateSpec produced by the Financial Instruments Toolbox function <code>intenvset</code> .
bootstrap	Bootstraps an interest rate curve from market data.

## Examples

```
CurveSettle = datenum('2-Mar-2016');
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data)
```

```
irdc =
```

```

      Type: Zero
      Settle: 736391 (02-Mar-2016)
  Compounding: 2
        Basis: 0 (actual/actual)
  InterpMethod: linear
        Dates: [8x1 double]
        Data: [8x1 double]
```

## Introduced in R2008b

## IRFitOptions

Construct specific options for fitting interest-rate curve object

### Class

@IRFitOptions on page A-10

### Syntax

```
myfitoptions = IRFitOptions(InitialGuess)
myfitoptions = IRFitOptions(InitialGuess,Name,Value)
```

### Arguments

InitialGuess	Initial guess for the parameters of the curve function. Vector of values for the starting point of the optimization.
FitType	(Optional) Price, Yield, or DurationWeightedPrice determines which is minimized in the curve fitting process. The default is DurationWeightedPrice.
UpperBound	(Optional) Lower bound for the parameters of the curve function.
LowerBound	(Optional) Upper bound for the parameters of the curve function.
OptOptions	(Optional) Optimization solver options constructed with optimoptions from the Optimization Toolbox (optimset is also supported).

### Description

`myfitoptions = IRFitOptions(InitialGuess,Name,Value)` constructs the `IRFitOptions` structure with an initial guess or with an initial guess and bounds. You must enter the optional arguments for `FitType`, `UpperBound`, `LowerBound`, and `OptOptions` as comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

---

**Note** `IRFitOptions` constructor must be used with `fitFunction` method when building a custom fitting function.

---

### Examples

```
myfitoptions = IRFitOptions([7 2 1 0], 'FitType', 'yield')
myfitoptions =
    Properties:
        FitType: 'yield'
        InitialGuess: [7 2 1 0]
```

```
UpperBound: []  
LowerBound: []  
OptOptions: []
```

## IRFunctionCurve

Construct interest-rate curve object from function handle or function and fit to market data

### Class

@IRFunctionCurve on page A-12

### Syntax

CurveObj = IRFunctionCurve(Type,Settle,FunctionHandle)

CurveObj = IRFunctionCurve(Type,Settle,FunctionHandle,Name,Value)

### Arguments

Type	Type of interest-rate curve: zero, forward, or discount.
Settle	Scalar for the Settle date of the curve.
Compounding	(Optional) Scalar that sets the compounding frequency per year for the IRFunctionCurve object: <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding (default)</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>

Basis	<p>(Optional) Day-count basis of the bond. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
FunctionHandle	<p>Function handle that defines the interest-rate curve. The function handle requires one numeric input (time-to-maturity) and returns one numeric output (interest rate or discount factor). For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.</p>
Parameters	<p>Fitted parameters for function.</p>

## Description

`CurveObj = IRFunctionCurve(Type,Settle,FunctionHandle,Name,Value)` constructs an interest-rate curve object directly by specifying a function handle. You must enter the optional arguments for **Basis** and **Compounding** as comma-separated pairs of **Name,Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

After you use the `IRFunctionCurve` constructor to create an `IRFunctionCurve` object, you can fit the bond using the following methods.

Method	Description
getForwardRates	Returns forward rates for input dates.
getZeroRates	Returns zero rates for input dates.
getDiscountFactors	Returns discount factors for input dates.
getParYields	Returns par yields for input dates.

Method	Description
toRateSpec	Converts to be a RateSpec object.  This RateSpec structure is identical to the RateSpec produced by the Financial Instruments Toolbox function <code>intenvset</code> .

Alternatively, you can construct an `IRFunctionCurve` object using the following static methods.

Static Method	Description
<code>fitNelsonSiegel</code>	Fits a Nelson-Siegel function to market data.
<code>fitSvensson</code>	Fits a Svensson function to market data.
<code>fitSmoothingSpline</code>	Fits a smoothing spline function to market data.
<code>fitFunction</code>	Fits a custom function to market data.

## Examples

```
irfc = IRFunctionCurve('Forward',today,@(t) polyval([-0.0001 0.003 0.02],t))
```

```
irfc =
```

```

      Type: Forward
      Settle: 737406 (12-Dec-2018)
      Compounding: 2
      Basis: 0 (actual/actual)
```

## Introduced in R2008b

# liborduration

Duration of LIBOR-based interest-rate swap

## Syntax

```
[PayFixDuration,GetFixDuration] = liborduration(SwapFixRate,Tenor,Settle)
```

## Description

[PayFixDuration,GetFixDuration] = liborduration(SwapFixRate,Tenor,Settle) computes the duration of LIBOR-based interest-rate swaps.

## Examples

### Compute the Duration of LIBOR-Based Interest-Rate Swaps

This example shows how to compute the duration of LIBOR-based interest-rate swaps using the following data.

```
SwapFixRate = 0.0383;
Tenor = 7;
Settle = datenum('11-Oct-2002');
```

```
[PayFixDuration GetFixDuration] = liborduration(SwapFixRate,...
Tenor, Settle)
```

```
PayFixDuration = -4.7567
```

```
GetFixDuration = 4.7567
```

## Input Arguments

### SwapFixRate — Par swap fixed rate

vector in decimals

Par swap fixed rate (quarterly compounded), specified as an N-by-1 vector in decimals. The Basis should be actual/360.

Data Types: double

### Tenor — Swap tenor in years

vector

Swap tenor in years, specified as a N-by-1 vector. Fractional numbers are rounded upward.

Data Types: double

### Settle — Settlement date

vector

Settlement date, specified as an N-by-1 vector using serial date numbers.

Data Types: `double`

## Output Arguments

**PayFixDuration** — Modified duration, in years, for the pay-fix side of the swap  
vector

Modified duration, in years, for the pay-fix side of the swap, returned as a N-by-1 vector.

**GetFixDuration** — Modified duration, in years, for the receive-fix side of the swap  
vector

Modified duration, in years, for the receive-fix side of the swap, returned as a N-by-1 vector.

# liborfloat2fixed

Compute par fixed-rate of swap given 3-month LIBOR data

## Syntax

```
[FixedSpec, ForwardDates, ForwardRates] = liborfloat2fixed(ThreeMonthRates,
Settle, Tenor)
Price = liborprice( ____, StartDate, Interpolation, ConvexAdj, RateParam, InArrears,
Sigma, FixedCompound, FixedBasis)
```

## Description

[FixedSpec, ForwardDates, ForwardRates] = liborfloat2fixed(ThreeMonthRates, Settle, Tenor) computes forward rates, dates, and the swap fixed rate.

---

**Note** The `liborfloat2fixed` function assumes that floating-rate observations occur quarterly on the third Wednesday of a delivery month. The first delivery month is the month of the first third Wednesday after `Settle`. Floating-side payments occur on the third-month anniversaries of observation dates. Fixed payments start on the same date as the first floating payment, and recur on the same date as the first-coupon date (on anniversary months).

---

`Price = liborprice( ____, StartDate, Interpolation, ConvexAdj, RateParam, InArrears, Sigma, FixedCompound, FixedBasis)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Par Fixed-Rate of a Swap Given 3-Month LIBOR Data

This example shows how to compute the par fixed-rate of a swap given 3-month LIBOR data. Use the supplied `EDdata.xls` file as input to a `liborfloat2fixed` computation.

```
[EDFutData, textdata] = xlsread('EDdata.xls');
Settle                 = datenum('15-Oct-2002');
Tenor                  = 2;

[FixedSpec, ForwardDates, ForwardRates] = ...
liborfloat2fixed(EDFutData(:,1:3), Settle, Tenor)

FixedSpec = struct with fields:
    Coupon: 0.0222
    Settle: '16-Oct-2002'
    Maturity: '16-Oct-2004'
    Period: 4
    Basis: 1

ForwardDates = 8x1
```

```
731505
731596
731687
731778
731869
731967
732058
732149
```

ForwardRates = 8×1

```
0.0177
0.0166
0.0170
0.0188
0.0214
0.0248
0.0279
0.0305
```

## Input Arguments

**ThreeMonthRates** — Three-month Eurodollar futures data or forward rate agreement data matrix

Three-month Eurodollar futures data or forward rate agreement data, specified as an N-by-3 matrix in the form of [month year IMMQuote]. A forward rate agreement stipulates that a certain interest rate applies to a certain principal amount for a given future time period. The floating rate is assumed to compound quarterly and to accrue on an actual/360 basis.

Data Types: double

**Settle** — Settlement date of fixed-rate of swap  
scalar numeric

Settlement date of fixed-rate of swap, specified as a scalar numeric using serial date numbers.

Data Types: double

**Tenor** — Life of the swap contract  
scalar integer

Life of the swap contract, specified as a scalar integer.

Data Types: double

**StartDate** — Reference date for valuation of forward swap  
Settle (default) | scalar numeric

(Optional) Reference date for valuation of forward swap, specified as a scalar numeric using serial date numbers. This in effect allows forward swap valuation.

Data Types: double

**Interpolation — Interpolation method to determine applicable forward rate for months when no Eurodollar data is available**

'linear' (1) (default) | scalar integer with value of 0, 1, or 2

(Optional) Interpolation method to determine applicable forward rate for months when no Eurodollar data is available, specified as a scalar numeric with values of:

- 0 is 'nearest'
- 1 is 'linear'
- 2 is 'cubic'

.

Data Types: double

**ConvexAdj — Indicates whether futures/forward convexity adjustment is required**

0 (off) (default) | scalar logical with a value of 0 or 1

(Optional) Indicates whether futures/forward convexity adjustment is required, specified as a scalar logical. Use ConvexAdj for forward rate adjustments when those rates are taken from Eurodollar futures data.

Data Types: logical

**RateParam — Short-rate model's parameters (Hull-White)**

[0.05 0.015] (default) | vector

(Optional) Short-rate model's parameters (Hull-White), specified a 1-by-2 vector to denote the parameters  $[a \ S]$ , where the short-rate process is:

$$dr = [\theta(t) - ar]dt + Sdz.$$

Data Types: double

**InArrears — Indicates whether the swap is in arrears**

0 (off) (default) | scalar logical with a value of 0 or 1

(Optional) Indicates whether the swap is in arrears, specified as a scalar logical.

Data Types: logical

**Sigma — Overall annual volatility of caplets**

scalar numeric

(Optional) Overall annual volatility of caplets, specified as a scalar numeric.

Data Types: double

**FixedCompound — Compounding or frequency of payment on the fixed side**

4 (quarterly) (default) | scalar numeric with possible values of 1, 2,4, or 12

(Optional) Compounding or frequency of payment on the fixed side, specified as a scalar numeric with one of the following possible values:

- 1 is annual
- 2 is semiannual

- 4 is quarterly
- 12 is monthly

Data Types: double

**FixedBasis — Basis of the fixed side**

0 (actual/actual ) (default) | scalar numeric

(Optional) Basis of the fixed side, specified as a scalar numeric using one of the supported values:.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

For more information, see “Basis” on page 2-129.

Data Types: double

**Output Arguments****FixedSpec — Structure of the fixed-rate side of the swap**

structure

Structure of the fixed-rate side of the swap, returned as a structure with the following fields:

- **Coupon:** Par-swap rate
- **Settle:** Start date
- **Maturity:** End date
- **Period:** Frequency of payment
- **Basis:** Accrual basis

**ForwardDates — Dates corresponding to ForwardRates**

numeric

Dates corresponding to `ForwardRates`, returned as serial date numbers. All of the dates are third Wednesdays of the month, spread three months apart. The first element is the third Wednesday immediately after `Settle`.

**ForwardRates — Forward rates corresponding to the forward dates**

numeric

Forward rates corresponding to the forward dates, quarterly compounded, and on the actual/360 basis, returned as numeric decimal values.

## liborprice

Price swap given swap rate

### Syntax

```
Price = liborprice(ThreeMonthRates,Settle,Tenor,SwapRate)
Price = liborprice(____,StartDate,Interpolation,ConvexAdj,RateParam,InArrears,
Sigma,FixedCompound,FixedBasis)
```

### Description

`Price = liborprice(ThreeMonthRates,Settle,Tenor,SwapRate)` computes the price per \$100 notional value of a swap given the swap rate. A positive result indicates that fixed side is more valuable than the floating side.

`Price = liborprice(____,StartDate,Interpolation,ConvexAdj,RateParam,InArrears, Sigma,FixedCompound,FixedBasis)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Price Per \$100 Notional Value of a Swap Given the Swap Rate

This example shows that a swap paying the par swap rate has a value of 0.

```
% load the input data
[EDFutData, textdata] = xlsread('EDdata.xls');
Settle = datenum('15-Oct-2002');
Tenor = 2;

% compute the fixed rate from the Eurodollar data
FixedSpec = liborfloat2fixed(EDFutData(:,1:3), Settle, Tenor)

FixedSpec = struct with fields:
    Coupon: 0.0222
    Settle: '16-Oct-2002'
    Maturity: '16-Oct-2004'
    Period: 4
    Basis: 1

% compute the price of a par swap
Price = liborprice(EDFutData(:,1:3), Settle, Tenor, FixedSpec.Coupon)

Price = 2.7756e-15
```

Price is effectively equal to 0.

## Input Arguments

### ThreeMonthRates — Three-month Eurodollar futures data or forward rate agreement data matrix

Three-month Eurodollar futures data or forward rate agreement data, specified as an N-by-3 matrix in the form of [month year IMMQuote]. A forward rate agreement stipulates that a certain interest rate applies to a certain principal amount for a given future time period. The floating rate is assumed to compound quarterly and to accrue on an actual/360 basis.

Data Types: double

### Settle — Settlement date of fixed-rate of swap

scalar numeric

Settlement date of fixed-rate of swap, specified as a scalar numeric using serial date numbers.

Data Types: double

### Tenor — Life of the swap contract

scalar integer

Life of the swap contract, specified as a scalar integer.

Data Types: double

### SwapRate — Swap rate

scalar decimal

Swap rate, specified as a scalar decimal.

Data Types: double

### StartDate — Reference date for valuation of forward swap

Settle (default) | scalar numeric

(Optional) Reference date for valuation of forward swap, specified as a scalar numeric using serial date numbers. This in effect allows forward swap valuation.

Data Types: double

### Interpolation — Interpolation method to determine applicable forward rate for months when no Eurodollar data is available

'linear' (1) (default) | scalar integer with value of 0, 1, or 2

(Optional) Interpolation method to determine applicable forward rate for months when no Eurodollar data is available, specified as a scalar numeric with values of:

- 0 is 'nearest'
- 1 is 'linear'
- 2 is 'cubic'

.

Data Types: double

**ConvexAdj — Indicates whether futures/forward convexity adjustment is required**

0 (off) (default) | scalar logical with a value of 0 or 1

(Optional) Indicates whether futures/forward convexity adjustment is required, specified as a scalar logical. Use ConvexAdj for forward rate adjustments when those rates are taken from Eurodollar futures data.

Data Types: logical

**RateParam — Short-rate model's parameters (Hull-White)**

[0.05 0.015] (default) | vector

(Optional) Short-rate model's parameters (Hull-White), specified a 1-by-2 vector to denote the parameters  $[a \ S]$ , where the short-rate process is:

$$dr = [\theta(t) - ar]dt + Sdz.$$

Data Types: double

**InArrears — Indicates whether the swap is in arrears**

0 (off) (default) | scalar logical with a value of 0 or 1

(Optional) Indicates whether the swap is in arrears, specified as a scalar logical.

Data Types: logical

**Sigma — Overall annual volatility of caplets**

scalar numeric

(Optional) Overall annual volatility of caplets, specified as a scalar numeric.

Data Types: double

**FixedCompound — Compounding or frequency of payment on the fixed side**

4 (quarterly) (default) | scalar numeric with possible values of 1, 2, 4, or 12

(Optional) Compounding or frequency of payment on the fixed side, specified as a scalar numeric with one of the following possible values:

- 1 is annual
- 2 is semiannual
- 4 is quarterly
- 12 is monthly

Data Types: double

**FixedBasis — Basis of the fixed side**

0 (actual/actual ) (default) | scalar numeric

(Optional) Basis of the fixed side, specified as a scalar numeric using one of the supported values:.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

For more information, see “Basis” on page 2-129.

Data Types: `double`

## Output Arguments

**Price** — Present value of the difference between floating and fixed-rate sides of the swap per \$100 notional

`numeric`

Present value of the difference between floating and fixed-rate sides of the swap per \$100 notional, returned as a numeric value.

## mbscfamounts

Cash flow and time mapping for mortgage pool

### Syntax

```
[CFlowAmounts, CFlowDates, TFactors, Factors, Payment, Principal, Interest,
Prepayment] = mbscfamounts(Settle, Maturity, IssueDate, GrossRate)
[CFlowAmounts, CFlowDates, TFactors, Factors, Payment, Principal, Interest,
Prepayment] = mbscfamounts( ____, CouponRate, Delay, PrepaySpeed, PrepayMatrix)
```

### Description

[CFlowAmounts, CFlowDates, TFactors, Factors, Payment, Principal, Interest, Prepayment] = mbscfamounts(Settle, Maturity, IssueDate, GrossRate) computes cash flows between Settle and Maturity dates, the corresponding time factors in months from Settle and the mortgage factor (the fraction of loan principal outstanding).

[CFlowAmounts, CFlowDates, TFactors, Factors, Payment, Principal, Interest, Prepayment] = mbscfamounts( \_\_\_\_, CouponRate, Delay, PrepaySpeed, PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Calculate Cash Flow Amounts and Dates, Time Factors, and Mortgage Factors for a Single Mortgage

Given a mortgage with the following characteristics, compute the cash flow amounts and dates, the time factors, and the mortgage factors.

Define the mortgage characteristics.

```
Settle      = datenum('17-April-2002');
Maturity    = datenum('1-Jan-2030');
IssueDate   = datenum('1-Jan-2000');
GrossRate   = 0.08125;
CouponRate  = 0.075;
Delay       = 14;
PrepaySpeed = 100;
```

Use mbscfamounts to evaluate the mortgage.

```
[CFlowAmounts, CFlowDates, TFactors, Factors] = ...
mbscfamounts(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, PrepaySpeed)
```

```
CFlowAmounts = 1x334
```

```
-0.0033    0.0118    0.0120    0.0121    0.0120    0.0119    0.0119    0.0118    0.0117    0.
```

```
CFlowDates = 1×334
```

```
    731323    731337    731368    731398    731429    731460    731490    731521
```

```
TFactors = 1×334
```

```
    0    0.9333    1.9333    2.9333    3.9333    4.9333    5.9333    6.9333    7.9333    8.9333
```

```
Factors = 1×334
```

```
    1.0000    0.9944    0.9887    0.9828    0.9769    0.9711    0.9653    0.9595    0.9538    0.9480
```

The result is contained in four 334-element row vectors.

### Compute Cash Flow Amounts and Dates, Time Factors, and Mortgage Factors for a Mortgage Portfolio

Given a portfolio of mortgage-backed securities, use `mbscfamounts` to compute the cash flows and other factors from the portfolio.

Define characteristics for a mortgage portfolio.

```
Settle = datenum(['13-Jan-2000'; '17-Apr-2002'; '17-May-2002']);
Maturity = datenum('1-Jan-2030');
IssueDate = datenum('1-Jan-2000');
GrossRate = 0.08125;
CouponRate = [0.075; 0.07875; 0.0775];
Delay = 14;
PrepaySpeed = 100;
```

Use `mbscfamounts` to evaluate the mortgage.

```
[CFlowAmounts, CFlowDates, TFactors, Factors] = ...
mbscfamounts(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, PrepaySpeed)
```

```
CFlowAmounts = 3×361
```

```
    -0.0025    0.0071    0.0072    0.0074    0.0076    0.0077    0.0079    0.0080    0.0082    0.0084
    -0.0035    0.0121    0.0123    0.0124    0.0123    0.0122    0.0122    0.0121    0.0120    0.0119
    -0.0034    0.0122    0.0123    0.0123    0.0122    0.0121    0.0121    0.0120    0.0119    0.0118
```

```
CFlowDates = 3×361
```

```
    730498    730517    730546    730577    730607    730638    730668    730699
    731323    731337    731368    731398    731429    731460    731490    731521
    731353    731368    731398    731429    731460    731490    731521    731551
```

```
TFactors = 3×361
```

```
    0    1.0667    2.0667    3.0667    4.0667    5.0667    6.0667    7.0667    8.0667    9.0667
```

```

0 0.9333 1.9333 2.9333 3.9333 4.9333 5.9333 6.9333 7.9333 8.9333
0 0.9333 1.9333 2.9333 3.9333 4.9333 5.9333 6.9333 7.9333 8.9333

```

Factors = 3×361

```

1.0000 0.9992 0.9982 0.9970 0.9957 0.9942 0.9925 0.9907 0.9887 0.9867
1.0000 0.9944 0.9887 0.9828 0.9769 0.9711 0.9653 0.9595 0.9538 0.9480
1.0000 0.9942 0.9883 0.9824 0.9766 0.9707 0.9649 0.9592 0.9534 0.9476

```

Each output is a 3-by-361 element matrix padded with NaN's wherever elements are missing.

### Calculate Payment, Principal, Interest, and Prepayment for a Single Mortgage

Given a mortgage with the following characteristics, compute payments, principal, interest, and prepayment.

Define the mortgage characteristics.

```

Settle      = datenum('17-April-2002');
Maturity    = datenum('1-Jan-2030');
IssueDate   = datenum('1-Jan-2000');
GrossRate   = 0.08125;
CouponRate  = 0.075;
Delay       = 14;
PrepaySpeed = 100;

```

Use `mbscfamonts` to evaluate the mortgage.

```

[Payment, Principal, Interest, Prepayment] = ...
mbscfamonts(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, PrepaySpeed)

```

Payment = 1×334

```

-0.0033  0.0118  0.0120  0.0121  0.0120  0.0119  0.0119  0.0118  0.0117  0.0116

```

Principal = 1×334

```

731323  731337  731368  731398  731429  731460  731490  731521

```

Interest = 1×334

```

0 0.9333 1.9333 2.9333 3.9333 4.9333 5.9333 6.9333 7.9333 8.9333

```

Prepayment = 1×334

```

1.0000 0.9944 0.9887 0.9828 0.9769 0.9711 0.9653 0.9595 0.9538 0.9480

```

## Input Arguments

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### Maturity — Maturity date

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### IssueDate — Issue date

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### GrossRate — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### CouponRate — Net coupon rate

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### Delay — Delay (in days) between payment from homeowner and receipt by bondholder

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

### PrepaySpeed — Speed relative to PSA standard

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

**Output Arguments****CFlowAmounts — Cash flow amounts**

matrix

Cash flows starting from `Settle` through end of the last month (`Maturity`), returned as a NMBS-by-P matrix.

**CFlowDates — Cash flow dates**

matrix

Cash flow dates (including at `Settle`), returned as a NMBS-by-P matrix.

**TFactors — Time factors**

matrix

Time factors (in months from `Settle`), returned as a NMBS-by-P matrix.

**Factors — Mortgage factors (the fraction of the balance still outstanding at the end of each month)**

matrix

Mortgage factors (the fraction of the balance still outstanding at the end of each month), returned as a NMBS-by-P matrix.

**Payment — Total monthly payment**

matrix

Total monthly payment, returned as a NMBS-by-P matrix.

**Principal — Principal portion of the payment**

matrix

Principal portion of the payment, returned as a NMBS-by-P matrix.

**Interest — Interest portion of the payment**

matrix

Interest portion of the payment, returned as a NMBS-by-P matrix.

**Prepayment — Unscheduled payment of principal**

matrix

Unscheduled payment of principal, returned as a NMBS-by-P matrix.

## mbsconvp

Convexity of mortgage pool given price

### Syntax

```
Convexity = mbsconvp(Price,Settle,Maturity,IssueDate,GrossRate)
Convexity = mbsconvp( ____,CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

### Description

`Convexity = mbsconvp(Price,Settle,Maturity,IssueDate,GrossRate)` computes mortgage-backed security convexity, given time information, price at settlement, and optionally, a prepayment model.

`Convexity = mbsconvp( ____,CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute a Mortgage-Backed Security Convexity

This example shows how to compute a mortgage-backed security convexity, given a mortgage-backed security with the following characteristics.

```
Price      = 101;
Settle     = '15-Apr-2002';
Maturity   = '1 Jan 2030';
IssueDate  = '1-Jan-2000';
GrossRate  = 0.08125;
CouponRate = 0.075;
Delay      = 14;
Speed      = 100;
```

```
Convexity = mbsconvp(Price, Settle, Maturity, IssueDate, ...
GrossRate, CouponRate, Delay, Speed)
```

```
Convexity = 71.6299
```

### Input Arguments

#### Price — Clean price for every \$100 face value

vector

Clean price for every \$100 face value, specified as an NMBS-by-1 vector.

Data Types: double

**Settle — Settlement dates**

vector

Settlement dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**Maturity — Maturity dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**IssueDate — Issue dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**GrossRate — Gross coupon rate (including fees)**

vector

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**Delay — Delay in days**

0 (no delay) (default) | vector

(Optional) Delay in days, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)-by-NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

## Output Arguments

### **Convexity — Periodic convexity of mortgage pool**

scalar numeric

Periodic convexity of mortgage pool, returned as a scalar numeric.

# mbsconvy

Convexity of mortgage pool given yield

## Syntax

```
Convexity = mbsconvy(Yield,Settle,Maturity,IssueDate,GrossRate)
Convexity = mbsconvy( ____,CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

## Description

`Convexity = mbsconvy(Yield,Settle,Maturity,IssueDate,GrossRate)` computes mortgage-backed security convexity, given time information, semiannual mortgage yield, and optionally, a prepayment model.

`Convexity = mbsconvy( ____,CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Convexity of a Mortgage Pool Given Yield

This example shows how to compute the convexity of mortgage pool given yield for a mortgage-backed security with the following characteristics.

```
Yield      = 0.07125;
Settle     = '15-Apr-2002';
Maturity   = '1 Jan 2030';
IssueDate  = '1-Jan-2000';
GrossRate  = 0.08125;
Speed      = 100;
CouponRate = 0.075;
Delay      = 14;
```

```
Convexity = mbsconvy(Yield, Settle, Maturity, IssueDate, ...
GrossRate, CouponRate, Delay, Speed)
```

```
Convexity = 72.8263
```

## Input Arguments

### Yield — Mortgage yield, compounded monthly

vector

Mortgage yield, compounded monthly, specified as an NMBS-by-1 vector in decimals.

Data Types: double

**Settle – Settlement dates**

vector

Settlement dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | cell

**Maturity – Maturity dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**IssueDate – Issue dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**GrossRate – Gross coupon rate (including fees)**

vector

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**CouponRate – Net coupon rate**

GrossRate (default) | vector

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**Delay – Delay in days**

0 (no delay) (default) | vector

(Optional) Delay in days, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed – Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the **PrepaySpeed** to [] if you input a customized **PrepayMatrix**.

---

Data Types: double

**PrepayMatrix – Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size  $\max(\text{TermRemaining})$ -by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

## Output Arguments

### **Convexity — Periodic convexity of mortgage pool**

scalar numeric

Periodic convexity of mortgage pool, returned as a scalar numeric.

## mbsdurp

Duration of mortgage pool given price

### Syntax

```
[YearDuration,ModDuration] = mbsdurp(Price,Settle,Maturity,IssueDate,  
GrossRate)  
[YearDuration,ModDuration] = mbsdurp( ____,CouponRate,Delay,PrepaySpeed,  
PrepayMatrix)
```

### Description

[YearDuration,ModDuration] = mbsdurp(Price,Settle,Maturity,IssueDate, GrossRate) computes the mortgage-backed security Macaulay (YearDuration) in years and modified (ModDuration) durations in years, given time information, price at settlement, and optionally, a prepayment model.

[YearDuration,ModDuration] = mbsdurp( \_\_\_\_,CouponRate,Delay,PrepaySpeed, PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Find the Duration of a Mortgage Pool

This example shows how to find the duration of mortgage pool given a mortgage-backed security with the following characteristics.

```
Price = 101;  
Settle = datenum('15-Apr-2002');  
Maturity = datenum('1 Jan 2030');  
IssueDate = datenum('1-Jan-2000');  
GrossRate = 0.08125;  
CouponRate = 0.075;;  
Delay = 14;  
Speed = 100;  
  
[YearDuration, ModDuration] = mbsdurp(Price, Settle, Maturity,...  
IssueDate, GrossRate, CouponRate, Delay, Speed)  
  
YearDuration = 6.4380  
ModDuration = 6.2080
```

### Input Arguments

**Price** — Clean price for every \$100 face of issue  
vector

Clean price for every \$100 face of issue, specified as an NMBS-by-1 vector.

Data Types: double

### **Settle — Settlement dates**

vector

Settlement dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | cell

### **Maturity — Maturity dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

### **IssueDate — Issue dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

### **GrossRate — Gross coupon rate (including fees)**

vector

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

### **CouponRate — Net coupon rate**

GrossRate (default) | vector

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

### **Delay — Delay in days**

0 (no delay) (default) | vector

(Optional) Delay in days, specified as an NMBS-by-1 vector.

Data Types: double

### **PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

**Output Arguments****YearDuration — Macaulay duration in years**

scalar numeric

Macaulay duration in years, returned as a scalar numeric.

**ModDuration — Modified duration in years**

scalar numeric

Modified duration in years, returned as a scalar numeric.

# mbsdury

Duration of mortgage pool given yield

## Syntax

```
[YearDuration,ModDuration] = mbsdury(Yield,Settle,Maturity,IssueDate,
GrossRate)
[YearDuration,ModDuration] = mbsdury( ____,CouponRate,Delay,PrepaySpeed,
PrepayMatrix)
```

## Description

[YearDuration,ModDuration] = mbsdury(Yield,Settle,Maturity,IssueDate, GrossRate) computes the mortgage-backed security Macaulay (YearDuration) in years and modified (ModDuration) durations in years, given time information, yield to maturity, and optionally, a prepayment model.

[YearDuration,ModDuration] = mbsdury( \_\_\_\_,CouponRate,Delay,PrepaySpeed, PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Find the Duration of a Mortgage Pool Given the Yield

This example shows how to find the duration of mortgage pool given a mortgage-backed security with the following characteristics.

```
Yield = 0.07298413;
Settle = '15-Apr-2002';
Maturity = '1 Jan 2030';
IssueDate = '1-Jan-2000';
GrossRate = 0.08125;
Speed = 100;
CouponRate = 0.075;
Delay = 14;
```

```
[YearDuration, ModDuration] = mbsdury(Yield, Settle, Maturity,...
IssueDate, GrossRate, CouponRate, Delay, Speed)
```

```
YearDuration = 6.4380
```

```
ModDuration = 6.2080
```

## Input Arguments

**Yield** — Mortgage yield, compounded monthly  
vector

Mortgage yield, compounded monthly, specified as an NMBS-by-1 vector in decimals.

Data Types: double

**Settle — Settlement dates**

vector

Settlement dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | cell

**Maturity — Maturity dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**IssueDate — Issue dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**GrossRate — Gross coupon rate (including fees)**

vector

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**Delay — Delay in days**

0 (no delay) (default) | vector

(Optional) Delay in days, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the **PrepaySpeed** to [] if you input a customized **PrepayMatrix**.

---

Data Types: double

## **PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

## **Output Arguments**

### **YearDuration — Macaulay duration in years**

scalar numeric

Macaulay duration in years, returned as a scalar numeric.

### **ModDuration — Modified duration in years**

scalar numeric

Modified duration in years, returned as a scalar numeric.

## mbsnoprepay

End-of-month mortgage cash flows and balances without prepayment

### Syntax

```
[Balance,Interest,Payment,Principal] = mbsnoprepay(OriginalBalance,GrossRate,Term)
```

### Description

[Balance,Interest,Payment,Principal] = mbsnoprepay(OriginalBalance,GrossRate,Term) computes end-of-month mortgage balance, interest payments, principal payments, and cash flow payments with zero prepayment rate.

mbsnoprepay returns amortizing cash flows and balances over a specified term with no prepayment. When the lengths of pass-throughs are not the same, MATLAB software pads the shorter ones with NaN.

### Examples

#### Compute an Amortization Schedule from Mortgage Pools

Given mortgage pools with the following characteristics, compute an amortization schedule.

```
OriginalBalance = 400000000;
CouponRate = 0.08125;
Term = [357; 355]; % Three- and five-month old mortgage pools.
```

```
[Balance, Interest, Payment, Principal] = mbsnoprepay(OriginalBalance, CouponRate, Term)
```

```
Balance = 357×2
108 ×
```

## Input Arguments

### **OriginalBalance** — Original face value in dollars

vector

Original face value in dollars, specified as a table or an NUMOBS-by-1 matrix.

Data Types: double

### **GrossRate** — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an NUMOBS-by-1 vector of decimal values.

Data Types: double

**Term — Term of the mortgage in months**

vector

Term of the mortgage in months, specified as an NUMOBS-by-1 vector.

Data Types: double

**Output Arguments****Balance — End-of-month balances over the life of the pass-through**

vector

End-of-month balances over the life of the pass-through, returned as a Term-by-1 vector.

**Interest — End-of-month interest payments over the life of the pass-through**

vector

End-of-month interest payments over the life of the pass-through, returned as a Term-by-1 vector.

**Payment — End-of-month payments over the life of the pass-through**

vector

End-of-month payments over the life of the pass-through, returned as a Term-by-1 vector.

**Principal — All scheduled end-of-month principal payments over the life of the pass-through**

vector

All scheduled end-of-month principal payments over the life of the pass-through, returned as a Term-by-1 vector.

# mbsoas2price

Price given option-adjusted spread

## Syntax

```
Price = mbsoas2price(ZeroCurve,OAS,Settle,Maturity,IssueDate,GrossRate)
Price = mbsoas2price( ____,CouponRate,Delay,Interpolation,PrepaySpeed,
PrepayMatrix)
```

## Description

Price = mbsoas2price(ZeroCurve,OAS,Settle,Maturity,IssueDate,GrossRate) computes the clean price of a pass-through security for each \$100 face value of outstanding principal.

Price = mbsoas2price( \_\_\_\_,CouponRate,Delay,Interpolation,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Theoretical Price of a Mortgage Pool

Given an option-adjusted spread, a spot curve, and a prepayment assumption, compute theoretical price of a mortgage pool. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002') 0      100 0 2 1;
          datenum('02/20/2003') 0      100 0 2 1;
          datenum('07/31/2004') 0.03   100 2 3 1;
          datenum('08/15/2007') 0.035  100 2 3 1;
          datenum('08/15/2012') 0.04875 100 2 3 1;
          datenum('02/15/2031') 0.05375 100 2 3 1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices = [ 98.97467;
           98.58044;
           100.10534;
           98.18054;
           101.38136;
           99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
105 ×
```

```
    7.3154    0.0000    0.0000
    7.3163    0.0000    0.0000
    7.3216    0.0000    0.0000
    7.3327    0.0000    0.0000
    7.3510    0.0000    0.0000
    7.4185    0.0000    0.0000
```

Assign the following parameters:

```
OAS           = [26.0502; 28.6348; 31.2222];
Maturity      = datenum('02-Jan-2030');
IssueDate     = datenum('02-Jan-2000');
GrossRate     = 0.08125;
CouponRate    = 0.075;
Delay         = 14;
Interpolation = 1;
PrepaySpeed   = [0 50 100];
```

Calculate the theoretical price from the option-adjusted spread.

```
Price = mbsoas2price(ZeroCurve, OAS, Settle, Maturity, ...
IssueDate, GrossRate, CouponRate, Delay, Interpolation, ...
PrepaySpeed)
```

```
Price = 3×1
```

```
    95.0006
    95.0006
    95.0006
```

## Input Arguments

### ZeroCurve — Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is serial date numbers.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).
- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual), 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datenum('1-Jan-2003') 0.0154 12;
 datenum('1-Jan-2004') 0.0250 12;
```

```
.....
datenum('1-Jan-2020') 0.0675 2];
```

Data Types: double | char | cell

### **OAS — Option-adjusted spreads**

vector

Option-adjusted spreads, in basis points, specified as an NMBS-by-1 vector.

Data Types: double

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### **Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [ ] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use PrepayMatrix only when PrepaySpeed is unspecified.

---

Data Types: double

**Output Arguments****Price — Clean price of passthrough per \$100 face of principal outstanding**

vector

Clean price of passthrough per \$100 face of principal outstanding, returned as a NMBS-by-1 vector.

## mbsoas2yield

Yield given option-adjusted spread

### Syntax

```
[MYield,BEMBSYield] = mbsoas2yield(ZeroCurve,OAS,Settle,Maturity,IssueDate,
GrossRate)
[MYield,BEMBSYield] = mbsoas2yield( ____,CouponRate,Delay,Interpolation,
PrepaySpeed,PrepayMatrix)
```

### Description

[MYield,BEMBSYield] = mbsoas2yield(ZeroCurve,OAS,Settle,Maturity,IssueDate, GrossRate) computes the mortgage and bond-equivalent yields of a pass-through security.

[MYield,BEMBSYield] = mbsoas2yield( \_\_\_\_,CouponRate,Delay,Interpolation, PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Theoretical Yield to Maturity of a Mortgage Pool

Given an option-adjusted spread, a spot curve, and a prepayment assumption, compute the theoretical yield to maturity of a mortgage pool. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002') 0      100 0 2 1;
          datenum('02/20/2003') 0      100 0 2 1;
          datenum('07/31/2004') 0.03   100 2 3 1;
          datenum('08/15/2007') 0.035  100 2 3 1;
          datenum('08/15/2012') 0.04875 100 2 3 1;
          datenum('02/15/2031') 0.05375 100 2 3 1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices = [ 98.97467;
           98.58044;
           100.10534;
           98.18054;
           101.38136;
           99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
105 ×
```

```
    7.3154    0.0000    0.0000
    7.3163    0.0000    0.0000
    7.3216    0.0000    0.0000
    7.3327    0.0000    0.0000
    7.3510    0.0000    0.0000
    7.4185    0.0000    0.0000
```

Assign the following parameters:

```
OAS           = [26.0502; 28.6348; 31.2222];
Maturity      = datenum('02-Jan-2030');
IssueDate    = datenum('02-Jan-2000');
GrossRate    = 0.08125;
CouponRate   = 0.075;
Delay        = 14;
Interpolation = 1;
PrepaySpeed  = [0 50 100];
```

Compute the mortgage yield and bond equivalent mortgage yield.

```
[MYield BEMBSYield] = mbssoas2yield(ZeroCurve, OAS, Settle, ...
Maturity, IssueDate, GrossRate, CouponRate, Delay, ...
Interpolation, PrepaySpeed)
```

```
MYield = 3×1
```

```
    0.0802
    0.0814
    0.0828
```

```
BEMBSYield = 3×1
```

```
    0.0816
    0.0828
    0.0842
```

## Input Arguments

### ZeroCurve — Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is serial date numbers.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).

- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual), 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datenum('1-Jan-2003') 0.0154 12;
 datenum('1-Jan-2004') 0.0250 12;
 .....
 datenum('1-Jan-2020') 0.0675 2];
```

Data Types: double | char | cell

### **OAS — Option-adjusted spreads**

vector

Option-adjusted spreads, in basis points, specified as an NMBS-by-1 vector.

Data Types: double

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### **Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use PrepayMatrix only when PrepaySpeed is unspecified.

---

Data Types: double

**Output Arguments****MYield — Yield to maturity of the mortgage-backed security**

vector

Yield to maturity of the mortgage-backed security, returned as a NMBS-by-1 vector. This yield is compounded monthly (12 times a year).

**BEMBSYield — Bond equivalent yield of the mortgage-backed security**

vector

Bond equivalent yield of the mortgage-backed security, returned as a NMBS-by-1 vector. This yield is compounded semiannually (two times a year).

# mbspassthrough

Mortgage pool cash flows and balances with prepayment

## Syntax

```
[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough(
OriginalBalance,GrossRate,OriginalTerm)
[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough( ____,
TermRemaining,PrepaySpeed,PrepayMatrix)
```

## Description

[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough(OriginalBalance,GrossRate,OriginalTerm) calculates mortgage pool cash flows and balances with prepayments.

If a standard (PSA) prepayment is specified, "aging" is applied to standard prepayment vector. Aging is the same amount as the age of the pool (OriginalTerm - TermRemaining).

[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough( \_\_\_\_, TermRemaining,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Cash Flow of Principal, Interest, and Prepayment of a Pass-Through Security

This example shows how to compute the cash flows and balances of a 3-month old mortgage pool with original term of 360 months, assuming a prepayment speed of 100.

```
OriginalBalance = 100000;
GrossRate = 0.08125;
OriginalTerm = 360;
TermRemaining = 357;
PrepaySpeed = 100;
```

```
[Balance, Payment, Principal, Interest, Prepayment] =...

## Input Arguments

### **OriginalBalance** — Original balance value in dollars

vector

Original balance value in dollars (balance at the beginning of each `TermRemaining`), specified as an `NMBS-by-1` vector.

Data Types: `double`

### **GrossRate** — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an `NMBS-by-1` vector of decimal values.

Data Types: `double`

### **OriginalTerm** — Term of the mortgage in months

vector

Term of the mortgage in months, specified as an `NMBS-by-1` vector.

Data Types: `double`

### **TermRemaining** — Number of full months between settlement and maturity

`OriginalTerm` (default) | vector

(Optional) Number of full months between settlement and maturity, specified as an `NMBS-by-1` vector. For this argument, "full months" means not including fractional first term (if there is one).

Data Types: `double`

### **PrepaySpeed** — Speed relative to PSA standard

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an `NMBS-by-1` vector. The PSA standard is 100.

---

**Note** Set the `PrepaySpeed` to `[]` if you input a customized `PrepayMatrix`.

---

Data Types: `double`

### **PrepayMatrix** — Customized prepayment vector

matrix

(Optional) Customized prepayment vector, specified as a `NaN`-padded matrix of size `max(TermRemaining)-by-NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: `double`

## Output Arguments

### **Balance — Principal balance at end of month**

vector

Principal balance at end of month, returned as a `TermRemaining-by-1` vectors of end-of-month values.

### **Payment — Total monthly payment**

vector

Total monthly payment, returned as a `TermRemaining-by-1` vectors of end-of-month values.

### **Principal — Principal portion of the payment**

vector

Principal portion of the payment, returned as a `TermRemaining-by-1` vectors of end-of-month values.

### **Interest — Interest portion of the payment**

vector

Interest portion of the payment, returned as a `TermRemaining-by-1` vectors of end-of-month values.

### **Prepayment — Unscheduled principal payment**

vector

Unscheduled principal payment, returned as a `TermRemaining-by-1` vectors of end-of-month values.

# mbsprice

Mortgage-backed security price given yield

## Syntax

```
[Price,AccrInt] = mbsprice(Yield,Settle,Maturity,IssueDate,GrossRate)
[Price,AccrInt] = mbsprice( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

## Description

[Price,AccrInt] = mbsprice(Yield,Settle,Maturity,IssueDate,GrossRate) computes a mortgage-backed security price, given time information and mortgage yield at settlement.

[Price,AccrInt] = mbsprice( \_\_\_ CouponRate,Delay,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Determine the Mortgage-Backed Security Price Given the Yield

This example shows how to determine the mortgage-backed security price given a mortgage-backed security with the following characteristics.

```
Yield = 0.0725;
Settle = datenum('15-Apr-2002');
Maturity = datenum('1 Jan 2030');
IssueDate = datenum('1-Jan-2000');
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;
```

```
[Price AccrInt] = mbsprice(Yield, Settle, Maturity, IssueDate,...
GrossRate, CouponRate, Delay, Speed)
```

```
Price = 101.3147
```

```
AccrInt = 0.2917
```

### Determine the Mortgage-Backed Security Price Using a Customized PrePaytMatrix

This example shows how to determine the mortgage-backed security price, given a mortgage-backed security, and PrePaytMatrix with the following characteristics:

```
Yield = 0.0725;
Settle = datenum('15-Apr-2002');
Maturity = datenum('1 Jan 2030');
```

```
IssueDate = datenum('1-Jan-2000');  
GrossRate = 0.08125;  
PrepayMatrix = 0.005*ones(360,1);  
  
[Price AccrInt] = mbsprice(Yield, Settle, Maturity, IssueDate,...  
GrossRate, PrepayMatrix)  
  
Price = 360x1

## Input Arguments

### **Yield — Mortgage yield compounded monthly**

vector of decimal values

Mortgage yield compounded monthly, specified as an NMBS-by-1 vector using decimal values.

Data Types: double

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### **Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use PrepayMatrix only when PrepaySpeed is unspecified.

---

Data Types: double

## Output Arguments

### **Price — Clean price for every \$100 face value of the securities**

vector

Clean price for every \$100 face value of the securities, returned as a NMBS-by-1 vector.

### **AccrInt — Accrued interest of the mortgage-backed securities**

vector

Accrued interest of the mortgage-backed securities, returned as a NMBS-by-1 vector.

# mbsprice2oas

Option-adjusted spread given price

## Syntax

```
OAS = mbsprice2oas(ZeroCurve,Price,Settle,Maturity,IssueDate,GrossRate)
OAS = mbsprice2oas( ____,CouponRate,Delay,Interpolation,PrepaySpeed,
PrepayMatrix)
```

## Description

OAS = mbsprice2oas(ZeroCurve,Price,Settle,Maturity,IssueDate,GrossRate) computes the option-adjusted spread in basis points.

OAS = mbsprice2oas( \_\_\_\_,CouponRate,Delay,Interpolation,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Calculate the Option-Adjusted Spread of a 30-Year Fixed-Rate Mortgage

Calculate the option-adjusted spread of a 30-year fixed-rate mortgage with about a 28-year weighted average maturity remaining, given assumptions of 0, 50, and 100 PSA prepayments. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002') 0      100 0 2 1;
          datenum('02/20/2003') 0      100 0 2 1;
          datenum('07/31/2004') 0.03   100 2 3 1;
          datenum('08/15/2007') 0.035  100 2 3 1;
          datenum('08/15/2012') 0.04875 100 2 3 1;
          datenum('02/15/2031') 0.05375 100 2 3 1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices = [ 98.97467;
           98.58044;
           100.10534;
           98.18054;
           101.38136;
           99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
105 ×
```

```
    7.3154    0.0000    0.0000
    7.3163    0.0000    0.0000
    7.3216    0.0000    0.0000
    7.3327    0.0000    0.0000
    7.3510    0.0000    0.0000
    7.4185    0.0000    0.0000
```

Assign the following parameters:

```
Price          = 95;
Maturity       = datenum('02-Jan-2030');
IssueDate     = datenum('02-Jan-2000');
GrossRate     = 0.08125;
CouponRate    = 0.075;
Delay         = 14;
Interpolation = 1;
PrepaySpeed   = [0; 50; 100];
Interpolation = 1;
```

Compute the option-adjusted spread.

```
OAS = mbsprice2oas(ZeroCurve, Price, Settle, Maturity, ...
IssueDate, GrossRate, CouponRate, Delay, Interpolation, ...
PrepaySpeed)
```

```
OAS = 3×1
```

```
    26.0508
    28.6355
    31.2232
```

## Input Arguments

### ZeroCurve – Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is serial date numbers.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).
- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual), 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datenum('1-Jan-2003') 0.0154 12;
 datenum('1-Jan-2004') 0.0250 12;
```

```
.....
datenum('1-Jan-2020') 0.0675 2];
```

Data Types: double | char | cell

**Price — Clean price for every \$100 face value of bond issue**

vector

Clean price for every \$100 face value of bond issue, specified as an NMBS-by-1 vector.

Data Types: double

**Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

**Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [ ] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use PrepayMatrix only when PrepaySpeed is unspecified.

---

Data Types: double

**Output Arguments****OAS — Zero volatility OAS**

vector

Zero volatility OAS, in basis point (bp), returned as a NMBS-by-1 vector.

## mbsprice2speed

Implied PSA prepayment speeds given price

### Syntax

```
[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsprice2speed(Price, Settle, Maturity,
IssueDate, GrossRate, PrepayMatrix)
[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsprice2speed( ____, CouponRate, Delay)
```

### Description

[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsprice2speed(Price, Settle, Maturity, IssueDate, GrossRate, PrepayMatrix) computes PSA prepayment speeds implied by pool prices and projected (user-defined) prepayment vectors. The calculated PSA speed produces the same price, modified duration, or modified convexity, depending upon the output requested.

[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsprice2speed( \_\_\_\_, CouponRate, Delay) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute PSA Prepayment Speeds

This example shows how to compute the equivalent PSA benchmark prepayment speeds for a mortgage pool with the following characteristics and prepayment matrix.

```
Price          = 101;
Settle         = datenum('1-Jan-2000');
Maturity       = datenum('1-Jan-2030');
IssueDate      = datenum('1-Jan-2000');
GrossRate      = 0.08125;
PrepayMatrix   = 0.005*ones(360,1);
CouponRate     = 0.075;
Delay          = 14;
```

```
[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = ...
mbsprice2speed(Price, Settle, Maturity, IssueDate, ...
GrossRate, PrepayMatrix, CouponRate, Delay)
```

```
ImpSpdOnPrc = 118.5980
```

```
ImpSpdOnDur = 118.3946
```

```
ImpSpdOnCnv = 109.5115
```

## Input Arguments

### Price — Clean price for every \$100 face value

vector

Clean price for every \$100 face value, specified as an NMBS-by-1 vector.

Data Types: double

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### Maturity — Maturity date

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### IssueDate — Issue date

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### GrossRate — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### PrepayMatrix — Customized prepayment vector

matrix

Customized prepayment vector, specified as a NaN-padded matrix of size  $\max(\text{TermRemaining})$ -by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use **PrepayMatrix** only when **PrepaySpeed** is unspecified.

---

Data Types: double

### CouponRate — Net coupon rate

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

## Output Arguments

**ImpSpd0nPrc — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price, returned as a NMBS-by-1 vector.

**ImpSpd0nDur — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration, returned as a NMBS-by-1 vector.

**ImpSpd0nCnv — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity, returned as a NMBS-by-1 vector.

# mbswal

Weighted average life of mortgage pool

## Syntax

```
WAL = mbswal(Settle,Maturity,IssueDate,GrossRate)
WAL = mbswal( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

## Description

`WAL = mbswal(Settle,Maturity,IssueDate,GrossRate)` computes the weighted average life, in number of years, of a mortgage pool, as measured from the settlement date.

`WAL = mbswal( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Determine the Weighted Average Life of a Mortgage Pool

This example shows how to determine the weighted average life of a mortgage pool, given a pass-through security with the following characteristics.

```
Settle = datenum('15-Apr-2002');
Maturity = datenum('1 Jan 2030');
IssueDate = datenum('1-Jan-2000');
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;
```

```
WAL = mbswal(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, Speed)
```

```
WAL = 10.5477
```

## Input Arguments

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. `Settle` must be earlier than `Maturity`.

Data Types: double | char | cell

### Maturity — Maturity date

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use PrepayMatrix only when PrepaySpeed is unspecified.

---

Data Types: double

## Output Arguments

### **WAL — Weighted Average Life of MBS, in number of years**

vector

Weighted Average Life (WAL) of MBS, in number of years, returned as a NMBS-by-1 vector.

## mbsyield

Mortgage-backed security yields given price

### Syntax

```
[MYield,BEMBSYield] = mbsyield(Price,Settle,Maturity,IssueDate,GrossRate)
[MYield,BEMBSYield] = mbsyield( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

### Description

[MYield,BEMBSYield] = mbsyield(Price,Settle,Maturity,IssueDate,GrossRate) computes a mortgage-backed security yield to maturity and the bond equivalent yield, given time information, and price at settlement.

[MYield,BEMBSYield] = mbsyield( \_\_\_ CouponRate,Delay,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Determine a Mortgage-Backed Security Yield Given the Price

This example shows how to determine the mortgage-backed security yield, given a mortgage-backed security with the following characteristics.

```
Price = 102;
Settle = '15-Apr-2002';
Maturity = '1 Jan 2030';
IssueDate = '1-Jan-2000';
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;

[MYield, BEMBSYield] = mbsyield(Price, Settle, Maturity, ...
IssueDate, GrossRate, CouponRate, Delay, Speed)

MYield = 0.0715
BEMBSYield = 0.0725
```

#### Determine Multiple Mortgage-Backed Securities Yields Given the Price

This example shows how to determine multiple mortgage-backed securities yields, given a portfolio of mortgage-backed securities with the following characteristics.

```
Price = 102;
Settle = datenum(['13-Feb-2000';'17-Apr-2002';'17-May-2002';...])
```

```

'13-Jan-2000']);
Maturity = datenum('1-Jan-2030');
IssueDate = datenum('1-Jan-2000');
GrossRate = 0.08125;
CouponRate = [0.075; 0.07875; 0.0775; 0.08125];
Delay = 14;
Speed = 100;

[MYield, BEMBSYield] = mbsyield(Price, Settle, Maturity,...
IssueDate, GrossRate, CouponRate, Delay, Speed)

MYield = 4×1

    0.0717
    0.0751
    0.0739
    0.0779

BEMBSYield = 4×1

    0.0728
    0.0763
    0.0750
    0.0791

```

## Input Arguments

### Price — Clean price for every \$100 face value

vector

Clean price for every \$100 face value, specified as an NMBS-by-1 vector.

Data Types: double

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### Maturity — Maturity date

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### IssueDate — Issue date

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size  $\max(\text{TermRemaining})$ -by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use PrepayMatrix only when PrepaySpeed is unspecified.

---

Data Types: double

**Output Arguments****MYield — Yield to maturity of the mortgage-backed security**

vector

Yield to maturity of the mortgage-backed security, returned as a NMBS-by-1 vector. This yield is compounded monthly (12 times a year).

**BEMBSYield — Bond equivalent yield of the mortgage-backed security**

vector

Bond equivalent yield of the mortgage-backed security, returned as a NMBS-by-1 vector. This yield is compounded semiannually (two times a year).

## mbsyield2oas

Option-adjusted spread given yield

### Syntax

```
OAS = mbsyield2oas(ZeroCurve,Yield,Settle,Maturity,IssueDate,GrossRate)
OAS = mbsyield2oas( ____,CouponRate,Delay,Interpolation,PrepaySpeed,
PrepayMatrix)
```

### Description

OAS = mbsyield2oas(ZeroCurve,Yield,Settle,Maturity,IssueDate,GrossRate) computes option-adjusted spread in basis points.

OAS = mbsyield2oas( \_\_\_\_,CouponRate,Delay,Interpolation,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Calculate the Option-Adjusted Spread of a 30-Year Fixed-Rate Mortgage Pool

Calculate the option-adjusted spread of a 30-year, fixed-rate mortgage pool with about 28-year weighted average maturity left, given assumptions of 0, 50, and 100 PSA prepayments. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002') 0      100 0 2 1;
          datenum('02/20/2003') 0      100 0 2 1;
          datenum('07/31/2004') 0.03   100 2 3 1;
          datenum('08/15/2007') 0.035  100 2 3 1;
          datenum('08/15/2012') 0.04875 100 2 3 1;
          datenum('02/15/2031') 0.05375 100 2 3 1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices = [ 98.97467;
           98.58044;
           100.10534;
           98.18054;
           101.38136;
           99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
105 ×
```

```
    7.3154    0.0000    0.0000
    7.3163    0.0000    0.0000
    7.3216    0.0000    0.0000
    7.3327    0.0000    0.0000
    7.3510    0.0000    0.0000
    7.4185    0.0000    0.0000
```

Assign the following parameters:

```
Price          = 95;
Maturity       = datenum('02-Jan-2030');
IssueDate     = datenum('02-Jan-2000');
GrossRate     = 0.08125;
CouponRate    = 0.075;
Delay         = 14;
Interpolation = 1;
PrepaySpeed   = [0 50 100];
```

Compute the yield, and from the yield, compute the option-adjusted spread.

```
[mbsyld, beyld] = mbsyield(Price, Settle, ...
Maturity, IssueDate, GrossRate, CouponRate, Delay, PrepaySpeed);
```

```
OAS = mbsyield2oas(ZeroCurve, mbsyld, Settle, ...
Maturity, IssueDate, GrossRate, CouponRate, Delay, ...
Interpolation, PrepaySpeed)
```

```
OAS = 3×1
```

```
    26.0508
    28.6355
    31.2232
```

## Input Arguments

### ZeroCurve — Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is serial date numbers.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).
- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual), 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datenum('1-Jan-2003') 0.0154 12;  
datenum('1-Jan-2004') 0.0250 12;  
.....  
datenum('1-Jan-2020') 0.0675 2];
```

Data Types: double | char | cell

### **Yield — Mortgage yield, compounded monthly**

vector in decimals

Mortgage yield, compounded monthly, specified as an NMBS-by-1 vector in decimals.

Data Types: double

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### **Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

### **Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: double

### **PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [ ] if you input a customized PrepayMatrix.

---

Data Types: double

### **PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use PrepayMatrix only when PrepaySpeed is unspecified.

---

Data Types: double

## **Output Arguments**

### **OAS — Zero volatility OAS**

vector

Zero volatility OAS, in basis point (bp), returned as a NMBS-by-1 vector.

# mbsyield2speed

Implied PSA prepayment speeds given yield

## Syntax

```
[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsyield2speed(Yield, Settle, Maturity,
IssueDate, GrossRate, PrepayMatrix)
[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsyield2speed( ____, CouponRate, Delay)
```

## Description

[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsyield2speed(Yield, Settle, Maturity, IssueDate, GrossRate, PrepayMatrix) computes PSA prepayment speeds implied by pool yields and projected (user-defined) prepayment vectors. The calculated PSA speed produces the same yield, modified duration, or modified convexity, depending upon the output requested.

[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsyield2speed( \_\_\_\_, CouponRate, Delay) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute PSA Prepayment Speeds

Calculate the equivalent PSA benchmark prepayment speeds for a security with these characteristics and prepayment matrix.

```
Yield          = 0.065;
Settle         = datenum('1-Jan-2000');
Maturity       = datenum('1-Jan-2030');
IssueDate      = datenum('1-Jan-2000');
GrossRate      = 0.08125;
PrepayMatrix   = 0.005*ones(360,1);
CouponRate     = 0.075;
Delay          = 14;
```

```
[ImpSpdOnYld, ImpSpdOnDur, ImpSpdOnCnv] = ...
mbsyield2speed(Yield, Settle, Maturity, IssueDate, GrossRate, ...
PrepayMatrix, CouponRate, Delay)
```

```
ImpSpdOnYld = 117.7644
```

```
ImpSpdOnDur = 116.7436
```

```
ImpSpdOnCnv = 108.3309
```

## Input Arguments

### **Yield — Mortgage yield, compounded monthly**

vector in decimals

Mortgage yield, compounded monthly, specified as an NMBS-by-1 vector in decimals.

Data Types: double

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### **Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **PrepayMatrix — Customized prepayment vector**

matrix

Customized prepayment vector, specified as a NaN-padded matrix of size  $\max(\text{TermRemaining})$ -by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use **PrepayMatrix** only when **PrepaySpeed** is unspecified.

---

Data Types: double

### **CouponRate — Net coupon rate**

**GrossRate** (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

## Output Arguments

**ImpSpd0nPrc — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price, returned as a NMBS-by-1 vector.

**ImpSpd0nDur — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration, returned as a NMBS-by-1 vector.

**ImpSpd0nCnv — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity, returned as a NMBS-by-1 vector.

## psaspeed2default

Benchmark default

### Syntax

```
[ADRPCSA,MDRPCSA] = psaspeed2default(DefaultSpeed)
```

### Description

[ADRPCSA,MDRPCSA] = psaspeed2default(DefaultSpeed) computes the benchmark default on the performing balance of mortgage-backed securities per PSA benchmark speed.

### Examples

#### Compute the Benchmark Default Rates on the Performing Balance of Mortgage-Backed Securities Per PSA Benchmark Speed

This example shows how to compute the benchmark default rates on the performing balance of mortgage-backed securities per PSA benchmark speed, given a mortgage-backed security with annual speed set at the PSA default benchmark.

```
DefaultSpeed = 100;
```

```
[ADRPCSA, MDRPSA] = psaspeed2default(DefaultSpeed)
```

```
ADRPCSA = 360×1

## Input Arguments

### **DefaultSpeed — Annual speed relative to the benchmark**

vector in decimals

Annual speed relative to the benchmark, specified as an NDEF-by-1 vector. The PSA benchmark is 100.

Data Types: double

## Output Arguments

### **ADRPSA — PSA default rate**

vector

PSA default rate, returned as a 360-by-NDEF vector in decimals.

### **MDRPSA — PSA monthly default rate**

vector

PSA monthly default rate, returned as a 360-by-NDEF vector in decimals.

## psaspeed2rate

Single monthly mortality rate given PSA speed

### Syntax

```
[CPRPSA, SMMPSA] = psaspeed2rate(PSASpeed)
```

### Description

[CPRPSA, SMMPSA] = psaspeed2rate(PSASpeed) calculates vectors of PSA prepayments, each containing 360 prepayment elements, to represent the 360 months in a 30-year mortgage pool.

### Examples

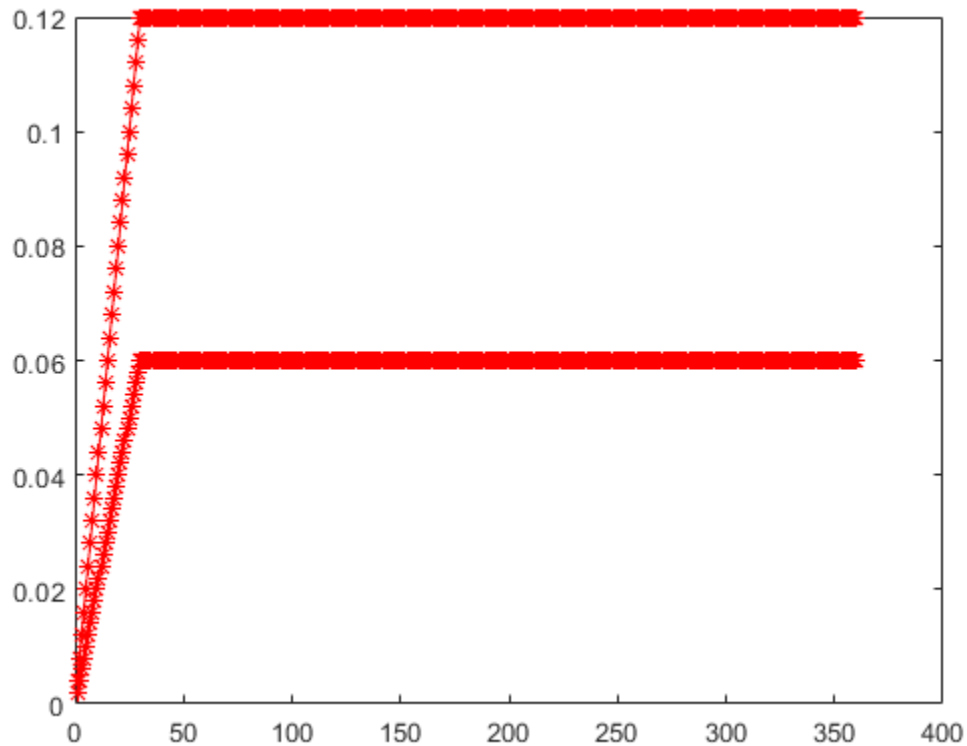

#### Compute the Prepayment and Mortality Rates

This example shows how to compute the prepayment and mortality rates, given a mortgage-backed security with annual speed set at the PSA default benchmark.

```
PSASpeed = [100 200];
```

```
[CPRPSA, SMMPSA]= psaspeed2rate(PSASpeed);
```

```
% view the plot of the output  
psaspeed2rate(PSASpeed)
```

## Input Arguments

### PSASpeed — Annual speed relative to the benchmark

vector in decimals

Annual speed relative to the benchmark, specified as any value  $> 0$  using an NSPD-by-1 vector. The PSA benchmark is 100.

Data Types: double

## Output Arguments

### CPRPSA — PSA conditional prepayment rate

vector

PSA conditional prepayment rate, returned as a 360-by-NSPD vector in decimals.

### SMMPSA — PSA single monthly mortality rate

vector

PSA monthly default rate, returned as a 360-by-NSPD vector in decimals.

# stepcpncfamounts

Cash flow amounts and times for bonds and stepped coupons

## Syntax

[CFlows, CDates, CTimes] = stepcpncfamounts(Settle, Maturity, ConvDates, CouponRates, Period, Basis, EndDate)

## Arguments

Settle	Settlement date. A scalar or vector of serial date numbers. <b>Settle</b> must be earlier than <b>Maturity</b> .
Maturity	Maturity date. A scalar or vector of serial date numbers.
ConvDates	Matrix of serial date numbers representing conversion dates after <b>Settle</b> . Size = number of instruments by maximum number of conversions. Fill unspecified entries with <b>NaN</b> .
CouponRates	<p>Matrix indicating the coupon rates for each bond in decimal form. Size = number of instruments by maximum number of conversions + 1. First column of this matrix contains rates applicable between <b>Settle</b> and the first conversion date (date in the first column of <b>ConvDates</b>). Fill unspecified entries with <b>NaN</b>.</p> <p><b>ConvDates</b> has the same number of rows as <b>CouponRates</b> to reflect the same number of bonds. However, <b>ConvDates</b> has one less column than <b>CouponRates</b>. This situation is illustrated by</p> <pre> Settle-----ConvDate1-----ConvDate2-----Maturity           Rate1           Rate2           Rate3 </pre>
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2, 3, 4, 6, and 12. Default = 2.

Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
EndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
Face	<p>(Optional) Face value of each bond in the portfolio. Default = 100.</p>

**Note** All arguments must be scalars or number of bonds (NUMBONDS)-by-1 vectors, except for **ConvDates** and **CouponRates**.

## Description

`[CFlows, CDates, CTimes] = stepcncfamounts(Settle, Maturity, ConvDates, CouponRates, Period, Basis, EndMonthRule, Face)` returns matrices of cash flow amounts, cash flow dates, and time factors for a portfolio of NUMBONDS stepped-coupon bonds.

**CFlows** is a matrix of cash flow amounts. The first entry in each row vector is a negative number indicating the accrued interest due at settlement. If no accrued interest is due, the first column is 0.

**CDates** is a matrix of cash flow dates in serial date number form. At least two columns are always present, one for settlement and one for maturity.

**CTimes** is a matrix of time factors for the SIA semiannual price/yield conversion.

$\text{DiscountFactor} = (1 + \text{Yield}/2)^{-\text{TFactor}}$

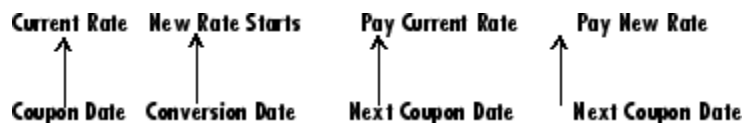

Time factors are in units of semiannual coupon periods. In computing time factors, use SIA actual/actual conventions for all time factor calculations.

**Note** For bonds with fixed coupons, use `cfamounts`. If you use a fixed-coupon bond with `stepcpncfamounts`, MATLAB software generates an error.

## Examples

This example generates stepped cash flows for three different bonds, all paying interest semiannually. Their life span is about 18-19 years each:

- Bond A has two conversions, but the first one occurs on the settlement date and immediately expires.
- Bond B has three conversions, with conversion dates exactly on the coupon dates.
- Bond C has three conversions, with some conversion dates not on the coupon dates. It has the longest maturity. This case illustrates that only cash flows for full periods after conversion dates are affected, as illustrated below.

The following table illustrates the interest rate characteristics of this bond portfolio.

Bond A Dates	Bond A Rates	Bond B Dates	Bond B Rates	Bond C Dates	Bond C Rates
Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	2.5%
First Conversion (02-Aug-92)	8.875%	First Conversion (15-Jun-97)	8.875%	First Conversion (14-Jun-97)	5.0%
Second Conversion (15-Jun-03)	9.25%	Second Conversion (15-Jun-01)	9.25%	Second Conversion (14-Jun-01)	7.5%
Maturity (15-Jun-10)	NaN	Third Conversion (15-Jun-05)	10.0%	Third Conversion (14-Jun-05)	10.0%
		Maturity (15-Jun-10)	NaN	Maturity (15-Jun-11)	NaN

```
Settle = datenum('02-Aug-1992');

ConvDates = [datenum('02-Aug-1992'), datenum('15-Jun-2003'), ...
             nan;
             datenum('15-Jun-1997'), datenum('15-Jun-2001'), ...
             datenum('15-Jun-2005');
             datenum('14-Jun-1997'), datenum('14-Jun-2001'), ...
             datenum('14-Jun-2005')];

Maturity = [datenum('15-Jun-2010');
            datenum('15-Jun-2010');
            datenum('15-Jun-2011')];

CouponRates = [0.075 0.08875 0.0925 nan;
               0.075 0.08875 0.0925 0.1;
               0.025 0.05 0.0750 0.1];

Basis = 1;
Period = 2;
```

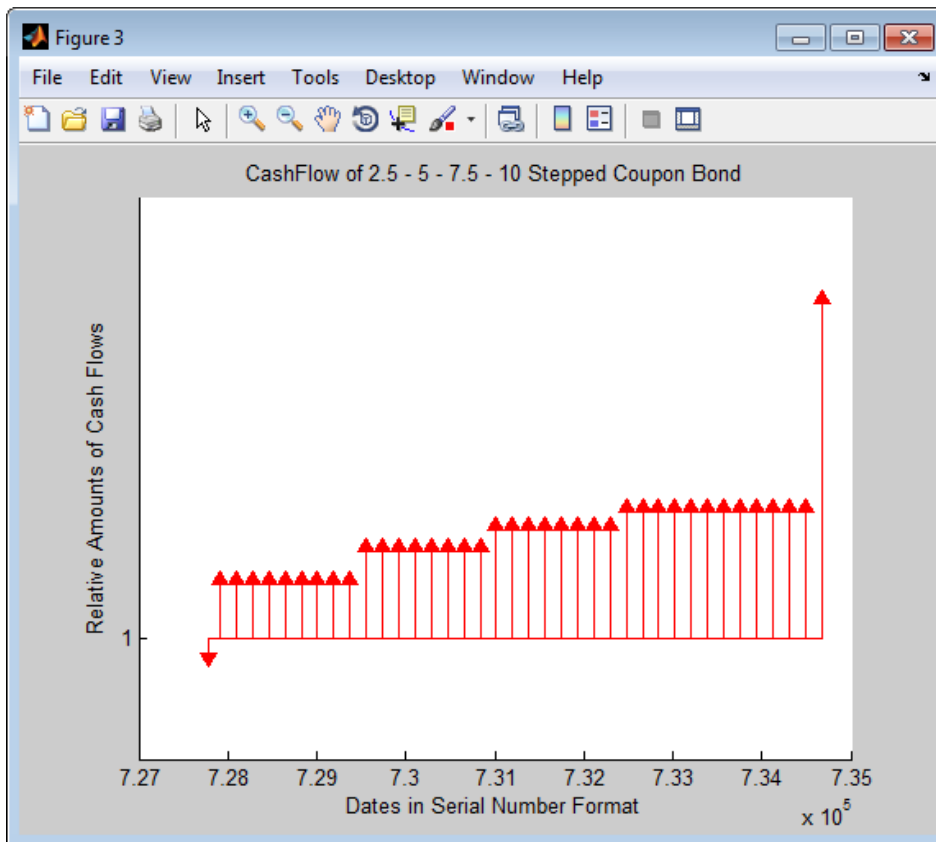

```
EndMonthRule = 1;
Face = 100;
```

Call `stepcpncfamounts` to compute cash flows and timings.

```
[CFloWs, CDates, CTimes] = stepcpncfamounts(Settle, Maturity, ...
ConvDates, CouponRates);
```

Visualize the third bond cash flows (2.5 - 5 - 7.5 - 10) using the `cfplot` function.

```
cfplot(CDates(3,:),CFloWs(3,:));
xlabel('Dates in Serial Number Format')
ylabel('Relative Amounts of Cash Flows')
title('CashFlow of 2.5 - 5 - 7.5 - 10 Stepped Coupon Bond')
```

# stepcpnprice

Price bond with stepped coupons

## Syntax

[Price,AccruedInterest] = stepcpnprice(Yield,Settle,Maturity,ConvDates,CouponRates,Period,Basis, ...)

## Arguments

Yield	Scalar or vector containing yield to maturity of instruments.
Settle	Settlement date. A scalar or vector of serial date numbers. <b>Settle</b> must be earlier than <b>Maturity</b> .
Maturity	Maturity date. A scalar or vector of serial date numbers.
ConvDates	Matrix of serial date numbers representing conversion dates after <b>Settle</b> . Size = number of instruments by maximum number of conversions. Fill unspecified entries with <b>NaN</b> .
CouponRates	<p>Matrix indicating the coupon rates for each bond in decimal form. Size = number of instruments by maximum number of conversions + 1. First column of this matrix contains rates applicable between <b>Settle</b> and the first conversion date (date in the first column of <b>ConvDates</b>). Fill unspecified entries with <b>NaN</b>.</p> <p><b>ConvDates</b> has the same number of rows as <b>CouponRate</b> to reflect the same number of bonds. However, <b>ConvDates</b> has one less column than <b>CouponRate</b>. This situation is illustrated by</p> <pre> Settle-----ConvDate1-----ConvDate2-----Maturity           Rate1           Rate2           Rate3 </pre>
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2, 3, 4, 6, and 12. Default = 2.

Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
EndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
Face	<p>(Optional) Face value of each bond in the portfolio. Default = 100.</p>

---

**Note** All arguments must be scalars or number of bonds (NUMBONDS)-by-1 vectors, except for **ConvDates** and **CouponRates**.

---

## Description

[Price, AccruedInterest] = stepcpnprice(Yield, Settle, Maturity, ConvDates, CouponRates, Period, Basis, EndMonthRule, Face) computes the price of bonds with stepped coupons given the yield to maturity. The function supports any number of conversion dates.

Price is a NUMBONDS-by-1 vector of clean prices.

AccruedInterest is a NUMBONDS-by-1 vector of accrued interest payable at settlement dates.

---

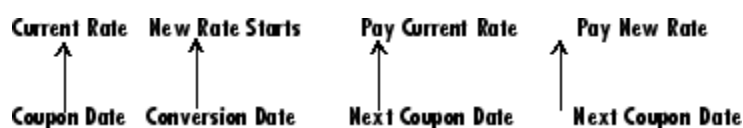

**Note** For bonds with fixed coupons, use **bndprice**. If you use a fixed-coupon bond with **stepcpnprice**, you receive the error: incorrect number of inputs.

---

## Examples

Compute the price and accrued interest due on a portfolio of stepped-coupon bonds having a yield of 7.221%, given three conversion scenarios:

- Bond A has two conversions, the first one falling on the settle date and immediately expiring.
- Bond B has three conversions, with conversion dates exactly on the coupon dates.
- Bond C has three conversions, with one or more conversion dates not on coupon dates. This case illustrates that only cash flows for full periods after conversion dates are affected, as illustrated below.

The following table illustrates the interest rate characteristics of this bond portfolio.

Bond A Dates	Bond A Rates	Bond B Dates	Bond B Rates	Bond C Dates	Bond C Rates
Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%
First Conversion (02-Aug-92)	8.875%	First Conversion (15-Jun-97)	8.875%	First Conversion (14-Jun-97)	8.875%
Second Conversion (15-Jun-03)	9.25%	Second Conversion (15-Jun-01)	9.25%	Second Conversion (14-Jun-01)	9.25%
Maturity (15-Jun-10)	NaN	Third Conversion (15-Jun-05)	10.0%	Third Conversion (14-Jun-05)	10.0%
		Maturity (15-Jun-10)	NaN	Maturity (15-Jun-10)	NaN

## stepcpnyield

Yield to maturity of bond with stepped coupons

### Syntax

Yield = stepcpnyield(Price,Settle,Maturity,ConvDates,CouponRate,Period,Basis,EndMonthRule,Face)

### Arguments

Price	Vector containing price of the bonds.
Settle	Settlement date. A vector of serial date numbers. <b>Settle</b> must be earlier than <b>Maturity</b> .
Maturity	Maturity date. A vector of serial date numbers.
ConvDates	Matrix of serial date numbers representing conversion dates after <b>Settle</b> . Size = number of instruments by maximum number of conversions. Fill unspecified entries with NaN.
CouponRates	<p>Matrix indicating the coupon rates for each bond in decimal form. Size = number of instruments by maximum number of conversions + 1. First column of this matrix contains rates applicable between <b>Settle</b> and the first conversion date (date in the first column of <b>ConvDates</b>). Fill unspecified entries with NaN.</p> <p><b>ConvDates</b> has the same number of rows as <b>CouponRate</b> to reflect the same number of bonds. However, <b>ConvDates</b> has one less column than <b>CouponRate</b>. This situation is illustrated by</p> <pre> Settle-----ConvDate1-----ConvDate2-----Maturity           Rate1           Rate2           Rate3 </pre>
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2, 3, 4, 6, and 12. Default = 2.

Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-129.</p>
EndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
Face	<p>(Optional) Face value of each bond in the portfolio. Default = 100.</p>

**Note** All arguments must be number of bonds (NUMBONDS)-by-1 vectors, except for **ConvDates** and **CouponRate**.

## Description

**Yield** = `stepcpnyield(Price, Settle, Maturity, ConvDates, CouponRate, Period, Basis, EndMonthRule, Face)` computes the yield to maturity of bonds with stepped coupons given the price. The function supports any number of conversion dates.

**Yield** is a NUMBONDS-by-1 vector of yields to maturity in decimal form.

**Note** For bonds with fixed coupons, use `bndyield`. You receive the error `incorrect number of inputs` if you use a fixed-coupon bond with `stepcpnyield`.

## Examples

Find the yield to maturity of three stepped-coupon bonds of known price, given three conversion scenarios:

- Bond A has two conversions, the first one falling on the settle date and immediately expiring.
- Bond B has three conversions, with conversion dates exactly on the coupon dates.
- Bond C has three conversions, with one or more conversion dates not on coupon dates. This case illustrates that only cash flows for full periods after conversion dates are affected, as illustrated below.

The following table illustrates the interest rate characteristics of this bond portfolio.

Bond A Dates	Bond A Rates	Bond B Dates	Bond B Rates	Bond C Dates	Bond C Rates
Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%
First Conversion (02-Aug-92)	8.875%	First Conversion (15-Jun-97)	8.875%	First Conversion (14-Jun-97)	8.875%
Second Conversion (15-Jun-03)	9.25%	Second Conversion (15-Jun-01)	9.25%	Second Conversion (14-Jun-01)	9.25%
Maturity (15-Jun-10)	NaN	Third Conversion (15-Jun-05)	10.0%	Third Conversion (14-Jun-05)	10.0%
		Maturity (15-Jun-10)	NaN	Maturity (15-Jun-10)	NaN

```

# tfutbyprice

Future prices of Treasury bonds given spot price

## Syntax

```
[QtdFutPrice,AccrInt] = tfutbyprice(SpotCurve,Price,SettleFut,MatFut,
ConvFactor,CouponRate,Maturity)
[QtdFutPrice,AccrInt] = tfutbyprice( ____,Interpolation)
```

## Description

[QtdFutPrice,AccrInt] = tfutbyprice(SpotCurve,Price,SettleFut,MatFut, ConvFactor, CouponRate, Maturity) computes future prices of Treasury notes and bonds given the spot price.

In addition, you can use the Financial Instruments Toolbox method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `tfutbyprice`. For more information, see “Converting an `IRDataCurve` or `IRFunctionCurve` Object” on page 9-33.

[QtdFutPrice,AccrInt] = tfutbyprice( \_\_\_\_, Interpolation) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Determine the Future Prices of Treasury Bonds Given the Spot Price

This example shows how to determine the future price of two Treasury bonds based upon a spot rate curve constructed from data for November 14, 2002.

```
% construct spot curve from Nov 14, data
Bonds = [datenum('02/13/2003'),      0;
         datenum('05/15/2003'),      0;
         datenum('10/31/2004'),    0.02125;
         datenum('11/15/2007'),     0.03;
         datenum('11/15/2012'),     0.04;
         datenum('02/15/2031'),    0.05375];

Yields = [1.20; 1.25; 1.86; 2.99; 4.02; 4.93]/100;

Settle = datenum('11/15/2002');

[ZeroRates, CurveDates] = ...
zbyield(Bonds, Yields, Settle);

SpotCurve = [CurveDates, ZeroRates];

% calculate a particular bond's future quoted price
RefDate    = [datenum('1-Dec-2002'); datenum('1-Mar-2003')];
MatFut     = [datenum('15-Dec-2002'); datenum('15-Mar-2003')];
```

```

Maturity = [datenum('15-Aug-2009');datenum('15-Aug-2010')];
CouponRate = [0.06;0.0575];
ConvFactor = convfactor(RefDate, Maturity, CouponRate);
Price = [114.416; 113.171];
Interpolation = 1;

[QtdFutPrice, AccrInt] = tfutbyprice(SpotCurve, Price, Settle, ...
MatFut, ConvFactor, CouponRate, Maturity, Interpolation)

QtdFutPrice = 2×1

    114.0409
    113.4029

AccrInt = 2×1

    1.9891
    0.4448

```

## Input Arguments

### SpotCurve — Treasury spot curve

matrix

Treasury spot curve, specified as a number of futures using one of the following forms:

- NFUT-by-2 matrix in the form of [SpotDates SpotRates] and these spot rates must be quoted as semiannual compounding (2) when the third column is not supplied.
- NFUT-by-3 matrix in the form of [SpotDates SpotRates Compounding], where allowed Compounding values for the third column are -1, 1, 2 (default), 3, 4, and 12, where -1 is continuous compounding.

Data Types: double

### Price — Prices of Treasury bonds or notes per \$100 notional at settlement date

scalar numeric | vector

Prices of Treasury bonds or notes per \$100 notional at settlement date, specified as a scalar numeric or an NINST-by-1 vector. Use `bndprice` for theoretical value of bond.

Data Types: double

### SettleFut — Settlement date of futures contract

serial date number | date character vector

Settlement date of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

### MatFut — Maturity dates (or anticipated delivery dates) of futures contract

serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### **ConvFactor — Conversion factor**

numeric

Conversion factor, specified using `convfactor`.

Data Types: `double` | `char` | `cell`

### **CouponRate — Underlying bond annual coupon**

scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an NINST-by-1 vector of decimals.

Data Types: `double`

### **Maturity — Underlying bond maturity date**

serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### **Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: `double`

## **Output Arguments**

### **QtdFutPrice — Quoted futures price, per \$100 notional**

vector

Quoted futures price, per \$100 notional, returned as a NINST-by-1 vector.

### **AccrInt — Accrued Interest due at delivery date, per \$100 notional**

vector

Accrued Interest due at delivery date, per \$100 notional, returned as a NINST-by-1 vector.

# tfutbyyield

Future prices of Treasury bonds given current yield

## Syntax

```
[QtdFutPrice,AccrInt] = tfutbyyield(SpotCurve,Yield,SettleFut,MatFut,
ConvFactor,CouponRate,Maturity)
[QtdFutPrice,AccrInt] = tfutbyyield( ____,Interpolation)
```

## Description

[QtdFutPrice,AccrInt] = tfutbyyield(SpotCurve,Yield,SettleFut,MatFut, ConvFactor,CouponRate,Maturity) computes prices of Treasury bond futures given a spot curve and bond yields at settlement.

In addition, you can use the Financial Instruments Toolbox method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `tfutbyyield`. For more information, see “Converting an `IRDataCurve` or `IRFunctionCurve` Object” on page 9-33.

[QtdFutPrice,AccrInt] = tfutbyyield( \_\_\_\_,Interpolation) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Determine Future Prices of Treasury Bonds Given the Current Yield

This example shows how to determine the future price of two Treasury bonds based upon a spot rate curve constructed from data for November 14, 2002.

```
% construct spot curve from Nov 14, data
Bonds = [datenum('02/13/2003'),    0;
         datenum('05/15/2003'),    0;

## Input Arguments

### SpotCurve — Treasury spot curve

matrix

Treasury spot curve, specified as a number of futures using one of the following forms:

- NFUT-by-2 matrix in the form of [SpotDates SpotRates] and these spot rates must be quoted as semiannual compounding (2) when the third column is not supplied.
- NFUT-by-3 matrix in the form of [SpotDates SpotRates Compounding], where allowed Compounding values for the third column are -1, 1, 2 (default), 3, 4, and 12, where -1 is continuous compounding.

Data Types: double

### Yield — Yield to maturities at settlement date

scalar numeric | vector

Yield to maturities at settlement date, specified as a scalar numeric or an NINST-by-1 vector. Use `bndyield` for theoretical value of bond yield.

Data Types: double

### SettleFut — Settlement date of futures contract

serial date number | date character vector

Settlement date of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

### MatFut — Maturity dates (or anticipated delivery dates) of futures contract

serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

### **ConvFactor — Conversion factor**

numeric

Conversion factor, specified using convfactor.

Data Types: double | char | cell

### **CouponRate — Underlying bond annual coupon**

scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an NINST-by-1 vector of decimals.

Data Types: double

### **Maturity — Underlying bond maturity date**

serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

### **Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: double

## **Output Arguments**

### **QtdFutPrice — Quoted futures price, per \$100 notional**

vector

Quoted futures price, per \$100 notional, returned as a NINST-by-1 vector.

### **AccrInt — Accrued Interest due at delivery date, per \$100 notional**

vector

Accrued Interest due at delivery date, per \$100 notional, returned as a NINST-by-1 vector.

# tfutimprepo

Implied repo rates for Treasury bond future given price

## Syntax

```
ImpliedRepo = tfutimprepo(ReinvestData,Price,QtdFutPrice,Settle,MatFut,
ConvFactor,CouponRate,Maturity)
```

## Description

ImpliedRepo = tfutimprepo(ReinvestData,Price,QtdFutPrice,Settle,MatFut,ConvFactor,CouponRate,Maturity) computes the implied repo rate that prevents arbitrage of Treasury bond futures, given the clean price at the settlement and delivery dates.

## Examples

### Compute the Implied Repo Rates for Treasury Bond Futures Given the Price

This example shows how to compute the implied repo rate given the following set of data.

```
ReinvestData = [0.018 3];
Price = [114.4160; 113.1710];
QtdFutPrice = [114.1201; 113.7090];
Settle = datenum('11/15/2002');
MatFut = [datenum('15-Dec-2002'); datenum('15-Mar-2003')];
ConvFactor = [1; 0.9854];
CouponRate = [0.06; 0.0575];
Maturity = [datenum('15-Aug-2009'); datenum('15-Aug-2010')];

ImpliedRepo = tfutimprepo(ReinvestData, Price, QtdFutPrice, ...
Settle, MatFut, ConvFactor, CouponRate, Maturity)

ImpliedRepo = 2×1

    0.0200
    0.0200
```

## Input Arguments

### ReinvestData — Reinvestment of intervening coupons

matrix

Reinvestment of intervening coupons, specified as a number of futures NFUT-by-2 matrix of rates and bases in the form of [ReinvestRate ReinvestBasis].

ReinvestRate is the simple reinvestment rate, in decimal. Specify ReinvestBasis as 0 = not reinvested, 2 = actual/360, or 3 = actual/365.

Data Types: double

**Price – Current bond price per \$100 notional**

scalar numeric | vector

Current bond price per \$100 notional, specified as a scalar numeric or an NINST-by-1 vector.

Data Types: double

**QtdFutPrice – Quoted bond futures price per \$100 notional**

scalar numeric | vector

Quoted bond futures price per \$100 notional, specified as a scalar numeric or an NINST-by-1 vector.

Data Types: double

**Settle – Settlement/valuation date of futures contract**

serial date number | date character vector

Settlement/valuation date of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

**MatFut – Maturity dates (or anticipated delivery dates) of futures contract**

serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

**ConvFactor – Conversion factor**

numeric

Conversion factor, specified using convfactor.

Data Types: double | char | cell

**CouponRate – Underlying bond annual coupon**

scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an NINST-by-1 vector of decimals.

Data Types: double

**Maturity – Underlying bond maturity date**

serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

## Output Arguments

**ImpliedRepo** — **Implied annual repo rate with an actual/360 basis**  
vector in decimals

Implied annual repo rate (in decimals) with an actual/360 basis, returned as a NINST-by-1 vector.

## tfutpricebyrepo

Calculates Treasury bond futures price given the implied repo rates

### Syntax

```
[QtdFutPrice,AccrInt] = tfutpricebyrepo(RepoData,ReinvestData,Price,Settle,
MatFut,ConvFactor,CouponRate,Maturity)
```

### Description

[QtdFutPrice,AccrInt] = tfutpricebyrepo(RepoData,ReinvestData,Price,Settle, MatFut,ConvFactor,CouponRate,Maturity) computes the theoretical futures bond price given the settlement price, the repo/funding rates, and the reinvestment rate.

### Examples

#### Compute Treasury Bond Futures Price Given the Implied Repo Rates

This example shows how to compute the quoted futures price and accrued interest due on the target delivery date, given the following data.

```
RepoData      = [0.020  2];
ReinvestData  = [0.018  3];
Price         = [114.416; 113.171];
Settle       = datenum('11/15/2002');
MatFut       = [datenum('15-Dec-2002'); datenum('15-Mar-2003')];
ConvFactor    = [1 ; 0.9854];
CouponRate   = [0.06;0.0575];
Maturity     = [datenum('15-Aug-2009'); datenum('15-Aug-2010')];
```

```
[QtdFutPrice AccrInt] = tfutpricebyrepo(RepoData, ...
ReinvestData, Price, Settle, MatFut, ConvFactor, CouponRate, ...
Maturity)
```

```
QtdFutPrice = 2×1
```

```
114.1201
113.7090
```

```
AccrInt = 2×1
```

```
1.9891
0.4448
```

### Input Arguments

**RepoData** — Simple term repo/funding rates

matrix

Simple term repo/funding rates, specified as a number of futures NFUT-by-2 matrix of rates in decimal and their bases in the form of [RepoRate RepoBasis].

Specify RepoBasis as 2 = actual/360 or 3 = actual/365.

Data Types: double

### **ReinvestData — Reinvestment of intervening coupons**

matrix

Reinvestment of intervening coupons, specified as a number of futures NFUT-by-2 matrix of rates and bases in the form of [ReinvestRate ReinvestBasis].

ReinvestRate is the simple reinvestment rate, in decimal. Specify ReinvestBasis as 0 = not reinvested, 2 = actual/360, or 3 = actual/365.

Data Types: double

### **Price — Current bond price per \$100 notional**

scalar numeric | vector

Current bond price per \$100 notional, specified as a scalar numeric or an NINST-by-1 vector.

Data Types: double

### **Settle — Settlement/valuation date of futures contract**

serial date number | date character vector

Settlement/valuation date of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

### **MatFut — Maturity dates (or anticipated delivery dates) of futures contract**

serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

### **ConvFactor — Conversion factor**

numeric

Conversion factor, specified using convfactor.

Data Types: double | char | cell

### **CouponRate — Underlying bond annual coupon**

scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an NINST-by-1 vector of decimals.

Data Types: double

### **Maturity — Underlying bond maturity date**

serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

## Output Arguments

### **QtdFutPrice** – Quoted futures price, per \$100 notional

vector

Quoted futures price, per \$100 notional, returned as a NINST-by-1 vector.

### **AccrInt** – Accrued Interest due at delivery date, per \$100 notional

vector

Accrued Interest due at delivery date, per \$100 notional, returned as a NINST-by-1 vector.

# tfutyieldbyrepo

Calculates Treasury bond futures yield given the implied repo rates

## Syntax

```
FwdYield = tfutyieldbyrepo(RepoData,ReinvestData,Yield,Settle,MatFut,
ConvFactor,CouponRate,Maturity)
```

## Description

FwdYield = tfutyieldbyrepo(RepoData,ReinvestData,Yield,Settle,MatFut, ConvFactor,CouponRate,Maturity) computes the theoretical futures bond yield given the settlement yield, the repo/funding rate, and the reinvestment rate.

## Examples

### Compute the Treasury Bond Futures Yield Given the Implied Repo Rates

This example shows how to compute the quoted futures bond yield, given the following data.

```
RepoData      = [0.020  2];
ReinvestData  = [0.018  3];
Yield         = [0.0215; 0.0257];
Settle        = datenum('11/15/2002');
MatFut        = [datenum('15-Dec-2002'); datenum('15-Mar-2003')];
ConvFactor    = [1; 0.9854];
CouponRate    = [0.06; 0.0575];
Maturity      = [datenum('15-Aug-2009'); datenum('15-Aug-2010')];
```

```
FwdYield = tfutyieldbyrepo(RepoData, ReinvestData, Yield,...
    Settle, MatFut, ConvFactor, CouponRate, Maturity)
```

```
FwdYield = 2×1
```

```
    0.0221
    0.0282
```

## Input Arguments

### RepoData — Simple term repo/funding rates

matrix

Simple term repo/funding rates, specified as a number of futures NFUT-by-2 matrix of rates in decimal and their bases in the form of [RepoRate RepoBasis].

Specify RepoBasis as 2 = actual/360 or 3 = actual/365.

Data Types: double

**ReinvestData — Reinvestment of intervening coupons**

matrix

Reinvestment of intervening coupons, specified as a number of futures NFUT-by-2 matrix of rates and bases in the form of [ReinvestRate ReinvestBasis].

ReinvestRate is the simple reinvestment rate, in decimal. Specify ReinvestBasis as 0 = not reinvested, 2 = actual/360, or 3 = actual/365.

Data Types: double

**Yield — Yield to maturity of Treasury bonds per \$100 notional at Settle**

scalar numeric | vector

Yield to maturity of Treasury bonds per \$100 notional at Settle, specified as a scalar numeric or an NINST-by-1 vector.

Data Types: double

**Settle — Settlement/valuation date of futures contract**

serial date number | date character vector

Settlement/valuation date of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

**MatFut — Maturity dates (or anticipated delivery dates) of futures contract**

serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

**ConvFactor — Conversion factor**

numeric

Conversion factor, specified using convfactor.

Data Types: double | char | cell

**CouponRate — Underlying bond annual coupon**

scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an NINST-by-1 vector of decimals.

Data Types: double

**Maturity — Underlying bond maturity date**

serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

## Output Arguments

### **FwdYield** — Forward yield to maturity compounded semiannually

vector in decimals

Forward yield to maturity, in decimals, compounded semiannually, returned as a NINST-by-1 vector.

## toRateSpec

Convert IRDataCurve object to RateSpec

### Class

@IRDataCurve on page A-7

### Syntax

F = toratespec(CurveObj, InpDates)

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRDataCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.

### Description

F = toratespec(CurveObj, InpDates) returns a RateSpec object that is identical to the RateSpec structure created by the Financial Instruments Toolbox function intenvset.

### Examples

#### Convert an IRDataCurve Object to a RateSpec

This example shows how to convert an IRDataCurve object to a RateSpec. First, an IRDataCurve object is created using the function IRDataCurve constructor with Dates and Data, then this object is converted to a RateSpec structure using the toRateSpec method.

```
CurveSettle = datenum('2-Mar-2016');
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Forward',CurveSettle,Dates,Data);
toRateSpec(irdc, CurveSettle+30:30:CurveSettle+365)
```

```
ans = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: [12x1 double]
    Rates: [12x1 double]
    EndTimes: [12x1 double]
    StartTimes: [12x1 double]
    EndDates: [12x1 double]
    StartDates: 736391
    ValuationDate: 736391
    Basis: 0
    EndMonthRule: 1
```

## toRateSpec

Convert IRFunctionCurve object to RateSpec

### Class

@IRFunctionCurve on page A-12

### Syntax

```
F = toRateSpec(CurveObj, InpDates)
```

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRFunctionCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.

### Description

`F = toRateSpec(CurveObj, InpDates)` returns a `RateSpec` object that is identical to the `RateSpec` structure created by the Financial Instruments Toolbox function `intenvset`.

### Examples

#### Convert an IRFunctionCurve Object to a RateSpec

This example shows how to convert an `IRFunctionCurve` object to a `RateSpec`. First, an `IRFunctionCurve` object is created using the function `IRFunctionCurve` constructor, then a `RateSpec` structure is created using the `toRateSpec` method.

```
irfc = IRFunctionCurve('Forward',today,@(t) polyval([-0.0001 0.003 0.02],t));
toRateSpec(irfc, today+30:30:today+365)
```

```
ans = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: [12x1 double]
    Rates: [12x1 double]
    EndTimes: [12x1 double]
    StartTimes: [12x1 double]
    EndDates: [12x1 double]
    StartDates: 737850
    ValuationDate: 737850
    Basis: 0
    EndMonthRule: 1
```

## zeroprice

Price zero-coupon instruments given yield

### Syntax

```
Price = zeroprice(Yield,Settle,Maturity)
Price = zeroprice( ____,Period,Basis,EndMonthRule)
```

### Description

`Price = zeroprice(Yield,Settle,Maturity)` prices zero-coupon instruments given a yield. `zeroprice` calculates the prices for a portfolio of general short and long-term zero-coupon instruments given the yield of reference bonds. In other words, if the zero-coupon computed with this yield is used to discount the reference bond, the value of that reference bond is equal to its price.

`Price = zeroprice( ____,Period,Basis,EndMonthRule)` adds optional arguments for `Period`, `Basis`, and `EndMonthRule`.

### Examples

#### Compute the Price of a Short-Term Zero-Coupon Instrument

This example shows how to compute the price of a short-term zero-coupon instrument.

```
Settle = '24-Jun-1993';
Maturity = '1-Nov-1993';
Period = 2;
Basis = 0;
Yield = 0.04;
```

```
Price = zeroprice(Yield, Settle, Maturity, Period, Basis)
```

```
Price = 98.6066
```

#### Compute the Prices of a Portfolio of Two Zero-Coupon Instruments

This example shows how to compute the prices of a portfolio of two zero-coupon instruments, one short-term, and the other long-term.

```
Settle = '24-Jun-1993';
Maturity = ['01-Nov-1993'; '15-Jan-2024'];
Basis = [0; 1];
Yield = [0.04; 0.1];
```

```
Price = zeroprice(Yield, Settle, Maturity, [], Basis)
```

```
Price = 2x1
```

98.6066  
5.0697

## Input Arguments

### Yield — Reference bond yield

scalar | vector

Reference bond yield, specified as a scalar or a NZERO-by-1 vector.

Data Types: double

### Settle — Settlement date

serial date number

Settlement date, specified as a NZERO-by-1 vector of serial date numbers.

Data Types: double

### Maturity — Maturity date

serial date number

Maturity date, specified as a NZERO-by-1 vector of serial date numbers.

Data Types: double

### Period — Number of coupons in one year

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

(Optional) Number of coupons in one year, specified as a positive integer for the values 1, 2, 4, 6, 12 in a NZERO-by-1 vector.

Data Types: double

### Basis — Day-count basis of bond

0 (actual/actual) (default) | vector of positive integers of the set [1 . . . 13]

(Optional) Day-count basis of the bond, specified as a positive integer using a NZERO-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with value of 0 or 1

(Optional) End-of-month rule flag, specified as a nonnegative integer with a value of 0 or 1 using a NZERO-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

**Output Arguments**

**Price — Price for each zero-coupon instrument**

vector

Price for each zero-coupon instrument (per \$100 notional), returned as a column vector.

**Algorithms**

To compute the price when Period is 1 or 0 for the quasi-coupon periods to redemption, zeroprice uses the formula

$$Price = \frac{RV}{1 + \left(\frac{DSR}{E} \times \frac{Y}{M}\right)}$$

*Quasi-coupon periods* are the coupon periods that would exist if the bond were paying interest at a rate other than zero.

When there is more than one quasi-coupon period to the redemption date, zeroprice uses the formula

$$Price = \frac{RV}{\left(1 + \frac{Y}{M}\right)^{Nq - 1} + \frac{DSC}{E}}$$

The elements of the equations are defined as follows.

Variable	Definition
<i>DSC</i>	Number of days from settlement date to next quasi-coupon date as if the security paid periodic interest.
<i>DSR</i>	Number of days from settlement date to the redemption date (call date, put date, and so on).
<i>E</i>	Number of days in quasi-coupon period.
<i>M</i>	Number of quasi-coupon periods per year (standard for the particular security involved).
<i>Nq</i>	Number of quasi-coupon periods between settlement date and redemption date. If this number contains a fractional part, raise it to the next whole number.
<i>Price</i>	Dollar price per \$100 par value.
<i>RV</i>	Redemption value.
<i>Y</i>	Annual yield (decimal) when held to redemption.

## zeroyield

Yield of zero-coupon instruments given price

### Syntax

```
Yield = zeroyield(Price,Settle,Maturity)
Yield = zeroyield( ____,Period,Basis,EndMonthRule)
```

### Description

`Yield = zeroyield(Price,Settle,Maturity)` computes the yield of zero-coupon instruments given price. `zeroyield` calculates the bond-equivalent yield for a portfolio of general short and long-term zero-coupon instruments given the price of the instruments. In other words, if the zero-coupon computed with this yield is used to discount the reference bond, the value of that reference bond is equal to its price

`Yield = zeroyield( ____,Period,Basis,EndMonthRule)` adds optional arguments for `Period`, `Basis`, and `EndMonthRule`.

### Examples

#### Compute the Yield of a Short-Term Zero-Coupon Instrument

This example shows how to compute the yield of a short-term zero-coupon instrument.

```
Settle = '24-Jun-1993';
Maturity = '1-Nov-1993';
Basis = 0;
Price = 95;
```

```
Yield = zeroyield(Price, Settle, Maturity, [], Basis)
```

```
Yield = 0.1490
```

#### Compute the Yield of a Short-Term Zero-Coupon Instrument Using a Day-Count Basis of 30/360 (SIA)

This example shows how to compute the yield of a short-term zero-coupon instrument using a day-count basis of 30/360 (SIA).

```
Settle = '24-Jun-1993';
Maturity = '1-Nov-1993';
Basis = 1;
Price = 95;
```

```
Yield = zeroyield(Price, Settle, Maturity, [], Basis)
```

```
Yield = 0.1492
```

## Compute the Yield of a Long-Term Zero-Coupon Instrument

This example shows how to compute the yield of a long-term zero-coupon instrument.

```
Settle = '24-Jun-1993';
Maturity = '15-Jan-2024';
Basis = 0;
Price = 9;
```

```
Yield = zeroyield(Price, Settle, Maturity, [], Basis)
```

```
Yield = 0.0804
```

## Input Arguments

### Price — Reference bond price

scalar | vector

Reference bond price, specified as a scalar or a NZERO-by-1 vector.

Data Types: double

### Settle — Settlement date

serial date number

Settlement date, specified as a NZERO-by-1 vector of serial date numbers.

Data Types: double

### Maturity — Maturity date

serial date number

Maturity date, specified as a NZERO-by-1 vector of serial date numbers.

Data Types: double

### Period — Number of coupons in one year

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

(Optional) Number of coupons in one year, specified as a positive integer for the values 1, 2, 4, 6, 12 in a NZERO-by-1 vector.

Data Types: double

### Basis — Day-count basis of bond

0 (actual/actual) (default) | vector of positive integers of the set [1 . . . 13]

(Optional) Day-count basis of the bond, specified as a positive integer using a NZERO-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

---

**Note** When the Maturity date is fewer than 182 days away and the Basis is actual/365, the `zeroyield` uses a simple-interest algorithm. If Maturity is more than 182 days away, `zeroyield` uses present value calculations.

When the Basis is actual/360, the simple interest algorithm gives the money-market yield for short (1-6 months to maturity) Treasury bills.

---

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with value of 0 or 1

(Optional) End-of-month rule flag, specified as a nonnegative integer with a value of 0 or 1 using a NZERO-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

## **Output Arguments**

### **Yield — Bond-equivalent yield for each zero-coupon instrument**

vector

Bond-equivalent yield for each zero-coupon instrument, returned as a column vector.

## **Algorithms**

To compute the yield when there is zero or one quasi-coupon period to redemption, `zeroyield` uses the formula

$$Yield = \left( \frac{RV - P}{P} \right) \times \left( \frac{M \times E}{DSR} \right)$$

*Quasi-coupon periods* are the coupon periods which would exist if the bond was paying interest at a rate other than zero. The first term calculates the yield on invested dollars. The second term converts this yield to a per annum basis.

When there is more than one quasi-coupon period to the redemption date, `zeroyield` uses the formula

$$Yield = \left( \left( \frac{RV}{P} \right)^{\frac{1}{Nq - 1 + \frac{DSC}{E}}} - 1 \right) \times M$$

The elements of the equations are defined as follows.

Variable	Definition
<i>DSC</i>	Number of days from the settlement date to next quasi-coupon date as if the security paid periodic interest.
<i>DSR</i>	Number of days from the settlement date to redemption date (call date, put date, and so on).
<i>E</i>	Number of days in quasi-coupon period.
<i>M</i>	Number of quasi-coupon periods per year (standard for the particular security involved).
<i>Nq</i>	Number of quasi-coupon periods between the settlement date and redemption date. If this number contains a fractional part, raise it to the next whole number.
<i>P</i>	Dollar price per \$100 par value.
<i>RV</i>	Redemption value.
<i>Yield</i>	Annual yield (decimal) when held to redemption.

## touchbybls

Price one-touch and no-touch binary options using Black-Scholes option pricing model

### Syntax

```
Price = touchybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)
```

### Description

Price = touchybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff) calculates one-touch and no-touch binary options using the Black-Scholes option pricing model.

### Examples

#### Price a One-Touch Option

Compute the price of a one-touch option using the following data:

```
AssetPrice = 105;  
Rate = 0.1;  
Volatility = 0.2;  
Settle = '01-Jan-2018';  
Maturity = '01-Jul-2018';
```

Define the RateSpec using intenvset.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...  
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the StockSpec using stockspect.

```
DividendType = "Continuous";  
DividendYield = Rate - 0.1;  
StockSpec = stockspect(Volatility, AssetPrice, DividendType, DividendYield);
```

Calculate the price of a one-touch binary option.

```
BarrierSpec = "OT";  
Barrier = 100;  
Payoff = 15;
```

```
Price = touchbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)
```

```
Price = 9.7264
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector | datetime object

Settlement or trade date for the touch option, specified as an NINST-by-1 matrix using serial date numbers, date character vectors, or datetime objects.

Data Types: `double` | `char` | `datetime`

### Maturity — Maturity date

serial date number | date character vector

Maturity date for the touch option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### BarrierSpec — Barrier option type

character vector with values 'OT' or 'NT'

Barrier option type, specified as an NINST-by-1 cell array of character vectors with the following values:

- 'OT' — One-touch

The one-touch option provides a payoff if the underlying asset ever trades at or beyond the Barrier level. Otherwise, the Payoff is zero.

- 'NT' — No-touch

The no-touch option provides a Payoff if the underlying asset never trades at or beyond the Barrier level. Otherwise, the Payoff is zero.

Data Types: `char` | `cell`

### Barrier — Barrier value

numeric

Barrier value, specified as an NINST-by-1 matrix of numeric values.

Data Types: double

**Payoff — Payoff value**

numeric

Payoff value, specified as an NINST-by-1 matrix of numeric values.

---

**Note** The payoff value is calculated for the point in time that the **Barrier** value is reached. The payoff is either cash or nothing. If a no-touch option is specified using the **BarrierSpec**, the payoff is at the **Maturity** of the option.

---

Data Types: double

**Output Arguments****Price — Expected prices for one-touch options**

matrix

Expected prices for one-touch options at time 0, returned as an NINST-by-1 matrix.

**More About****Touch and No-Touch Options**

The one-touch and no-touch options provide a payoff if the underlying spot either ever or never trades at or beyond the barrier level. Otherwise, the payoff is zero.

Only two outcomes are possible with a one-touch option if a trader holds the contract all the way through expiration:

- The target price (**Barrier**) is reached and the trader collects the full premium.
- The target price (**Barrier**) is not reached and the trader loses the amount originally paid to open the trade.

# touchsensbybls

Calculate price or sensitivities for one-touch and no-touch binary options using Black-Scholes option pricing model

## Syntax

```
PriceSens = touchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec,
Barrier, Payoff)
```

```
PriceSens = touchsensbybls( ___, Name, Value)
```

## Description

`PriceSens = touchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)` calculates the price and sensitivities for one-touch and no-touch binary options using the Black-Scholes option pricing model.

`PriceSens = touchsensbybls( ___, Name, Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Calculate the Price and Sensitivities for a One-Touch Option

Compute the price and sensitivities for a one-touch option using the following data:

```
AssetPrice = 105;
Rate = 0.1;
Volatility = 0.2;
Settle = '01-Jan-2018';
Maturity = '01-Jul-2018';
```

Define the `RateSpec` using `intenvset`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the `StockSpec` using `stockspec`.

```
DividendType = "Continuous";
DividendYield = Rate - 0.1;
StockSpec = stockspec(Volatility, AssetPrice, DividendType, DividendYield);
```

Define the sensitivities.

```
OutSpec = {'price', 'delta', 'gamma'};
```

Calculate the price and sensitivities for a one-touch binary option.

```
BarrierSpec = "OT";
Barrier = 100;
Payoff = 15;
```

```
[Price, Delta, Gamma] = touchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, BarrierLevel)

Price = 9.7264
Delta = -0.8939
Gamma = 0.0616
```

## Input Arguments

### **RateSpec — Interest-rate term structure**

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### **StockSpec — Stock specification for underlying asset**

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### **Settle — Settlement or trade date**

serial date number | date character vector | datetime object

Settlement or trade date for the touch option, specified as an NINST-by-1 matrix using serial date numbers, date character vectors, or datetime objects.

Data Types: `double` | `char` | `datetime`

### **Maturity — Maturity date**

serial date number | date character vector

Maturity date for the touch option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### **BarrierSpec — Barrier option type**

character vector with values 'OT' or 'NT'

Barrier option type, specified as an NINST-by-1 cell array of character vectors with the following values:

- 'OT' — One-touch. The one-touch option provides a payoff if the underlying spot ever trades at or beyond the `Barrier` level and the payoff is zero otherwise.

- 'NT' — No-touch. The no-touch option provides a Payoff if the underlying spot ever never trades at or beyond the Barrier level and the Payoff is zero otherwise.

Data Types: char | cell

### **Barrier — Barrier value**

numeric

Barrier value, specified as an NINST-by-1 matrix of numeric values.

Data Types: double

### **Payoff — Payoff value**

numeric

Payoff value, specified as an NINST-by-1 matrix of numeric values.

---

**Note** The payoff value is calculated for the point in time that the Barrier value is reached. The payoff is either cash or nothing. If a no-touch option is specified using the BarrierSpec, the payoff is at the Maturity of the option.

---

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: Price =  
touchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff,  
'OutSpec', 'Delta')

### **OutSpec — Define outputs**

{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and an NOUT- by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity.

Example: OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}

Data Types: char | cell

## **Output Arguments**

### **PriceSens — Expected prices or sensitivities for one-touch options**

matrix

Expected prices at time 0 or sensitivities (defined using OutSpec) for one-touch options, returned as an NINST-by-1 matrix.

## **More About**

### **Touch and No-Touch Options**

The one-touch and no-touch options provide a payoff if the underlying spot either ever or never trades at or beyond the barrier level. Otherwise, the payoff is zero.

Only two outcomes are possible with a one-touch option if a trader holds the contract all the way through expiration:

- The target price (**Barrier**) is reached and the trader collects the full premium.
- The target price (**Barrier**) is not reached and the trader loses the amount originally paid to open the trade.

# dbltouchbybls

Price double one-touch and double no-touch binary options using Black-Scholes option pricing model

## Syntax

Price = dbltouchbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)

## Description

Price = dbltouchbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff) calculates double one-touch and double no-touch binary options using Black-Scholes option pricing model.

## Examples

### Price a Double No-Touch Option

Compute the price of a double no-touch option using the following data:

```
AssetPrice = 105;
Rate = 0.1;
Volatility = 0.2;
Settle = '01-Jan-2018';
Maturity = '01-Jul-2018';
```

Define the RateSpec using intenvset.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the StockSpec using stockspect.

```
DividendType = "Continuous";
DividendYield = Rate - 0.03;
StockSpec = stockspect(Volatility, AssetPrice, DividendType, DividendYield);
```

Calculate the price of a double no-touch binary option.

```
BarrierSpec = "DNT";
Barrier = [120 80];
Payoff = 10;
```

```
Price = dbltouchbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)
```

```
Price = 5.6368
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset, specified by the `StockSpec` obtained from `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector | datetime object

Settlement or trade date for the double touch option, specified as an NINST-by-1 matrix using serial date numbers, date character vectors, or datetime objects.

Data Types: `double` | `char` | `datetime`

### Maturity — Maturity date

serial date number | date character vector

Maturity date for the double touch option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### BarrierSpec — Double barrier option type

cell array of character vectors with values of 'DOT' or 'DNT' | string array with values of "DOT" or "DNT"

Double barrier option type, specified as an NINST-by-1 cell array of character vectors or string array with the following values:

- 'DOT' — Double one-touch. The double one-touch option defines two `Barrier` levels. A double one-touch option provides a `Payoff` if the underlying asset ever touches either the upper or lower `Barrier` levels.
- 'DNT' — Double no-touch. The double no-touch option defines two `Barrier` levels. A double no-touch option provides a `Payoff` if the underlying asset ever never touches either the upper or lower `Barrier` levels.

Data Types: `char` | `cell` | `string`

### Barrier — Double barrier value

numeric

Double barrier value, specified as an NINST-by-2 matrix of numeric values, where the first column is Upper Barrier(1)(UB) and the second column is Lower Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: double

### **Payoff — Payoff value**

numeric

Payoff value, specified as an NINST-by-1 matrix of numeric values, where each element is a 1-by-2 vector in which the first column is Barrier(1)(UB) and the second column is Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

---

**Note** The payoff value is calculated for the point in time that the **Barrier** value is reached. The payoff is either cash or nothing. If you specify a double no-touch option using **BarrierSpec**, the payoff is at the **Maturity** of the option.

---

Data Types: double

## **Output Arguments**

### **Price — Expected prices for double one-touch options**

matrix

Expected prices for double one-touch options at time 0, returned as an NINST-by-1 matrix.

## **More About**

### **Double One-Touch and Double No-Touch Options**

Double one-touch options and double no-touch options work the same way as one-touch options, except that there are two barriers.

A double one-touch or double no-touch option provides a payoff if the underlying spot either ever or never touches either the upper or lower **Barrier** levels. If neither barrier level is breached prior to expiration, the option expires worthless and the trader loses all the premium paid to the broker for setting up the trade. For example, if the current USD/EUR rate is 1.15, and the trader believes that this rate will change significantly over the next 15 days, the trader can use a double one-touch option with barriers at 1.10 and 1.20. The trader can profit if the rate moves beyond either of the two barriers.

# dbltouchsensbybls

Calculate prices and sensitivities for double one-touch and double no-touch binary options using Black-Scholes option pricing model

## Syntax

```
PriceSens = dbltouchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec,
Barrier, Payoff)
```

```
PriceSens = dbltouchsensbybls( ____, Name, Value)
```

## Description

`PriceSens = dbltouchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)` calculates prices and sensitivities for double one-touch and double no-touch binary options using the Black-Scholes option pricing model.

`PriceSens = dbltouchsensbybls( ____, Name, Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Calculate the Price and Sensitivities for a Double No-Touch Option

Compute the price and sensitivities for a double no-touch option using the following data:

```
AssetPrice = 105;
Rate = 0.1;
Volatility = 0.2;
Settle = '01-Jan-2018';
Maturity = '01-Jul-2018';
```

Define the `RateSpec` using `intenvset`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the `StockSpec` using `stockspec`.

```
DividendType = "Continuous";
DividendYield = Rate - 0.03;
StockSpec = stockspec(Volatility, AssetPrice, DividendType, DividendYield);
```

Define the sensitivities.

```
OutSpec = {'price', 'delta', 'gamma'};
```

Calculate the price and sensitivities for a double no-touch binary option.

```
BarrierSpec = "DNT";
Barrier = [120 80];
Payoff = 10;
```

```
[Price, Delta, Gamma] = dbltouchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Ba  
Price = 5.6368  
Delta = -0.2536  
Gamma = -0.0275
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset, specified by the `StockSpec` obtained from `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector | datetime object

Settlement or trade date for the double touch option, specified as an NINST-by-1 matrix using serial date numbers, date character vectors, or datetime objects.

Data Types: `double` | `char` | `datetime`

### Maturity — Maturity date

serial date number | date character vector

Maturity date for the double touch option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### BarrierSpec — Double barrier option type

cell array of character vectors with values of 'DOT' or 'DNT' | string array with values of "DOT" or "DNT"

Double barrier option type, specified as an NINST-by-1 cell array of character vectors or string array with the following values:

- 'DOT' — Double one-touch. The double one-touch option defines two `Barrier` levels. A double one-touch option provides a `Payoff` if the underlying asset ever touches either the upper or lower `Barrier` levels.

- 'DNT' — Double no-touch. The double no-touch option defines two **Barrier** levels. A double no-touch option provides a **Payoff** if the underlying asset ever touches either the upper or lower **Barrier** levels.

Data Types: char | cell | string

### **Barrier — Double barrier value**

numeric

Double barrier value, specified as an NINST-by-2 matrix of numeric values, where the first column is Upper Barrier(1)(UB) and the second column is Lower Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: double

### **Payoff — Payoff value**

numeric

Payoff value, specified as an NINST-by-1 matrix of numeric values, where each element is a 1-by-2 vector in which the first column is Barrier(1)(UB) and the second column is Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

---

**Note** The payoff value is calculated for the point in time that the **Barrier** value is reached. The payoff is either cash or nothing. If you specify a double no-touch option using **BarrierSpec**, the payoff is at the **Maturity** of the option.

---

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `PriceSens = dbltouchsensbybls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity, BarrierSpec, Barrier, 'OutSpec', 'Delta')`

### **OutSpec — Define outputs**

{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | string array with values "Price", "Delta", "Gamma", "Vega", "Lambda", "Rho", "Theta", and "All"

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and an NOUT-by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

`OutSpec = {'All'}` specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}`

Data Types: char | cell

## Output Arguments

### **PriceSens** — Expected prices or sensitivities for double one-touch options

matrix

Expected prices at time 0 or sensitivities (defined using `OutSpec`) for double one-touch options, returned as an NINST-by-1 matrix.

## More About

### **Double One-Touch and Double No-Touch Options**

Double one-touch options and double no-touch options work the same way as one-touch options, except that there are two barriers.

A double one-touch or double no-touch option provides a payoff if the underlying spot either ever or never touches either the upper or lower `Barrier` levels. If neither barrier level is breached prior to expiration, the option expires worthless and the trader loses all the premium paid to the broker for setting up the trade. For example, if the current USD/EUR rate is 1.15, and the trader believes that this rate will change significantly over the next 15 days, the trader can use a double one-touch option with barriers at 1.10 and 1.20. The trader can profit if the rate moves beyond either of the two barriers.

# fininstrument

Create specified instrument object type

## Syntax

```
Instrument = fininstrument(InstrumentType,Name,Value)
```

## Description

`Instrument = fininstrument(InstrumentType,Name,Value)` creates an instrument object specified by `InstrumentType` and specifies options using one or more name-value pair arguments. The available name-value pair arguments depend on the `InstrumentType` you specify.

For more information on the workflow for creating an instrument object, a model object, and a pricer object, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Examples

### Use `fininstrument` to Create `OptionEmbeddedFixedBond` Instrument

Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object.

```
CallDates = datetime(2025,9,15) + calyears([0 1 2]');
CallStrikes = [101 103 105]';
CallSchedule = timetable(CallDates,CallStrikes);
OptionEmbedFixedBOption = fininstrument("OptionEmbeddedFixedBond", 'Maturity', "15-Sep-2031", 'Coups
```

```
OptionEmbedFixedBOption =
    OptionEmbeddedFixedBond with properties:
```

```

        CouponRate: 0.0300
            Period: 1
            Basis: 0
        EndMonthRule: 1
            Principal: 100
    DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
            Holidays: NaT
            IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
            StartDate: NaT
            Maturity: 15-Sep-2031
            CallDates: [3x1 datetime]
            PutDates: [0x1 datetime]
        CallSchedule: [3x1 timetable]
        PutSchedule: [0x0 timetable]
```

```
CallExerciseStyle: "bermudan"  
PutExerciseStyle: [0x0 string]  
Name: "option_embedded_fixedbond"
```

## Input Arguments

### InstrumentType — Type of instrument

character vector | string

Type of instrument, specified as a scalar string or character vector.

Use these options for interest-rate instruments:

- "Deposit" — For more information, see [Deposit](#).
- "FRA" — For more information, see [FRA](#).
- "FixedBond" — For more information, see [FixedBond](#).
- "FloatBond" — For more information, see [FloatBond](#).
- "FixedBondOption" — For more information, see [FixedBondOption](#).
- "OptionEmbeddedFixedBond" — For more information, see [OptionEmbeddedFixedBond](#).
- "Swap" — For more information, see [Swap](#).
- "Cap" — For more information, see [Cap](#).
- "Floor" — For more information, see [Floor](#).
- "Swaption" — For more information, see [Swaption](#).

Use these options for equity instruments:

- "Vanilla" — For more information, see [Vanilla](#).
- "Lookback" — For more information, see [Lookback](#).
- "Barrier" — For more information, see [Barrier](#).
- "Asian" — For more information, see [Asian](#).
- "Spread" — For more information, see [Spread](#).

Use these options for credit derivative instruments:

- "CDS" — For more information, see [CDS](#).
- "CDSOption" — For more information, see [CDSOption](#).

Data Types: string | char

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Instrument = fininstrument("Cap", Name, Value)`

The available name-value pair arguments depend on the value you specify for `InstrumentType`.

### **Name-Value Pair Arguments for Interest-Rate Instruments**

- `Deposit` — For more information, see “Deposit Name-Value Pair Arguments” on page 11-2291.
- `FRA` — For more information, see “FRA Name-Value Pair Arguments” on page 11-2214.
- `FixedBond` — For more information, see “FixedBond Name-Value Pair Arguments” on page 11-2170.
- `FloatBond` — For more information, see “FloatBond Name-Value Pair Arguments” on page 11-2192.
- `FixedBondOption` — For more information, see “FixedBondOption Name-Value Pair Arguments” on page 11-2183.
- `OptionEmbeddedFixedBond` — For more information, see “OptionEmbeddedFixedBond Name-Value Pair Arguments” on page 11-2227.
- `Swap` — For more information, see “Swap Name-Value Pair Arguments” on page 11-2251.
- `Cap` — For more information, see “Cap Name-Value Pair Arguments” on page 11-2146.
- `Floor` — For more information, see “Floor Name-Value Pair Arguments” on page 11-2203.
- `Swaption` — For more information, see “Swaption Name-Value Pair Arguments” on page 11-2263.

### **Name-Value Pair Arguments for Equity Instruments**

- `Vanilla` — For more information, see “Vanilla Name-Value Pair Arguments” on page 11-2276.
- `Lookback` — For more information, see “Lookback Name-Value Pair Arguments” on page 11-2221.
- `Barrier` — For more information, see “Barrier Name-Value Pair Arguments” on page 11-2139.
- `Asian` — For more information, see “Asian Name-Value Pair Arguments” on page 11-2131.
- `Spread` — For more information, see “Spread Name-Value Pair Arguments” on page 11-2244.

### **Name-Value Pair Arguments for Credit Derivative Instruments**

- `CDS` — For more information, see “CDS Name-Value Pair Arguments” on page 11-2157.
- `CDSOption` — For more information, see “CDSOption Name-Value Pair Arguments” on page 11-2164.

## **Output Arguments**

### **Instrument — Instrument**

instrument object

Instrument, returned as an instrument object.

### **See Also**

finmodel | finpricer

### **Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-42

### **Introduced in R2020a**

## finmodel

Create specified model object type

### Syntax

```
Model = finmodel(ModelType,Name,Value)
```

### Description

`Model = finmodel(ModelType,Name,Value)` creates a `Model` object based on `ModelType` creates a model object specified by `ModelType` and specifies options using one or more name-value pair arguments.

For more information on the workflow for creating an instrument object, a model object, and a pricer object, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Examples

#### Use finmodel to Create SABR Model

Use `finmodel` to create a SABR model object.

```
SabrModel = finmodel("SABR",'Alpha',0.032,'Beta',0.04, 'Rho', .08, 'Nu', 0043,'Shift',0.002)
```

```
SabrModel =  
  SABR with properties:  
  
      Alpha: 0.0320  
      Beta: 0.0400  
      Rho: 0.0800  
      Nu: 43  
      Shift: 0.0020  
  VolatilityType: "black"
```

### Input Arguments

#### ModelType — Model type

character vector | string

Model type, specified as a scalar string or character vector.

These options are available for interest-rate instruments:

- "Black" — For more information, see `Black`.
- "HullWhite" — For more information, see `HullWhite`.
- "BlackKarasinski" — For more information, see `BlackKarasinski`.
- "Normal" — For more information, see `Normal`.
- "Sabr" — For more information, see `Sabr`.

These options are available for equity instruments:

- "BlackScholes" — For more information, see `BlackScholes`.
- "Heston" — For more information, see `Heston`.
- "Bates" — For more information, see `Bates`.
- "Merton" — For more information, see `Merton`.
- "Dupire" — For more information, see `Dupire`.

These options are available for credit derivative instruments:

- "CDSBlack" — For more information, see `CDSBlack`.

Data Types: `string` | `char`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Model = finmodel("Black", Name, Value)`

The available name-value pair arguments depend on the value you specify for `ModelType`.

#### **Name-Value Pair Arguments for Interest-Rate Models**

- `Black` — For more information, see “Black Name-Value Pair Arguments” on page 11-2304.
- `HullWhite` — For more information, see “HullWhite Name-Value Pair Arguments” on page 11-2327.
- `BlackKarasinski` — For more information, see “BlackKarasinski Name-Value Pair Arguments” on page 11-2317.
- `Normal` — For more information, see “Normal Name-Value Pair Arguments” on page 11-2335.
- `Sabr` — For more information, see “SABR Name-Value Pair Arguments” on page 11-2345

#### **Name-Value Pair Arguments for Equity Models**

# finpricer

Create pricing method

## Syntax

```
Pricer = finpricer(PricerType,Name,Value)
```

## Description

`Pricer = finpricer(PricerType,Name,Value)` creates a `Pricer` object based on `PricerType` creates a pricer object and specifies options using one or more name-value pair arguments. The available name-value pair arguments depend on the `PricerType` you specify.

For more information on the workflow for creating an instrument object, a model object, and a pricer object, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Examples

### Use finpricer to Create ConzeViswanathan Pricer

This example shows the workflow to create a `BlackScholes` model and `ratecurve` object to use with a `ConzeViswanathan` pricing method.

#### Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .358)
```

```
BlackScholesModel =  
    BlackScholes with properties:
```

```
    Volatility: 0.3580  
    Correlation: 1
```

#### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);  
Type = 'zero';  
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];  
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';  
ZeroDates = Settle + ZeroTimes;  
  
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =  
  ratecurve with properties:  
  
      Type: "zero"  
    Compounding: -1  
      Basis: 0  
      Dates: [10x1 datetime]  
      Rates: [10x1 double]  
    Settle: 15-Sep-2020  
    InterpMethod: "linear"  
ShortExtrapMethod: "next"  
LongExtrapMethod: "previous"
```

### Create ConzeViswanathan Pricer Object

Use `finpricer` to create a `ConzeViswanathan` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', 950,  
outPricer =  
  ConzeViswanathan with properties:  
  
    DiscountCurve: [1x1 ratecurve]  
      Model: [1x1 finmodel.BlackScholes]  
    SpotPrice: 950  
DividendValue: 2.5000  
DividendType: "continuous"
```

## Input Arguments

### PricerType — Pricer type

character vector | string

Pricer type, specified as a scalar string or character vector.

These options are available for interest-rate instruments:

- "Discount" — For more information, see `Discount`.
- "IRTree" — For more information, see `IRTree`.
- "HullWhite" — For more information, see `HullWhite`.
- "Analytic" — The "Analytic" pricer can be any one of the following types of pricing methods:
  - SABR — For more information, see `SABR`.
  - Normal — For more information, see `Normal`.
  - Black — For more information, see `Black`.

These options are available for equity instruments:

- "Analytic" — The "Analytic" pricer can be any one of the following types of pricing methods:
  - BlackScholes — For more information, see `BlackScholes`.

- Levy — For more information, see Levy.
- KemnaVorst — For more information, see KemnaVorst.
- TurnbullWakeman — For more information, see TurnbullWakeman.
- ConzeViswanathan — For more information, see ConzeViswanathan.
- GoldmanSosinGatto — For more information, see GoldmanSosinGatto.
- RollGeskeWhaley — For more information, see RollGeskeWhaley.
- Kirk — For more information, see Kirk.
- BjerksundStensland — For more information, see BjerksundStensland.
- "FiniteDifference" — For more information, see FiniteDifference.
- "FFT" — For more information, see FFT.
- "NumericalIntegration" — For more information, see NumericalIntegration.

These options are available for credit derivative instruments:

- "Credit" — For more information, see Credit.
- "Analytic" — The "Analytic" pricer can be any one of the following types of pricing methods:
  - CDSBlack — For more information, see CDSBlack.

Data Types: `string` | `char`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Pricer = finpricer("Black", Name, Value)`

Depending on the `PricerType`, the associated name-value pair arguments are different.

#### **Name-Value Pair Arguments for Interest-Rate Pricers**

- `IRTree` — For more information, see `IRTree`.
- `Black` — For more information, see `Black`.
- `HullWhite` — For more information, see `HullWhite`.
- `Normal` — For more information, see `Normal`.
- `Sabr` — For more information, see `Sabr`.
- `Discount` — For more information, see `Discount`.

#### **Name-Value Pair Arguments for Equity Pricers**

- Levy — For more information, see Levy.
- KemnaVorst — For more information, see KemnaVorst.
- TurnbullWakeman — For more information, see TurnbullWakeman.
- BlackScholes — For more information, see BlackScholes.
- ConzeViswanathan — For more information, see ConzeViswanathan.
- GoldmanSosinGatto — For more information, see GoldmanSosinGatto.

- `RollGeskeWhaley` — For more information, see `RollGeskeWhaley`.
- `Kirk` — For more information, see `Kirk`.
- `BjerksundStensland` — For more information, see `BjerksundStensland`.
- `FiniteDifference` — For more information, see `FiniteDifference`.
- `FFT` — For more information, see `FFT`.
- `NumericalIntegration` — For more information, see `NumericalIntegration`.

**Name-Value Pair Arguments for Credit Derivative Pricers**

- `Credit` — For more information, see `Credit`.
- `CDSBlack` — For more information, see `CDSBlack`.

**Output Arguments****Pricer — Pricer**

`pricer` object

`Pricer`, returned as a `pricer` object.

**See Also**

`fininstrument` | `finmodel`

**Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

**Introduced in R2020a**

# irbootstrap

Bootstrap interest-rate curve from market data

## Syntax

```
outCurve = irbootstrap(BootInstruments,Settle)
outCurve = irbootstrap( ____,Name,Value)
```

## Description

`outCurve = irbootstrap(BootInstruments,Settle)` creates a data structure for storing interest-rate term structure data. The `outCurve` output is a `ratecurve` object.

`outCurve = irbootstrap( ____,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntax. For example, `OutCurve = irbootstrap("zero",BootInstruments,Settle,'Compounding',2,'Basis',5,'InterpMethod','cubic')` bootstraps a zero curve from `BootInstruments`.

## Examples

### Bootstrap ratecurve Object from Market Data

#### Define Deposit and Swap Parameters

```
Settle = datetime(2018,3,21);
DepRates = [.0050769 .0054934 .0061432 .0072388 .0093263]';
DepTimes = [1 2 3 6 12]';
DepDates = datemnth(Settle,DepTimes);
nDeposits = length(DepTimes);

SwapRates = [.0112597 0;.0128489 0;.0138917 0;.0146135 0;.0151175 0;...
             .0155184 0;.0158536 0;.0161435 0];
SwapTimes = (2:9)';
SwapDates = datemnth(Settle,12*SwapTimes);
nSwaps = length(SwapTimes);

nInst = nDeposits + nSwaps;
```

#### Create a Vector of Market Swap Instruments

Use `fininstrument` to create a vector of market Deposit and Swap instrument objects.

```
BootInstruments(nInst,1) = fininstrument.FinInstrument;
for ii=1:length(DepDates)
    BootInstruments(ii) = fininstrument("deposit",'Maturity',DepDates(ii),'Rate',DepRates(ii))
end

for ii=1:length(SwapDates)
    BootInstruments(ii+nDeposits) = fininstrument("swap",'Maturity',SwapDates(ii),'LegRate',[S
end
```

### Create ratecurve Object for Zero-Rate Curve

Use `irbootstrap` to create a ratecurve object for the zero-rate curve.

```
ZeroCurve = irbootstrap(BootInstruments,Settle)
```

```
ZeroCurve =  
    ratecurve with properties:  
  
        Type: "zero"  
    Compounding: -1  
        Basis: 0  
        Dates: [13x1 datetime]  
        Rates: [13x1 double]  
        Settle: 21-Mar-2018  
    InterpMethod: "linear"  
ShortExtrapMethod: "linear"  
LongExtrapMethod: "linear"
```

## Input Arguments

### BootInstruments — Collection of instruments

array of instrument objects

Collection of instruments, specified as an array of instrument objects.

Data Types: object

### Settle — Settlement date

datetime | serial date number | date character vector | date string

Settlement date, specified as a scalar datetime, serial date number, date character vector, or date string.

Data Types: double | char | string | datetime

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

```
Example: OutCurve =  
irbootstrap("zero",BootInstruments,Settle,'Compounding',2,'Basis',5,'InterpMethod',"cubic")
```

### Type — Type of interest-rate curve

"zero" (default) | string with value "discount", "forward", or "zero" | character vector with value 'discount', 'forward', or 'zero'

Type of interest-rate curve, specified as a scalar string or character vector.

When you use `irbootstrap`, the value you specify for `Type` can impact the curve construction because it affects the type of data that is interpolated on (that is, forward rates, zero rates, or discount factors) during the bootstrapping process.

Data Types: char | string

### **Compounding — Compounding frequency**

Compounding for the ratecurve object (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency, specified as the comma-separated pair consisting of 'Compounding' and a scalar numeric using the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **InterpMethod — Interpolation method**

"linear" (default) | string with value "linear", "cubic", "next", "previous", "pchip", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'cubic', 'next', 'previous', 'pchip', 'v5cubic', 'makima', or 'spline'

Interpolation method, specified as the comma-separated pair consisting of 'InterpMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: char | string

### **ShortExtrapMethod — Extrapolation method for data before first data**

"next" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'next', 'previous', 'pchip', 'cubic', 'v5cubic', 'makima', or 'spline'

Extrapolation method for data before first data, specified as the comma-separated pair consisting of 'ShortExtrapMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char` | `string`

**LongExtrapMethod — Extrapolation method for data after last data**

"previous" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'next', 'previous', 'pchip', 'cubic', 'v5cubic', 'makima', or 'spline'

Extrapolation method for data after last data, specified as the comma-separated pair consisting of 'LongExtrapMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char` | `string`

## Output Arguments

**outCurve — Rate curve**

ratecurve object

Rate curve, returned as a `ratecurve` object. The object has the following properties:

- Type
- Settle
- Compounding
- Basis
- Dates
- Rates
- InterpMethod
- ShortExtrapMethod
- LongExtrapMethod

## See Also

`discountfactors` | `forwardrates` | `ratecurve` | `zerorates`

### Introduced in R2020a

# fitNelsonSiegel

Fit Nelson-Siegel model to bond market data

## Syntax

```
outCurve = fitNelsonSiegel(Settle, Instruments, CleanPrice)
```

## Description

`outCurve = fitNelsonSiegel(Settle, Instruments, CleanPrice)` fits a Nelson-Siegel model to bond data.

## Examples

### Fit Nelson-Siegel Model to Bond Market Data

Define the bond data and use `fininstrument` to create `FixedBond` instrument objects.

```
Settle = datetime(2017,9,15);
Maturity = [datetime(2019,9,15);datetime(2021,9,15);...
            datetime(2023,9,15);datetime(2026,9,7);...
            datetime(2035,9,15);datetime(2047,9,15)];

CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];

nInst = numel(CouponRate);
Bonds(nInst,1) = fininstrument.FinInstrument;
for ii=1:nInst
    Bonds(ii) = fininstrument("FixedBond", 'Maturity',Maturity(ii),...
                             'CouponRate',CouponRate(ii));
end
```

Use `fitNelsonSiegel` to create a `parametercurve` object.

```
NSModel = fitNelsonSiegel(Settle,Bonds,CleanPrice)
```

Local minimum possible.

`lsqnonlin` stopped because the final change in the sum of squares relative to its initial value is less than the value of the function tolerance.

```
NSModel =
    parametercurve with properties:

        Type: "zero"
        Settle: 15-Sep-2017
        Compounding: -1
        Basis: 0
        FunctionHandle: @(t)fitF(Params,t)
        Parameters: [1.2476e-05 0.0362 0.0903 16.4263]
```

## Input Arguments

### **Settle** — Settlement date

datetime | serial date number | date character vector | date string

Settlement date, specified as a scalar datetime, serial date number, date character vector, or date string.

Data Types: double | char | string | datetime

### **Instruments** — Bond instrument objects

array

Bond instrument objects, specified as an array of bond instruments objects.

Data Types: object

### **CleanPrice** — Observed market prices

vector

Observed market prices, specified as a vector.

Data Types: double

## Output Arguments

### **outCurve** — Fitted Nelson-Siegel model

parametercurve object

Fitted Nelson-Siegel model, returned as a parametercurve object.

## See Also

discountfactors | forwardrates | zerorates

### Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-42

**Introduced in R2020a**

# price

**Package:** `finpricer.analytic`

Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

## Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

The Analytic pricer supports the following pricer objects:

- `BjerksundStensland`
- `Black`
- `BlackScholes`
- `CDSBlack`
- `ConzeViswanathan`
- `GoldmanSosinGatto`
- `HullWhite`
- `KemnaVorst`
- `Kirk`
- `Levy`
- `Normal`
- `RollGeskeWhaley`
- `SABR`
- `TurnbullWakeman`

`[Price,PriceResult] = price( ____,inpSensitivity)` adds an optional argument to specify sensitivities.

## Examples

### Use Bjerksund-Stensland Pricer and Black-Scholes Model to Price Spread Instrument

This example shows the workflow to price a European exercise Spread instrument when you use a `BlackScholes` model and a `BjerksundStensland` pricing method.

### Create Spread Instrument Object

Use `fininstrument` to create a Spread instrument object.

```
SpreadOpt = fininstrument("Spread", 'Strike', 5, 'ExerciseDate', datetime(2021, 9, 15), 'OptionType', "put")
SpreadOpt =
    Spread with properties:
        OptionType: "put"
        ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2021
        Strike: 5
        Name: "spread_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', [.2;.1])
BlackScholesModel =
    BlackScholes with properties:
        Volatility: [2x1 double]
        Correlation: [2x2 double]
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018, 9, 15);
Maturity = datetime(2023, 9, 15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 12
        Dates: 15-Sep-2023
        Rates: 0.0350
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create BjerksundStensland Pricer Object

Use `finpricer` to create a BjerksundStensland pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', [100
```

```

outPricer =
  BjerksundStensland with properties:

    DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: [2x1 double]
    DividendValue: [0.0900 0.1700]
    DividendType: "continuous"

```

## Price Spread Instrument

Use `price` to compute the price and sensitivities for the Spread instrument.

```
[Price, outPR] = price(outPricer,SpreadOpt,["all"])
```

```
Price = 7.0596
```

```

outPR =
  pricerresult with properties:

    Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta		Gamma		Lambda		Vega
7.0596	-0.23249	0.27057	0.0069887	0.0055319	-3.2932	3.8327	41.938

## Input Arguments

### inpPricer — Pricer object

BjerksundStensland object | Black object | BlackScholes object | CDSBlack object | ConzeViswanathan object | GoldmanSosinGatto object | HullWhite object | KemnaVorst object | Kirk object | Levy object | Normal object | RollGeskeWhaley object | SABR object | TurnbullWakeman object

Pricer object (previously created using `finpricer`), specified as a scalar. The supported pricer objects are: BjerksundStensland, Black, BlackScholes, CDSBlack, ConzeViswanathan, GoldmanSosinGatto, HullWhite, KemnaVorst, Kirk, Levy, Normal, RollGeskeWhaley, SABR, or TurnbullWakeman

Data Types: object

### inpInstrument — Instrument object

Cap object | Floor object | Swaption object | Vanilla object | Lookback object | Barrier object | Asian object | Spread object | CDSOption object

Instrument object (previously created using `fininstrument`), specified as a scalar. The supported instrument objects are: Cap, Floor, Swaption, Vanilla, Lookback, Barrier, Asian, Spread, or CDSOption.

Data Types: object

**inpSensitivity – List of sensitivities to compute**

[ ] (default) | string array of character vectors with values dependent on pricer object | cell array of character vectors with values dependent on pricer object

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array.

The supported sensitivities depend on the pricing method.

<b>inpPricer Object</b>	<b>Supported Sensitivities</b>
Bjerk SundStensland	{'delta','gamma','vega','theta','rho','price','lambda'}
Black	'price'
BlackScholes	{'delta','gamma','vega','theta','rho','price','lambda'}
CDSBlack	'price'
ConzeViswanathan	{'delta','gamma','vega','theta','rho','price','lambda'}
GoldmanSosinGatto	{'delta','gamma','vega','theta','rho','price','lambda'}
HullWhite	'price'
KemnaVorst	{'delta','gamma','vega','theta','rho','price','lambda'}
Kirk	{'delta','gamma','vega','theta','rho','price','lambda'}
Levy	{'delta','gamma','vega','theta','rho','price','lambda'}
Normal	'price'
RollGeskeWhaley	{'delta','gamma','vega','theta','rho','price','lambda'}
SABR	'price'
TurnbullWakeman	{'delta','gamma','vega','theta','rho','price',}

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that all sensitivities for the pricing method are returned. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = ["delta","gamma","vega","lambda","rho","theta","price"]`

Data Types: cell | string

**Output Arguments****Price – Instrument price**

numeric

Instrument price, returned as a numeric.

**PriceResult — Price result**

PriceResult object

Price result, returned as a PriceResult object. The object has the following fields:

- PriceResult.Results — Table of results that includes sensitivities (if you specify inpSensitivity)
- PriceResult.PricerData — Structure for pricer data

---

**Note** The inpPricer options that do not support sensitivities do not return a PriceResult. For example, there is no PriceResult returned for when using a Black, CDSBlack, HullWhite, Normal, or SABR pricing method.

---

## price

**Package:** finpricer

Compute price for interest-rate instrument with IRTree pricer

### Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

### Description

[Price,PriceResult] = price(inpPricer,inpInstrument) computes the instrument price and related pricing information based on the pricing object inpPricer and the instrument object inpInstrument.

[Price,PriceResult] = price( \_\_\_\_,inpSensitivity) adds an optional argument to specify sensitivities.

### Examples

#### Use Hull-White Tree Pricer and Hull-White Model to Price FixedBondOption Instrument

This example shows the workflow to price a FixedBondOption instrument when you use a HullWhite model and an IRTree pricing method.

##### Create FixedBond Instrument Object

Use fininstrument to create a FixedBond instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond", 'Maturity',datetime(2029,9,15), 'CouponRate',0.025, 'Period',
```

```
BondInst =
    FixedBond with properties:

        CouponRate: 0.0250
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2029
        Name: "fixed_bond_instrument"
```

### Create FixedBondOption Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object.

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 98, 'B
FixedBOption =
  FixedBondOption with properties:

    OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2025
    Strike: 98
    Bond: [1x1 fininstrument.FixedBond]
    Name: "fixed_bond_option_instrument"
```

### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 15-Sep-2019
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.01, 'Sigma', 0.05)

HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0100
    Sigma: 0.0500
```

## Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object with the 'DiscountCurve' name-value pair argument.

```
HWTreepricer = finpricer("irtree", 'Model', HullWhiteModel, 'DiscountCurve', myRC, 'TreeDates', ZeroDa
```

```
HWTreepricer =
  HWBKTreepricer with properties:

      Tree: [1x1 struct]
   TreeDates: [10x1 datetime]
      Model: [1x1 finmodel.HullWhite]
DiscountCurve: [1x1 ratecurve]
```

`HWTreepricer.Tree`

```
ans = struct with fields:
   FinObj: 'HWFwdTree'
   tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
   dObs: [1x10 datetime]
   CFlowT: {1x10 cell}
   Probs: {1x9 cell}
   Connect: {1x9 cell}
   FwdTree: {1x10 cell}
```

## Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(HWTreepricer, FixedBOption, ["all"])
```

```
Price = 11.1370
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x4 table]
   PricerData: [1x1 struct]
```

`outPR.Results`

```
ans=1x4 table
   Price      Vega      Gamma      Delta
   _____  _____  _____  _____
   11.137    242.76    3662.6    -271.74
```

## Input Arguments

### `inpPricer` — Pricer object

`IRTree` object

Pricer, specified as a scalar `IRTree` pricer object. Use `finpricer` to create the `IRTree` pricer object.

Data Types: object

### **inpInstrument — Instrument object**

FixedBond object | OptionEmbeddedFixedBond object | FixedBondOption object | FloatBond object

Instrument object, specified as scalar FixedBond, OptionEmbeddedFixedBond, FixedBondOption, or FloatBond instrument object. Use finstrument to create the FixedBond, OptionEmbeddedFixedBond, FixedBondOption, or FloatBond instrument object.

Data Types: object

### **inpSensitivity — List of sensitivities to compute**

[ ] (default) | string array with values "Price", "Delta", "Gamma", "Vega", and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', and 'All'

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array with possible values of 'Price', 'Delta', 'Gamma', 'Vega', and 'All'.

inpSensitivity = {'All'} or inpSensitivity = ["All"] specifies that the output is Delta, Gamma, Vega, and Price. This is the same as specifying inpSensitivity to include each sensitivity.

The sensitivities supported depend on the inpInstrument.

<b>inpInstrument</b>	<b>Supported Sensitivities</b>
FixedBond	{'delta', 'gamma', 'vega', 'price'}
OptionEmbeddedFixedBond	{'delta', 'gamma', 'vega', 'price'}
FixedBondOption	{'delta', 'gamma', 'vega', 'price'}
FloatBond	{'delta', 'gamma', 'vega', 'price'}

**Note** Sensitivities are calculated based on yield shifts of 1 basis point, where the ShiftValue = 1/10000. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide the sensitivities by their respective instrument price.

Example: inpSensitivity = {'delta', 'gamma', 'vega', 'price'}

Data Types: string | cell

## **Output Arguments**

### **Price — Instrument price**

numeric

Instrument price, returned as a numeric.

### **PriceResult — Price result**

PriceResult object

Price result, returned as a PriceResult object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data that depends on the instrument that is being priced

`FixedBond`, `FloatBond`, `FixedBondOption`, and `OptionEmbeddedFixedBond` have the following shared fields for `PriceResult.PricerData.PriceTree`:

- `FinObj` contains 'HWPriceTree' or 'BKPriceTree' depending whether you use a HullWhite or BlackKarasinski model.
- `tObs` contains the observation times.
- `Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicates where the down branch connects to.

The following additional fields for `PriceResult.PricerData.PriceTree` depend on the instrument type:

- `Ptree` contains the clean prices.
- `AITree` contains the accrued interest.
- `Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.
- `dObs` contains the date of each level of the tree.
- `CFlowT` is a cell array with as many elements as levels of the tree. Each cell array element contains the time factors (`tObs`) corresponding to its level of the tree and those levels ahead of it.
- `FwdTree` contains the forward spot rate from one node to the next. The forward spot rate is defined as the inverse of the discount factor.
- `ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.
- `ProbTree` contains the probability of reaching each node from root node.
- `ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.
- `ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

A `FixedBond` instrument has these additional fields within `PriceResult.PricerData.PriceTree`:

- `Ptree`
- `AITree`
- `Probs`.

A `FloatBond` instrument has these additional fields within `PriceResult.PricerData.PriceTree`:

- `dObs`

- CFlowT
- Probs
- FwdTree

A `FixedBondOption` instrument has these additional fields within `PriceResult.PricerData.PriceTree`:

- PTree
- Probs
- ExTree

A `OptionEmbeddedFixedBond` instrument has these additional fields within `PriceResult.PricerData.PriceTree`:

- PTree
- ExTree
- ProbTree
- ExProbTree
- ExProbsByTreeLevel

The following table displays the `PriceResult.PricerData.PriceTree` fields related to each instrument.

<b>PriceResult.PricerData.PriceTree Fields</b>	<b>FixedBond</b>	<b>FloatBond</b>	<b>FixedBondOption</b>	<b>OptionEmbeddedFixedBond</b>
FinObj	✓	✓	✓	✓
tObs	✓	✓	✓	✓
Connect	✓	✓	✓	✓
PTree	✓	No	✓	✓
AITree	✓	No	No	No
Probs	✓	✓	✓	No
dObs	No	✓	No	No
CFlowT	No	✓	No	No
FwdTree	No	✓	✓	✓
ExTree	No	No	✓	✓
ProbTree	No	No	No	✓
ExProbTree	No	No	No	✓
ExProbsByTreeLevel	No	No	No	✓

# price

**Package:** finpricer

Compute price for credit derivative instrument with `Credit` pricer

## Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
```

## Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

## Examples

### Use Credit Pricer and Default Probability Curve to Price CDS Instrument

This example shows the workflow to price a CDS instrument when you use a `defprobcurve` model and a `Credit` pricing method.

#### Create CDS Instrument Object

Use `fininstrument` to create a CDS instrument object.

```
CDS = fininstrument("cds", 'Maturity',datetime(2027,9,20), 'ContractSpread', 50, 'Name', "CDS_instrument")
```

```
CDS =
  CDS with properties:
      ContractSpread: 50
      Maturity: 20-Sep-2027
      Period: 4
      Basis: 2
      RecoveryRate: 0.4000
      BusinessDayConvention: "actual"
      Holidays: NaT
      PayAccruedPremium: 1
      Notional: 10000000
      Name: "CDS_instrument"
```

#### Create defprobcurve Object

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2017, 9, 20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities)
```

```
DefaultProbCurve =
  defprobcurve with properties:

        Settle: 20-Sep-2017
        Basis: 2
        Dates: [10x1 datetime]
  DefaultProbabilities: [10x1 double]
```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

        Type: "zero"
  Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 20-Sep-2017
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create Credit Pricer Object

Use finpricer to create a Credit pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
CDSpricer = finpricer("credit", 'DiscountCurve', ZeroCurve, 'DefaultProbabilityCurve', DefaultProbCurve)
```

```
CDSpricer =
  Credit with properties:

        DiscountCurve: [1x1 ratecurve]
        TimeStep: 10
  DefaultProbabilityCurve: [1x1 defprobcurve]
```

### Price CDS Instrument

Use price to compute the price for the CDS instrument.

```
outPrice = price(CDSpricer, CDS)
```

```
outPrice = 6.9363e+04
```

## Input Arguments

### inpPricer — Pricer object

Credit pricer object

Pricer object, specified as a scalar `Credit` pricer object. Use `finpricer` to create the `Credit` pricer object.

Data Types: `object`

### **inpInstrument — Instrument object**

`CDS` object

Instrument object, specified as a scalar `CDS` instrument object. Use `fininstrument` to create the `CDS` instrument object.

Data Types: `object`

## **Output Arguments**

### **Price — Instrument price**

`numeric`

Instrument price, returned as a `numeric`.

### **PriceResult — Price result**

`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes the `CDS` price and accrued premium
- `PriceResult.PricerData` — Structure that includes the premium leg payment dates, times, and cash flows

## **See Also**

`fininstrument` | `finmodel` | `finpricer`

### **Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-42

### **Introduced in R2020a**

## price

**Package:** finpricer

Compute price for interest-rate instrument with Discount pricer

### Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

### Description

[Price,PriceResult] = price(inpPricer,inpInstrument) computes the instrument price and related pricing information based on the pricing object inpPricer and the instrument object inpInstrument.

[Price,PriceResult] = price( \_\_\_\_,inpSensitivity) adds an optional argument to specify sensitivities.

### Examples

#### Use Discount Pricer and ratecurve to Price Swap Instrument

This example shows the workflow to price a Swap instrument when using a ratecurve and a Discount pricing method.

##### Create ratecurve Object

Create a ratecurve object using ratecurve for the underlying interest-rate curve for the Swap instrument.

```
Settle = datetime(2022,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Jan-2022
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
```

```
LongExtrapMethod: "previous"
```

### Create Swap Instrument Object

Use `fininstrument` to create a Swap instrument object.

```
SwapOpt = fininstrument("Swap", 'Maturity', datetime(2023,6,15), 'LegRate', [0.024 0.015], 'LegType',
```

```
SwapOpt =
```

```
Swap with properties:
```

```

        LegRate: [0.0240 0.0150]
        LegType: ["fixed"    "float"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
        LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
        DaycountAdjustedCashFlow: [0 0]
        ProjectionCurve: [1x2 ratecurve]
        BusinessDayConvention: ["actual"    "actual"]
        Holidays: NaT
        EndMonthRule: [1 1]
        StartDate: NaT
        Maturity: 15-Jun-2023
        Name: "swap_instrument"
```

### Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
outPricer =
```

```
Discount with properties:
```

```
DiscountCurve: [1x1 ratecurve]
```

### Price Swap Instrument

Use `price` to compute the price and sensitivities for the Swap instrument.

```
[Price, outPR] = price(outPricer, SwapOpt, ["all"])
```

```
Price = 0.2845
```

```
outPR =
```

```
pricerresult with properties:
```

```

        Results: [1x2 table]
        PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
    Price      DV01
    _____  _____
    0.28451    0.0075236
```

## Input Arguments

### inpPricer — Pricer object

Discount pricer object

Pricer object, specified as a scalar Discount pricer object. Use `finpricer` to create the Discountpricer object.

Data Types: object

### inpInstrument — Instrument object

Deposit object | FixedBond object | FloatBond object | FRA object | Swap object

Pricer object, specified as a scalar Deposit, FixedBond, FloatBond, FRA, or Swap instrument object. Use `fininstrument` to create the Deposit, FixedBond, FloatBond, FRA, or Swap instrument object.

Data Types: object

### inpSensitivity — List of sensitivities to compute

[ ] (default) | string array of character vector with values "Price", "DV01", and "All" | cell array of character vectors with values 'Price', 'DV01', and 'All'

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array with possible values of 'Price' and 'DV01'.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is Price and DV01. This is the same as specifying `inpSensitivity` to include each sensitivity.

The sensitivities supported depend on the `inpInstrument`.

inpInstrument	Supported Sensitivities
Deposit	{'DV01', 'price'}
FixedBond	{'DV01', 'price'}
FloatBond	{'DV01', 'price'}
FRA	{'DV01', 'price'}
Swap	{'DV01', 'price'}

Example: `inpSensitivity = {'DV01', 'price'}`

Data Types: cell | string

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### **PriceResult – Price result**

PriceResult object

Price result, returned as an object. The object has the following fields:

- `PriceResult.Results` – Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` – Structure for pricer data

### **See Also**

`fininstrument` | `finmodel` | `finpricer`

### **Topics**

“Choose Instruments, Models, and Pricers” on page 1-42

**Introduced in R2020a**

## price

**Package:** finpricer

Compute price for equity instrument with FFT pricer

### Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price(___,inpSensitivity)
```

### Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price(___,inpSensitivity)` adds an optional argument to specify sensitivities.

### Examples

#### Use FFT Pricer and Heston Model to Price Vanilla Instrument

This example shows the workflow to price a Vanilla instrument when you use a Heston model and an FFT pricing method.

##### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'ExerciseSty
```

```
VanillaOpt =
    Vanilla with properties:
```

```
    OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
    Strike: 105
    Name: "vanilla_option"
```

##### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)
```

```
HestonModel =
    Heston with properties:
```

```

V0: 0.0320
ThetaV: 0.1000
Kappa: 0.0030
SigmaV: 0.2000
RhoSV: 0.9000

```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create FFT Pricer Object

Use finpricer to create an FFT pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("fft",'DiscountCurve',myRC,'Model',HestonModel,'SpotPrice',100,'CharacteristicFcn',@characteristicFcnHeston)

```

```

outPricer =
  FFT with properties:
      Model: [1x1 finmodel.Heston]
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 100
      DividendType: "continuous"
      DividendValue: 0
      NumFFT: 8192
      CharacteristicFcnStep: 0.2000
      LogStrikeStep: 0.0038
      CharacteristicFcn: @characteristicFcnHeston
      DampingFactor: 1.5000
      Quadrature: "simpson"
      VolRiskPremium: 0
      LittleTrap: 1

```

### Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
Price = 14.7545
outPR =
    pricerresult with properties:
        Results: [1x7 table]
        PricerData: []

outPR.Results
ans=1x7 table
    Price      Delta      Gamma      Theta      Rho      Vega      VegaLT
    _____  _____  _____  _____  _____  _____  _____
    14.754    0.44868    0.021649   -0.20891   120.45    88.192    1.3248
```

## Input Arguments

### inpPricer — Pricer object

FFT object

Pricer object, specified as a scalar FFT pricer object. Use `finpricer` to create the FFT pricer object.

Data Types: object

### inpInstrument — Instrument object

Vanilla object

Instrument object, specified as a Vanilla instrument object. Use `fininstrument` to create the Vanilla instrument object.

Data Types: object

### inpSensitivity — List of sensitivities to compute

[ ] (default) | string array with values "Price", "Delta", "Gamma", "Vega", "Rho", "Theta", "Vegalt", and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Rho', 'Theta', 'Vegalt', and 'All'

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Rho', 'Theta', 'Vegalt', and 'All'.

---

**Note** For a Vanilla instrument using a Heston model, 'Vegalt' is not supported.

---

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is Delta, Gamma, Vega, Rho, Theta, Vegalt, and Price. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = {'delta', 'gamma', 'vega', 'rho', 'theta', 'vegalt', 'price'}`

Data Types: string | cell

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### PriceResult — Price result

PriceResult object

Price result, returned as a PriceResult object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

## See Also

“Choose Instruments, Models, and Pricers” on page 1-42

## Introduced in R2020a

## price

**Package:** finpricer

Compute price for equity instrument with FiniteDifference pricer

### Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
```

```
[Price,PriceResult] = price( ____,inpSensitivity)
```

### Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ____,inpSensitivity)` adds an optional argument to specify sensitivities.

### Examples

#### Use Finite Difference Pricer and Black-Scholes Model to Price Barrier Instrument

This example shows the workflow to price a Barrier instrument when you use a BlackScholes model and a FiniteDifference pricing method.

##### Create Barrier Instrument Object

Use `fininstrument` to create a Barrier instrument object.

```
BarrierOpt = fininstrument("Barrier", 'Strike', 105, 'ExerciseDate', datetime(2019,1,1), 'OptionType'
```

```
BarrierOpt =  
  Barrier with properties:  
  
    OptionType: "call"  
        Strike: 105  
    BarrierType: "do"  
BarrierValue: 40  
        Rebate: 0  
ExerciseStyle: "american"  
ExerciseDate: 01-Jan-2019  
        Name: "barrier_option"
```

##### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.30)
```

```

BlackScholesModel =
  BlackScholes with properties:

    Volatility: 0.3000
    Correlation: 1

```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```

Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)

myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 1
    Dates: 01-Jan-2023
    Rates: 0.0350
    Settle: 01-Jan-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create FiniteDifference Pricer Object

Use finpricer to create a FiniteDifference pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("FiniteDifference",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice')

outPricer =
  FiniteDifference with properties:

    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 100
    GridProperties: [1x1 struct]
    DividendType: "continuous"
    DividendValue: 0

```

### Price Barrier Instrument

Use price to compute the price and sensitivities for the Barrier instrument.

```

[Price, outPR] = price(outPricer,BarrierOpt,["all"])

Price = 11.3230

outPR =
  pricerresult with properties:

```

```
Results: [1x7 table]
PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Theta	Rho	Vega
11.323	0.54126	0.0132	4.7802	-7.4408	42.766	39.627

## Input Arguments

### **inpPricer** — Pricer object

FiniteDifference object

Pricer object, specified as a scalar FiniteDifference pricer object. Use `finpricer` to create the FiniteDifference pricer object.

Data Types: object

### **inpInstrument** — Instrument object

Vanilla object

Instrument object, specified as a scalar Vanilla instrument object. Use `fininstrument` to create the Vanilla instrument object.

Data Types: object

### **inpSensitivity** — List of sensitivities to compute

[ ] (default) | string array with values "Price", "Delta", "Gamma", "Vega", "Rho", "Theta", "Lambda", "Vegalt", and "All" | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Lambda', 'Vegalt', 'Vega', 'Rho', 'Theta', and 'All'

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array with supported values.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is Delta, Gamma, Vega, Vegalt, Lambda, Rho, Theta, and Price. This is the same as specifying `inpSensitivity` to include each sensitivity.

---

**Note** When you price a Barrier instrument using a BlackScholes model, 'Vegalt' is not supported.

---

```
Example: inpSensitivity =
{'delta', 'gamma', 'vega', 'vegalt', 'rho', 'lambda', 'theta', 'price'}
```

Data Types: string | cell

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### PriceResult — Price result

PriceResult object

Price result, returned as a PriceResult object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

**Introduced in R2020a**

## price

**Package:** finpricer

Compute price for equity instrument with NumericalIntegration pricer

### Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

### Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ____,inpSensitivity)` adds an optional argument to specify sensitivities.

### Examples

#### Use Numerical Integration Pricer and Merton Model to Price Vanilla Instrument

This example shows the workflow to price a Vanilla instrument when you use a Merton model and a NumericalIntegration pricing method.

##### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2020,3,15), 'ExerciseStyle', "european")
```

```
VanillaOpt =
  Vanilla with properties:
```

```
    OptionType: "call"
  ExerciseStyle: "european"
    ExerciseDate: 15-Mar-2020
        Strike: 105
        Name: "vanilla_option"
```

##### Create Merton Model Object

Use `finmodel` to create a Merton model object.

```
MertonModel = finmodel("Merton", 'Volatility', 0.45, 'MeanJ', 0.02, 'JumpVol', 0.07, 'JumpFreq', 0.09)
```

```
MertonModel =
  Merton with properties:
```

```

Volatility: 0.4500
  MeanJ: 0.0200
  JumpVol: 0.0700
  JumpFreq: 0.0900

```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
myRC = ratecurve('zero',datetime(2019,9,15),datetime(2020,3,15),0.02)
```

```

myRC =
  ratecurve with properties:

      Type: "zero"
  Compounding: -1
      Basis: 0
      Dates: 15-Mar-2020
      Rates: 0.0200
      Settle: 15-Sep-2019
  InterpMethod: "linear"
ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"

```

### Create NumericalIntegration Pricer Object

Use finpricer to create a NumericalIntegration pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("numericalintegration", 'Model', MertonModel, 'DiscountCurve', myRC, 'SpotPrice
```

```

outPricer =
  NumericalIntegration with properties:

      Model: [1x1 finmodel.Merton]
  DiscountCurve: [1x1 ratecurve]
      SpotPrice: 100
  DividendType: "continuous"
  DividendValue: 0.0100
      AbsTol: 0.5000
      RelTol: 0.4000
  IntegrationRange: [1.0000e-09 Inf]
  CharacteristicFcn: @characteristicFcnMerton76
      Framework: "lewis2001"
  VolRiskPremium: 0.9000
  LittleTrap: 0

```

### Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 10.7325
```

```

outPR =
  pricerresult with properties:

```

```
Results: [1x6 table]
PricerData: []
```

```
outPR.Results
```

```
ans=1x6 table
```

Price	Delta	Gamma	Theta	Rho	Vega
10.732	0.5058	0.012492	-12.969	19.815	27.954

## Input Arguments

### **inpPricer** — Pricer object

NumericalIntegration object

Pricer object, specified as a scalar NumericalIntegration pricer object. Use `finpricer` to create the NumericalIntegration pricer object.

Data Types: object

### **inpInstrument** — Instrument object

Vanilla object

Instrument object, specified as a scalar Vanilla instrument object. Use `fininstrument` to create the Vanilla instrument object.

Data Types: object

### **inpSensitivity** — List of sensitivities to compute

[ ] (default) | string array with values "Price", "Delta", "Gamma", "Vega", "Rho", "Theta", "Vegalt", and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Rho', 'Theta', 'Vegalt', and 'All'

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Rho', 'Theta', 'Vegalt', and 'All'.

---

**Note** 'Vegalt' is not supported when you price a Vanilla option with a Merton model.

---

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is Delta, Gamma, Vega, Rho, Theta, Vegalt, and Price. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = {'delta', 'gamma', 'vega', 'rho', 'theta', 'vegalt', 'price'}`

Data Types: string | cell

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### PriceResult — Price result

PriceResult object

Price result, returned as an object. The PriceResult object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

## See Also

## pricePortfolio

Compute price and sensitivities for portfolio of instruments

### Syntax

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(inPort)
```

### Description

[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(inPort) calculates the price and sensitivities for a portfolio of instruments that is previously created using finportfolio.

### Examples

#### Price Portfolio of Heterogeneous Instruments

Use finportfolio and pricePortfolio to create and price a portfolio containing a FixedBond instrument and an American Vanilla option instrument.

#### Create FixedBond Instrument Object

Use fininstrument to create a FixedBond instrument object.

```
FixB = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.05, 'Name', "fixed_
```

```
FixB =
    FixedBond with properties:
        CouponRate: 0.0500
        Period: 2
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2022
        Name: "fixed_bond"
```

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create Discount Pricer Object for FixedBond Instrument

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
FBPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
FBPricer =
  Discount with properties:
      DiscountCurve: [1x1 ratecurve]
```

### Create Vanilla Instrument Object

Use `fininstrument` to create an American Vanilla instrument object.

```
Maturity = "15-Sep-2023";
AmericanOpt = fininstrument("Vanilla", 'ExerciseDate', Maturity, 'Strike', 120, 'ExerciseStyle', "amer
```

```
AmericanOpt =
  Vanilla with properties:
      OptionType: "call"
      ExerciseStyle: "american"
      ExerciseDate: 15-Sep-2023
      Strike: 120
      Name: "vanilla_option"
```

### Create BlackScholes Model Object for Vanilla Instrument

Use `finmodel` to create a BlackScholes model object.

```
BSModel = finmodel("BlackScholes", 'Volatility', 0.12)
```

```
BSModel =
  BlackScholes with properties:
      Volatility: 0.1200
```

```
Correlation: 1
```

### Create BjerksundStensland Pricer Object for Vanilla Instrument

Use `finpricer` to create an analytic pricer object for the BjerksundStensland pricing method and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
BJSPricer = finpricer("analytic", 'Model', BSMModel, 'DiscountCurve', myRC, 'SpotPrice', 100, 'DividendValue', 0.0200, 'DividendType', "continuous")
```

```
BJSPricer =
  BjerksundStensland with properties:

  DiscountCurve: [1x1 ratecurve]
  Model: [1x1 finmodel.BlackScholes]
  SpotPrice: 100
  DividendValue: 0.0200
  DividendType: "continuous"
```

### Add the Instruments to a finportfolio Object

Create a `finportfolio` object using `finportfolio` and add the two instruments with their associated pricers to the portfolio.

```
f1 = finportfolio([AmericanOpt, FixB], [BJSPricer, FBPricer])
```

```
f1 =
  finportfolio with properties:

  Instruments: [2x1 fininstrument.FinInstrument]
  Pricers: [2x1 finpricer.FinPricer]
  PricerIndex: [2x1 double]
  Quantity: [2x1 double]
```

### Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the instruments in the portfolio.

```
[PortPrice, InstPrice, PortSens, InstSens] = pricePortfolio(f1)
```

```
PortPrice = 119.1665
```

```
InstPrice = 2x1
```

```
 3.1912
115.9753
```

```
PortSens=1x8 table
```

Price	DV01	Delta	Gamma	Lambda	Vega	Theta	Rho
119.17	0.04295	0.23188	0.011522	7.2661	65.472	-0.81408	86.71

```
InstSens=2x8 table
```

Price	DV01	Delta	Gamma	Lambda	Vega	Theta
-------	------	-------	-------	--------	------	-------

vanilla_option	3.1912	NaN	0.23188	0.011522	7.2661	65.472	-0.81408
fixed_bond	115.98	0.04295	NaN	NaN	NaN	NaN	NaN

## Price Portfolio of Bond and Bond Option Instruments

This example shows the workflow to create and price a portfolio of bond and bond option instruments. You can use `finportfolio` and `pricePortfolio` to price `FixedBond`, `FixedBondOption`, `OptionEmbeddedFixedBond`, and `FloatBond` instruments using an `IRTree` pricing method.

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018, 1, 1);
ZeroTimes = calyears(1:4)';
ZeroRates = [0.035; 0.042147; 0.047345; 0.052707];
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
    ratecurve with properties:

        Type: "zero"
        Compounding: 1
        Basis: 0
        Dates: [4x1 datetime]
        Rates: [4x1 double]
        Settle: 01-Jan-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create Bond and Option Instruments

Use `fininstrument` to create a `FixedBond`, `FixedBondOption`, `OptionEmbeddedFixedBond`, and `FloatBond` instrument objects.

```
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates,CRates);
Maturity = datetime(2022,1,1);
Period = 1;
```

```
% Vanilla FixedBond
```

```
VBond = fininstrument("FixedBond", 'Maturity', Maturity, 'CouponRate', 0.0425, 'Period', Period, 'Name'
```

```
VBond =
    FixedBond with properties:

        CouponRate: 0.0425
```

```

        Period: 1
        Basis: 0
    EndMonthRule: 1
    Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2022
    Name: "vanilla_fixed"

% Stepped coupon bond
SBond = fininstrument("FixedBond", 'Maturity', Maturity, 'CouponRate', CouponRate, 'Period', Period, 'Name', Name)

SBond =
    FixedBond with properties:
        CouponRate: [2x1 timetable]
        Period: 1
        Basis: 0
    EndMonthRule: 1
    Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2022
    Name: "stepped_coupon_bond"

% FloatBond
Spread = 0;
Reset = 1;
Float = fininstrument("FloatBond", 'Maturity', Maturity, 'Spread', Spread, 'Reset', Reset, 'ProjectionCurve', ZeroCurve, 'Name', "floatbond")

Float =
    FloatBond with properties:
        Spread: 0
    ProjectionCurve: [1x1 ratecurve]
        ResetOffset: 0
        Reset: 1
        Basis: 0
    EndMonthRule: 1
    Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        LatestFloatingRate: NaN
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT

```

```

        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
        Name: "floatbond"

% Call option
Strike = 100;
ExerciseDates = datetime(2020,1,1);
OptionType = 'call';
Period = 1;
CallOption = fininstrument("FixedBondOption", 'Strike', Strike, 'ExerciseDate', ExerciseDates, ...
    'OptionType', OptionType, 'ExerciseStyle', "american", 'Bond', VBond, 'Name', "fixed_bond_option")

CallOption =
    FixedBondOption with properties:

        OptionType: "call"
        ExerciseStyle: "american"
        ExerciseDate: 01-Jan-2020
        Strike: 100
        Bond: [1x1 fininstrument.FixedBond]
        Name: "fixed_bond_option"

% Option for embedded bond (callable bond)
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates, CRates);
StrikeOE = [100; 100];
ExerciseDatesOE = [datetime(2020,1,1); datetime(2021,1,1)];
CallSchedule = timetable(ExerciseDatesOE, StrikeOE, 'VariableNames', {'Strike Schedule'});
CallableBond = fininstrument("OptionEmbeddedFixedBond", 'Maturity', Maturity, ...
    'CouponRate', CouponRate, 'Period', Period, ...
    'CallSchedule', CallSchedule, 'Name', "option_embedded_fixedbond")

CallableBond =
    OptionEmbeddedFixedBond with properties:

        CouponRate: [2x1 timetable]
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
        CallDates: [2x1 datetime]
        PutDates: [0x1 datetime]
        CallSchedule: [2x1 timetable]
        PutSchedule: [0x0 timetable]
        CallExerciseStyle: "american"
        PutExerciseStyle: [0x0 string]

```

```
Name: "option_embedded_fixedbond"
```

### Create HullWhite Model

Use `finmodel` to create a HullWhite model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("hullwhite", 'alpha', AlphaCurve, 'sigma', VolCurve)

HWModel =
    HullWhite with properties:

        Alpha: 0.1000
        Sigma: 0.0100
```

### Create IRTree Pricer for HullWhite Model

Use `finpricer` to create an IRTree pricer object for a HullWhite model and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
HWTreepricer = finpricer("IRTree", 'Model', HWModel, 'DiscountCurve', ZeroCurve, 'TreeDates', ZeroDates)

HWTreepricer =
    HWBKTree with properties:

        Tree: [1x1 struct]
        TreeDates: [4x1 datetime]
        Model: [1x1 finmodel.HullWhite]
        DiscountCurve: [1x1 ratecurve]
```

### Create finportfolio Object and Add Callable Bond Instrument

Create a `finportfolio` object with the vanilla bond, stepped coupon bond, float bond, and the call option.

```
myportfolio = finportfolio([VBond, SBond, Float, CallOption], HWTreepricer, [1, 2, 2, 1])

myportfolio =
    finportfolio with properties:

        Instruments: [4x1 fininstrument.FinInstrument]
        Pricers: [1x1 finpricer.irtree.HWBKTree]
        PricerIndex: [4x1 double]
        Quantity: [4x1 double]
```

Use `addInstrument` to add the callable bond instrument to the existing portfolio.

```
myportfolio = addInstrument(myportfolio, CallableBond, HWTreepricer, 1)

myportfolio =
    finportfolio with properties:

        Instruments: [5x1 fininstrument.FinInstrument]
```

```

    Pricers: [1x1 finpricer.irtree.HWBKTree]
    PricerIndex: [5x1 double]
    Quantity: [5x1 double]

```

```
myportfolio.PricerIndex
```

```
ans = 5x1
```

```

1
1
1
1
1

```

The `PricerIndex` property has a length equal to the length of instrument objects in the `finportfolio` object and stores the index of which pricer is used for each instrument object. In this case, because there is only one pricer, each instrument must use that pricer.

### Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the bond and option instruments in the portfolio.

```
format bank
```

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(myportfolio)
```

```
PortPrice =

## Input Arguments

### **inPort — Portfolio object**

finportfolio object

Portfolio object, previously created using finportfolio.

Data Types: object

## Output Arguments

### **PortPrice — Price of portfolio of instruments**

numeric

Price of the portfolio of instruments, returned as a numeric.

### **InstPrice — Instrument prices**

numeric

Instrument prices, returned as a numeric.

### **PortSens — Portfolio sensitivities**

numeric

Portfolio sensitivities, returned as a numeric.

### **InstSens — Instrument sensitivities**

numeric

Instrument sensitivities, returned as a numeric.

## See Also

addInstrument | fininstrument | removeInstrument | setPricer

# addInstrument

Add instrument to portfolio of instruments

## Syntax

```
outPort = addInstrument(inPort,inInst)
outPort = addInstrument(inPort,inInst,inPricer)
outPort = addInstrument( ____,inQuant)
```

## Description

`outPort = addInstrument(inPort,inInst)` adds the instrument `inInst` to a portfolio `inPort` of instruments previously created using `finportfolio`.

`outPort = addInstrument(inPort,inInst,inPricer)` adds the instrument `inInst` and the associated pricer `inPricer` to a portfolio `inPort` of instruments previously created using `finportfolio`.

`outPort = addInstrument( ____,inQuant)` optionally specifies the number (`inQuant`) of added instruments. Use this syntax with any of the input argument combinations in previous syntaxes.

## Examples

### Add Instruments to Portfolio

Use `finportfolio` to create an empty portfolio and then use `addInstrument` to add instruments to the portfolio.

### Create FixedBond Instrument Objects

Use `fininstrument` to create two `FixedBond` instrument objects.

```
FixB1 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15),'CouponRate',0.045,'Name',"fix
```

```
FixB1 =
```

```
FixedBond with properties:
```

```

    CouponRate: 0.0450
    Period: 2
    Basis: 0
    EndMonthRule: 1
    Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 15-Sep-2022
```

```
Name: "fixed_bond1"
```

```
FixB2 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15),'CouponRate',0.035,'Name',"fix
```

```
FixB2 =
```

```
FixedBond with properties:
```

```

    CouponRate: 0.0350
    Period: 2
    Basis: 0
    EndMonthRule: 1
    Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 15-Sep-2022
    Name: "fixed_bond2"
```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
```

```
Type = "zero";
```

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
```

```
ratecurve with properties:
```

```

    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create Discount Pricer Object for FixedBond Instruments

Use finpricer to create a Discount pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
DiscountPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
DiscountPricer =
```

```
Discount with properties:
```

```
DiscountCurve: [1x1 ratecurve]
```

### Add Instruments to finportfolio Object

Create an empty `finportfolio` object using `finportfolio` and then use `addInstrument` to put the `FixedBond` instruments into the portfolio.

```
f1 = finportfolio;
f1 = addInstrument(f1,FixB1)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
    Quantity: 1
```

```
f1 = addInstrument(f1,FixB2)

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
    Quantity: [2x1 double]
```

### Set Pricer for Portfolio

Use `setPricer` to set the pricer for the portfolio and then use `pricePortfolio` to calculate the price and sensitivities for the instruments in the portfolio.

```
f1 = setPricer(f1,DiscountPricer,[1,2])

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
      Pricers: [1x1 finpricer.Discount]
    PricerIndex: [2x1 double]
    Quantity: [2x1 double]

[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)

PortPrice = 224.0834

InstPrice = 2x1

    114.0085
    110.0749

PortSens=1x2 table
    Price    DV01
```

224.08	0.084139
--------	----------

InstSens=2x2 *table*

	Price	DV01
fixed_bond1	114.01	0.04251
fixed_bond2	110.07	0.041629

## Input Arguments

### **inPort** — **finportfolio** object

finportfolio object

finportfolio object, specified as a scalar finportfolio object.

Data Types: object

### **inInst** — **Instrument object to add to portfolio**

scalar instrument object | array of instrument objects

Instrument object to add to portfolio, specified as a scalar instrument object or an array of instrument objects that are previously created using fininstrument.

Data Types: object

### **inPricer** — **Pricer object associated with an added instrument object**

scalar pricer object | array of pricer objects

Pricer object associated with an added instrument object, specified as a scalar pricer object or an array of pricer objects that are previously created using finpricer.

Data Types: object

### **inQuant** — **Number of added instruments**

1 (default) | positive or negative numeric

Number of instruments, specified as a scalar numeric. Use a positive value for a long position and a negative value for a short position.

Data Types: double

## Output Arguments

### **outPort** — **Updated finportfolio** object

finportfolio object

Updated finportfolio, returned as a finportfolio object.

## See Also

## removeInstrument

Remove instrument from portfolio of instruments

### Syntax

```
outPort = removeInstrument(inPort,inInst)
```

### Description

`outPort = removeInstrument(inPort,inInst)` removes an instrument object (`inInst`) from a portfolio of instruments (`inPort`) previously created using `finportfolio`.

### Examples

#### Remove Instrument From a Portfolio

Use `addInstrument` to add instruments to an empty portfolio and then remove an instrument from the portfolio using `removeInstrument`.

#### Create FixedBond Instrument Objects

Use `fininstrument` to create two `FixedBond` instrument objects.

```
FixB1 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15), 'CouponRate',0.045, 'Name', "fixed_bond1")
```

```
FixB1 =
    FixedBond with properties:
        CouponRate: 0.0450
        Period: 2
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2022
        Name: "fixed_bond1"
```

```
FixB2 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15), 'CouponRate',0.035, 'Name', "fixed_bond2")
```

```
FixB2 =
    FixedBond with properties:
        CouponRate: 0.0350
        Period: 2
```

```

        Basis: 0
      EndMonthRule: 1
      Principal: 100
    DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
      FirstCouponDate: NaT
      LastCouponDate: NaT
      StartDate: NaT
      Maturity: 15-Sep-2022
      Name: "fixed_bond2"

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
    Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
    InterpMethod: "linear"
  ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Discount Pricer Object for FixedBond Instruments

Use finpricer to create a Discount pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
DiscountPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```

DiscountPricer =
  Discount with properties:
      DiscountCurve: [1x1 ratecurve]

```

### Add Instruments to finportfolio Object

Create an empty finportfolio object using finportfolio and then use addInstrument to add the two FixedBond instruments to the portfolio.

```
f1 = finportfolio;
f1 = addInstrument(f1,FixB1)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
    Quantity: 1
```

```
f1 = addInstrument(f1,FixB2)

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
    Quantity: [2x1 double]
```

### **Remove Instrument from finportfolio Object**

Use `removeInstrument` to remove the first `FixedBond` instrument from the portfolio.

```
f1 = removeInstrument(f1,1)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
    Quantity: 1
```

### **Set Pricer for Portfolio**

Use `setPricer` to set the `Discount` pricer for the portfolio and then use `pricePortfolio` to calculate the price and sensitivities for the single instrument in the portfolio.

```
f1 = setPricer(f1,DiscountPricer)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
      Pricers: [1x1 finpricer.Discount]
    PricerIndex: 1
    Quantity: 1

[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)

PortPrice = 110.0749
InstPrice = 110.0749
```

```

PortSens=1x2 table
  Price      DV01
  _____  _____
  110.07     0.041629

```

```

InstSens=1x2 table
              Price      DV01
              _____  _____
  fixed_bond2  110.07     0.041629

```

## Input Arguments

### **inPort** — finportfolio object

finportfolio object

finportfolio object, specified as a scalar finportfolio object.

Data Types: object

### **inInst** — Instrument to remove from finportfolio object

instrument object | index | string for the instrument object 'Name' property

Instrument to remove from finportfolio object, specified as a scalar instrument object, string for the instrument object 'Name' property, or index value for the position of instrument in the finportfolio object.

Data Types: object | double | string

## Output Arguments

### **outPort** — Updated finportfolio object

finportfolio object

Updated finportfolio, returned as a finportfolio object.

## See Also

addInstrument | fininstrument | pricePortfolio | setPricer

### Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-42

**Introduced in R2020a**

## setPricer

Set pricer for finportfolio object

### Syntax

```
outPort = setPricer(inPort,inPricer,Index)
```

### Description

outPort = setPricer(inPort,inPricer,Index) sets a specified pricer for the previously created finportfolio object.

### Examples

#### Set Pricer for Portfolio Containing Instruments

Use finportfolio to create a portfolio of instruments and then use setPricer to set the pricer for the portfolio.

#### Create FixedBond Instrument Objects

Use fininstrument to create two FixedBond instrument objects.

```
FixB1 = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.045, 'Name', "fixed_bond1")
```

```
FixB1 =
```

```
FixedBond with properties:
```

```

    CouponRate: 0.0450
    Period: 2
    Basis: 0
    EndMonthRule: 1
    Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 15-Sep-2022
    Name: "fixed_bond1"
```

```
FixB2 = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.035, 'Name', "fixed_bond2")
```

```
FixB2 =
```

```
FixedBond with properties:
```

```

    CouponRate: 0.0350
    Period: 2
```

```

        Basis: 0
      EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
      StartDate: NaT
      Maturity: 15-Sep-2022
      Name: "fixed_bond2"

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
    Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
    Settle: 15-Sep-2018
    InterpMethod: "linear"
  ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Discount Pricer Object for FixedBond Instruments

Use finpricer to create a Discount pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
DiscountPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```

DiscountPricer =
  Discount with properties:
      DiscountCurve: [1x1 ratecurve]

```

### Add Instruments to finportfolio Object

Create a finportfolio object using finportfolio and use addInstrument to put the FixedBond instruments in the portfolio.

```
f1 = finportfolio;
f1 = addInstrument(f1,FixB1)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
    Quantity: 1
```

```
f1 = addInstrument(f1,FixB2)

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
    Quantity: [2x1 double]
```

### Set Pricer for Portfolio

Use `setPricer` to set the pricer for the portfolio and then use `pricePortfolio` to calculate the price and sensitivities for the instruments in the portfolio.

```
f1 = setPricer(f1,DiscountPricer,[1,2])

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
      Pricers: [1x1 finpricer.Discount]
    PricerIndex: [2x1 double]
    Quantity: [2x1 double]
```

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)
```

```
PortPrice = 224.0834
```

```
InstPrice = 2x1
```

```
114.0085
110.0749
```

```
PortSens=1x2 table
```

Price	DV01
224.08	0.084139

```
InstSens=2x2 table
```

Price	DV01
-------	------

```
fixed_bond1    114.01    0.04251
fixed_bond2    110.07    0.041629
```

## Input Arguments

### **inPort – Portfolio**

finportfolio object

Portfolio, specified using a previously created finportfolio object.

Data Types: object

### **inPricer – Pricer object to set for an instrument in a finportfolio object**

object

Pricer object to set for an instrument in a finportfolio object, specified using a previously created pricer object with finpricer.

Data Types: object

### **Index – Index to instruments in finportfolio object**

numeric

Index to instruments in the finportfolio object, specified as a numeric value.

Data Types: double

## Output Arguments

### **outPort – Updated portfolio**

finportfolio object

Updated portfolio, returned as an finportfolio object.

## See Also

addInstrument | finportfolio | pricePortfolio | removeInstrument

## Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-42

## Introduced in R2020a

## cashflows

**Package:** fininstrument

Computes cash flow for FixedBond, FloatBond, Swap, FRA, Swap, or Deposit instrument

### Syntax

```
CF = cashflows(InstrumentObject,Settle)
```

### Description

CF = cashflows(InstrumentObject,Settle) computes cash flow for a Deposit, FRA, Swap, FixedBond, or FloatBond instrument.

### Examples

#### Calculate Cash Flow for FRA Instrument

This example shows the workflow to price a FRA (forward rate agreement) instrument and then use cashflows to determine the cash flow for the FRA instrument.

#### Create FRA Instrument Object

Use fininstrument to create a FRA instrument object.

```
FRAObj = fininstrument("FRA", 'StartDate', datetime(2020,9,15), 'Maturity', datetime(2022,9,15), 'Rate
```

```
FRAObj =  
    FRA with properties:
```

```
        Rate: 0.1750  
        Basis: 2  
    StartDate: 15-Sep-2020  
        Maturity: 15-Sep-2022  
    Principal: 100  
BusinessDayConvention: "actual"  
        Holidays: NaT  
        Name: ""
```

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);  
Type = "zero";  
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];  
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';  
ZeroDates = Settle + ZeroTimes;  
  
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object with the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("Discount", 'DiscountCurve', myRC)
outPricer =
  Discount with properties:
      DiscountCurve: [1x1 ratecurve]

```

### Price FRA Instrument

Use `price` to compute the price and sensitivities for the FRA instrument.

```

[Price, outPR] = price(outPricer, FRAObj, ["all"])
Price = 34.1757
outPR =
  pricerresult with properties:
      Results: [1x2 table]
      PricerData: []

```

`outPR.Results`

```

ans=1x2 table
  Price      DV01
  _____  _____
  34.176     0.01368

```

Use `cashflows` for the FRA instrument with a `Settle` date of 15-Dec-2021. The specified `Settle` date must be before the instrument `Maturity` date.

```
CF = cashflows(FRAObj, datetime(2021,12,15))
```

```

CF= 1x1 timetable
      Time      CFA
  _____  _____

```

15-Sep-2022 35.486

### Calculate Cash Flow for FixedBond Instrument

This example shows the workflow to price a FixedBond instrument and then use cashflows to calculate the cash flow for the FixedBond instrument.

#### Create FixedBond Instrument Object

Use `fininstrument` to create a FixedBond instrument object.

```
FixB = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.05, 'Period', 4, 'Bas
```

```
FixB =
    FixedBond with properties:
        CouponRate: 0.0500
        Period: 4
        Basis: 7
        EndMonthRule: 1
        Principal: 1000
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "follow"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2022
        Name: "fixed_bond_instrument"
```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
```

```
LongExtrapMethod: "previous"
```

### Create Discount Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
outPricer =
  Discount with properties:
    DiscountCurve: [1x1 ratecurve]
```

### Price FixedBond Instrument

Use `price` to compute the price and sensitivities for the `FixedBond` instrument.

```
[Price, outPR] = price(outPricer, FixB, ["all"])
```

```
Price = 1.1600e+03
```

```
outPR =
  pricerresult with properties:
    Results: [1x2 table]
    PricerData: []
```

#### outPR.Results

```
ans=1x2 table
  Price    DV01
  _____
```

Price	DV01
1160	0.42712

Use `cashflows` to calculate the cash flow for the `FixedBond` instrument for any specified `Settle` date before the instrument `Maturity` date.

```
CF = cashflows(FixB, datetime(2021,9,15))
```

```
CF=5x1 timetable
  Time          Var1
  _____
```

Time	Var1
15-Sep-2021	0
15-Dec-2021	12.5
15-Mar-2022	12.5
15-Jun-2022	12.5

15-Sep-2022 1012.5

## Input Arguments

### **InstrumentObject** — Instrument object

Deposit object | FixedBond object | FloatBond object | Swap object | FRA object

Instrument object, specified using a previously created instrument object for one of the following: Deposit, FixedBond, FloatBond, Swap, or FRA.

Data Types: object

### **Settle** — Settlement date for instrument cash flow

datetime | serial date number | date character vector | string array

Settlement date for instrument cash flow, specified as a scalar using a datetime, serial date number, date character vector, or date string.

---

**Note** The Settle date you specify must be before the Maturity date for the Deposit, FixedBond, FloatBond, Swap, or FRA instrument.

---

Data Types: double | char | datetime | string

## Output Arguments

### **CF** — Cash flow

timetable

Cash flow, returned as a timetable.

## See Also

fininstrument | finmodel | finpricer | timetable

### Introduced in R2020a

# fitSvensson

Fit Svensson model to bond market data

## Syntax

```
outCurve = fitSvensson(Settle, Instruments, CleanPrice)
```

## Description

`outCurve = fitSvensson(Settle, Instruments, CleanPrice)` fits a Svensson model to bond data.

## Examples

### Fit Svensson Model to Bond Market Data

Define the bond data and use `fininstrument` to create `FixedBond` instrument objects.

```
Settle = datetime(2017,9,15);
Maturity = [datetime(2019,9,15);datetime(2021,9,15);...
            datetime(2023,9,15);datetime(2026,9,7);...
            datetime(2035,9,15);datetime(2047,9,15)];

CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];

nInst = numel(CouponRate);
Bonds(nInst,1) = fininstrument.FinInstrument;
for ii=1:nInst
    Bonds(ii) = fininstrument("FixedBond", 'Maturity', Maturity(ii), ...
                             'CouponRate', CouponRate(ii));
end
```

Use `fitSvensson` to create a `parametercurve` object.

```
SvenModel = fitSvensson(Settle, Bonds, CleanPrice)
```

Local minimum possible.

`lsqnonlin` stopped because the final change in the sum of squares relative to its initial value is less than the value of the function tolerance.

```
SvenModel =
    parametercurve with properties:

        Type: "zero"
        Settle: 15-Sep-2017
        Compounding: -1
        Basis: 0
        FunctionHandle: @(t)fitF(Params,t)
        Parameters: [1.4568 -40.1541 42.3215 -3.7271 0.3367 2.8631]
```

## Input Arguments

### **Settle – Settlement date**

datetime | serial date number | date character vector | date string

Settlement date, specified as a scalar datetime, serial date number, date character vector, or date string.

Data Types: double | char | string | datetime

### **Instruments – Bond instrument objects**

array

Bond instrument objects, specified as an array of bond instrument objects.

Data Types: object

### **CleanPrice – Observed market prices**

vector

Observed market prices, specified as a vector.

Data Types: double

## Output Arguments

### **outCurve – Fitted Svensson model**

object

Fitted Svensson model, returned as a `parametercurve` object.

## See Also

# discountfactors

Calculate discount factors for a ratecurve object

## Syntax

```
outDF = discountfactors(obj,inpDates)
```

## Description

outDF = discountfactors(obj,inpDates) calculates the discount factors for a ratecurve object.

## Examples

### Calculate Discount Factors for a ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod','pchip');
```

```
myRC =
    ratecurve with properties:
```

```

        Type: "zero"
    Compounding: 2
         Basis: 5
         Dates: [10x1 datetime]
         Rates: [10x1 double]
         Settle: 15-Sep-2019
    InterpMethod: "pchip"
ShortExtrapMethod: "linear"
LongExtrapMethod: "pchip"
```

Compute the discount factors using discountfactors.

```
CurveSettle = datetime(2019,9,15);
outRates = discountfactors(myRC,CurveSettle+30:30:CurveSettle+720)
```

```
outRates = 1x24
```

```

    0.9996    0.9992    0.9988    0.9983    0.9979    0.9974    0.9970    0.9965    0.9961    0.9957
```

## Input Arguments

### **obj — ratecurve object**

ratecurve object

ratecurve object, specified using a previously created ratecurve object.

Data Types: object

### **inpDates — Input dates**

datetime | serial date number | date character vector | date string

Input dates, specified as a scalar or an NPOINTS-by-1 vector of datetimes, serial date numbers, cell array of date character vectors, or string array.

Data Types: string | datetime | double | char | cell

## Output Arguments

### **outDF — Discount factors**

numeric

Discount factors, returned as a numeric.

## See Also

forwardrates | irbootstrap | ratecurve | zerorates

# forwardrates

Calculate forward rates for ratecurve object

## Syntax

```
outRates = forwardrates(obj,startDates,endDates)
outRates = forwardrates( ____,inpComp,inpBasis)
```

## Description

`outRates = forwardrates(obj,startDates,endDates)` calculates forward rates for the ratecurve object (`obj`) based on the `startDates` and `endDates`.

`outRates = forwardrates( ____,inpComp,inpBasis)` optionally specifies the input compounding frequency (`inpComp`) and the input day-count basis (`inpBasis`) in addition to any of the input argument combinations in the previous syntax.

## Examples

### Calculate Forward Rates for ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod','pchip');
```

```
myRC =
    ratecurve with properties:
```

```

        Type: "zero"
    Compounding: 2
         Basis: 5
         Dates: [10x1 datetime]
         Rates: [10x1 double]
        Settle: 15-Sep-2019
    InterpMethod: "pchip"
ShortExtrapMethod: "linear"
LongExtrapMethod: "pchip"
```

Compute the forward rates using `forwardrates`.

```
outRates = forwardrates(myRC,datetime(2019,12,15),datetime(2021,9,15),6,7)
outRates = 0.0062
```

## Input Arguments

### **obj — ratecurve object**

ratecurve object

ratecurve object, specified using a previously created ratecurve object.

Data Types: object

### **startDates — Start dates of interval to discount over**

datetime | serial date number | date character vector | date string

Start dates of the interval to discount over, specified as a scalar or an NPOINTS-by-1 vector of datetimes, serial date numbers, cell array of date character vectors, or string array. **startDates** must be earlier than **endDates**.

Data Types: string | datetime | double | char | cell

### **endDates — Maturity dates ending interval to discount over**

datetime | serial date number | date character vector | date string

Maturity dates ending the interval to discount over, specified as a scalar or an NPOINTS-by-1 vector of datetimes, serial date numbers, cell array of date character vectors, or string array.

Data Types: string | datetime | double | char | cell

### **inpComp — Input compounding frequency**

Compounding for the ratecurve object (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### **inpBasis — Input day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

## Output Arguments

### **outRates – Forward rates**

numeric

Forward rates, returned as a numeric.

## See Also

[discountfactors](#) | [irbootstrap](#) | [ratecurve](#) | [zerorates](#)

## Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

## zerorates

Calculate zero rates for ratecurve object

### Syntax

```
outRates = zerorates(obj,inpDates)
outRates = zerorates( ____,inpComp,inpBasis)
```

### Description

`outRates = zerorates(obj,inpDates)` computes zero rates for the ratecurve object (`obj`) based on `inpDates`.

`outRates = zerorates( ____,inpComp,inpBasis)` optionally specifies the input compounding frequency (`inpComp`) and the input day-count basis (`inpBasis`) in addition to any of the input argument combinations in the previous syntax.

### Examples

#### Calculate Zero Rates for ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod','pchip');
```

```
myRC =
    ratecurve with properties:
```

```

        Type: "zero"
    Compounding: 2
         Basis: 5
         Dates: [10x1 datetime]
         Rates: [10x1 double]
         Settle: 15-Sep-2019
    InterpMethod: "pchip"
ShortExtrapMethod: "linear"
LongExtrapMethod: "pchip"
```

Compute the zero rates using `zerorates`.

```
CurveSettle = datetime(2019,9,15);
outRates = zerorates(myRC,CurveSettle+30:30:CurveSettle+720)

outRates = 1x24
```

0.0049 0.0050 0.0050 0.0051 0.0051 0.0052 0.0052 0.0053 0.0053 0.

## Input Arguments

### **obj** – ratecurve object

ratecurve object

ratecurve object, specified using a previously created ratecurve object.

Data Types: object

### **inpDates** – Input dates

datetime | serial date number | date character vector | date string

Input dates, specified as a scalar or an NPOINTS-by-1 vector of datetimes, serial date numbers, cell array of date character vectors, or string array.

Data Types: string | datetime | double | char | cell

### **inpComp** – Input compounding frequency

Compounding for the ratecurve object (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### **inpBasis** – Input day-count basis

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

## **Output Arguments**

### **outRates — Zero rates**

numeric

Zero rates, returned as a numeric.

# discountfactors

Calculate discount factors for parametercurve object

## Syntax

```
outDF = discountfactors(obj,inpDates)
```

## Description

`outDF = discountfactors(obj,inpDates)` calculates the discount factors for a parametercurve object.

## Examples

### Calculate Discount Factors for parametercurve Object

Create a parametercurve object using parametercurve.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compounding')
```

```
PCobj =  
parametercurve with properties:
```

```
    Type: "zero"  
    Settle: 15-Sep-2019  
    Compounding: 4  
    Basis: 5  
    FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)  
    Parameters: [-1.0000e-04 0.0030 0.0200]
```

Compute the discount factors using `discountfactors`.

```
CurveSettle = datetime(2019,9,15);  
outDF = discountfactors(PCobj,CurveSettle+30:30:CurveSettle+720)
```

```
outDF = 1x24
```

```
    0.9983    0.9967    0.9949    0.9932    0.9914    0.9895    0.9876    0.9857    0.9838    0.9819
```

## Input Arguments

### **obj** — parametercurve object

parametercurve object

parametercurve object, specified as a previously created parametercurve object.

Data Types: object

**inpDates — Input dates**

datetime | serial date number | date character vector | date string

Input dates, specified as a scalar or an NPOINTS-by-1 vector of a datetimes, serial date numbers, cell array of date character vectors, or string array.

Data Types: string | datetime | double | char | cell

**Output Arguments****outDF — Discount factors**

numeric

Discount factors, returned as a numeric.

**See Also**

fitNelsonSiegel | fitSvensson | forwardrates | ratecurve | zerorates

# forwardrates

Calculate forward rates for parametercurve object

## Syntax

```
outRates = forwardrates(obj,startDates,endDates)
outRates = forwardrates( ____,inpComp,inpBasis)
```

## Description

`outRates = forwardrates(obj,startDates,endDates)` computes forward rates for the parametercurve object (`obj`) based on `startDates` and `endDates`.

`outRates = forwardrates( ____,inpComp,inpBasis)` specifies options in addition to any of the input argument combinations in the previous syntax.

## Examples

### Calculate Forward Rates for parametercurve Object

Create a parametercurve object using parametercurve.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compoundi
```

```
PCobj =
    parametercurve with properties:
```

```

        Type: "zero"
        Settle: 15-Sep-2019
    Compounding: 4
        Basis: 5
    FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)
        Parameters: [-1.0000e-04 0.0030 0.0200]
```

Compute the forward rates using forwardrates.

```
CurveSettle = datetime(2019,9,15);
outRates = forwardrates(PCobj,datetime(2019,12,15),datetime(2020,9,15),6,7)

outRates = 0.0236
```

## Input Arguments

### **obj** — parametercurve object

parametercurve object

parametercurve object, specified as a previously created parametercurve object.

Data Types: object

**startDates — Start dates of interval to discount over**

datetime | serial date number | date character vector | date string

Start dates of the interval to discount over, specified as a scalar or an NPOINTS-by-1 vector of a datetimes, serial date numbers, cell array of date character vectors, or string array. `startDates` must be earlier than `endDates`.

Data Types: string | datetime | double | char | cell

**endDates — Maturity dates ending the interval to discount over**

serial date number | date character vector | date string | datetime

Maturity dates ending the interval to discount over, specified as a scalar or an NPOINTS-by-1 vector of a datetimes, serial date numbers, cell array of date character vectors, or string array.

Data Types: string | datetime | double | char | cell

**inpComp — Input compounding frequency**

Compounding for the parametercurve object (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**inpBasis — Input day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

## Output Arguments

### **outRates — Forward rates**

numeric

Forward rates, returned as a numeric.

## zerorates

Calculate zero rates for parametercurve object

### Syntax

```
outRates = zerorates(obj,inpDates)
outRates = zerorates( ____,inpComp,inpBasis)
```

### Description

`outRates = zerorates(obj,inpDates)` computes zero rates for the parametercurve object (`obj`) based on `inpDates`.

`outRates = zerorates( ____,inpComp,inpBasis)` specifies options in addition to any of the input argument combinations in the previous syntax.

### Examples

#### Calculate Zero Rates for parametercurve Object

Create a parametercurve object using parametercurve.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compoundi
```

```
PCobj =
```

```
parametercurve with properties:
```

```

    Type: "zero"
    Settle: 15-Sep-2019
    Compounding: 4
    Basis: 5
    FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)
    Parameters: [-1.0000e-04 0.0030 0.0200]
```

Compute the zero rates using zerorates.

```
CurveSettle = datetime(2019,9,15);
outRates = zerorates(PCobj,CurveSettle+30:30:CurveSettle+720)
```

```
outRates = 1×24
```

```
    0.0202    0.0205    0.0207    0.0210    0.0212    0.0215    0.0217    0.0219    0.0222    0.0225
```

### Input Arguments

**obj** — parametercurve object

parametercurve object

parametercurve object, specified as a previously created parametercurve object.

Data Types: object

### **inpDates – Input dates**

datetime | serial date number | date character vector | date string

Input dates, specified as a scalar or an NPOINTS-by-1 vector of a datetimes, serial date numbers, cell array of date character vectors, or string array. StartDates must be earlier than EndDates.

Data Types: string | datetime | double | char | cell

### **inpComp – Input compounding frequency**

Compounding for the parametercurve object (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### **inpBasis – Input day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

## **Output Arguments**

### **outRates – Zero rates**

numeric

Zero rates, returned as a numeric.

**See Also**

`discountfactors` | `fitNelsonSiegel` | `fitSvensson` | `forwardrates` | `ratecurve`

“Choose Instruments, Models, and Pricers” on page 1-42

**Introduced in R2020a**

# finportfolio

Create a `finportfolio` object

## Description

Create a `finportfolio` object for a collection of instrument objects.

After creating instruments, models, and pricer objects, use `finportfolio` to create a `finportfolio` object for a collection of instruments. For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
finportfolio_obj = finportfolio
finportfolio_obj = finportfolio(inInstruments)
finportfolio_obj = finportfolio(inInstruments,inPricers)
finportfolio_obj = finportfolio( ____,inQuant)
```

### Description

`finportfolio_obj = finportfolio` creates an empty `finportfolio` object.

`finportfolio_obj = finportfolio(inInstruments)` creates a `finportfolio` object containing the instrument objects `inInstruments`.

`finportfolio_obj = finportfolio(inInstruments,inPricers)` creates a `finportfolio` object containing the instrument objects `inInstruments` and the pricer objects `inPricers`.

`finportfolio_obj = finportfolio( ____,inQuant)` optionally sets the `inQuant` property which specifies the number of instruments. Use this syntax with any of the input argument combinations in previous syntaxes to set the properties on page 11-2110 for the `finportfolio` object. For example, `finportfolio_obj =`

```
finportfolio([CapObj,FloorObj,SwaptionObj],
[BlackPricerObj,NormalPricerObj,SabrPricerObj])
```

creates a `finportfolio` object that contains instrument and pricer objects. You can specify multiple name-value pair arguments.

### Input Arguments

#### **inInstruments — Instrument objects in the portfolio**

scalar Instrument object | array of Instrument objects

Instrument objects in the portfolio, specified as a scalar Instrument object or an array of Instrument objects.

Data Types: object

**inPricers – Pricer objects in the portfolio**

scalar Pricer object | array of Pricer objects

Pricer objects in the portfolio, specified as a scalar Pricer object or an array of Pricer objects.

Data Types: object

**inQuant – Number of instruments**

positive or negative numeric | array of positive or negative numerics

Number of instruments, specified as a scalar numeric or an NINST-by-1 array of numeric values. Use a positive value for long positions and a negative value for short positions.

Data Types: double

**Properties****Instruments – Instrument objects in the portfolio**

scalar instrument object | array of instrument objects

Instrument objects in the portfolio, returned as a scalar instrument object or an array of instrument objects.

Data Types: struct

**Pricers – Pricer objects in the portfolio**

scalar pricer object | array of pricer objects

Pricer objects in the portfolio, returned as a scalar pricer object or an array of pricer objects.

Data Types: struct

**PricerIndex – Mapping of instrument objects to pricer objects in the portfolio**

numeric

This property is read-only.

Mapping of instrument objects to pricer objects in the portfolio, returned as numeric.

PricerIndex has a length equal to the number of instrument objects in the finportfolio object and stores an index of which pricer is used for each instrument object.

Data Types: struct

**Quantity – Number of instruments**

numeric

Number of instruments, returned as a scalar numeric or numeric array.

Data Types: double

**Object Functions**

pricePortfolio      Compute price and sensitivities for portfolio of instruments

addInstrument	Add instrument to portfolio of instruments
removeInstrument	Remove instrument from portfolio of instruments
setPricer	Set pricer for finportfolio object

## Examples

### Price Portfolio of Heterogeneous Instruments

Use `finportfolio` and `pricePortfolio` to create and price a portfolio containing a `FixedBond` instrument and an American Vanilla option instrument.

#### Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.05, 'Name', "fixed_
```

```
FixB =
  FixedBond with properties:
      CouponRate: 0.0500
      Period: 2
      Basis: 0
      EndMonthRule: 1
      Principal: 100
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      IssueDate: NaT
      FirstCouponDate: NaT
      LastCouponDate: NaT
      StartDate: NaT
      Maturity: 15-Sep-2022
      Name: "fixed_bond"
```

#### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
```

```

        Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Discount Pricer Object for FixedBond Instrument

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
FBPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
FBPricer =
    Discount with properties:

        DiscountCurve: [1x1 ratecurve]

```

### Create Vanilla Instrument Object

Use `fininstrument` to create an American Vanilla instrument object.

```
Maturity = "15-Sep-2023";
AmericanOpt = fininstrument("Vanilla", 'ExerciseDate', Maturity, 'Strike', 120, 'ExerciseStyle', "amer
```

```
AmericanOpt =
    Vanilla with properties:

        OptionType: "call"
        ExerciseStyle: "american"
        ExerciseDate: 15-Sep-2023
        Strike: 120
        Name: "vanilla_option"

```

### Create BlackScholes Model Object for Vanilla Instrument

Use `finmodel` to create a BlackScholes model object.

```
BSModel = finmodel("BlackScholes", 'Volatility', 0.12)
```

```
BSModel =
    BlackScholes with properties:

        Volatility: 0.1200
        Correlation: 1

```

### Create BjerksundStensland Pricer Object for Vanilla Instrument

Use `finpricer` to create an analytic pricer object for the BjerksundStensland pricing method and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
BJSPricer = finpricer("analytic", 'Model', BSModel, 'DiscountCurve', myRC, 'SpotPrice', 100, 'DividendV
```

```
BJSPricer =
    BjerksundStensland with properties:

```

```
DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
      DividendValue: 0.0200
      DividendType: "continuous"
```

### Add the Instruments to a finportfolio Object

Create a `finportfolio` object using `finportfolio` and add the two instruments with their associated pricers to the portfolio.

```
f1 = finportfolio([AmericanOpt,FixB],[BJSPricer,FBPricer])
```

```
f1 =
  finportfolio with properties:

  Instruments: [2x1 fininstrument.FinInstrument]
  Pricers: [2x1 finpricer.FinPricer]
  PricerIndex: [2x1 double]
  Quantity: [2x1 double]
```

### Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the instruments in the portfolio.

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)
```

```
PortPrice = 119.1665
```

```
InstPrice = 2x1
```

```
    3.1912
   115.9753
```

```
PortSens=1x8 table
```

Price	DV01	Delta	Gamma	Lambda	Vega	Theta	Rho
119.17	0.04295	0.23188	0.011522	7.2661	65.472	-0.81408	86.71

```
InstSens=2x8 table
```

	Price	DV01	Delta	Gamma	Lambda	Vega	Theta
vanilla_option	3.1912	NaN	0.23188	0.011522	7.2661	65.472	-0.81408
fixed_bond	115.98	0.04295	NaN	NaN	NaN	NaN	NaN

### Price Portfolio of Bond and Bond Option Instruments

This example shows the workflow to create and price a portfolio of bond and bond option instruments. You can use `finportfolio` and `pricePortfolio` to price `FixedBond`,

FixedBondOption, OptionEmbeddedFixedBond, and FloatBond instruments using an IRTree pricing method.

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018, 1, 1);
ZeroTimes = calyears(1:4)';
ZeroRates = [0.035; 0.042147; 0.047345; 0.052707];
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
    ratecurve with properties:
        Type: "zero"
        Compounding: 1
        Basis: 0
        Dates: [4x1 datetime]
        Rates: [4x1 double]
        Settle: 01-Jan-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create Bond and Option Instruments

Use fininstrument to create a FixedBond, FixedBondOption, OptionEmbeddedFixedBond, and FloatBond instrument objects.

```
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates,CRates);
Maturity = datetime(2022,1,1);
Period = 1;
```

```
% Vanilla FixedBond
```

```
VBond = fininstrument("FixedBond", 'Maturity',Maturity, 'CouponRate',0.0425, 'Period',Period, 'Name'
```

```
VBond =
    FixedBond with properties:
        CouponRate: 0.0425
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
```

```

        Name: "vanilla_fixed"

% Stepped coupon bond
SBond = fininstrument("FixedBond", 'Maturity', Maturity, 'CouponRate', CouponRate, 'Period', Period, 'Name', Name)

SBond =
    FixedBond with properties:
        CouponRate: [2x1 timetable]
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
        Name: "stepped_coupon_bond"

% FloatBond
Spread = 0;
Reset = 1;
Float = fininstrument("FloatBond", 'Maturity', Maturity, 'Spread', Spread, 'Reset', Reset, 'Name', Name, 'ProjectionCurve', ZeroCurve, 'Name', "floatbond")

Float =
    FloatBond with properties:
        Spread: 0
        ProjectionCurve: [1x1 ratecurve]
        ResetOffset: 0
        Reset: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        LatestFloatingRate: NaN
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
        Name: "floatbond"

% Call option
Strike = 100;
ExerciseDates = datetime(2020,1,1);
OptionType = 'call';
Period = 1;

```

```

CallOption = fininstrument("FixedBondOption", 'Strike', Strike, 'ExerciseDate', ExerciseDates, ...
                          'OptionType', OptionType, 'ExerciseStyle', "american", 'Bond', VBond, 'Name', "fixed_bond_option")

CallOption =
    FixedBondOption with properties:

        OptionType: "call"
        ExerciseStyle: "american"
        ExerciseDate: 01-Jan-2020
        Strike: 100
        Bond: [1x1 fininstrument.FixedBond]
        Name: "fixed_bond_option"

% Option for embedded bond (callable bond)
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates, CRates);
StrikeOE = [100; 100];
ExerciseDatesOE = [datetime(2020,1,1); datetime(2021,1,1)];
CallSchedule = timetable(ExerciseDatesOE, StrikeOE, 'VariableNames', {'Strike Schedule'});
CallableBond = fininstrument("OptionEmbeddedFixedBond", 'Maturity', Maturity, ...
                             'CouponRate', CouponRate, 'Period', Period, ...
                             'CallSchedule', CallSchedule, 'Name', "option_embedded_fixedbond")

CallableBond =
    OptionEmbeddedFixedBond with properties:

        CouponRate: [2x1 timetable]
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
        CallDates: [2x1 datetime]
        PutDates: [0x1 datetime]
        CallSchedule: [2x1 timetable]
        PutSchedule: [0x0 timetable]
        CallExerciseStyle: "american"
        PutExerciseStyle: [0x0 string]
        Name: "option_embedded_fixedbond"

```

### Create HullWhite Model

Use `finmodel` to create a `HullWhite` model object.

```

VolCurve = 0.01;
AlphaCurve = 0.1;

HWMModel = finmodel("hullwhite", 'alpha', AlphaCurve, 'sigma', VolCurve)

```

```

HWModel =
  HullWhite with properties:

    Alpha: 0.1000
    Sigma: 0.0100

```

### Create IRTree Pricer for HullWhite Model

Use `finpricer` to create an `IRTree` pricer object for a `HullWhite` model and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

HWTrePricer = finpricer("IRTree", 'Model', HWModel, 'DiscountCurve', ZeroCurve, 'TreeDates', ZeroDates)

HWTrePricer =
  HWBKTree with properties:

    Tree: [1x1 struct]
    TreeDates: [4x1 datetime]
    Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]

```

### Create finportfolio Object and Add Callable Bond Instrument

Create a `finportfolio` object with the vanilla bond, stepped coupon bond, float bond, and the call option.

```

myportfolio = finportfolio([VBond, SBond, Float, CallOption], HWTrePricer, [1, 2, 2, 1])

myportfolio =
  finportfolio with properties:

    Instruments: [4x1 fininstrument.FinInstrument]
    Pricers: [1x1 finpricer.irtree.HWBKTree]
    PricerIndex: [4x1 double]
    Quantity: [4x1 double]

```

Use `addInstrument` to add the callable bond instrument to the existing portfolio.

```

myportfolio = addInstrument(myportfolio, CallableBond, HWTrePricer, 1)

myportfolio =
  finportfolio with properties:

    Instruments: [5x1 fininstrument.FinInstrument]
    Pricers: [1x1 finpricer.irtree.HWBKTree]
    PricerIndex: [5x1 double]
    Quantity: [5x1 double]

```

```
myportfolio.PricerIndex
```

```

ans = 5x1

    1
    1
    1

```

```
1
1
```

The `PricerIndex` property has a length equal to the length of instrument objects in the `finportfolio` object and stores the index of which pricer is used for each instrument object. In this case, because there is only one pricer, each instrument must use that pricer.

### Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the bond and option instruments in the portfolio.

```
format bank
```

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(myportfolio)
```

```
PortPrice =
    600.40
```

```
InstPrice = 5×1
```

```
    96.59
   204.14
   200.00
     0.05
    99.62
```

```
PortSens=1×4 table
```

Price	Vega	Gamma	Delta
600.40	-91.88	5729.66	-1285.76

```
InstSens=5×4 table
```

	Price	Vega	Gamma	Delta
vanilla_fixed	96.59	-0.00	1603.49	-344.81
stepped_coupon_bond	204.14	0.00	3364.60	-725.96
floatbond	200.00	-0.00	0.00	-0.00
fixed_bond_option	0.05	12.49	24.15	-3.69
option_embedded_fixedbond	99.62	-104.37	737.41	-211.30

## ratecurve

Create `ratecurve` object for interest-rate curve from dates and data

### Description

Build a `ratecurve` object using `ratecurve`.

After creating a `ratecurve` object, you can use the associated object functions `forwardrates`, `discountfactors`, and `zerorates`.

---

**Note** If you have the `RateSpec` obtained previously from `intenvset` or `toRateSpec` for an `IRDataCurve` or `toRateSpec` for an `IRFunctionCurve`, refer to “Convert `RateSpec` to a `ratecurve` Object” on page 1-38.

---

To price a `Swap`, `FixedBond`, `FloatBond`, `FRA`, or `Deposit` instrument, you must create a `ratecurve` object and then create `Discount` pricer object.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
ratecurve_obj = ratecurve(Type,Settle,Dates,Rates)
ratecurve_obj = ratecurve( ___,Name,Value)
```

### Description

`ratecurve_obj = ratecurve(Type,Settle,Dates,Rates)` creates a `ratecurve` object.

`ratecurve_obj = ratecurve( ___,Name,Value)` creates a `ratecurve` object using name-value pairs and any of the arguments in the previous syntax. For example, `myRC = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod',"pchip','ShortExtrapMethod',"linear','LongExtrapMethod',"cubic")` creates a `ratecurve` object for a zero curve. You can specify multiple name-value pair arguments.

### Input Arguments

#### Type — Type of interest-rate curve

string with value "zero", "forward", or "discount" | character vector with value 'zero', 'forward', or 'discount'

Type of interest-rate curve, specified as a string or character vector for one of the supported types.

Data Types: char | string

### Settle — Settlement date

datetime | serial date number | date character vector | date string

Settlement date, specified as a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Settle` property is stored as a datetime.

Data Types: double | char | string | datetime

### Dates — Dates corresponding to rate data

datetime | serial date number | date character vector | date string

Dates corresponding to the rate data, specified as a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Dates` property is stored as a datetime.

Data Types: double | char | string | datetime

### Rates — Interest-rate data for the curve

numeric

Interest-rate data for the curve, specified as a scalar numeric.

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `myRC =`

```
ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'Interp
Method',"pchip",'ShortExtrapMethod',"linear",'LongExtrapMethod',"cubic")
```

### Compounding — Compounding frequency

-1 (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, or 12.

Compounding frequency, specified as the comma-separated pair consisting of `'Compounding'` and a scalar numeric using the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)

- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)

For more information, see “Basis” on page 2-129.

Data Types: double

#### **InterpMethod — Interpolation method**

"linear" (default) | string with value "linear", "cubic", "next", "previous", "pchip", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'cubic', 'next', 'previous', 'pchip', 'v5cubic', 'makima', or 'spline'

Interpolation method, specified as the comma-separated pair consisting of 'InterpMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: char | string

#### **ShortExtrapMethod — Extrapolation method for data before first data**

"next" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'next', 'previous', 'pchip', 'cubic', 'v5cubic', 'makima', or 'spline'

Extrapolation method for data before first data, specified as the comma-separated pair consisting of 'ShortExtrapMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: char | string

#### **LongExtrapMethod — Extrapolation method for data after last data**

"previous" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'next', 'previous', 'pchip', 'cubic', 'v5cubic', 'makima', or 'spline'

Extrapolation method for data after last data, specified as the comma-separated pair consisting of 'LongExtrapMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: char | string

## Properties

### Type — Type of interest-rate curve

string with value "zero", "forward", or "discount"

Type of interest-rate curve, returned as a string.

Data Types: string

### Compounding — Compounding frequency

-1 (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, or 12.

Compounding frequency, returned as a scalar numeric.

Data Types: double

### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis of the instrument, returned as a scalar integer.

Data Types: double

### Dates — Dates corresponding to rate data

datetime

Dates corresponding to the rate data, returned as a datetime.

Data Types: datetime

### Rates — Rates corresponding to dates data

vector

Rates corresponding to dates data, returned as vector.

Data Types: datetime

### Settle — Settlement date

datetime

Settlement date, returned as a datetime.

Data Types: datetime

### InterpMethod — Interpolation method

"linear" (default) | string with value "linear", "cubic", "next", "previous", "pchip", "v5cubic", "makima", or "spline"

Interpolation method, returned as a scalar string.

Data Types: string

### ShortExtrapMethod — Short extrapolation method

"next" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline"

Short extrapolation method, returned as a scalar string.

Data Types: string

**LongExtrapMethod — Long extrapolation method**

"previous" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline"

Log extrapolation method, returned as a scalar string.

Data Types: string

**Object Functions**

forwardrates      Calculate forward rates for ratecurve object  
 discountfactors   Calculate discount factors for a ratecurve object  
 zerorates          Calculate zero rates for ratecurve object  
 irbootstrap        Bootstrap interest-rate curve from market data

**Examples****Create ratecurve Object**

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod',"pchip");
```

```
myRC =
  ratecurve with properties:
```

```

      Type: "zero"
  Compounding: 2
      Basis: 5
      Dates: [10x1 datetime]
      Rates: [10x1 double]
    Settle: 15-Sep-2018
  InterpMethod: "pchip"
ShortExtrapMethod: "linear"
LongExtrapMethod: "cubic"
```

## parametercurve

Create parametercurve object for storing interest-rate curve function

### Description

Build a parametercurve object using parametercurve.

After creating a parametercurve object, you can use the associated object functions `discountfactors`, `zerorates`, `forwardrates`, `fitNelsonSiegel`, and `fitSvensson`.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
parametercurve_obj = parametercurve(Type,Settle,FunctionHandle)
parametercurve_obj = parametercurve( ____,Name,Value)
```

#### Description

`parametercurve_obj = parametercurve(Type,Settle,FunctionHandle)` creates a parametercurve object.

`parametercurve_obj = parametercurve( ____,Name,Value)` sets properties on page 11-2128 using name-value pairs and any of the arguments in the previous syntax. For example, `parametercurve_obj = parametercurve('zero',datetime(2017,1,30),@(t)polyval([-0.0001 0.003 0.02],t),'Compounding',4,'Basis',5,'Parameters',[-0.0001 0.003 0.02])` creates a parametercurve object for a zero curve. You can specify multiple name-value pair arguments.

#### Input Arguments

##### Type — Type of interest-rate curve

string with value "zero", "forward", or "discount" | character vector with value 'zero', 'forward', or 'discount'

Type of interest-rate curve, specified as a scalar string or character vector for one of the supported types.

Data Types: char | string

##### Settle — Settlement date for the curve

datetime | serial date number | date character vector | date string

Settlement date for the curve, specified as a scalar datetime, serial date number, date character vector, or date string.

Data Types: double | char | string | datetime

### FunctionHandle — Dates corresponding to rate data

function handle

Dates corresponding to the rate data, specified as a function handle. The function handle requires one numeric input (time to maturity) and returns one numeric output (interest rate or discount factor). For more information on creating a function handle, see “Create Function Handle” (MATLAB).

Data Types: function\_handle

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

```
Example: parametercurve_obj =
parametercurve('zero',datetime(2017,1,30),@(t)polyval([-0.0001 0.003
0.02],t),'Compounding',4,'Basis',5,'Parameters',[-0.0001 0.003 0.02])
```

### Compounding — Compounding frequency for curve

-1 (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency for the curve, specified as the comma-separated pair consisting of 'Compounding' and a scalar numeric using the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

**Parameters — Curve parameters**

[ ] (default) | numeric

Curve parameters, specified as the comma-separated pair consisting of 'Parameters' and a numeric value.

Data Types: double

**Properties****Type — Type of interest-rate curve**

string with value "zero", "forward", or "discount"

Instrument type, returned as a string.

Data Types: string

**Settle — Settlement date**

datetime

Settlement date, returned as a datetime.

Data Types: datetime

**FunctionHandle — Dates corresponding to rate data**

function handle

Function handle that defines the interest-rate curve, returned as a scalar function handle.

Data Types: function\_handle

**Compounding — Compounding frequency for curve**

-1 (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency for curve, returned as a scalar numeric.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, returned as a scalar integer.

Data Types: double

**Parameters — Curve parameters**

[ ] (default) | numeric

Curve parameters, returned as a numeric value.

Data Types: double

## Object Functions

discountfactors	Calculate discount factors for parametercurve object
zerorates	Calculate zero rates for parametercurve object
forwardrates	Calculate forward rates for parametercurve object
fitNelsonSiegel	Fit Nelson-Siegel model to bond market data
fitSvensson	Fit Svensson model to bond market data

## Examples

### Create parametercurve Object

Create a parametercurve object using parametercurve.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compounding:4')
```

```
PCobj =
```

```
parametercurve with properties:
```

```

    Type: "zero"
    Settle: 15-Sep-2019
    Compounding: 4
    Basis: 5
    FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)
    Parameters: [-1.0000e-04 0.0030 0.0200]
```

### Introduced in R2020a

# Asian

Asian instrument object

## Description

Create and price an Asian instrument object using this workflow:

- 1 Use `fininstrument` to create an Asian instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Asian instrument.
- 3 Use `finpricer` to specify a Levy, KemnaVorst, or TurnbullWakeman pricing method for the Asian instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an Asian instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
AsianOpt = fininstrument(InstrumentType,'Strike',strike_price,'
ExerciseDate',exercise_date)
AsianOpt = fininstrument( ___,Name,Value)
```

### Description

`AsianOpt = fininstrument(InstrumentType,'Strike',strike_price,'ExerciseDate',exercise_date)` creates an Asian object by specifying `InstrumentType` and sets the properties on page 11-2132 for the required name-value pair arguments `Strike` and `ExerciseDate`.

The Asian instrument supports arithmetic and geometric average price Asian options. Average price Asian options are also known as fixed-strike Asian options.

`AsianOpt = fininstrument( ___,Name,Value)` sets optional properties on page 11-2132 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `AsianOpt = fininstrument("Asian",'Strike',100,'ExerciseDate',datetime(2019,1,30),'OptionType',"put",'ExerciseStyle',"European",'Name',"asian_option")` creates an Asian put option with an European exercise. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Asian" | character vector with value 'Asian'

Instrument type, specified as a string with the value of "Asian" or a character vector with the value of 'Asian'.

Data Types: string | char

### Asian Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: AsianOpt =  
`fininstrument("Asian", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'Option Type', "put", 'ExerciseStyle', "European", 'Name', "asian_option")`

### Required Asian Name-Value Pair Arguments

#### Strike — Option strike price value

nonnegative value

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative value.

Data Types: double

#### ExerciseDate — Option exercise dates

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For an Asian European option, there is only one ExerciseDate on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

### Optional Asian Name-Value Pair Arguments

#### OptionType — Option type

"call" (default) | character vector with value 'call' or 'put' | string with value "call" or "put"

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar character vector or string.

Data Types: char | string

#### ExerciseStyle — Option exercise style

"European" (default) | string with value "European" | character vector with value 'European'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

Data Types: string | char

**AverageType — Average type**

"arithmetic" (default) | string with value "arithmetic" or "geometric" | character vector with value 'arithmetic' or 'geometric'

Average types, specified as the comma-separated pair consisting of 'AverageType' and a scalar string or character vector. Use "arithmetic" for an arithmetic average, or "geometric" for a geometric average.

---

**Note** When you use a RollGeskeWhaley pricer, the AverageType must be "geometric".

---

Data Types: char | string

**AvgPrice — Average price of underlying asset**

[ ] (default) | scalar numeric

Average price of the underlying asset, specified as the comma-separated pair consisting of 'AvgPrice' and a scalar numeric.

Data Types: double

**AvgDate — Start date of averaging period**

[ ] (default) | datetime | serial date number | date character vector | date string

Start date of averaging period, specified as the comma-separated pair consisting of 'AvgDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the AvgDate property is stored as a datetime.

Data Types: char | double | datetime | string

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

**Properties****Strike — Option strike price value**

nonnegative value

Option strike price value, returned as a scalar nonnegative value.

Data Types: double

**ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

**OptionType – Option type**

"call" (default) | string with value "call" or "put"

Option type, returned as a string with the value "call" or "put".

Data Types: string

**ExerciseStyle – Option exercise style**

"European" (default) | string with value "European"

Option exercise style, returned as a string with the value "European".

Data Types: string

**AverageType – Average type**

"arithmetic" (default) | string with value "arithmetic" or "geometric"

Average types, returned as a scalar string with the value "arithmetic" for arithmetic average or "geometric" for geometric average.

Data Types: string

**AvgPrice – Average price of underlying asset at Settle**

scalar numeric

Average price of underlying asset at Settle, returned as a scalar numeric.

Data Types: double

**AvgDate – Start date of averaging period**

datetime object

Start date of averaging period, returned as a scalar datetime object.

Data Types: datetime

**Name – User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

**Examples****Price Asian Instrument Using a Black-Scholes Model and Turnbull-Wakeman Pricer**

This example shows the workflow to price a fixed-strike Asian instrument when you use a BlackScholes model and a TurnbullWakeman pricing method.

**Create Asian Instrument Object**

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 1000, 'OptionType', "p
```

```
AsianOpt =  
    Asian with properties:
```

```
        OptionType: "put"  
          Strike: 1000  
    AverageType: "arithmetic"  
    AveragePrice: 0  
    AverageStartDate: NaT  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Sep-2022  
      Name: "asian_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .2)
```

```
BlackScholesModel =  
  BlackScholes with properties:
```

```
    Volatility: 0.2000  
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =  
  ratecurve with properties:
```

```
        Type: "zero"  
    Compounding: -1  
      Basis: 12  
      Dates: 15-Sep-2023  
      Rates: 0.0350  
      Settle: 15-Sep-2018  
    InterpMethod: "linear"  
ShortExtrapMethod: "next"  
LongExtrapMethod: "previous"
```

### Create TurnbullWakeman Pricer Object

Use `finpricer` to create a TurnbullWakeman pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', 1000)
```

```
outPricer =  
  TurnbullWakeman with properties:  
  
    DiscountCurve: [1x1 ratecurve]  
      Model: [1x1 finmodel.BlackScholes]
```

```

    SpotPrice: 1000
    DividendValue: 0
    DividendType: "continuous"

```

### Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 56.7068
```

```
outPR =
    pricerresult with properties:
```

```

    Results: [1x7 table]
    PricerData: []

```

#### outPR.Results

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
56.707	-0.3155	0.0014381	-5.5637	408.87	-2.9341	-832.53

### Price Asian Instrument for Foreign Exchange Using Black-Scholes Model and Levy Pricer

This example shows the workflow to price an Asian instrument for an arithmetic average currency option when you use a BlackScholes model and a Levy pricing method. Assume that the current exchange rate is \$0.52 and has a volatility of 12% per annum. The annualized continuously compounded foreign risk-free rate is 8% per annum.

#### Create Asian Instrument Object

Use fininstrument to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 0.65, 'OptionType', "put")
```

```

AsianOpt =
    Asian with properties:
        OptionType: "put"
        Strike: 0.6500
        AverageType: "arithmetic"
        AveragePrice: 0
        AverageStartDate: NaT
        ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
        Name: "asian_fx_option"

```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
Sigma = .12;
BlackScholesModel = finmodel("BlackScholes", 'Volatility', Sigma)

BlackScholesModel =
    BlackScholes with properties:

        Volatility: 0.1200
        Correlation: 1
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)

myRC =
    ratecurve with properties:

        Type: "zero"
        Compounding: -1
        Basis: 12
        Dates: 15-Sep-2023
        Rates: 0.0350
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create Levy Pricer Object

Use `finpricer` to create a Levy pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument. When you price currencies using an Asian instrument for an arithmetic average currency option, the `DividendType` must be 'continuous' and `DividendValue` is the annualized risk-free interest rate in the foreign country.

```
ForeignRate = 0.08;
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', .52,

outPricer =
    Levy with properties:

        DiscountCurve: [1x1 ratecurve]
        Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 0.5200
        DividendValue: 0.0800
        DividendType: "continuous"
```

## Price Asian FX Instrument

Use `price` to compute the price and sensitivities for the Asian FX instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 0.1516
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x7 table]
  PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
0.15161	-0.78532	0.37534	-2.6935	0.015702	-0.0038317	-1.3974

## More About

### Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-33.

# Barrier

Barrier instrument object

## Description

Create and price a `Barrier` instrument object using this workflow:

- 1 Use `fininstrument` to create a `Barrier` instrument object.
- 2 Use `finmodel` to specify a `BlackScholes` model for the `Barrier` instrument.
- 3 Use `finpricer` to specify a `FiniteDifference` or `BlackScholes` pricing method for the `Barrier` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Barrier` instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
BarrierOpt = fininstrument(InstrumentType, 'Strike', strike_value, '
ExerciseDate', exercise_date, 'BarrierValue', barrier_value)
BarrierOpt = fininstrument( ___, Name, Value)
```

### Description

`BarrierOpt = fininstrument(InstrumentType, 'Strike', strike_value, 'ExerciseDate', exercise_date, 'BarrierValue', barrier_value)` creates a `Barrier` object by specifying `InstrumentType` and sets the properties on page 11-2141 for the required name-value pair arguments `Strike`, `ExerciseDate`, and `BarrierValue`.

`BarrierOpt = fininstrument( ___, Name, Value)` sets optional properties on page 11-2141 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BarrierOpt = fininstrument("Barrier", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'BarrierValue', 110, 'OptionType', "put", 'ExerciseStyle', "European", 'BarrierType', "D0", 'Name', "barrier_option")` creates a `Barrier` put option with an European exercise. You can specify multiple name-value pair arguments.

### Input Arguments

#### **InstrumentType** — Instrument type

string with value "Barrier" | character vector with value 'Barrier' | string with value "Barrier"

Instrument type, specified as the string with the value of "Barrier" or a character vector with the value of 'Barrier'.

Data Types: char | string

### Barrier Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `BarrierOpt = fininstrument("Barrier", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'BarrierValue', 110, 'OptionType', "put", 'ExerciseStyle', "European", 'BarrierType', "D0", 'Name', "barrier_option")`

### Required Barrier Name-Value Pair Arguments

#### Strike — Option strike price value

nonnegative value

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative value.

Data Types: double

#### ExerciseDate — Option exercise date

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For a European option, there is only one ExerciseDate on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

#### BarrierValue — Barrier level

numeric

Barrier level, specified as the comma-separated pair consisting of 'BarrierLevel' and a scalar numeric value.

Data Types: double

### Optional Barrier Name-Value Pair Arguments

#### OptionType — Option type

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European" or "American" | character vector with value 'European' or 'American'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

---

**Note** For a `Barrier` option, the `BlackScholes` pricer supports only a "European" exercise and the `FiniteDifference` pricer supports an "American" or "European" exercise.

---

Data Types: string | char

**BarrierType — Barrier option type**

"UO" (default) | string with value: "UI", "UO", "DI", or "DO" | character vector with value: 'UI', 'UO', 'DI', or 'DO'

Barrier option type, specified as the comma-separated pair consisting of 'BarrierType' and a string or character vector with one of the following values:

- "UI" — Up knock-in

This option becomes effective when the price of the underlying asset passes above the barrier level. If the underlying asset goes above the barrier level during the life of the option, the option holder has the right, but not the obligation, to buy or sell (call or put) the underlying security at the strike price.

- "UO" — Up knock-out

This option gives the option holder the right, but not the obligation, to buy or sell (call or put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying security passes above the barrier level. If the spot price of the underlying asset reaches or exceeds the barrier level with an up-and-out option, the rebate is paid.

- "DI" — Down knock-in

This option becomes effective when the price of the underlying stock passes below the barrier level. If the underlying security goes below the barrier level during the life of the option, the option holder has the right, but not the obligation, to buy or sell (call or put) the underlying security at the strike price. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option. Note that a `Barrier` instrument using the `FiniteDifference` pricer does not support American knock-in barrier options.

- "DO" — Down knock-up

This option gives the option holder the right, but not the obligation, to buy or sell (call or put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. If the option is worthless when it expires, the option holder receives a rebate amount.

Option	Barrier Type	Payoff If Barrier Crossed	Payoff If Barrier Not Crossed
Call or Put	Down knock-out	Worthless	Standard Call or Put
Call or Put	Down knock-in	Call or Put	Worthless
Call or Put	Up knock-out	Worthless	Standard Call or Put
Call or Put	Up knock-in	Standard Call or Put	Worthless

Data Types: char | string

### Rebate — Rebate value

0 (default) | numeric

Rebate value, specified as the comma-separated pair consisting of 'Rebate' and a scalar numeric.

- For knock-in options, the Rebate is paid at expiry.
- For knock-out options, the Rebate is paid when BarrierValue is reached.

Data Types: double

### Name — User-defined name for instrument

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### Strike — Option strike price value

nonnegative value

Option strike price value, returned as a scalar nonnegative value.

Data Types: double

### ExerciseDate — Option exercise date

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

### OptionType — Option type

"call" (default) | string with value "call" or "put"

Option type, returned as a string with the value "call" or "put".

Data Types: string

### ExerciseStyle — Option exercise style

"European" (default) | string with value "European" or "American"

Option exercise style, returned as a string with the value of "European" or "American".

Data Types: string

**BarrierSpec – Barrier option type**

"U0" European (default) | string with value: "UI", "U0", "DI", or "D0"

Barrier option type, returned as a string with a value of "UI", "U0", "DI", or "D0".

Data Types: string

**BarrierValue – Barrier level**

numeric

Barrier level, returned as a scalar numeric value.

Data Types: double

**Rebate – Rebate value**

0 (default) | numeric

Rebate value, returned as a scalar numeric.

Data Types: double

**Name – User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

**Price Barrier Instrument Using Black-Scholes Model and Finite Difference Pricer**

This example shows the workflow to price an Barrier instrument when you use a BlackScholes model and a FiniteDifference pricing method.

**Create Barrier Instrument Object**

Use `fininstrument` to create an Barrier instrument object.

```
BarrierOpt = fininstrument("Barrier", 'Strike', 45, 'ExerciseDate', datetime(2019,1,1), 'OptionType', 'U0')
```

```
BarrierOpt =  
  Barrier with properties:  
  
    OptionType: "call"  
        Strike: 45  
    BarrierType: "do"  
    BarrierValue: 40  
        Rebate: 0  
    ExerciseStyle: "american"  
    ExerciseDate: 01-Jan-2019  
        Name: "barrier_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:

    Volatility: 0.3000
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1)
```

```
myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 1
    Dates: 01-Jan-2023
    Rates: 0.0350
    Settle: 01-Jan-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create FiniteDifference Pricer Object

Use `finpricer` to create a FiniteDifference pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("FiniteDifference", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice')
```

```
outPricer =
  FiniteDifference with properties:

    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 50
    GridProperties: [1x1 struct]
    DividendType: "continuous"
    DividendValue: 0
```

### Price Barrier Instrument

Use `price` to compute the price and sensitivities for the Barrier instrument.

```
[Price, outPR] = price(outPricer, BarrierOpt, ["all"])
```

```
Price = 8.5014
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Theta	Rho	Vega
8.5014	0.85673	0.0057199	5.0388	-1.8461	26.238	6.1837

## More About

### Barrier Option

A barrier option has not only a strike price but also a barrier level and sometimes a rebate.

The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `BarrierValue`, during the life of the option. If the option cannot be exercised because the barrier level either has or has not been reached, a fixed rebate amount is paid. For more information, see “Barrier Option” on page 3-19.

### Tips

After creating an `Barrier` instrument object with an `ExerciseStyle` set to "American", you can modify the `ExerciseStyle` property to change it to "European" using dot notation.

```
Barrier.ExerciseStyle = "European"
```

Because a European option has a scalar `Strike` and `ExerciseDate` value and an American option has a 2-element vector for `Strike` and `ExerciseDate` values, when you change to `ExerciseStyle` from "American" to "European" the `Strike` and `ExerciseDate` values become the last element in the 2-element vector for `Strike` and `ExerciseDate` values.

### Introduced in R2020a

# Cap

Cap instrument object

## Description

Create and price a Cap instrument object using this workflow:

- 1 Use `fininstrument` to create a Cap instrument object.
- 2 Use `finmodel` to specify a `HullWhite`, `Black`, or `Normal` model for the Cap instrument.
- 3 Use `finpricer` to specify a `Normal`, `Black`, or `HullWhite` pricing method for the Cap instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Cap instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
CapOpt = fininstrument(InstrumentType, 'Strike', strike_value, '
Maturity', maturity_date)
CapOpt = fininstrument( ____, Name, Value)
```

### Description

`CapOpt = fininstrument(InstrumentType, 'Strike', strike_value, 'Maturity', maturity_date)` creates a Cap object by specifying `InstrumentType` and sets the properties on page 11-2148 for the required name-value pair arguments `Strike` and `Maturity`.

The Cap instrument supports vanilla and amortizing caps.

`CapOpt = fininstrument( ____, Name, Value)` sets optional properties on page 11-2148 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `CapOpt = fininstrument("Cap", 'Strike', 0.65, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Principal', 100, 'ResetOffset', 1, 'Basis', 1, 'DaycountAdjustedCashFlow', true, 'BusinessDayConvention', "follow", 'ProjectionCurve', ratecurve_object, 'Name', "cap_option")` creates a Cap option with a strike of 0.65. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Cap" | character vector with value 'Cap'

Instrument type, specified as a string with the value "Cap" or a character vector with the value 'Cap'.

Data Types: char | string

### Cap Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: CapOpt =

```
fininstrument("Cap", 'Strike', 0.65, 'Maturity', datetime(2019, 1, 30), 'Reset', 4, 'Principal', 100, 'ResetOffset', 1, 'Basis', 1, 'DaycountAdjustedCashFlow', true, 'BusinessDayConvention', "follow", 'ProjectionCurve', ratecurve_object, 'Name', "cap_option")
```

### Required Cap Name-Value Pair Arguments

#### Strike — Cap strike price

nonnegative decimal value

Cap strike price, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative decimal value.

Data Types: double

#### Maturity — Cap maturity date

datetime | serial date number | date character vector | date string

Cap maturity date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

Data Types: double | char | string | datetime

### Optional Cap Name-Value Pair Arguments

#### Reset — Reset frequency payments per year

1 (default) | numeric with value of 0, 1, 2, 3, 4, 6, or 12

Reset frequency payments per year, specified as the comma-separated pair consisting of 'Reset' and a scalar numeric.

Data Types: double

#### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer with one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360

- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Principal — Principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or timetable.

Principal accepts a timetable, where the first column is dates and the second column is its associated principal value. The date indicates the last day that the principal value is valid.

Data Types: double | timetable

### **ResetOffset — Lag in rate setting**

0 (default) | numeric

Lag in rate setting, specified as the comma-separated pair consisting of 'ResetOffset' and a scalar numeric.

Data Types: double

### **DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on the actual period day count, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar with a value of true or false.

Data Types: logical

### **BusinessDayConvention — Business day conventions**

"actual" (default) | string | character vector

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector for a business day convention. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | string

### Holidays — Holidays used in computing business days

NaN (default) | datetime | cell array of character vectors | date string array | serial date number

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
CapOpt = fininstrument("Cap",'Strike',100,'Maturity',datetime(2025,12,15),'Holidays',H)
```

Data Types: double | cell | datetime | string

### ProjectionCurve — Rate curve used in generating future cash flows

ratecurve.empty (default) | ratecurve object

Rate curve used in projecting the future cash flows, specified as the comma-separated pair consisting of 'ProjectionCurve' and a ratecurve object. This object must be created using ratecurve. Use this optional input if the forward curve is different from the discount curve.

Data Types: object

### Name — User-defined name for instrument

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### Strike — Option strike price value

nonnegative value

Option strike price value, returned as a scalar nonnegative value.

Data Types: double

### Maturity — Cap maturity date

datetime

Cap maturity date, returned as a datetime.

Data Types: datetime

**Reset — Reset frequency payments per year**

1 (default) | numeric

Reset frequency payments per year, returned as a scalar numeric.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, returned as a scalar integer.

Data Types: double

**Principal — Principal amount or principal value schedule**

100 (default) | numeric | timetable

Principal amount or principal value schedule, returned as a scalar numeric for a principal amount or a timetable for a principal value schedule.

Data Types: double | timetable

**ResetOffset — Lag in rate setting**

0 (default) | numeric

Lag in rate setting, returned as a scalar numeric.

Data Types: double

**DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on the actual period day count, returned as a logical with a value of true or false.

Data Types: logical

**BusinessDayConvention — Business day conventions**

"actual" (default) | string

Business day conventions, returned as a string.

Data Types: string

**Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

**ProjectionCurve — Rate curve used in generating future cash flows**

ratecurve.empty (default) | structure

Rate curve used in projecting the future cash flows, returned as a ratecurve object.

Data Types: object

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

### Price Vanilla Cap Instrument Using Hull-White Model and Hull-White Pricer

This example shows the workflow to price a vanilla Cap instrument when using a HullWhite model and a HullWhite pricing method.

#### Create Cap Instrument Object

Use `fininstrument` to create a Cap instrument object.

```
CapOpt = fininstrument("Cap", 'Strike', 0.02, 'Maturity', datetime(2019, 1, 30), 'Reset', 4, 'Principal', 100)
```

```
CapOpt =
```

```
Cap with properties:
```

```

        Strike: 0.0200
        Maturity: 30-Jan-2019
    ResetOffset: 0
        Reset: 4
        Basis: 8
    Principal: 100
    ProjectionCurve: [0x0 ratecurve]
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        Name: "cap_option"
```

#### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.62, 'Sigma', 0.99)
```

```
HullWhiteModel =
```

```
HullWhite with properties:
```

```

    Alpha: 0.6200
    Sigma: 0.9900
```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018, 9, 15);
Type = 'zero';
```

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
  Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create HullWhite Pricer Object

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model',HullWhiteModel, 'DiscountCurve',myRC)
```

```
outPricer =
  HullWhite with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.HullWhite]
```

### Price Cap Instrument

Use `price` to compute the price for the Cap instrument.

```
Price = price(outPricer,CapOpt)
```

```
Price = 2.9366
```

### Price Vanilla Cap Instrument Using Normal Model and Normal Pricer

This example shows the workflow to price a vanilla Cap instrument when you use a `Normal` model and a `Normal` pricing method.

#### Create ratecurve Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the cap instrument.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create Cap Instrument Object

Use `fininstrument` to create a Cap instrument object.

```
CapOpt = fininstrument("Cap", 'Maturity', datetime(2022,9,15), 'Strike', 0.04, 'ProjectionCurve', myRC)
```

```
CapOpt =
  Cap with properties:
      Strike: 0.0400
      Maturity: 15-Sep-2022
      ResetOffset: 0
      Reset: 1
      Basis: 0
      Principal: 100
      ProjectionCurve: [1x1 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: ""
```

### Create Normal Model Object

Use `finmodel` to create a Normal model object.

```
NormalModel = finmodel("Normal", 'Volatility', 0.01)
```

```
NormalModel =
  Normal with properties:
      Volatility: 0.0100
```

### Create Normal Pricer Object

Use `finpricer` to create a Normal pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', NormalModel)
```

```
outPricer =
  Normal with properties:
```

```
DiscountCurve: [1x1 ratecurve]
Shift: 0
Model: [1x1 finmodel.Normal]
```

### Price Cap Instrument

Use `price` to compute the price for the Cap instrument.

```
[Price, outPR] = price(outPricer, CapOpt)
```

```
Price = 0.0701
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x1 table]
  PricerData: []
```

### Price Amortizing Cap Instrument Using Black Model and Black Pricer

This example shows the workflow to price an amortizing Cap instrument when you use a Black model and a Black pricing method.

#### Create Cap Instrument Object

Use `fininstrument` to create an amortizing Cap instrument object.

```
CADates = datetime({'1-Sep-2020'; '1-Sep-2023'});
CAPrincipal = [100; 85];
Principal = timetable(CADates,CAPrincipal);
```

```
CapOpt = fininstrument("Cap", 'Maturity',datetime(2023,9,1), 'Strike',0.015, 'Principal',Principal,
```

```
CapOpt =
  Cap with properties:
```

```
    Strike: 0.0150
    Maturity: 01-Sep-2023
  ResetOffset: 0
    Reset: 1
    Basis: 0
    Principal: [2x1 timetable]
  ProjectionCurve: [0x0 ratecurve]
DaycountAdjustedCashFlow: 0
  BusinessDayConvention: "actual"
    Holidays: NaT
    Name: "cap_amortizing_option"
```

#### Create Black Model Object

Use `finmodel` to create a Black model object.

```
BlackModel = finmodel("Black", 'Volatility',0.2)
```

```
BlackModel =  
  Black with properties:  
  
    Volatility: 0.2000  
    Shift: 0
```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,1);  
Type = 'zero';  
ZeroTimes = [calyears([1 2 3 4 5 7 10])]';  
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168]';  
ZeroDates = Settle + ZeroTimes;  
  
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates);
```

### Create Black Pricer Object

Use finpricer to create a Black pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackModel,'DiscountCurve',myRC)  
  
outPricer =  
  Black with properties:  
  
    Model: [1x1 finmodel.Black]  
    DiscountCurve: [1x1 ratecurve]
```

### Price Cap Instrument

Use price to compute the price for the Cap instrument.

```
Price = price(outPricer,CapOpt)  
  
Price = 0.3897
```

## More About

### Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate the holder pays, based on an otherwise floating interest rate.

The payoff for a cap is:  $\max(\text{CurrentRate} - \text{CapRate}, 0)$

For more information, see “Cap” on page 2-11.

## CDS

CDS instrument object

### Description

Create and price a CDS instrument object using this workflow:

- 1 Use `fininstrument` to create a CDS instrument object.
- 2 Use `defprobcurve` to specify a default probability curve for the CDS instrument.
- 3 Use `finpricer` to specify a Credit pricing method for the CDS instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a CDS instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
CDSobj = fininstrument(InstrumentType, 'Maturity', maturity_date, '
ContractSpread', contractspread_value)
CDSobj = fininstrument( ___, Name, Value)
```

#### Description

`CDSobj = fininstrument(InstrumentType, 'Maturity', maturity_date, 'ContractSpread', contractspread_value)` creates a CDS object by specifying `InstrumentType` and sets the properties on page 11-2159 for the required name-value pair arguments `Maturity` and `ContractSpread`.

`CDSobj = fininstrument( ___, Name, Value)` sets optional properties on page 11-2159 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `CDSobj = fininstrument("CDS", 'Maturity', datetime(2019,1,30), 'ContractSpread', 200, 'Period', 4, 'Basis', 5, 'BusinessDayConvention', 'follow', 'Name', "cds_instrument")` creates a CDS instrument with contract spread of 200. You can specify multiple name-value pair arguments.

#### Input Arguments

##### InstrumentType — Instrument type

character vector with value 'CDS' | string with value "CDS"

Instrument type, specified as a string with the value "CDS" or the character vector with the value 'CDS'.

Data Types: char | string

### CDS Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `CDSobj = fininstrument("CDS", 'Maturity', datetime(2019,1,30), 'ContractSpread', 200, 'Period', 4, 'Basis', 5, 'BusinessDayConvention', "follow", 'Name', "cds_instrument")`

### Required CDS Name-Value Pair Arguments

#### Maturity — Maturity date

datetime | serial date number | character vector | date string

Maturity date, specified as the comma-separated pair consisting of 'Maturity' and a datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Data Types: char | double | string | datetime

#### ContractSpread — Contract spreads expressed in basis points

numeric

Contract spreads expressed in basis points, specified as the comma-separated pair consisting of 'ContractSpread' and a scalar numeric.

Data Types: double

### Optional CDS Name-Value Pair Argument

#### Period — Premium payments per year

1 (default) | numeric with values 1, 2, 3, 4, 6, 12

Premium payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar numeric with values of 1, 2, 3, 4, 6, or 12.

Data Types: double

#### Basis — Day-count basis

0 (actual/actual) (default) | scalar of positive integers of the set [1 . . . 13]

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar positive integer using one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)

- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **BusinessDayConvention — Business day convention for cash flow dates**

`"actual"` (default) | `string` | `character vector`

Business day conventions for cash flow dates, specified as the comma-separated pair consisting of `'BusDayConvention'` and a string or character vector. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `string`

### **PayAccruedPremium — Flag for accrued premiums**

`true` (default) | `value or true or false`

Flag for accrued premiums, specified as the comma-separated pair consisting of `'PayAccruedPremium'` and a scalar Boolean flag that is `true` if accrued premiums are paid upon default, `false` otherwise.

Data Types: `logical`

### **RecoveryRate — Recovery rate**

`0.4` (default) | `decimal`

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a scalar decimal from 0 to 1.

Data Types: `double`

**Notional — Contract notional value**

100 (default) | positive integer

Contract notional value, specified as the comma-separated pair consisting of 'Notional' and a scalar positive integer.

Data Types: double

**Holidays — Holidays used in computing business days**

NaN (default) | datetime | cell array of character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
CDSobj = fininstrument("CDS",'Maturity',datetime(2025,12,15),'ContractSpread',200,'Holidays',H)
```

Data Types: double | cell | datetime | string

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

**Properties****Maturity — Maturity date**

datetime

Maturity date, returned as a datetime.

Data Types: datetime

**ContractSpread — Contract spreads expressed in basis points**

numeric

Contract spreads expressed in basis points, returned as a scalar numeric.

Data Types: double

**Period — Premium payments per year**

1 (default) | numeric with values 1, 2, 3, 4, 6 or 12

Premium payments per year, returned as a scalar numeric.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | positive integers of the set [1...13]

Day-count basis, returned as a scalar positive integer.

Data Types: double

**BusinessDayConvention — Business day convention for cash flow dates**`"actual" (default) | string`

Business day conventions for cash flow dates, returned as a string.

Data Types: `string`

**PayAccruedPremium — Flag for accrued premiums**`true (default) | value true or false`

Flag for accrued premiums, returned as a scalar Boolean flag.

Data Types: `logical`

**RecoveryRate — Recovery rate**`0.4 (default) | decimal`

Recovery rate, returned as a scalar decimal.

Data Types: `double`

**Notional — Contract notional value**`100 (default) | positive integer`

Contract notional value, returned as a scalar positive integer.

Data Types: `double`

**Holidays — Holidays used in computing business days**`NaT (default) | datetime`

Holidays used in computing business days, returned as datetimes.

Data Types: `datetime`

**Name — User-defined name for instrument**`" " (default) | string`

User-defined name for the instrument, returned as a string.

Data Types: `string`

## Examples

**Price CDS Instrument Using Default Probability Curve and Credit Pricer**

This example shows the workflow to price a CDS instrument when you use a `defprobcurve` model and a `Credit` pricing method.

**Create CDS Instrument Object**

Use `fininstrument` to create a CDS instrument object.

```
CDS = fininstrument("CDS", 'Maturity', datetime(2021,9,15), 'ContractSpread', 15, 'Notional', 20000, 'P
```

```
CDS =  
    CDS with properties:
```

```

ContractSpread: 15
Maturity: 15-Sep-2021
Period: 4
Basis: 3
RecoveryRate: 0.4000
BusinessDayConvention: "follow"
Holidays: NaT
PayAccruedPremium: 1
Notional: 20000
Name: "CDS_instrument"

```

### Create defprobcurve Object

Create a defprobcurve object using defprobcurve.

```

Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',5)

```

```

DefaultProbCurve =
  defprobcurve with properties:

      Settle: 20-Sep-2020
      Basis: 5
      Dates: [10x1 datetime]
  DefaultProbabilities: [10x1 double]

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

```

```

myRC =
  ratecurve with properties:

      Type: "zero"
  Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2020
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"

```

### Create Credit Pricer Object

Use `finpricer` to create a `Credit` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("credit", 'DefaultProbabilityCurve', DefaultProbCurve, 'DiscountCurve', myRC)
outPricer =
    Credit with properties:
        DiscountCurve: [1x1 ratecurve]
        TimeStep: 10
        DefaultProbabilityCurve: [1x1 defprobcurve]
```

### Price CDS Instrument

Use `price` to compute the price for the CDS instrument.

```
Price = price(outPricer, CDS)
```

```
Price = 52.7426
```

# CDSOption

CDSOption instrument object

## Description

Create and price a CDSOption instrument object using this workflow:

- 1 Use `fininstrument` to create a CDSOption instrument object.
- 2 Use `finmodel` to specify a CDSBlack model for the CDSOption instrument.
- 3 Use `finpricer` to specify a CDSBlack pricing method for the CDSOption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods using a CDSOption instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
CDSOptionObj = fininstrument(InstrumentType, 'ExerciseDate', exercise_date, 'Strike', strike_value, 'CDS', cds_obj)
CDSOptionObj = fininstrument( ___, Name, Value)
```

### Description

`CDSOptionObj = fininstrument(InstrumentType, 'ExerciseDate', exercise_date, 'Strike', strike_value, 'CDS', cds_obj)` creates a CDSOption object by specifying `InstrumentType` and sets the properties on page 11-2165 for the required name-value pair arguments `ExerciseDate`, `Strike`, and `CDS`.

`CDSOptionObj = fininstrument( ___, Name, Value)` sets optional properties on page 11-2165 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `CDSOptionObj = fininstrument("CDSoption", 'ExerciseDate', datetime(2019,1,30), 'Strike', 500, 'CDS', cds_object, 'Name', "cdsoption_instrument")` creates a CDSOption instrument with a strike of 500. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "CDSoption" | character vector with value 'CDSoption'

Instrument type, specified as a string with the value of "CDSoption" or a character vector with the value of 'CDSoption'.

Data Types: char | string

**CDSOption Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

```
Example: CDSOptionObj =  
fininstrument("CDSoption", 'ExerciseDate', datetime(2019,1,30), 'Strike', 500, 'CDS', cds_object, 'Name', "cdsoption_instrument")
```

**Required CDSOption Name-Value Pair Arguments****ExerciseDate — Option exercise date**

`datetime` | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar `datetime`, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a `datetime`.

Data Types: `double` | `char` | `string` | `datetime`

**Strike — Option strike price**

nonnegative numeric

Option strike price, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative numeric.

Data Types: `double`

**CDS — CDS object**

CDS object

CDS object, specified as the comma-separated pair consisting of 'CDS' and a scalar CDS object.

Data Types: `object`

**Optional CDSOption Name-Value Pair Argument****OptionType — Option type**

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: `char` | `string`

**Knockout — Flag indicating if option is knockout type**

false (default) | logical with value true or false

Flag indicating if option is knockout type, specified as the comma-separated pair consisting of 'Knockout' and a scalar logical.

Data Types: `logical`

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: `char` | `string`

## Properties

### **ExerciseDate — Option exercise date**

`datetime`

Option exercise date, returned as a `datetime`.

Data Types: `datetime`

### **Strike — Option strike price**

`nonnegative numeric`

Option strike price, returned as a scalar `nonnegative numeric` value.

Data Types: `double`

### **CDS — CDS object**

`CDS object`

CDS object, returned as a scalar `CDS object`.

Data Types: `object`

### **OptionType — Definition of option**

`"call"` (default) | `string` with value `"call"` or `"put"`

Definition of option, returned as a `string` using `"call"` or `"put"`.

Data Types: `string`

### **Knockout — Flag indicating if option is knockout type**

`false` (default) | `logical` with value `true` or `false`

Flag indicating if option is knockout type, returned as a scalar `logical`.

Data Types: `logical`

### **Name — User-defined name for instrument**

`" "` (default) | `string`

User-defined name for the instrument, returned as a `string`.

Data Types: `string`

## Examples

### **Price CDSOption Instrument Using CDS Black Model and CDS Black Pricer**

This example shows the workflow to price a `CDSOption` instrument when you use a `CDSBlack` model and a `CDSBlack` pricing method.

### Create CDS Instrument Object

Use `fininstrument` to create the underlying CDS instrument object.

```
CDS0pt = fininstrument("CDS", 'Maturity', datetime(2021,9,15), 'ContractSpread', 150, 'Notional', 100,
CDS0pt =
    CDS with properties:
        ContractSpread: 150
        Maturity: 15-Sep-2021
        Period: 4
        Basis: 2
        RecoveryRate: 0.4000
        BusinessDayConvention: "actual"
        Holidays: NaT
        PayAccruedPremium: 1
        Notional: 100
        Name: "CDS_option"
```

### Create defprobcurve Object

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities, 'Basis', 5)

DefaultProbCurve =
    defprobcurve with properties:
        Settle: 20-Sep-2020
        Basis: 5
        Dates: [10x1 datetime]
        DefaultProbabilities: [10x1 double]
```

### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)

myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
```

```

        Settle: 15-Sep-2020
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create CDSOption Instrument Object

Use `fininstrument` to create a CDSOption instrument object.

```
CDSOptionInst = fininstrument("CDSOption", 'ExerciseDate', datetime(2021,8,15), 'Strike', 20, 'CDS', CDS)
```

```

CDSOptionInst =
  CDSOption with properties:

    OptionType: "put"
    Strike: 20
    Knockout: 1
    ExerciseDate: 15-Aug-2021
    CDS: [1x1 fininstrument.CDS]
    Name: "CDSOption_option"

```

### Create CDSBlack Model Object

Use `finmodel` to create a CDSBlack model object.

```
CDSBlackModel = finmodel("CDSBlack", 'SpreadVolatility', .2)
```

```

CDSBlackModel =
  CDSBlack with properties:

    SpreadVolatility: 0.2000

```

### Create CDSBlack Pricer Object

Use `finpricer` to create a CDSBlack pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', CDSBlackModel, 'DefaultProbabilityCurve', DefaultProbCurve)
```

```

outPricer =
  CDSBlack with properties:

    Model: [1x1 finmodel.CDSBlack]
    DiscountCurve: [1x1 ratecurve]
    DefaultProbabilityCurve: [1x1 defprobcurve]

```

### Price CDSOption Instrument

Use `price` to compute the price for the CDSOption instrument.

```
Price = price(outPricer, CDSOptionInst)
```

Price = 3.3016e-04

## **More About**

### **Credit Default Swap Option**

A credit default swap (CDS) option, or credit default swaption, is a contract that provides the option holder with the right, but not the obligation, to enter into a credit default swap in the future.

CDS options can be either payer swaptions or receiver swaptions. In a payer swaption, the option holder has the right to enter into a CDS in which they are paying premiums, and in a receiver swaption, the option holder is receiving premiums.

# FixedBond

FixedBond instrument object

## Description

Create and price a FixedBond instrument object using this workflow:

- 1 Use `fininstrument` to create a FixedBond instrument object.
- 2 Use `ratecurve` to specify a curve model for the FixedBond instrument.
- 3 Use `finpricer` to specify a Discount pricing method for the FixedBond instrument.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a FixedBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
FixedBondObj = fininstrument(InstrumentType, 'CouponRate', couponrate_value, '
Maturity', maturity_date)
FixedBondObj = fininstrument( ____, Name, Value)
```

### Description

`FixedBondObj = fininstrument(InstrumentType, 'CouponRate', couponrate_value, 'Maturity', maturity_date)` creates a FixedBond object by specifying `InstrumentType` and sets the properties on page 11-2173 for the required name-value pair arguments `CouponRate` and `Maturity`.

The FixedBond instrument supports a vanilla bond, a stepped coupon bond, and an amortizing bond. For more information, see “More About” on page 11-2180.

`FixedBondObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2173 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FixedBondObj = fininstrument("FixedBond", 'CouponRate', 0.34, 'Maturity', datetime(2019,1,30), 'Period', 2, 'Basis', 1, 'Principal', 100, 'FirstCouponDate', datetime(2016,1,30), 'EndMonthRule', true, 'Name', "fixedbond_instrument")` creates a FixedBond option with a coupon rate of 0.34 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Fixedbond" | character vector with value 'FixedBond'

Instrument type, specified as a string with the value of "FixedBond" or a character vector with a value of 'FixedBond'.

Data Types: char | string

### FixedBond Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: FixedBondObj =

```
fininstrument("FixedBond", 'CouponRate', 0.34, 'Maturity', datetime(2019,1,30), 'Period', 2, 'Basis', 1, 'Principal', 100, 'FirstCouponDate', datetime(2016,1,30), 'EndMonthRule', true, 'Name', "fixedbond_instrument")
```

### Required FixedBond Name-Value Pair Arguments

#### CouponRate — FixedBond coupon rate

decimal | timetable

FixedBond coupon rate, specified as the comma-separated pair consisting of 'CouponRate' and a scalar decimal for an annual rate or a timetable where the first column is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | timetable

#### Maturity — FixedBond maturity date

datetime | serial date number | date character vector | date string

FixedBond maturity date, specified as the comma-separated pair consisting of 'Maturity' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

Data Types: char | double | string | datetime

### Optional FixedBond Name-Value Pair Arguments

#### Period — Frequency of payments per year

1 (default) | numeric value of 0, 1, 2, 3, 4, 6, or 12

Frequency of payments, specified as the comma-separated pair consisting of 'Period' and a scalar integer. Values for Period are: 1, 2, 3, 4, 6, or 12.

Data Types: double

#### Basis — Day count basis

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of 'Basis' and scalar integer using one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360

- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Principal — Principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or timetable.

Principal accepts a timetable, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: double | timetable

### **DaycountAdjustedCashFlow — Flag indicating whether cash flow adjusts for day count convention**

false (default) | value of true or false

Flag indicating whether cash flow is adjusted by day count convention, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar logical with a value of true or false.

Data Types: logical

### **BusinessDayConvention — Business day conventions for cash flow dates**

"actual" (default) | string | character vector

Business day conventions for cash flow dates, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.

- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | string

### Holidays — Holidays used in computing business days

NaT (default) | datetime | cell array of character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
FixedBondObj = fininstrument("FixedBond",'CouponRate',0.34,'Maturity',datetime(2025,12,15),'Holidays',H);
```

Data Types: double | cell | datetime | string

### EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days

true (in effect) (default) | value of true or false

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar logical value of true or false.

- If you set EndMonthRule to false, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set EndMonthRule to true, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

### IssueDate — Bond issue date

NaT (default) | datetime | serial date number | date character vector | date string

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the IssueDate property is stored as a datetime.

Data Types: double | char | string | datetime

### FirstCouponDate — Irregular first coupon date

NaT (default) | datetime | serial date number | date character vector | date string

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar datetime, serial date number, date character vector, or date string.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify FirstCouponDate, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

Data Types: `double` | `char` | `string` | `datetime`

### **LastCouponDate — Irregular last coupon date**

`NaN` (default) | `datetime` | serial date number | date character vector | date string

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar datetime, serial date number, date character vector, or date string.

If you specify `LastCouponDate` but not `FirstCouponDate`, `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify `LastCouponDate`, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `LastCouponDate` property is stored as a datetime.

Data Types: `double` | `char` | `string` | `datetime`

### **StartDate — Forward starting date of payments**

`NaN` (default) | `datetime` | serial date number | date character vector | date string

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

Data Types: `char` | `double` | `string` | `datetime`

### **Name — User-defined name for instrument**

`" "` (default) | `string` | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector.

Data Types: `char` | `string`

## **Properties**

### **CouponRate — FixedBond coupon annual rate**

scalar decimal | timetable

`FixedBond` coupon annual rate, returned as a scalar decimal or timetable.

Data Types: `double` | `timetable`

### **Maturity — FixedBond maturity date**

`datetime`

`FixedBond` maturity date, returned as a datetime.

Data Types: `datetime`

**Period — Frequency of payments per year**

1 (default) | integer

Frequency of payments per year, returned as a scalar integer.

Data Types: double

**Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as a scalar integer.

Data Types: double

**Principal — Principal amount or principal value schedules**

100 (default) | scalar numeric | timetable

Principal amount or principal value schedules, returned as a scalar numeric or timetable.

Data Types: double

**DaycountAdjustedCashFlow — Flag indicating whether cash flow adjusts for day count convention**

false (default) | value of true or false

Flag indicating whether cash flow adjusts for day count convention, returned as scalar logical with a value of true or false.

Data Types: logical

**BusinessDayConvention — Business day conventions**

"actual" (default) | string

Business day conventions, returned as a string

Data Types: string

**Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

**EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

true (in effect) (default) | value of true or false

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month having 30 or fewer days, returned as a scalar logical.

Data Types: logical

**IssueDate — Bond issue date**

NaT (default) | datetime

Bond issue date, returned as a datetime.

Data Types: datetime

**FirstCouponDate — Irregular first coupon date**

NaT (default) | datetime

Irregular first coupon date, returned as a datetime.

Data Types: datetime

**LastCouponDate — Irregular last coupon date**

NaT (default) | datetime

Irregular last coupon date, returned as a datetime.

Data Types: datetime

**StartDate — Forward starting date of payments**

NaT (default) | datetime

Forward starting date of payments, returned as a datetime.

Data Types: datetime

**Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

**Object Functions**

cashflows Computes cash flow for FixedBond, FloatBond, Swap, FRA, Swap, or Deposit instrument

**Examples****Price Vanilla FixedBond Instrument Using ratecurve and Discount Pricer**

This example shows the workflow to price a vanilla FixedBond instrument when you use a ratecurve and a Discount pricing method.

**Create FixedBond Instrument Object**

Use `fininstrument` to create a FixedBond instrument object.

```
FixB = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.021, 'Period', 2, 'B
```

```
FixB =
```

```
FixedBond with properties:
```

```

        CouponRate: 0.0210
        Period: 2
        Basis: 1
    EndMonthRule: 1
        Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT

```

```

FirstCouponDate: NaT
LastCouponDate: NaT
StartDate: NaT
Maturity: 15-Sep-2022
Name: "fixed_bond_instrument"

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
    ratecurve with properties:

        Type: "zero"
    Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Discount Pricer Object

Use finpricer to create a Discount pricer object and use the ratecurve object with the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```

outPricer =
    Discount with properties:

        DiscountCurve: [1x1 ratecurve]

```

### Price FixedBond Instrument

Use price to compute the price and sensitivities for the FixedBond instrument.

```
[Price, outPR] = price(outPricer, FixB, ["all"])
```

```
Price = 104.5679
```

```

outPR =
    pricerresult with properties:

        Results: [1x2 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
104.57	0.040397

## Price Stepped FixedBond Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a stepped FixedBond instrument when you use a ratecurve and a Discount pricing method.

### Create FixedBond Instrument Object

Use `fininstrument` to create a stepped FixedBond instrument object.

```
Maturity = datetime(2024,1,1);
Period = 1;
CDates = datetime([2020,1,1 ; 2024,1,1]);
CRates = [.025; .03];
CouponRate = timetable(CDates,CRates);
```

```
SBond = fininstrument("FixedBond", 'Maturity',Maturity, 'CouponRate',CouponRate, 'Period',Period)
```

```
SBond =
```

```
FixedBond with properties:
```

```

    CouponRate: [2x1 timetable]
    Period: 1
    Basis: 0
    EndMonthRule: 1
    Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2024
    Name: ""
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
```

```
ratecurve with properties:
```

```

        Type: "zero"
    Compounding: 1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
    Settle: 01-Jan-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Discount Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', ZeroCurve)
```

```
outPricer =
    Discount with properties:
        DiscountCurve: [1x1 ratecurve]
```

### Price FixedBond Instrument

Use `price` to compute the price and sensitivities for the vanilla `FixedBond` instrument.

```
[Price, outPR] = price(outPricer, SBond, ["all"])
```

```
Price = 109.6218
```

```
outPR =
    pricerresult with properties:
        Results: [1x2 table]
        PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
    Price      DV01
    _____  _____
    109.62     0.061108
```

### Price Amortizing FixedBond Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a amortizing `FixedBond` instrument when you use a `ratecurve` and a `Discount` pricing method.

#### Create FixedBond Instrument Object

Use `fininstrument` to create a amortizing `FixedBond` instrument object.

```

Maturity = datetime(2024,1,1);
Period = 1;
ADates = datetime([2020,1,1 ; 2024,1,1]);
APrincipal = [100; 85];
Principal = timetable(ADates,APrincipal);
Bondamort = fininstrument("FixedBond", 'Maturity',Maturity, 'CouponRate',0.025, 'Period',Period, 'Pr

Bondamort =
    FixedBond with properties:
        CouponRate: 0.0250
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: [2x1 timetable]
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2024
    Name: ""

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);

```

### Create Discount Pricer Object

Use finpricer to create a Discount pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',ZeroCurve)
```

```

outPricer =
    Discount with properties:
        DiscountCurve: [1x1 ratecurve]

```

### Price FixedBond Instrument

Use price to compute the price and sensitivities for the vanilla FixedBond instrument.

```
[Price, outPR] = price(outPricer,Bondamort,["all"])
```

```
Price = 107.1273
```

```

outPR =
    pricerresult with properties:

```

```
Results: [1x2 table]
PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
107.13	0.054279

## More About

### Fixed-Rate Note

A fixed-rate note is a long-term debt security with a preset interest rate and maturity, by which the interest must be paid.

The principal might or might not be paid at maturity. In Financial Instruments Toolbox, the principal is always paid at maturity. For more information, see “Fixed-Rate Note” on page 2-8.

### Vanilla Bond

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment.

### Stepped Coupon Bond

A step-up bond and a step-down bond are debt securities with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond.

### Bond with an Amortization Schedule

An amortized bond is treated as an asset, with the discount amount being amortized to interest expense over the life of the bond.

### Topics

“Price Portfolio of Bond and Bond Option Instruments”

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-42

**Introduced in R2020a**

# FixedBondOption

FixedBondOption instrument object

## Description

Create and price a FixedBondOption instrument object using this workflow:

- 1 Use `fininstrument` to create a FixedBondOption instrument object.
- 2 Use `finmodel` to specify a HullWhite or BlackKarasinski model for the FixedBondOption instrument.
- 3 Use `finpricer` to specify an IRTree pricing method for the FixedBondOption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a FixedBondOption instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
FixedBondOptionObj = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercise_date,'Bond',bond_obj)
FixedBondOptionObj = fininstrument(___,Name,Value)
```

### Description

`FixedBondOptionObj = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercise_date,'Bond',bond_obj)` creates a FixedBondOption object by specifying `InstrumentType` and sets the properties on page 11-2184 for the required name-value pair arguments `Strike`, `ExerciseDate`, and `Bond`.

The FixedBondOption instrument supports a European or American option. For more information, see “More About” on page 11-2190.

`FixedBondOptionObj = fininstrument(___,Name,Value)` sets optional properties on page 11-2184 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FixedBondOptionObj = fininstrument("FixedBondOption",'Strike',100,'ExerciseDate',datetime(2019,1,30),'Bond',bond_obj,'OptionType','put','ExerciseStyle',"American",'Name',"fixed_bond_option")` creates a FixedBondOption instrument with a strike of 100 and an American exercise. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "FixedBondOption" | character vector with value 'FixedBondOption'

Instrument type, specified as a string with the value of "FixedBondOption" or a character vector with the value of 'FixedBondOption'.

Data Types: char | string

### FixedBondOption Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: FixedBondOptionObj =  
`fininstrument("FixedBondOption", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'Bond', bond_obj, 'OptionType', 'put', 'ExerciseStyle', "American", 'Name', "fixed_bond_option")`

### Required FixedBondOption Name-Value Pair Arguments

#### Strike — Option strike price value

nonnegative numeric

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative numeric.

Data Types: double

#### ExerciseDate — Option exercise date

datetime | serial date number | date character vector | date string | datetime

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

- For a European option, there is only one ExerciseDate on the option expiry date.
- For an American option, the option can be exercised between Settle of the ratecurve and the single listed ExerciseDate.

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

#### Bond — Underlying FixedBond instrument

FixedBond object

Underlying FixedBond instrument, specified as the comma-separated pair consisting of 'BondInstrument' and a FixedBond object.

Data Types: object

### Optional FixedBondOption Name-Value Pair Arguments

#### OptionType — Option type

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European" or "American" | character vector with value 'European' or 'American'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

Data Types: string | char

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

**Properties****Strike — Option strike price value**

nonnegative numeric

Option strike price value, returned as a scalar nonnegative numeric.

Data Types: double

**ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

**OptionType — Option type**

"call" (default) | string with value "call" or "put"

Option type, returned as a string with a value of "call" or "put".

Data Types: string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European", "American"

Option exercise style, returned as a string with a value of "European" or "American".

Data Types: string

**Bond — Underlying FixedBond instrument**

FixedBond object

Underlying FixedBond instrument, returned as a FixedBond object.

Data Types: object

**Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

### Price a FixedBondOption Instrument Using Hull-White Model and Hull-White Tree Pricer

This example shows the workflow to price a FixedBondOption instrument when you use a HullWhite model and an IRTree pricing method.

#### Create FixedBond Instrument Object

Use `fininstrument` to create a FixedBond instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond", 'Maturity', datetime(2029,9,15), 'CouponRate', .021, 'Period', 1)
```

```
BondInst =
  FixedBond with properties:
      CouponRate: 0.0210
      Period: 1
      Basis: 0
      EndMonthRule: 1
      Principal: 100
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      IssueDate: NaT
      FirstCouponDate: NaT
      LastCouponDate: NaT
      StartDate: NaT
      Maturity: 15-Sep-2029
      Name: "bond_instrument"
```

#### Create FixedBondOption Instrument Objects

Use `fininstrument` to create two callable FixedBondOption instrument objects with European and American exercise.

```
FixedBOptionEuro = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 98)
```

```
FixedBOptionEuro =
  FixedBondOption with properties:
      OptionType: "call"
      ExerciseStyle: "european"
      ExerciseDate: 15-Sep-2025
      Strike: 98
      Bond: [1x1 fininstrument.FixedBond]
      Name: "fixed_bond_option_european"
```

```
FixedBOptionAmerican = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 98)
```

```
FixedBOptionAmerican =
  FixedBondOption with properties:
```

```

    OptionType: "call"
    ExerciseStyle: "american"
    ExerciseDate: 15-Sep-2025
    Strike: 98
    Bond: [1x1 fininstrument.FixedBond]
    Name: "fixed_bond_option_american"

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]' ;
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2019
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create a HullWhite Model Object

Use finmodel to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite",'Alpha',0.01,'Sigma',0.05)
```

```

HullWhiteModel =
    HullWhite with properties:

```

```

    Alpha: 0.0100
    Sigma: 0.0500

```

### Create IRTree Pricer Object

Use finpricer to create an IRTree pricer object and use the ratecurve object with the 'DiscountCurve' name-value pair argument.

```
HWTrePricer = finpricer("IRTree",'Model',HullWhiteModel,'DiscountCurve',myRC,'TreeDates',ZeroDates)
```

```

HWTrePricer =
    HWBKTree with properties:
        Tree: [1x1 struct]
        TreeDates: [10x1 datetime]

```

```

      Model: [1x1 finmodel.HullWhite]
DiscountCurve: [1x1 ratecurve]

```

### HWTrePricer.Tree

```

ans = struct with fields:
  FinObj: 'HWFwdTree'
  tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
  dObs: [1x10 datetime]
  CFlowT: {1x10 cell}
  Probs: {1x9 cell}
  Connect: {1x9 cell}
  FwdTree: {1x10 cell}

```

### Price FixedBondOption Instruments

Use price to compute the price and sensitivities for the two FixedBondOption instruments.

```
[Price, outPR] = price(HWTrePricer,FixedBOptionEuro,["all"])
```

```
Price = 10.7151
```

```
outPR =
  pricerresult with properties:
```

```

      Results: [1x4 table]
  PricerData: [1x1 struct]

```

#### outPR.Results

```
ans=1x4 table
  Price      Vega      Gamma      Delta
  _____  _____  _____  _____
  10.715     307.76    2202.8    -178.34
```

```
[Price, outPR] = price(HWTrePricer,FixedBOptionAmerican,["all"])
```

```
Price = 19.2387
```

```
outPR =
  pricerresult with properties:
```

```

      Results: [1x4 table]
  PricerData: [1x1 struct]

```

#### outPR.Results

```
ans=1x4 table
  Price      Vega      Gamma      Delta
  _____  _____  _____  _____
  19.239     436.39    4971.4    -458.47
```

## Price a FixedBondOption Instrument on a Stepped FixedBond Using Hull-White Model and Hull-White Tree Pricer

This example shows the workflow to price a FixedBondOption instrument on a stepped FixedBond instrument when you use a HullWhite model and an IRTree pricing method.

### Create Stepped FixedBond Instrument Object

Use `fininstrument` to create a stepped FixedBond instrument object as the underlying bond.

```
Maturity = datetime(2027,1,1);
Period = 1;
CDates = datetime([2022,1,1 ; 2027,1,1]);
CRates = [.022; .027];
CouponRate = timetable(CDates,CRates);
```

```
SBond = fininstrument("FixedBond", 'Maturity',Maturity, 'CouponRate',CouponRate, 'Period',Period, 'Name', 'stepped_bond_instrument');
```

```
SBond =
```

```
FixedBond with properties:
```

```

    CouponRate: [2x1 timetable]
    Period: 1
    Basis: 0
    EndMonthRule: 1
    Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2027
    Name: "stepped_bond_instrument"
```

### Create FixedBondOption Instrument Object

Use `fininstrument` to create a FixedBondOption instrument object with European exercise.

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate',datetime(2026,1,1), 'Strike',90, 'Bond',SBond, 'Name', 'fixed_bond_option_european');
```

```
FixedBOption =
```

```
FixedBondOption with properties:
```

```

    OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 01-Jan-2026
    Strike: 90
    Bond: [1x1 fininstrument.FixedBond]
    Name: "fixed_bond_option_european"
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
```

```
ZeroRates = [0.0055 0.0063 0.0071 0.0083 0.0099 0.0131 0.0178 0.0262 0.0343 0.0387]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
VolCurve = 0.15;
AlphaCurve = 0.03;

HWModel = finmodel("HullWhite",'Alpha',AlphaCurve,'Sigma',VolCurve)
```

```
HWModel =
  HullWhite with properties:

      Alpha: 0.0300
      Sigma: 0.1500
```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
HWTreepricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates)
```

```
HWTreepricer =
  HWBKTree with properties:

      Tree: [1x1 struct]
      TreeDates: [10x1 datetime]
      Model: [1x1 finmodel.HullWhite]
      DiscountCurve: [1x1 ratecurve]
```

`HWTreepricer.Tree`

```
ans = struct with fields:
  FinObj: 'HWFwdTree'
  tObs: [0 1 2 3.0027 4.0027 5.0027 6.0027 7.0055 8.0055 9.0055]
  dObs: [1x10 datetime]
  CFlowT: {1x10 cell}
  Probs: {1x9 cell}
  Connect: {1x9 cell}
  FwdTree: {1x10 cell}
```

### Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the FixedBondOption instrument.

```
[Price, outPR] = price(HWTreepricer,FixedBOption,"all")
```

```
Price = 12.2800
```

```
outPR =
  pricerresult with properties:
```

```
Results: [1x4 table]
PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
```

Price	Vega	Gamma	Delta
12.28	100.79	1439.8	-130.21

## More About

### Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

The `FixedBondOption` instrument supports two types of put and call options on bonds:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.

For more information, see “Bond Options” on page 2-5.

### Tips

After creating an `FixBondOption` instrument object with an "American" `ExerciseStyle`, you can modify the `ExerciseStyle` property to change it to "European" using dot notation.

```
FixedBondOption.ExerciseStyle = "European"
```

Because a European option has a scalar `Strike` and `ExerciseDate` value and an American option has a 2-element vector for `Strike` and `ExerciseDate` values, when you change to `ExerciseStyle` from "American" to "European", the `Strike` and `ExerciseDate` values become the last element in the 2-element vector for `Strike` and `ExerciseDate` values.

### Introduced in R2020a

# FloatBond

FloatBond instrument object

## Description

Create and price a FloatBond instrument object using this workflow:

- 1 Use `fininstrument` to create a FloatBond instrument object.
- 2 Use `ratecurve` to specify a curve model for the FloatBond instrument.
- 3 Use `finpricer` to specify a Discount pricing method for the FloatBond instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a FloatBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
FloatBondObj = fininstrument(InstrumentType, 'Spread', spread_value, '
Maturity', maturity_date)
FloatBondObj = fininstrument( ____, Name, Value)
```

### Description

`FloatBondObj = fininstrument(InstrumentType, 'Spread', spread_value, 'Maturity', maturity_date)` creates a FloatBond object by specifying `InstrumentType` and sets the properties on page 11-2196 for the required name-value pair arguments `Spread` and `Maturity`.

The FloatBond instrument supports a vanilla floating rate note and an amortizing floating rate note. For more information, see “Floating-Rate Note” on page 11-2201.

`FloatBondObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2196 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FloatBondObj = fininstrument("FloatBond", 'Spread', 0.6, 'Maturity', datetime(2019,1,30), 'Basis', 1, 'Principal', 100, 'FirstCouponDate', datetime(2016,1,30), 'EndMonthRule', true, 'Name', "float_bond_instrument")` creates a FloatBond instrument with a spread of 0.6 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "FloatBond" | character vector with value 'FloatBond'

Instrument type, specified as a string with the value of "FloatBond" or a character vector with the value of 'FloatBond'.

Data Types: char | string

### FloatBond Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: FloatBondObj =  
fininstrument("FloatBond", 'Spread', 0.6, 'Maturity', datetime(2019, 1, 30), 'Basis', 1, 'Principal', 100, 'FirstCouponDate', datetime(2016, 1, 30), 'EndMonthRule', true, 'Name', "float\_bond\_instrument")

### Required FloatBond Name-Value Pair Arguments

#### Spread — Decimal value over the reference rate

nonnegative decimal

Decimal value over the reference rate, specified as the comma-separated pair consisting of 'Spread' and a scalar nonnegative decimal.

Data Types: double

#### Maturity — Maturity date

datetime | serial date number | data character vector | date string

Maturity date, specified as the comma-separated pair consisting of 'Maturity' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

Data Types: char | double | string | datetime

### Optional FloatBond Name-Value Pair Arguments

#### Reset — Frequency of payments per year

1 (default) | integer

Frequency of payments per year, specified as the comma-separated pair consisting of 'Reset' and a scalar integer. Values for Reset are: 1, 2, 3, 4, 6, or 12.

Data Types: double

#### Basis — Day count basis

[0 0] (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer using one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360

- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Principal — Principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or timetable.

Principal accepts a timetable, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: double | timetable

### **ProjectionCurve — Rate curve for projecting floating cash flows**

ratecurve.empty (default) | ratecurve object

Rate curve for projecting floating cash flows, specified as the comma-separated pair consisting of 'ProjectionCurve' and a ratecurve object. You must create this object using ratecurve.

Data Types: object

### **ResetOffset — Lag in rate setting**

0 (default) | numeric

Lag in rate setting, specified as the comma-separated pair consisting of 'ResetOffset' and a scalar numeric.

Data Types: double

### **LatestFloatingRate — Latest floating rate**

[] (default) | decimal

Latest floating rate for the FloatBond object, specified as the comma-separated pair consisting of 'LatestFloatingRate' and a scalar decimal.

Data Types: double

### **DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'DaycountAdjustedCashFlow'` and a scalar logical with a value of `true` or `false`.

Data Types: `logical`

### **BusinessDayConvention — Business day conventions**

`"actual"` (default) | `string` | `character vector`

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a scalar string or character vector. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `string`

### **Holidays — Holidays used in computing business days**

`NaN` (default) | `datetime` | `cell array of date character vectors` | `date string array` | `serial date numbers`

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
FloatBondObj = fininstrument("floatbond",'Spread',100,'Maturity',datetime(2025,12,15),'Holidays')
```

Data Types: `double` | `cell` | `datetime` | `string`

### **EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

`true` (in effect) (default) | `logical true or false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar logical value of `true` or `false`.

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

**IssueDate — Bond issue date**

NaT (default) | datetime | serial date number | date character vector | date string

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `IssueDate` property is stored as a datetime.

Data Types: double | char | string | datetime

**FirstCouponDate — Irregular first coupon date**

NaT (default) | datetime | serial date number | date character vector | date string

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar datetime, serial date number, date character vector, or date string.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

Data Types: double | char | string | datetime

**LastCouponDate — Irregular last coupon date**

NaT (default) | datetime | serial date number | date character vector | date string

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar datetime, serial date number, date character vector, or date string.

If you specify `LastCouponDate` but not `FirstCouponDate`, `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify `LastCouponDate`, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `LastCouponDate` property is stored as a datetime.

Data Types: double | char | string | datetime

**StartDate — Forward starting date of payments**

NaT (default) | datetime | serial date number | character vector | date string

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar datetime, serial date number, character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

Data Types: char | double | string | datetime

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### **Spread — Number of basis points over the reference rate**

nonnegative numeric

Number of basis points over the reference rate, returned as a scalar nonnegative numeric.

Data Types: double

### **Maturity — Maturity date**

datetime

Maturity date, returned as a datetime.

Data Types: datetime

### **Reset — Frequency of payment per year**

1 (default) | integer

Coupons per year, returned as a scalar integer.

Data Types: double

### **Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as a scalar integer.

Data Types: double

### **Principal — Notional principal amount or principal value schedules**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedules, returned as a scalar numeric or timetable.

Data Types: timetable | double

### **ProjectionCurve — Rate curve used in generating future cash flows**

ratecurve.empty (default) | ratecurve object

Rate curve to be used in projecting the future cash flows, returned as a ratecurve object.

Data Types: object

### **ResetOffset — Lag in rate setting**

0 (default) | numeric

Lag in rate setting, returned as a scalar numeric.

Data Types: double

### **LatestFloatingRate — Latest floating rate for FloatBond**

[ ] (default) | decimal

Latest floating rate for FloatBond, returned as a scalar decimal.

Data Types: `double`

**DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

`false` (default) | value of `true` or `false`

Flag to adjust cash flows based on actual period day count, returned as scalar logical with a value of `true` or `false`.

Data Types: `logical`

**BusinessDayConvention — Business day conventions**

`"actual"` (default) | string

Business day conventions, returned as a string

Data Types: `string`

**Holidays — Holidays used in computing business days**

`NaT` (default) | `datetime`

Holidays used in computing business days, returned as datetimes.

Data Types: `datetime`

**EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

`true` (in effect) (default) | logical with value of `true` or `false`

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month with 30 or fewer days, returned as a scalar logical.

Data Types: `logical`

**IssueDate — Bond issue date**

`NaT` (default) | `datetime`

Bond issue date, returned as a datetime.

Data Types: `datetime`

**FirstCouponDate — Irregular first coupon date**

`NaT` (default) | `datetime`

Irregular first coupon date, returned as a datetime.

Data Types: `datetime`

**LastCouponDate — Irregular last coupon date**

`NaT` (default) | `datetime`

Irregular last coupon date, returned as a datetime.

Data Types: `datetime`

**StartDate — Forward starting date of payments**

`NaT` (default) | `datetime`

Forward starting date of payments, returned as a datetime.

Data Types: datetime

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Object Functions

cashflows Computes cash flow for FixedBond, FloatBond, Swap, FRA, Swap, or Deposit instrument

## Examples

### Price Vanilla FloatBond Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a vanilla FloatBond instrument when you use a ratecurve and a Discount pricing method.

#### Create FloatBond Instrument Object

Use `fininstrument` to create a vanilla FloatBond instrument object.

```
FloatB = fininstrument("FloatBond", 'Maturity', datetime(2022,9,15), 'Spread', 0.025, 'Reset', 2, 'Basis', 1)
```

```
FloatB =
```

```
FloatBond with properties:
```

```

        Spread: 0.0250
    ProjectionCurve: [0x0 ratecurve]
        ResetOffset: 0
            Reset: 2
            Basis: 1
        EndMonthRule: 0
        Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    LatestFloatingRate: NaN
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: 15-Jan-2020
    LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2022
        Name: "float_bond_instrument"
```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
```

```
Type = 'zero';
```

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
  Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create Discount Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
outPricer =
  Discount with properties:
      DiscountCurve: [1x1 ratecurve]
```

### Price FloatBond Instrument

Use `price` to compute the price and sensitivities for the vanilla `FloatBond` instrument.

```
[Price, outPR] = price(outPricer, FloatB, ["all"])
```

```
Price = 107.2834
```

```
outPR =
  pricerresult with properties:
      Results: [1x2 table]
  PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
  Price      DV01
  _____  _____
  107.28     0.025955
```

## Price Amortizing FloatBond Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price an amortizing FloatBond instrument when you use a ratecurve and a Discount pricing method.

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

### Create FloatBond Instrument Object

Use fininstrument to create an amortizing FloatBond instrument object.

```
Maturity = datetime(2024,1,1);
Spread = 0.02;
Reset = 1;
ADates = datetime([2020,1,1 ; 2024,1,1]);
APrincipal = [100; 80];
Principal = timetable(ADates,APrincipal);
Floatamort = fininstrument("FloatBond", 'Maturity',Maturity, 'Spread',Spread, 'Reset',Reset, 'Project
```

Floatamort =

FloatBond with properties:

```

        Spread: 0.0200
    ProjectionCurve: [1x1 ratecurve]
        ResetOffset: 0
            Reset: 1
            Basis: 0
        EndMonthRule: 1
        Principal: [2x1 timetable]
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    LatestFloatingRate: NaN
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2024
        Name: ""
```

### Create Discount Pricer Object

Use finpricer to create a Discount pricer object and use the ratecurve object with the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',ZeroCurve)
```

outPricer =

Discount with properties:

```
DiscountCurve: [1x1 ratecurve]
```

## Price FloatBond Instrument

Use price to compute the price and sensitivities for the vanilla FloatBond instrument.

```
[Price, outPR] = price(outPricer,Floatamort,["all"])
```

```
Price = 110.1101
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x2 table]
  PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
110.11	0.028613

## More About

### Floating-Rate Note

A floating-rate note is a security like a bond, but the interest rate of the note is reset periodically, relative to a reference index rate, to reflect fluctuations in market interest rates.

### Introduced in R2020a

# Floor

Floor instrument object

## Description

Create and price a Floor instrument object using this workflow:

- 1 Use `fininstrument` to create a Floor instrument object.
- 2 Use `finmodel` to specify a HullWhite, Black, or Normal model for the Floor instrument.
- 3 Use `finpricer` to specify a Normal, Black, or HullWhite pricing method for the Floor instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Floor instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
FloorOpt = fininstrument(InstrumentType,'Strike',strike_value,'
Maturity',maturity_date)
FloorOpt = fininstrument( ___,Name,Value)
```

### Description

`FloorOpt = fininstrument(InstrumentType,'Strike',strike_value,'Maturity',maturity_date)` creates a Floor object by specifying `InstrumentType` and sets the properties on page 11-2205 for the required name-value pair arguments `Strike` and `Maturity`.

The Floor instrument supports vanilla and amortizing floors.

`FloorOpt = fininstrument( ___,Name,Value)` sets optional properties on page 11-2205 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FloorOpt = fininstrument("floor",'Strike',100,'Maturity',datetime(2019,1,30),'Reset',4,'Principal',100,'ResetOffset',1,'Basis',4,'DaycountAdjustedCashFlow',true,'BusinessDayConvention',"follow",'ProjectionCurve',ratecurve_object,'Name',"floor_option")` creates a Floor instrument with a strike of 100 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

### Input Arguments

#### **InstrumentType** — Instrument type

string with value "Floor" | character vector with value 'Floor'

Instrument type, specified as a string with the value of "Floor" or a character vector with the value of 'Floor'.

Data Types: char | string

### Floor Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `FloorOpt = fininstrument("floor", 'Strike', 100, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Principal', 100, 'ResetOffset', 1, 'Basis', 4, 'DaycountAdjustedCashFlow', true, 'BusinessDayConvention', "follow", 'ProjectionCurve', ratecurve_object, 'Name', "floor_option")`

### Required Floor Name-Value Pair Arguments

#### Strike — Option strike price value

nonnegative decimal

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative decimal value.

Data Types: double

#### Maturity — Cap maturity date

datetime | serial date number | date character vector | date string

Cap maturity date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a `datetime`.

Data Types: double | char | string | datetime

### Optional Floor Name-Value Pair Arguments

#### Reset — Reset frequency payments per year

1 (default) | numeric with value of 0, 1, 2, 3, 4, 6, or 12

Reset frequency payments per year, specified as the comma-separated pair consisting of 'Reset' and a scalar numeric.

Data Types: double

#### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer with one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360

- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **Principal — Principal amount or principal value schedule**

100 (default) | `scalar numeric` | `timetable`

Principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or timetable.

Principal accepts a `timetable`, where the first column is dates and the second column is its associated principal value. The date indicates the last day that the principal value is valid.

Data Types: `double` | `timetable`

### **ResetOffset — Lag in rate setting**

0 (default) | `numeric`

Lag in rate setting, specified as the comma-separated pair consisting of 'ResetOffset' and a scalar numeric.

Data Types: `double`

### **DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar with a value of true or false.

Data Types: `logical`

### **BusinessDayConvention — Business day conventions**

"actual" (default) | `string` | `character vector`

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector for a business day convention. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | string

### Holidays — Holidays used in computing business days

NaN (default) | datetime | cell array of date character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
FloorOpt = fininstrument("floor",'Strike',100,'Maturity',datetime(2025,12,15),'Holidays',H)
```

Data Types: double | cell | datetime | string

### ProjectionCurve — Rate curve used in generating future cash flows

ratecurve.empty (default) | ratecurve object

Rate curve used in projecting the future cash flows, specified as the comma-separated pair consisting of 'ProjectionCurve' and a ratecurve object. This object is created using ratecurve. Use this optional input if the forward curve is different from the discount curve.

Data Types: object

### Name — User-defined name for instrument

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### Strike — Option strike price value

nonnegative numeric

Option strike price value, returned as a scalar nonnegative numeric value.

Data Types: double

### Maturity — Floor maturity date

datetime

Floor maturity date, returned as a datetime.

Data Types: `datetime`

**Reset — Reset frequency payments per year**

1 (default) | numeric

Reset frequency payments per year, returned as a scalar numeric.

Data Types: `double`

**Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, returned as a scalar integer.

Data Types: `double`

**Principal — Principal amount or principal value schedule**

100 (default) | numeric | timetable

Principal amount or principal value schedule, returned as a scalar numeric for principal amount or a timetable for a principal value schedule.

Data Types: `double` | `timetable`

**ResetOffset — Lag in rate setting**

0 (default) | numeric

Lag in rate setting, returned as a scalar numeric.

Data Types: `double`

**DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on actual period day count, returned as a logical with a value of true or false.

Data Types: `logical`

**BusinessDayConvention — Business day conventions**

"actual" (default) | string

Business day conventions, returned as a string.

Data Types: `string`

**Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: `datetime`

**ProjectionCurve — Rate curve used in generating future cash flows**

`ratecurve.empty` (default) | structure

Rate curve used in projecting the future cash flows, returned as a `ratecurve` object.

Data Types: object

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

### Price Vanilla Floor Instrument Using Black Model and Black Pricer

This example shows the workflow to price a vanilla Floor instrument when you use a Black model and a Black pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve for the underlying interest-rate curve for the floor instrument.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307];
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
```

```
ratecurve with properties:
```

```

    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

#### Create Floor Instrument Object

Use fininstrument to create a Floor instrument object.

```
FloorOpt = fininstrument("Floor", 'Maturity', datetime(2022,9,15), 'Strike', 0.03, 'ProjectionCurve', ,r
```

```
FloorOpt =
```

```
Floor with properties:
```

```

    Strike: 0.0300
    Maturity: 15-Sep-2022
    ResetOffset: 0
    Reset: 1
```

```
        Basis: 0
        Principal: 100
        ProjectionCurve: [1x1 ratecurve]
DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        Name: ""
```

### Create Black Model Object

Use `finmodel` to create a Black model object.

```
BlackModel = finmodel("Black", 'Volatility', 0.2)
```

```
BlackModel =
    Black with properties:

        Volatility: 0.2000
        Shift: 0
```

### Create Black Pricer Object

Use `finpricer` to create a Black pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackModel)

outPricer =
    Black with properties:

        Model: [1x1 finmodel.Black]
        DiscountCurve: [1x1 ratecurve]
```

### Price Floor Instrument

Use `price` to compute the price for the Floor instrument.

```
[Price, outPR] = price(outPricer, FloorOpt)
```

```
Price = 8.0878
```

```
outPR =
    pricerresult with properties:

        Results: [1x1 table]
        PricerData: []
```

### Price Vanilla Floor Instrument Using Hull-White Model and Hull-White Pricer

This example shows the workflow to price a vanilla Floor instrument when you use a HullWhite model and a HullWhite pricing method.

### Create Floor Instrument Object

Use `fininstrument` to create a Floor instrument object.

```
FloorOpt = fininstrument("Floor", 'Strike', 0.039, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Princi
```

```
FloorOpt =
  Floor with properties:
      Strike: 0.0390
      Maturity: 30-Jan-2019
      ResetOffset: 0
      Reset: 4
      Basis: 12
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "floor_option"
```

### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.032, 'Sigma', 0.04)
```

```
HullWhiteModel =
  HullWhite with properties:
      Alpha: 0.0320
      Sigma: 0.0400
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
```

```
LongExtrapMethod: "previous"
```

### Create HullWhite Pricer Object

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', HullWhiteModel, 'DiscountCurve', myRC)
```

```
outPricer =  
    HullWhite with properties:  
  
    DiscountCurve: [1x1 ratecurve]  
    Model: [1x1 finmodel.HullWhite]
```

### Price Floor Instrument

Use `price` to compute the price for the `Floor` instrument.

```
Price = price(outPricer, FloorOpt)
```

```
Price = 1.2676
```

### Price Amortizing Floor Instrument Using Black Model and Black Pricer

This example shows the workflow to price an amortizing `Floor` instrument when you use a `Black` model and a `Black` pricing method.

### Create Floor Instrument Object

Use `fininstrument` to create an amortizing `Floor` instrument object.

```
CADates = datetime({'1-Sep-2020'; '1-Sep-2023'});  
CAPrincipal = [100; 85];  
Principal = timetable(CADates, CAPrincipal);
```

```
FloorOpt = fininstrument("Floor", 'Maturity', datetime(2023,9,1), 'Strike', 0.015, 'Principal', Principal);
```

```
FloorOpt =  
    Floor with properties:  
  
    Strike: 0.0150  
    Maturity: 01-Sep-2023  
    ResetOffset: 0  
    Reset: 1  
    Basis: 0  
    Principal: [2x1 timetable]  
    ProjectionCurve: [0x0 ratecurve]  
    DaycountAdjustedCashFlow: 0  
    BusinessDayConvention: "actual"  
    Holidays: NaT  
    Name: "floor_amortizing_option"
```

### Create Black Model Object

Use `finmodel` to create a Black model object.

```
BlackModel = finmodel("Black", 'Volatility', 0.2)
```

```
BlackModel =
  Black with properties:
    Volatility: 0.2000
    Shift: 0
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,1);
Type = 'zero';
ZeroTimes = [calyears([1 2 3 4 5 7 10])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates);
```

### Create Black Pricer Object

Use `finpricer` to create a Black pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackModel, 'DiscountCurve', myRC)
```

```
outPricer =
  Black with properties:
    Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]
```

### Price Floor Instrument

Use `price` to compute the price for the Floor instrument.

```
Price = price(outPricer, FloorOpt)
```

```
Price = 3.0030
```

## More About

### Floor

A floor is a contract that includes a guarantee setting the minimum interest rate received by the holder, based on an otherwise floating interest rate.

The payoff for a floor is:  $\max(\text{FloorRate} - \text{CurrentRate}, 0)$

# FRA

FRA instrument object

## Description

Create and price a FRA (forward rate agreement) instrument object using this workflow:

- 1 Use `fininstrument` to create a FRA instrument object.
- 2 Use `ratecurve` to specify an interest-rate model for the FRA instrument.
- 3 Use `finpricer` to specify a `Discount` pricing method for the FRA instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a FRA instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
FRAObj = fininstrument(InstrumentType, 'StartDate', start_date, 'Maturity', maturity_date, 'Rate', rate_value)
FRAObj = fininstrument( ___, Name, Value)
```

### Description

`FRAObj = fininstrument(InstrumentType, 'StartDate', start_date, 'Maturity', maturity_date, 'Rate', rate_value)` creates a FRA object by specifying `InstrumentType` and sets the properties on page 11-2216 for the required name-value pair arguments `StartDate`, `Maturity`, and `Rate`. For more information on a FRA instrument, see “More About” on page 11-2218.

`FRAObj = fininstrument( ___, Name, Value)` sets optional properties on page 11-2216 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FRAObj = fininstrument("FRA", 'StartDate', datetime(2016,1,30), 'Maturity', datetime(2019,1,30), 'Rate', 0.025, 'Principal', 100, 'Basis', 1, 'BusinessDayConvention', "follow", 'Name', "FRA_instrument")` creates a FRA instrument with a principal of 100 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "FRA" | character vector with value 'FRA'

Instrument type, specified as a string with the value of "FRA" or a character vector with the value of 'FRA'.

Data Types: char | string

### **FRA Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `FRAObj = fininstrument("FRA", 'StartDate', datetime(2016,1,30), 'Maturity', datetime(2019,1,30), 'Rate', 0.025, 'Principal', 100, 'Basis', 1, 'BusinessDayConvention', "follow", 'Name', "FRA_instrument")`

### **Required FRA Name-Value Pair Arguments**

#### **StartDate — FRA start date**

datetime | serial date number | date character vector | date string

FRA start date, specified as the comma-separated pair consisting of `'StartDate'` and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

Data Types: char | double | string | datetime

#### **Maturity — FRA maturity date**

datetime | serial date number | date character vector | date string

FRA maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Data Types: char | double | string | datetime

#### **Rate — FRA coupon rate**

decimal

FRA coupon rate, specified as the comma-separated pair consisting of `'Rate'` and a scalar decimal.

Data Types: double

### **Optional FRA Name-Value Pair Arguments**

#### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and scalar value from one of the following:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365

- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Principal — Principal amount**

100 (default) | numeric

Principal amount, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric.

Data Types: double

### **BusinessDayConvention — Business day convention**

"actual" (default) | string | character vector

Business day convention, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | string

### **Holidays — Holidays used in computing business days**

NaN (default) | datetime | cell array of date character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));  
FRAObj = fininstrument("FRA",'StartDate',datetime(2016,1,30),'Maturity',datetime(2025,12,15),'Ra
```

Data Types: double | cell | datetime | string

### **Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## **Properties**

### **StartDate — FRA start date**

datetime

FRA start date, returned as a datetime.

Data Types: datetime

### **Maturity — FRA maturity date**

datetime

FRA maturity date, returned as a datetime.

Data Types: datetime

### **Rate — FRA coupon rate**

decimal

FRA coupon rate, returned as a scalar decimal.

Data Types: double

### **Basis — Day count basis**

[0 0] (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as a scalar integer.

Data Types: double

### **Principal — Principal amount**

100 (default) | numeric

Principal amount, returned as a scalar numeric value.

Data Types: cell | double

### **BusinessDayConvention — Business day convention**

"actual" (default) | string

Business day convention, returned as a string.

Data Types: string

### Holidays — Holidays used in computing business days

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Object Functions

cashflows Computes cash flow for FixedBond, FloatBond, Swap, FRA, Swap, or Deposit instrument

## Examples

### Price FRA Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a FRA (forward rate agreement) instrument when you use a ratecurve and a Discount pricing method.

#### Create FRA Instrument Object

Use `fininstrument` to create a FRA instrument object.

```
FRAObj = fininstrument("FRA", 'StartDate', datetime(2020,9,15), 'Maturity', datetime(2022,9,15), 'Rate
```

```
FRAObj =  
    FRA with properties:
```

```
        Rate: 0.0175  
        Basis: 2  
    StartDate: 15-Sep-2020  
        Maturity: 15-Sep-2022  
    Principal: 100  
BusinessDayConvention: "actual"  
        Holidays: NaT  
        Name: ""
```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);  
Type = 'zero';  
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];  
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';  
ZeroDates = Settle + ZeroTimes;  
  
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create Discount Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```

outPricer =
    Discount with properties:
        DiscountCurve: [1x1 ratecurve]

```

### Price FRA Instrument

Use `price` to compute the price and sensitivities for the FRA instrument.

```
[Price, outPR] = price(outPricer, FRAObj, ["all"])
```

```
Price = 3.4176
```

```

outPR =
    pricerresult with properties:
        Results: [1x2 table]
        PricerData: []

```

```
outPR.Results
```

```

ans=1x2 table
    Price      DV01
    _____
    3.4176     0.001368

```

## More About

### FRA Instrument

A FRA (forward rate agreement) instrument is an over-the-counter contract between parties that determines the rate of interest to be paid on an agreed upon date in the future.

The FRA determines the rates to be used along with the termination date and notional value. FRAs are cash-settled with the payment based on the net difference between the interest rate of the contract and the floating rate in the market, called the reference rate. The notional amount is not exchanged, but is rather a cash amount based on the rate differentials and the notional value of the contract.

# Lookback

Lookback instrument

## Description

Create and price a Lookback instrument object using this workflow:

- 1 Use `fininstrument` to create a Lookback instrument object.
- 2 Use `finmodel` to specify a `BlackScholes` model for the Lookback instrument.
- 3 Use `finpricer` to specify a `ConzeViswanathan` or `GoldmanSosinGatto` pricing method for the Lookback instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Lookback instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
LookbackObj = fininstrument(InstrumentType, 'Strike', strike_value, '
ExerciseDate', exercise_date)
LookbackObj = fininstrument( ____, Name, Value)
```

### Description

`LookbackObj = fininstrument(InstrumentType, 'Strike', strike_value, 'ExerciseDate', exercise_date)` creates a Lookback object by specifying `InstrumentType` and sets the properties on page 11-2222 for the required name-value pair arguments `Strike` and `ExerciseDate`.

The Lookback instrument supports fixed and floating strike lookback options. For more information on a Lookback instrument, see “More About” on page 11-2224.

`LookbackObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2222 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `LookbackObj = fininstrument("Lookback", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'OptionType', "put", 'ExerciseStyle', "European", 'Name', "lookback_option")` creates a Lookback put option with an European exercise. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Lookback" | character vector with value 'Lookback'

Instrument type, specified as a string with the value of "Lookback" or a character vector with the value of 'Lookback'.

Data Types: char | string

### Lookback Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: LookbackObj =  
`fininstrument("Lookback", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'OptionType', "put", 'ExerciseStyle', "European", 'Name', "lookback_option")`

### Required Lookback Name-Value Pair Arguments

#### Strike — Option strike price value

nonnegative numeric | NaN

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative numeric value for a fixed strike Lookback option or a NaN for a floating strike Lookback option.

---

**Note** Use the ConzeViswanathan pricer for a fixed strike Lookback option and use the GoldmanSosinGatto pricer for a floating strike Lookback option.

---

Data Types: double

#### ExerciseDate — Option exercise date

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For a European option, there is only one ExerciseDate on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

### Optional Lookback Name-Value Pair Arguments

#### OptionType — Option type

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

#### ExerciseStyle — Option exercise style

"European" (default) | string with value "European" | character vector with value 'European'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

Data Types: string | char

**AssetMinMax — Maximum or minimum underlying asset price**

NaN where SpotPrice of the underlying asset is used (default) | scalar numeric

Maximum or minimum underlying asset price, specified as the comma-separated pair consisting of 'AssetMinMax' and a scalar numeric.

Data Types: double

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

**Strike — Option strike price value**

nonnegative numeric

Option strike price value, returned as a scalar nonnegative numeric.

Data Types: double

**ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

**OptionType — Option type**

"call" (default) | string with value "call" or "put"

Option type, returned as a string with a value of "call" or "put".

Data Types: string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European"

Option exercise style, returned as a string with a value of "European".

Data Types: string

**AssetMinMax — Maximum or minimum underlying asset price**

NaN where SpotPrice of the underlying asset is used (default) | scalar numeric

Maximum or minimum underlying asset price, returned as a scalar numeric.

Data Types: double

**Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

**Examples****Price Lookback Instrument Using a Black-Scholes Model and Conze-Viswanathan Pricer**

This example shows the workflow to price a LookBack instrument when you use a BlackScholes model and a ConzeViswanathan pricing method.

**Create Lookback Instrument Object**

Use `fininstrument` to create a Lookback instrument object.

```
LookbackOpt = fininstrument("Lookback", 'Strike', 105, 'ExerciseDate', datetime(2022, 9, 15), 'OptionType', 'put')
```

LookbackOpt =

Lookback with properties:

```

    OptionType: "put"
    Strike: 105
    AssetMinMax: NaN
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
    Name: "lookback_option"
```

**Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.2)
```

BlackScholesModel =

BlackScholes with properties:

```

    Volatility: 0.2000
    Correlation: 1
```

**Create ratecurve Object**

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018, 9, 15);
Maturity = datetime(2023, 9, 15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

myRC =

ratecurve with properties:

```

    Type: "zero"
```

```

    Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
    InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"

```

### Create ConzeViswanathan Pricer Object

Use `finpricer` to create a `ConzeViswanathan` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic","Model",BlackScholesModel,"DiscountCurve",myRC,"SpotPrice",100,
outPricer =
  ConzeViswanathan with properties:

    DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
    DividendValue: 0.2500
    DividendType: "continuous"

```

### Price Lookback Instrument

Use `price` to compute the price and sensitivities for the Lookback instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])
```

```
Price = 49.1850
```

```

outPR =
  pricerresult with properties:

    Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
49.185	1.4047	1.4211e-06	2.8559	32.593	-5.4906	-315.64

## More About

### Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-38.

# OptionEmbeddedFixedBond

OptionEmbeddedFixedBond instrument object

## Description

Create and price a `OptionEmbeddedFixedBond` instrument object using this workflow:

- 1 Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object.
- 2 use `finmodel` to specify a `HullWhite` or `BlackKarasinski` model for the `OptionEmbeddedFixedBond` instrument.
- 3 Use `finpricer` to specify an `IRTtree` pricing method for the `OptionEmbeddedFixedBond` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an `OptionEmbeddedFixedBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
OptionEmbeddedFixedBondObj = fininstrument(InstrumentType, '
CouponRate', couponrate_value, 'Maturity', maturity_date, '
CallSchedule', call_schedule_value)
OptionEmbeddedFixedBondObj = fininstrument(InstrumentType, '
CouponRate', couponrate_value, 'Maturity', maturity_date, '
PutSchedule', put_schedule_value)
OptionEmbeddedFixedBondObj = fininstrument( ____, Name, Value)
```

### Description

`OptionEmbeddedFixedBondObj = fininstrument(InstrumentType, 'CouponRate', couponrate_value, 'Maturity', maturity_date, 'CallSchedule', call_schedule_value)` creates a `OptionEmbeddedFixedBond` object by specifying `InstrumentType` and sets the properties on page 11-2232 for the required name-value pair arguments `CouponRate`, `Maturity`, and `CallSchedule`.

The `OptionEmbeddedFixedBond` instrument supports a vanilla bond with embedded option, stepped coupon bond with embedded option, and an amortizing bond with embedded option. For more information, see “More About” on page 11-2242.

```
OptionEmbeddedFixedBondObj = fininstrument(InstrumentType, '
CouponRate', couponrate_value, 'Maturity', maturity_date, '
PutSchedule', put_schedule_value) creates a OptionEmbeddedFixedBond object by
```

specifying `InstrumentType` and sets the properties on page 11-2232 for the required name-value pair arguments `CouponRate`, `Maturity`, and `PutSchedule`.

`OptionEmbeddedFixedBondObj = fininstrument(____,Name,Value)` sets optional properties on page 11-2232 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `OptionEmbeddedFixedBondObj = fininstrument("OptionEmbeddedFixedBond", 'CouponRate',0.34, 'Maturity',datetime(2019,1,30), 'Period',2, 'Basis',1, 'Principal',100, 'CallSchedule',schedule, 'CallExerciseStyle',"American", 'Name',"optionembeddedfixedbond_instrument")` creates an `OptionEmbeddedFixedBond` instrument with an American exercise and a call schedule. You can specify multiple name-value pair arguments.

## Input Arguments

### InstrumentType — Instrument type

string with value "OptionEmbeddedFixedBond" | character vector with value 'OptionEmbeddedFixedBond'

Instrument type, specified as a string with the value of "OptionEmbeddedFixedBond" or a character vector with the value of 'OptionEmbeddedFixedBond'.

Data Types: char | string

### OptionEmbeddedFixedBond Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `OptionEmbeddedFixedBondObj = fininstrument("OptionEmbeddedFixedBond", 'CouponRate',0.34, 'Maturity',datetime(2019,1,30), 'Period',2, 'Basis',1, 'Principal',100, 'CallSchedule',schedule, 'CallExerciseStyle',"American", 'Name',"optionembeddedfixedbond_instrument")`

### Required OptionEmbeddedFixedBond Name-Value Pair Arguments

#### CouponRate — Coupon rate for OptionEmbeddedFixedBond

scalar decimal | timetable

Coupon rate for `OptionEmbeddedFixedBond`, specified as the comma-separated pair consisting of 'CouponRate' as a scalar decimal for an annual rate or a timetable where the first column is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | timetable

#### Maturity — Maturity date for OptionEmbeddedFixedBond

datetime | serial date number | date character vector | date string

Maturity date for `OptionEmbeddedFixedBond`, specified as the comma-separated pair consisting of 'Maturity' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Data Types: char | double | string | datetime

**CallSchedule — Call schedule**

timetable

Call schedule, specified as the comma-separated pair consisting of 'CallSchedule' and a timetable of call dates and strikes.

If you use a date character vector or date string for the dates in this timetable, the format must be recognizable by `datetime` because the `CallSchedule` property is stored as a `datetime`.

---

**Note** The `OptionEmbeddedFixedBond` instrument supports either `CallSchedule` and `CallExerciseStyle` or `PutSchedule` and `PutExerciseStyle`, but not both.

---

Data Types: timetable

**PutSchedule — Call schedule**

timetable

Put schedule, specified as the comma-separated pair consisting of 'PutSchedule' and a timetable of call dates and strikes.

If you use a date character vector or date string for dates in this timetable, the format must be recognizable by `datetime` because the `PutSchedule` property is stored as a `datetime`.

---

**Note** The `OptionEmbeddedFixedBond` instrument supports either `CallSchedule` and `CallExerciseStyle` or `PutSchedule` and `PutExerciseStyle`, but not both.

---

Data Types: timetable

**Optional OptionEmbeddedFixedBond Name-Value Pair Arguments****Period — Frequency of payments per year**

1 (default) | integer

Frequency of payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar integer. Values for Period are: 1, 2, 3, 4, 6, and 12.

Data Types: double

**CallExerciseStyle — Call option exercise style**

"European" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Call option exercise style, specified as the comma-separated pair consisting of 'CallExerciseStyle' and a scalar string or character vector.

Data Types: string | char

**PutExerciseStyle — Put option exercise style**

"European" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Put option exercise style, specified as the comma-separated pair consisting of 'PutExerciseStyle' and a scalar string or character vector.

Data Types: string | char

### **Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of 'Basis' and scalar integer using one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Principal — Notional principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or timetable.

Principal accepts a timetable, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: double | timetable

### **DaycountAdjustedCashFlow — Flag indicating whether cash flow adjusts for day count convention**

false (default) | value of true or false

Flag indicating whether cash flow adjusts for day count convention, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar logical with a value of true or false.

Data Types: logical

### **BusinessDayConvention — Business day conventions**

"actual" (default) | string | character vector

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a scalar string or character vector. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `string`

### **Holidays — Holidays used in computing business days**

`NaT` (default) | `datetime` | cell array of date character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and dates using `datetimes`, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
OptionEmbeddedFixedBondObj = fininstrument("OptionEmbeddedFixedBond",'CouponRate',0.34,'Maturity','CallSchedule',schedule,'CallExerciseStyle',"american",'Holidays',H)
```

Data Types: `double` | `cell` | `datetime` | `string`

### **EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

`true` (in effect) (default) | value of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar logical value of `true` or `false`.

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

### **IssueDate — Bond issue date**

`NaT` (default) | `datetime` | serial date number | date character vector | date string

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar `datetime`, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `IssueDate` property is stored as a datetime.

Data Types: `double` | `char` | `string` | `datetime`

### **FirstCouponDate — Irregular first coupon date**

`NaT` (default) | `datetime` | serial date number | date character vector | date string

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar datetime, serial date number, date character vector, or date string.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

Data Types: `double` | `char` | `string` | `datetime`

### **LastCouponDate — Irregular last coupon date**

`NaT` (default) | `datetime` | serial date number | date character vector | date string

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar datetime, serial date number, date character vector, or date string.

If you specify `LastCouponDate` but not `FirstCouponDate`, `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify `LastCouponDate`, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `LastCouponDate` property is stored as a datetime.

Data Types: `double` | `char` | `string` | `datetime`

### **StartDate — Forward starting date of payments**

`NaT` (default) | `datetime` | serial date number | date character vector | date string

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

Data Types: `char` | `double` | `string` | `datetime`

### **Name — User-defined name for instrument**

`" "` (default) | `string` | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector.

Data Types: `char` | `string`

## Properties

### **CouponRate — Coupon annual rate**

scalar decimal | timetable

Coupon annual rate, returned as a scalar decimal or timetable.

Data Types: double | timetable

### **Maturity — Maturity date**

datetime

Maturity date, returned as a datetime.

Data Types: datetime

### **CallSchedule — Call schedule**

timetable

Call schedule, returned as a timetable.

Data Types: cell | datetime

### **PutSchedule — Call schedule**

timetable

Put schedule, returned as a timetable.

Data Types: cell | datetime

### **Period — Coupons per year**

1 (default) | integer

Coupons per year, returned as a scalar integer.

Data Types: double

### **Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as a scalar integer.

Data Types: double

### **Principal — Notional principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedule, returned as a scalar numeric or timetable.

Data Types: timetable | double

### **DaycountAdjustedCashFlow — Flag indicating whether cash flow adjusts for day count convention**

false (default) | value of true or false

Flag indicating whether cash flow adjusted for day count convention, returned as scalar logical with a value of true or false.

Data Types: logical

**BusinessDayConvention — Business day conventions**

"actual" (default) | string

Business day conventions, returned as a string

Data Types: string

**Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

**EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

true (in effect) (default) | value of true or false

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month with 30 or fewer days, returned as a scalar logical.

Data Types: logical

**IssueDate — Bond issue date**

NaT (default) | datetime

Bond issue date, returned as a datetime.

Data Types: datetime

**FirstCouponDate — Irregular first coupon date**

NaT (default) | datetime

Irregular first coupon date, returned as a datetime.

Data Types: datetime

**LastCouponDate — Irregular last coupon date**

NaT (default) | datetime

Irregular last coupon date, returned as a datetime.

Data Types: datetime

**StartDate — Forward starting date of payments**

NaT (default) | datetime

Forward starting date of payments, returned as a datetime.

Data Types: datetime

**CallExerciseStyle — Call option exercise style**

"European" (default) | string with value "European", "American", or "Bermuda"

This property is read-only.

Call option exercise style, returned as a string with a value of "European", "American", or "Bermuda".

Data Types: string

### PutExerciseStyle — Put option exercise style

"European" (default) | string with value "European", "American", or "Bermuda"

This property is read-only.

Put option exercise style, returned as a string with a value of "European", "American", or "Bermuda".

Data Types: string

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

### Price OptionEmbeddedFixedBond Instruments Using Hull-White Model and IRTree Pricer

This example shows the workflow to price American, European, and Bermudan exercise styles for three callable OptionEmbeddedFixedBond instruments when you use a HullWhite model and an IRTree pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

#### Create OptionEmbeddedFixedBond Instrument Objects

Use fininstrument to create three OptionEmbeddedFixedBond instrument objects with different exercise styles.

```
Maturity = datetime(2024,1,1);
```

```
% Option embedded bond (Bermudan callable bond)
```

```
Strike = [100; 100];
```

```
ExerciseDates = [datetime(2020,1,1); datetime(2024,1,1)];
```

```
Period = 1;
```

```
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
```

```
CallableBondBermudan = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
    'CouponRate',0.025,'Period',Period, ...
    'CallSchedule',CallSchedule,'CallExerciseStyle', "bermudan")
```

```
CallableBondBermudan =
```

```
OptionEmbeddedFixedBond with properties:
```

```

        CouponRate: 0.0250
          Period: 1
            Basis: 0
      EndMonthRule: 1
        Principal: 100
DaycountAdjustedCashFlow: 0
  BusinessDayConvention: "actual"
    Holidays: NaT
      IssueDate: NaT
FirstCouponDate: NaT
LastCouponDate: NaT
  StartDate: NaT
    Maturity: 01-Jan-2024
    CallDates: [2x1 datetime]
    PutDates: [0x1 datetime]
    CallSchedule: [2x1 timetable]
    PutSchedule: [0x0 timetable]
CallExerciseStyle: "bermudan"
PutExerciseStyle: [0x0 string]
  Name: ""

% Option embedded bond (American callable bond)
Strike = 100;
ExerciseDates = datetime(2024,1,1);
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Period = 1;

CallableBondAmerican = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
    'CouponRate',0.025,'Period',Period,...
    'CallSchedule',CallSchedule,'CallExerciseStyle',"american")

CallableBondAmerican =
  OptionEmbeddedFixedBond with properties:

    CouponRate: 0.0250
      Period: 1
        Basis: 0
    EndMonthRule: 1
      Principal: 100
DaycountAdjustedCashFlow: 0
  BusinessDayConvention: "actual"
    Holidays: NaT
      IssueDate: NaT
FirstCouponDate: NaT
LastCouponDate: NaT
  StartDate: NaT
    Maturity: 01-Jan-2024
    CallDates: 01-Jan-2024
    PutDates: [0x1 datetime]
    CallSchedule: [1x1 timetable]
    PutSchedule: [0x0 timetable]
CallExerciseStyle: "american"
PutExerciseStyle: [0x0 string]
  Name: ""

```

```

% Option embedded bond (European callable bond)
Strike = 100;
ExerciseDates = datetime(2024,1,1);
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Period = 1;

CallableBondEuropean = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
    'CouponRate',0.025,'Period',Period, ...
    'CallSchedule',CallSchedule)

CallableBondEuropean =
    OptionEmbeddedFixedBond with properties:

        CouponRate: 0.0250
           Period: 1
            Basis: 0
    EndMonthRule: 1
        Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2024
        CallDates: 01-Jan-2024
        PutDates: [0x1 datetime]
    CallSchedule: [1x1 timetable]
    PutSchedule: [0x0 timetable]
CallExerciseStyle: "european"
PutExerciseStyle: [0x0 string]
        Name: ""

```

### Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```

VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite",'alpha',AlphaCurve,'sigma',VolCurve);

```

### Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```

HWTreepricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates)

HWTreepricer =
    HWBKTree with properties:

        Tree: [1x1 struct]
    TreeDates: [10x1 datetime]
        Model: [1x1 finmodel.HullWhite]
DiscountCurve: [1x1 ratecurve]

```

## Price OptionEmbeddedFixedBond Instruments

Use price to compute the price and sensitivities for the three OptionEmbeddedFixedBond instruments.

```
[Price, outPR] = price(HWTreePricer,CallableBondBermudan,["all"])
```

```
Price = 103.2720
```

```
outPR =  
  pricerresult with properties:
```

```
    Results: [1x4 table]  
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table  
  Price      Vega      Gamma      Delta  
  _____  _____  _____  _____  
  103.27    -148.37    1375.9    -290.33
```

```
[Price, outPR] = price(HWTreePricer,CallableBondAmerican,["all"])
```

```
Price = 100
```

```
outPR =  
  pricerresult with properties:
```

```
    Results: [1x4 table]  
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table  
  Price      Vega      Gamma      Delta  
  _____  _____  _____  _____  
  100         0         0         0
```

```
[Price, outPR] = price(HWTreePricer,CallableBondEuropean,["all"])
```

```
Price = 107.7023
```

```
outPR =  
  pricerresult with properties:
```

```
    Results: [1x4 table]  
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table  
  Price      Vega      Gamma      Delta
```

```
107.7    1.4211e-10    4086.4    -602.56
```

### Price OptionEmbeddedFixedBond Instrument and Obtain Exercise Probabilities Using Black-Karasinski Model and IRTree Pricer

This example shows the workflow to price a callable OptionEmbeddedFixedBond instrument and obtain the exercise probabilities when you use a BlackKarasinski model and an IRTree pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018, 1, 1);
ZeroTimes = calyears(1:4)';
ZeroRates = [0.035; 0.042147; 0.047345; 0.052707];
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
    ratecurve with properties:
        Type: "zero"
        Compounding: 1
        Basis: 0
        Dates: [4x1 datetime]
        Rates: [4x1 double]
        Settle: 01-Jan-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

#### Create OptionEmbeddedFixedBond Instrument Object

Use fininstrument to create an OptionEmbeddedFixedBond instrument object with an American exercise style.

```
CouponRate = 0.0425;
Strike = [95; 98];
ExerciseDates = [datetime(2021,1,1); datetime(2022,1,1)];
Maturity = datetime(2022,1,1);
Period = 1;
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
CallableBond = fininstrument("OptionEmbeddedFixedBond", 'Maturity',Maturity,...
    'CouponRate',CouponRate,'Period', Period, ...
    'CallSchedule',CallSchedule,...
    'CallExerciseStyle', "American",...
    'Name',"MyCallableBond")
```

```
CallableBond =
    OptionEmbeddedFixedBond with properties:
```

```

        CouponRate: 0.0425
        Period: 1
        Basis: 0
    EndMonthRule: 1
    Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2022
    CallDates: [2x1 datetime]
    PutDates: [0x1 datetime]
    CallSchedule: [2x1 timetable]
    PutSchedule: [0x0 timetable]
    CallExerciseStyle: "American"
    PutExerciseStyle: [0x0 string]
    Name: "MyCallableBond"

```

### Create BlackKarasinski Model Object

Use `finmodel` to create a BlackKarasinski model object.

```

VolCurve = 0.01;
AlphaCurve = 0.1;
BKModel = finmodel("BlackKarasinski", 'alpha', AlphaCurve, 'sigma', VolCurve)

```

```

BKModel =
    BlackKarasinski with properties:

```

```

    Alpha: 0.1000
    Sigma: 0.0100

```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

BKTreePricer = finpricer("IRTree", 'Model', BKModel, 'DiscountCurve', ZeroCurve, 'TreeDates', ZeroDates)

```

```

BKTreePricer =
    HWBKTree with properties:

```

```

    Tree: [1x1 struct]
    TreeDates: [4x1 datetime]
    Model: [1x1 finmodel.BlackKarasinski]
    DiscountCurve: [1x1 ratecurve]

```

### Price OptionEmbeddedFixedBond Instrument

Use `price` to compute the price and sensitivities for the OptionEmbeddedFixedBond instrument.

```

[Price, PriceResults]= price(BKTreePricer, CallableBond)

```

```
Price = 94.3981
PriceResults =
  pricerresult with properties:
    Results: [1x1 table]
    PricerData: [1x1 struct]
```

Examine the output `PriceResults.PricerData.PriceTree.ExTree`, which contains the exercise indicator arrays. In the cell array, a 1 indicates an exercised option and a 0 indicates an unexercised option.

```
PriceResults.PricerData.PriceTree.ExTree{5}
```

```
ans = 1x7
      0      0      0      0      0      0      0
```

No options are exercised.

```
PriceResults.PricerData.PriceTree.ExTree{4}
```

```
ans = 1x7
      1      1      1      1      1      1      1
```

The instrument is exercised at all nodes.

```
PriceResults.PricerData.PriceTree.ExTree{3}
```

```
ans = 1x5
      0      0      0      0      0
```

No options are exercised.

```
PriceResults.PricerData.PriceTree.ExTree{2}
```

```
ans = 1x3
      0      0      0
```

No options are exercised.

View the probability of reaching each node from the root node using `PriceResults.PricerData.PriceTree.ProbTree`.

```
PriceResults.PricerData.PriceTree.ProbTree{2}
```

```
ans = 1x3
    0.1667    0.6667    0.1667
```

```
PriceResults.PricerData.PriceTree.ProbTree{3}
```

```
ans = 1x5
```

```
0.0203    0.2206    0.5183    0.2206    0.0203
```

```
PriceResults.PricerData.PriceTree.ProbTree{4}
```

```
ans = 1x7
```

```
0.0017    0.0394    0.2370    0.4437    0.2370    0.0394    0.0017
```

```
PriceResults.PricerData.PriceTree.ProbTree{5}
```

```
ans = 1x7
```

```
0.0017    0.0394    0.2370    0.4437    0.2370    0.0394    0.0017
```

View the exercise probabilities using `PriceResults.PricerData.PriceTree.ExProbTree`. `PriceResults.PricerData.PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceResults.PricerData.PriceTree.ExProbTree{5}
```

```
ans = 1x7
```

```
0    0    0    0    0    0    0
```

```
PriceResults.PricerData.PriceTree.ExProbTree{4}
```

```
ans = 1x7
```

```
0.0017    0.0394    0.2370    0.4437    0.2370    0.0394    0.0017
```

```
PriceResults.PricerData.PriceTree.ExProbTree{3}
```

```
ans = 1x5
```

```
0    0    0    0    0
```

```
PriceResults.PricerData.PriceTree.ExProbTree{2}
```

```
ans = 1x3
```

```
0    0    0
```

View the exercise probabilities at each tree level using `PriceResults.PricerData.PriceTree.ExProbsByTreeLevel`. `PriceResults.PricerData.PriceTree.ExProbsByTreeLevel` is an array in which each row holds the exercise probability for a given option at each tree observation time.

```
PriceResults.PricerData.PriceTree.ExProbsByTreeLevel
```

```
ans = 1x5
```

0 0 0 1.0000 0

## More About

### Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

### Stepped Coupon Bond with Callable and Puttable Features

A step-up bond and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

### Amortizing Callable and Puttable Bond

An amortizing callable bond or amortizing puttable bond work under a scheduled `Principal`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Principal` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

# Spread

Spread instrument object

## Description

Create and price a Spread instrument object using this workflow:

- 1 Use `fininstrument` to create a Spread instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Spread instrument.
- 3 Use `finpricer` to specify a Kirk or BjerksundStensland pricing method for the Spread instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Spread instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
SpreadObj = fininstrument(InstrumentType, 'Strike', strike_value, '
ExerciseDate', exercise_date)
SpreadObj = fininstrument( ____, Name, Value)
```

### Description

`SpreadObj = fininstrument(InstrumentType, 'Strike', strike_value, 'ExerciseDate', exercise_date)` creates a Spread object by specifying `InstrumentType` and sets the properties on page 11-2245 for the required name-value pair arguments `Strike` and `ExerciseDate`.

`SpreadObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2245 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `SpreadObj = fininstrument("Spread", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'OptionType', "put", 'ExerciseStyle', "American", 'Name', "spread_instrument")` creates a Spread put option with an American exercise. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Spread" | character vector with value 'Spread'

Instrument type, specified as a string with the value of "Spread" or a character vector with a value of 'Spread'.

Data Types: char | string

### **Spread Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, . . . , `NameN`, `ValueN`.

Example: `SpreadObj = fininstrument("Spread", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'OptionType', "put", 'ExerciseStyle', "American", 'Name', "spread_instrument")`

### **Required Spread Name-Value Pair Arguments**

#### **Strike — Option strike price value**

nonnegative numeric

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative numeric value.

Data Types: double

#### **ExerciseDate — Option exercise date**

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For a European option, there is only one `ExerciseDate` on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a `datetime`.

Data Types: double | char | string | datetime

### **Optional Spread Name-Value Pair Arguments**

#### **OptionType — Option type**

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

#### **ExerciseStyle — Option exercise style**

"European" (default) | string with value "European" | character vector with value 'European'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

Data Types: string | char

#### **Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### Strike — Option strike price value

nonnegative numeric

Option strike price value, returned as a scalar nonnegative numeric value.

Data Types: double

### ExerciseDate — Option exercise date

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

### OptionType — Option type

"call" (default) | string with value "call" or "put"

Option type, returned as a string with a value of "call" or "put".

Data Types: string

### ExerciseStyle — Option exercise style

"European" (default) | string with value "European"

Option exercise style, returned as a string with a value of "European".

Data Types: string

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

### Price Spread Instrument with American Option Using Black-Scholes Model and Bjerksund-Stensland Pricer

This example shows the workflow to price a Spread instrument with an American option when using a BlackScholes model and a BjerksundStensland pricing method.

#### Create Spread Instrument Object

Use `fininstrument` to create a Spread instrument object.

```
SpreadOpt = fininstrument("Spread", 'Strike', 105, 'ExerciseDate', datetime(2021,9,15), 'OptionType',
```

```
SpreadOpt =  
    Spread with properties:  
  
        OptionType: "put"  
        ExerciseStyle: "european"  
        ExerciseDate: 15-Sep-2021  
        Strike: 105  
        Name: "spread_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', [0.2 ; 0.1])
```

```
BlackScholesModel =  
    BlackScholes with properties:  
  
        Volatility: [2x1 double]  
        Correlation: [2x2 double]
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =  
    ratecurve with properties:  
  
        Type: "zero"  
        Compounding: -1  
        Basis: 12  
        Dates: 15-Sep-2023  
        Rates: 0.0350  
        Settle: 15-Sep-2018  
        InterpMethod: "linear"  
        ShortExtrapMethod: "next"  
        LongExtrapMethod: "previous"
```

### Create BjerksundStensland Pricer Object

Use `finpricer` to create a BjerksundStensland pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', [103
```

```
outPricer =  
    BjerksundStensland with properties:  
  
        DiscountCurve: [1x1 ratecurve]  
        Model: [1x1 finmodel.BlackScholes]  
        SpotPrice: [2x1 double]
```

```
DividendValue: [0.0250 28]
DividendType: "continuous"
```

### Price Spread Instrument

Use price to compute the price and sensitivities for the Spread instrument.

```
[Price, outPR] = price(outPricer,SpreadOpt,["all"])
```

```
Price = 12.5642
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x7 table]
  PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega
12.564	-0.38878	0	-3.1872	64.665

### Price Spread Instrument for a Commodity Using Black-Scholes Model and Analytic Pricers

This example shows the workflow to price a commodity Spread instrument when you use a BlackScholes model and Kirk and BjerksundStensland analytic pricing methods.

#### Understanding Crack Spread Options

In the petroleum industry, refiners are concerned about the difference between their input costs (crude oil) and output prices (refined products — gasoline, heating oil, diesel fuel, and so on). The differential between these two underlying commodities is referred to as a *crack spread*. It represents the profit margin between crude oil and the refined products.

A *spread option* is an option on the spread where the holder has the right, but not the obligation, to enter into a spot or forward spread contract. Crack spread options are often used to protect against declines in the crack spread or to monetize volatility or price expectations on the spread.

#### Define the Commodity

Assume that current gasoline prices are strong, and you want to model a crack spread option strategy to protect the gasoline margin. A crack spread option strategy is used to maintain profits for the following season. The WTI crude oil futures are at \$93.20 per barrel and RBOB gasoline futures contract are at \$2.85 per gallon.

```
Strike = 20;
Rate = 0.05;
```

```
Settle = datetime(2020,1,1);
Maturity = datemnth(Settle,3);
```

```

% Price and volatility of RBOB gasoline
PriceGallon1 = 2.85;           % Dollars per gallon
Price1 = PriceGallon1 * 42;   % Dollars per barrel
Vol1 = 0.29;

% Price and volatility of WTI crude oil
Price2 = 93.20;              % Dollars per barrel
Vol2 = 0.36;

% Correlation between the prices of the commodities
Corr = 0.42;

```

### Create Spread Instrument Object

Use `fininstrument` to create a Spread instrument object.

```

SpreadOpt = fininstrument("Spread", 'ExerciseDate', Maturity, 'Strike', Strike, 'ExerciseStyle', "
SpreadOpt =
    Spread with properties:
        OptionType: "call"
        ExerciseStyle: "european"
        ExerciseDate: 01-Apr-2020
        Strike: 20
        Name: "spread_instrument"

```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```

BlackScholesModel = finmodel("BlackScholes", 'Volatility', [Vol1; Vol2], 'Correlation', [1 Corr;

```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

ZeroCurve = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1);

```

### Create BjerksundStensland Pricer Object

Use `finpricer` to create a BjerksundStensland pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

BJSPricer = finpricer("Analytic", 'Model', BlackScholesModel, 'SpotPrice', [Price1; Price2], 'Di

```

### Create Kirk Pricer Object

Use `finpricer` to create a Kirk pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

KirkPricer = finpricer("Analytic", 'Model', BlackScholesModel, 'SpotPrice', [Price1; Price2], 'Di

```

### Price Spread Instrument Using BjerksundStensland and Kirk Analytic Pricing Methods

Use `price` to compute the price and sensitivities for the commodity Spread instrument.

```
[PriceKirk, outPR_Kirk] = price(KirkPricer, SpreadOpt, "all");
[PriceBJS, outPR_BJS] = price(BJSPricer, SpreadOpt, "all");
```

```
[outPR_Kirk.Results; outPR_BJS.Results]
```

```
ans=2x7 table
```

Price	Delta		Gamma		Lambda		Vega	
11.19	0.67224	-0.60665	0.019081	0.021662	7.1907	-6.4891	11.299	9.886
11.2	0.67371	-0.60816	0.018992	0.021572	7.2003	-6.4997	11.198	9.987

## More About

### Spread Option

A spread option is written on the difference of two underlying assets.

For example, a European call on the difference of two assets  $X1$  and  $X2$  has the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

$K$  is the strike price.

For more information, see “Spread Option” on page 3-29.

## Swap

Swap instrument object

### Description

Create and price a Swap instrument object using this workflow:

- 1 Use `fininstrument` to create a Swap instrument object.
- 2 Use `ratecurve` to specify a curve model for the Swap instrument.
- 3 Use `finpricer` to specify a Discount pricing method for the Swap instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Swap instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
SwapInstrument = fininstrument(InstrumentType, 'Maturity', maturity_date, '
LegRate', leg_rate)
SwapInstrument = fininstrument( ____, Name, Value)
```

#### Description

`SwapInstrument = fininstrument(InstrumentType, 'Maturity', maturity_date, 'LegRate', leg_rate)` creates a Swap object by specifying `InstrumentType` and sets the properties on page 11-2255 for the required name-value pair arguments `Maturity` and `LegRate`.

The Swap instrument supports vanilla swaps, amortizing swaps and forward swaps. You can use the Swap instrument for a single currency swap but not a cross-currency swap. For more information on a Swap instrument, see “More About” on page 11-2260.

`SwapInstrument = fininstrument( ____, Name, Value)` sets optional properties on page 11-2255 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `SwapInstrument = fininstrument("Swap", 'Maturity', datetime(2019,1,30), 'LegRate', [0.06 0.12], 'LegType', ["fixed", "fixed"], 'Basis', 1, 'Notional', 100, 'StartDate', datetime(2016,1,30), 'DaycountAdjustedCashFlow', true, 'BusinessDayConvention', "follow", 'ProjectionCurve', ratecurve, 'Name', "swap_instrument")` creates a Swap option with a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

## Input Arguments

### InstrumentType — Instrument type

string with value "Swap" | character vector with value 'Swap'

Instrument type, specified as a string with the value of "Swap" or a character vector with the value of 'Swap'.

Data Types: char | string

### Swap Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `SwapInstrument = fininstrument("Swap", 'Maturity', datetime(2019,1,30), 'LegRate', [0.06 0.12], 'LegType', ["fixed", "fixed"], 'Basis', 1, 'Notional', 100, 'StartDate', datetime(2016,1,30), 'DaycountAdjustedCashFlow', true, 'BusinessDayConvention', "follow", 'ProjectionCurve', ratecurve, 'Name', "swap_instrument")`

### Required Swap Name-Value Pair Arguments

#### Maturity — Swap maturity date

datetime | serial date number | date character vector | date string

Swap maturity date, specified as the comma-separated pair consisting of 'Maturity' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Data Types: char | double | string | datetime

#### LegRate — Leg rate in decimal values

matrix

Leg rate in decimal values, specified as the comma-separated pair consisting of 'LegRate' and a NINST-by-2 matrix. Each row can be defined as one of the following:

- [CouponRate Spread] (fixed-float)
- [Spread CouponRate] (float-fixed)
- [CouponRate CouponRate] (fixed-fixed)
- [Spread Spread] (float-float)

CouponRate is the decimal annual rate. Spread is the number of basis points in decimals over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

### Optional Swap Name-Value Pair Arguments

#### LegType — Leg type

["fixed", "float"] for each instrument (default) | cell array of character vectors with values {'fixed', 'fixed'}, {'fixed', 'float'}, {'float', 'fixed'}, or {'float', 'float'} |

string array with values ["fixed", "fixed"], ["fixed", "float"], ["float", "fixed"], or ["float", "float"]

Leg type, specified as the comma-separated pair consisting of 'LegType' and a cell array of character vectors or a string array with the supported values. The LegType defines the interpretation of the values entered in LegRate.

---

**Note** When you specify a Swap instrument as the underlying asset for a Swaption instrument while using a Normal, Sabr, Black, or HullWhite pricer, the Swap LegType must be ["fixed", "float"] or ["float", "fixed"]. You must also set the ExerciseStyle name-value pair argument of the associated Swaption instrument to 'European'.

---

Data Types: cell | string

### ProjectionCurve — Rate curve for projecting floating cash flows

ratecurve.empty (default) | ratecurve object

Rate curve for projecting floating cash flows, specified as the comma-separated pair consisting of 'ProjectionCurve' and a ratecurve object. You must create this object using ratecurve. Use this optional input if the forward curve is different from the discount curve.

Data Types: object

### Reset — Frequency of payments per year

[2 2] (default) | numeric value of 0, 1, 2, 3, 4, 6, or 12 | vector

Frequency of payments per year, specified as the comma-separated pair consisting of 'Reset' and scalar or NINST-by-2 if Reset is different for each leg) with one of the following values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### Basis — Day-count basis representing the basis for each leg

[0 0] (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 array (or NINST-by-2 if Basis is different for each leg).

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)

- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: double

### **Notional — Notional principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Notional' and a scalar numeric or timetable. Use a scalar for a vanilla Swap instrument and a timetable for an amortizing Swap instrument.

Notional accepts a scalar for a principal amount (or a NINST-by-2 matrix if Notional is different for each leg) or a timetable for principal value schedules. For schedules, the first column of the timetable is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: timetable | double

### **LatestFloatingRate — Latest floating rate for float legs**

if not specified, then ratecurve must contain this information (default) | scalar numeric | vector

Latest floating rate for float legs, specified as the comma-separated pair consisting of 'LatestFloatingRate' and a scalar numeric value.

LatestFloatingRate is a NINST-by-1 matrix (or NINST-by-2 matrix if LatestFloatingRate is different for each leg).

Data Types: double

### **ResetOffset — Lag in rate setting**

[0 0] (default) | vector

Lag in rate setting, specified as the comma-separated pair consisting of 'ResetOffset' and a NINST-by-2 vector.

Data Types: double

### **DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a NINST-by-1 (or NINST-by-2 if AdjustCashFlowsBasis is different for each leg) of logicals with values of true or false.

Data Types: logical

### **BusinessDayConvention — Business day conventions**

"actual" (default) | string | string array | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and string (or string array if BusinessDayConvention is different for each leg) or a character vector (or NINST-by-2 cell array of character vectors if

`BusinessDayConvention` is different for each leg). The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

### Holidays — Holidays used in computing business days

`NaT` (default) | `datetime` | cell array of date character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
Swap = fininstrument("Swap",'Maturity',datetime(2025,12,15),'LegRate',[0.06 20],'Holidays',H)
```

Data Types: `double` | `cell` | `datetime` | `string`

### EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days

[`true true`] (in effect) (default) | logical with value of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a logical value of `true` or `false` using a `NINST-by-1` (or `NINST-by-2` if `EndMonthRule` is different for each leg).

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

### StartDate — Date swap starts

Settle date (default) | `datetime` | serial date number | date character vector | date string

Date swap starts, specified as the comma-separated pair consisting of 'StartDate' and a scalar `datetime`, serial date number, date character vector, or date string.

Use `StartDate` to price a forward swap, that is, a swap that starts at a future date.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

Data Types: `char` | `double` | `string` | `datetime`

### **Name — User-defined name for instrument**

" " (default) | `string` | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: `char` | `string`

## **Properties**

### **Maturity — Maturity date**

`datetime`

Maturity date, returned as a datetime.

Data Types: `datetime`

### **LegRate — Leg rate**

`matrix`

Leg rate, returned as a NINST-by-2 matrix of decimal values, with each row defined as one of the following:

- [CouponRate Spread] (fixed-float)
- [Spread CouponRate] (float-fixed)
- [CouponRate CouponRate] (fixed-fixed)
- [Spread Spread] (float-float)

Data Types: `double`

### **LegType — Leg type**

["fixed", "float"] for each instrument (default) | string array with values ["fixed", "fixed"], ["fixed", "float"], ["float", "fixed"], or ["float", "float"]

Leg type, returned as a string array with the values ["fixed", "fixed"], ["fixed", "float"], ["float", "fixed"], or ["float", "float"].

Data Types: `string`

### **ProjectionCurve — Rate curve used in generating future cash flows**

`ratecurve.empty` (default) | `ratecurve` object

Rate curve used in projecting the future cash flows, returned as a `ratecurve` object.

Data Types: `object`

### **Reset — Reset frequency per year for each swap**

[2 2] (default) | vector

Reset frequency per year for each swap, returned as an NINST-by-2 vector.

Data Types: double

**Basis — Day count basis**

[0 0] (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as an NINST-by-2 vector.

Data Types: double

**ResetOffset — Lag in rate setting**

[0 0] (default) | vector

Lag in rate setting, returned as an NINST-by-2 vector.

Data Types: double

**Notional — Notional principal amount or principal value schedules**

100 (default) | scalar numeric | timetable

Notional principal amount, returned as a scalar numeric or timetable.

Data Types: cell | double

**LatestFloatingRate — Rate for the next floating payment**

if not specified, then `ratecurve` must contain this information (default) | scalar numeric

Rate for the next floating payment, set at the last reset date, returned as a scalar numeric value.

Data Types: double

**DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on actual period day count, returned as an NINST-by-1 matrix (or an NINST-by-2 matrix if `AdjustCashFlowsBasis` is different for each leg) of logicals with values of true or false.

Data Types: logical

**BusinessDayConvention — Business day conventions**

"actual" (default) | string | string array

Business day conventions, returned as a string or a NINST-by-2 string array if `BusinessDayConvention` is different for each leg.

Data Types: char | cell | string

**Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

**EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

[true true] (in effect) (default) | logical with value of true or false

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, returned as a scalar logical.

Data Types: `logical`

### **StartDate — Date swap starts**

Settle date (default) | `datetime`

Date swap starts, returned as a `datetime`.

Data Types: `datetime`

### **Name — User-defined name for instrument**

" " (default) | `string`

User-defined name for the instrument, returned as a `string`.

Data Types: `string`

## **Object Functions**

`cashflows` Computes cash flow for `FixedBond`, `FloatBond`, `Swap`, `FRA`, `Swap`, or `Deposit` instrument

## **Examples**

### **Price Vanilla Swap Instrument Using ratecurve and Discount Pricer**

This example shows the workflow to price a vanilla Swap instrument when you use a `ratecurve` and a `Discount` pricing method.

#### **Create ratecurve Object**

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the Swap instrument.

```
Settle = datetime(2019,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10×1 datetime]
        Rates: [10×1 double]
        Settle: 15-Jan-2019
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create Swap Instrument Object

Use `fininstrument` to create a vanilla Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2020,9,15), 'LegRate', [0.022 0.019 ], 'LegType', ["float", "fixed"])

Swap =
    Swap with properties:
        LegRate: [0.0220 0.0190]
        LegType: ["float"    "fixed"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
        LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
        DaycountAdjustedCashFlow: [0 0]
        ProjectionCurve: [1x2 ratecurve]
        BusinessDayConvention: ["actual"    "actual"]
        Holidays: NaT
        EndMonthRule: [1 1]
        StartDate: NaT
        Maturity: 15-Sep-2020
        Name: "swap_instrument"
```

### Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)

outPricer =
    Discount with properties:
        DiscountCurve: [1x1 ratecurve]
        ShiftValue: 1.0000e-04
```

### Price Swap Instrument

Use `price` to compute the price and sensitivities for the vanilla Swap instrument.

```
[Price, outPR] = price(outPricer, Swap, ["all"])

Price = 2.3902

outPR =
    pricerresult with properties:
        Results: [1x2 table]
        PricerData: []

outPR.Results
ans=1x2 table
    Price    DV01
```

---

```
2.3902    -0.0098199
```

## Price Amortizing Swap Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price an amortizing Swap instrument when you use a ratecurve and a Discount pricing method.

### Create ratecurve Object

Create a ratecurve object using ratecurve for the underlying interest-rate curve for the Swap instrument.

```
Settle = datetime(2019,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Jan-2019
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create Swap Instrument Object

Use fininstrument to create an amortizing Swap instrument object.

```
Maturity = datetime(2024,1,1);
ADates = datetime([2020,1,1 ; 2024,1,1]);
APrincipal = [100; 85];
Notional = timetable(ADates,APrincipal);
Swap = fininstrument("Swap", 'Maturity',Maturity, 'LegRate', [0.035,0.01], 'Reset', [1 1], 'Notional', Notional);
```

```
Swap =
    Swap with properties:
        LegRate: [0.0350 0.0100]
        LegType: ["fixed"      "float"]
        Reset: [1 1]
        Basis: [0 0]
        Notional: [2x1 timetable]
        LatestFloatingRate: [NaN NaN]
```

```

ResetOffset: [0 0]
DaycountAdjustedCashFlow: [0 0]
ProjectionCurve: [0x0 ratecurve]
BusinessDayConvention: ["actual" "actual"]
Holidays: NaT
EndMonthRule: [1 1]
StartDate: NaT
Maturity: 01-Jan-2024
Name: "swap_instrument"

```

## Create Discount Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
outPricer =
Discount with properties:
DiscountCurve: [1x1 ratecurve]
```

## Price Swap Instrument

Use `price` to compute the price and sensitivities for the amortizing Swap instrument.

```
[Price, outPR] = price(outPricer, Swap,["all"])
```

```
Price = 5.6465
```

```
outPR =
pricerresult with properties:
Results: [1x2 table]
PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
Price      DV01
-----
5.6465     0.022987
```

## More About

### Swap

A swap is contract between two parties obligating the parties to exchange future cash flows.

A vanilla swap is composed of a floating-rate leg and a fixed-rate leg.

## Swap with Amortization

A swap with an amortization schedule repays part of the principal (face value) along with the coupon payments.

A swap with an amortization schedule is used to manage interest-rate risk and serve as a cash flow management tool. For this particular type of swap, the notional amount decreases over time. This means that interest payments decrease not only on the floating leg but also on the fixed leg. Use the `Notional` name-value pair argument to support an amortization schedule.

## Forward Swap

In a forward interest-rate swap, a fixed interest-rate loan is exchanged for a floating interest-rate loan at a future specified date.

The `StartDate` name-value pair argument supports the future date for the forward swap.

# Swaption

Swaption instrument object

## Description

Create and price a `Swaption` instrument object using this workflow:

- 1 Use `fininstrument` to create a `Swaption` instrument object.
- 2 Use `finmodel` to specify a `HullWhite`, `Black`, `Normal`, or `Sabr` model for the `Swaption` instrument.
- 3 Use `finpricer` to specify a `Normal`, `Sabr`, `Black`, or `HullWhite` pricing method for the `Swaption` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Swaption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
SwaptionInstrument = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercice_date)
SwaptionInstrument = fininstrument( ____,Name,Value)
```

### Description

`SwaptionInstrument = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercice_date)` creates a `Swaption` object by specifying `InstrumentType` and sets the properties on page 11-2264 for the required name-value pair arguments `Strike` and `ExerciseDate`. For more information on a `Swaption` instrument, see “More About” on page 11-2273.

`SwaptionInstrument = fininstrument( ____,Name,Value)` sets optional properties on page 11-2264 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `SwaptionInstrument = fininstrument("Swaption",'Strike',0.67,'ExerciseDate',datetime(2019,1,30),'Swap','Swap_obj','OptionType',"put",'ExerciseStyle',"European",'Name',"swaption_instrument")` creates a `Swaption` put instrument with a strike of 0.67 and an European exercise. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Swaption" | character vector with value 'Swaption'

Instrument type, specified as a string with the value of "Swaption" or a character vector with the value of 'Swaption'.

Data Types: char | string

### Swaption Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `SwaptionInstrument = fininstrument("Swaption", 'Strike', .67, 'ExerciseDate', datetime(2019,1,30), 'Swap', Swap_obj, 'OptionType', "put", 'ExerciseStyle', "European", 'Name', "swaption_instrument")`

### Required Swaption Name-Value Pair Arguments

#### Strike — Option strike price value

nonnegative decimal

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative decimal value.

Data Types: double

#### ExerciseDate — Option exercise date

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For a European option, there is only one ExerciseDate on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

#### Swap — Underlying Swap object

Swap object

Underlying Swap object, specified as the comma-separated pair consisting of 'Swap' and a scalar Swap object.

Data Types: object

### Optional Swaption Name-Value Pair Arguments

#### OptionType — Option type

"call" (default) | string with values "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European" | character vector with value 'European'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

---

**Note** When you specify a Swap instrument as the underlying asset for a Swaption instrument and use a Normal, Sabr, Black, or HullWhite pricer, the Swap instrument LegType must be ["fixed", "float"] or ["float", "fixed"] and the Swaption instrument ExerciseStyle must be "European".

---

Data Types: string | char

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

**Properties****Strike — Option strike price value**

nonnegative decimal

Option strike price value, returned as a scalar nonnegative decimal value.

Data Types: double

**ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

**Swap — Underlying Swap object**

Swap object

Swap object, returned as a scalar Swap object.

Data Types: object

**OptionType — Option type**

"call" (default) | string with value "call" or "put"

Option type, returned as a string with a value of "call" or "put".

Data Types: string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European"

Option exercise style, returned as a string with a value of "European".

Data Types: string

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

### Price Swaption Instrument Using SABR Model and SABR Pricer

This example shows the workflow to price a Swaption instrument when you use a SABR model and a SABR pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10×1 datetime]
        Rates: [10×1 double]
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

#### Create Swap Instrument Object

Use `fininstrument` to create the underlying Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2027,3,15), 'LegRate', [0 0], 'LegType', ...
    ["float", "fixed"], 'Notional', 100, 'StartDate', datetime(2022,3,15), 'Name', "swap_instrument")
```

```
Swap =
    Swap with properties:
        LegRate: [0 0]
        LegType: ["float" "fixed"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
```

```
LatestFloatingRate: [NaN NaN]
ResetOffset: [0 0]
DaycountAdjustedCashFlow: [0 0]
ProjectionCurve: [0x0 ratecurve]
BusinessDayConvention: ["actual" "actual"]
Holidays: NaT
EndMonthRule: [1 1]
StartDate: 15-Mar-2022
Maturity: 15-Mar-2027
Name: "swap_instrument"
```

### Create Swaption Instrument Object

Use `fininstrument` to create a `Swaption` instrument object.

```
Swaption = fininstrument("Swaption", 'Strike', 0.02, 'ExerciseDate', datetime(2022, 3, 15), 'Swap', Swap
```

```
Swaption =
```

```
Swaption with properties:
```

```
OptionType: "call"
ExerciseStyle: "european"
ExerciseDate: 15-Mar-2022
Strike: 0.0200
Swap: [1x1 fininstrument.Swap]
Name: "swaption_option"
```

### Create SABR Model Object

Use `finmodel` to create a `SABR` model object.

```
SabrModel = finmodel("SABR", 'Alpha', 0.032, 'Beta', 0.04, 'Rho', .08, 'Nu', 0.49, 'Shift', 0.002)
```

```
SabrModel =
```

```
SABR with properties:
```

```
Alpha: 0.0320
Beta: 0.0400
Rho: 0.0800
Nu: 0.4900
Shift: 0.0020
VolatilityType: "black"
```

### Create SABR Pricer Object

Use `finpricer` to create a `SABR` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', SabrModel, 'DiscountCurve', myRC)
```

```
outPricer =
```

```
SABR with properties:
```

```
DiscountCurve: [1x1 ratecurve]
Model: [1x1 finmodel.SABR]
```

## Price Swaption Instrument

Use price to compute the price for the Swaption instrument.

```
Price = price(outPricer,Swaption)
```

```
Price = 10.8558
```

## Price Swaption Instrument Using Black Model and Black Pricer

This example shows the workflow to price a Swaption instrument when you use a Black model and a Black pricing method.

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
```

```
Type = 'zero';
```

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
```

```
ratecurve with properties:
```

```

        Type: "zero"
    Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
    InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"

```

### Create Swap Instrument Object

Use fininstrument to create the underlying Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2027,3,15), 'LegRate', [0 0], 'LegType', ...
    ["float", "fixed"], 'Notional', 100, 'StartDate', datetime(2022,3,15), 'Name', "swap_instrument")
```

```
Swap =
```

```
Swap with properties:
```

```

        LegRate: [0 0]
        LegType: ["float"    "fixed"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
DaycountAdjustedCashFlow: [0 0]

```

```
ProjectionCurve: [0x0 ratecurve]
BusinessDayConvention: ["actual" "actual"]
Holidays: NaT
EndMonthRule: [1 1]
StartDate: 15-Mar-2022
Maturity: 15-Mar-2027
Name: "swap_instrument"
```

### Create Swaption Instrument Object

Use `fininstrument` to create a `Swaption` instrument object.

```
Swaption = fininstrument("Swaption", 'Strike', 0.02, 'ExerciseDate', datetime(2022, 3, 15), 'Swap', Swap)
```

```
Swaption =
  Swaption with properties:

    OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Mar-2022
    Strike: 0.0200
    Swap: [1x1 fininstrument.Swap]
    Name: "swaption_option"
```

### Create Black Model Object

Use `finmodel` to create a `Black` model object.

```
BlackModel = finmodel("Black", 'Volatility', 0.032, 'Shift', 0.002)
```

```
BlackModel =
  Black with properties:

    Volatility: 0.0320
    Shift: 0.0020
```

### Create Black Pricer Object

Use `finpricer` to create a `Black` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackModel, 'DiscountCurve', myRC)
```

```
outPricer =
  Black with properties:

    Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]
```

### Price Swaption Instrument

Use `price` to compute the price for the `Swaption` instrument.

```
Price = price(outPricer, Swaption)
```

Price = 3.3116

## Calibrate Shifted SABR Model Parameters for Swaption Instrument

This example shows how to calibrate the shifted SABR model parameters for a Swaption instrument when you use a SABR pricing method.

### Load Market Data

```
% Zero curve
ValuationDate = datetime("5-Mar-2016", 'Locale', 'en_US');
ZeroDates = datemnth(ValuationDate,[1 2 3 6 9 12*[1 2 3 4 5 6 7 8 9 10 12]]);
ZeroRates = [-0.33 -0.28 -0.24 -0.12 -0.08 -0.03 0.015 0.028 ...
    0.033 0.042 0.056 0.095 0.194 0.299 0.415 0.525]'/100;
Compounding = 1;
ZeroCurve = ratecurve("zero",ValuationDate,ZeroDates,ZeroRates,'Compounding',Compounding)

ZeroCurve =
    ratecurve with properties:

        Type: "zero"
    Compounding: 1
        Basis: 0
        Dates: [16x1 datetime]
        Rates: [16x1 double]
        Settle: 05-Mar-2016
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

```
% Define the swaptions
SwaptionSettle = datetime("5-Mar-2016", 'Locale', 'en_US');
SwaptionExerciseDate = datetime("5-Mar-2017", 'Locale', 'en_US');
SwaptionStrikes = (-0.6:0.01:1.6)'/100; % Include negative strikes
SwapMaturity = datetime("5-Mar-2022", 'Locale', 'en_US'); % Maturity of underlying swap
OptSpec = 'call';
```

### Compute Forward Swap Rate by Creating Swap Instrument

Use `fininstrument` to create a Swap instrument object.

```
LegRate = [0 0];
Swap = fininstrument("Swap", 'Maturity', SwapMaturity, 'LegRate', LegRate, "LegType",["fixed" "float"]
    "ProjectionCurve", ZeroCurve, "StartDate", SwaptionExerciseDate)

Swap =
    Swap with properties:

        LegRate: [0 0]
        LegType: ["fixed" "float"]
        Reset: [2 2]
        Basis: [0 0]
    Notional: 100
    LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
```

```

ProjectionCurve: [1x2 ratecurve]
BusinessDayConvention: ["actual" "actual"]
Holidays: NaT
EndMonthRule: [1 1]
StartDate: 05-Mar-2017
Maturity: 05-Mar-2022
Name: ""

```

```
ForwardValue = parswaprate(Swap,ZeroCurve)
```

```
ForwardValue = 7.3271e-04
```

### Load the Market Implied Volatility Data

The market swaption volatilities are quoted in terms of shifted Black volatilities with a 0.8 percent shift.

```

StrikeGrid = [-0.5; -0.25; -0.125; 0; 0.125; 0.25; 0.5; 1.0; 1.5]/100;
MarketStrikes = ForwardValue + StrikeGrid;
Shift = 0.008; % 0.8 percent shift
MarketShiftedBlackVolatilities = [21.1; 15.3; 14.0; 14.6; 16.0; 17.7; 19.8; 23.9; 26.2]/100;
ATMShiftedBlackVolatility = MarketShiftedBlackVolatilities(StrikeGrid==0);

```

### Calibrate Shifted SABR Model Parameters

The Beta parameter is predetermined at 0.5.

```
Beta = 0.5;
```

```
% Calibrate Alpha, Rho, and Nu
```

```

objFun = @(X) MarketShiftedBlackVolatilities - volatilities(finpricer("Analytic", 'Model', ...
    finmodel("SABR", 'Alpha', X(1), 'Beta', Beta, 'Rho', X(2), 'Nu', X(3), 'Shift', Shift), ...
    'DiscountCurve', ZeroCurve), SwaptionExerciseDate, ForwardValue, MarketStrikes);

```

```
X = lsqnonlin(objFun, [0.5 0 0.5], [0 -1 0], [Inf 1 Inf]);
```

Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to its initial value is less than the value of the function tolerance.

```

Alpha = X(1);
Rho = X(2);
Nu = X(3);

```

### Create SABR Model Using the Calibrated Parameters

Use `finmodel` to create a SABR model object.

```
SABRModel = finmodel("SABR", 'Alpha', Alpha, 'Beta', Beta, 'Rho', Rho, 'Nu', Nu, 'Shift', Shift)
```

```

SABRModel =
    SABR with properties:

```

```

    Alpha: 0.0135
    Beta: 0.5000

```

```

    Rho: 0.4654
    Nu: 0.4957
    Shift: 0.0080
    VolatilityType: "black"

```

### Create SABR Pricer Using Calibrated SABR Model and Compute Volatilities

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
SABRPricer = finpricer("Analytic", 'Model', SABRModel, 'DiscountCurve', ZeroCurve)
```

```
SABRPricer =
    SABR with properties:
```

```

    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.SABR]

```

```
SABRShiftedBlackVolatilities = volatilities(SABRPricer, SwaptionExerciseDate, ForwardValue, Swap
```

```
SABRShiftedBlackVolatilities = 221x1
```

```

    0.2978
    0.2911
    0.2848
    0.2787
    0.2729
    0.2673
    0.2620
    0.2568
    0.2518
    0.2470
    :

```

```

figure;
plot(MarketStrikes, MarketShiftedBlackVolatilities, 'o', ...
     SwaptionStrikes, SABRShiftedBlackVolatilities);
h = gca;
line([0,0],[min(h.YLim),max(h.YLim)],'LineStyle','--');
ylim([0.13 0.31])
xlabel('Strike');
legend('Market quotes','Shifted SABR', 'location', 'southeast');
title(['Shifted Black Volatility (' ,num2str(Shift*100),' percent shift)']);

```

### Price Swaption Instruments Using Calibrated SABR Model and SABR Pricer

```

% Create swaption instruments
NumInst = length(SwaptionStrikes);
Swaptions(NumInst, 1) = fininstrument("Swaption", ...
    'Strike', SwaptionStrikes(1), 'ExerciseDate', SwaptionExerciseDate(1), 'Swap', Swap);
for k = 1:NumInst
    Swaptions(k) = fininstrument("Swaption", 'Strike', SwaptionStrikes(k), ...
        'ExerciseDate', SwaptionExerciseDate, 'Swap', Swap, 'OptionType', OptSpec);
end
Swaptions

Swaptions=221x1 object
    16x1 Swaption array with properties:

        OptionType
        ExerciseStyle
        ExerciseDate
        Strike
        Swap
        Name
        :

% Price swaptions using the SABR pricer
SwaptionPrices = price(SABRPricer,Swaptions);

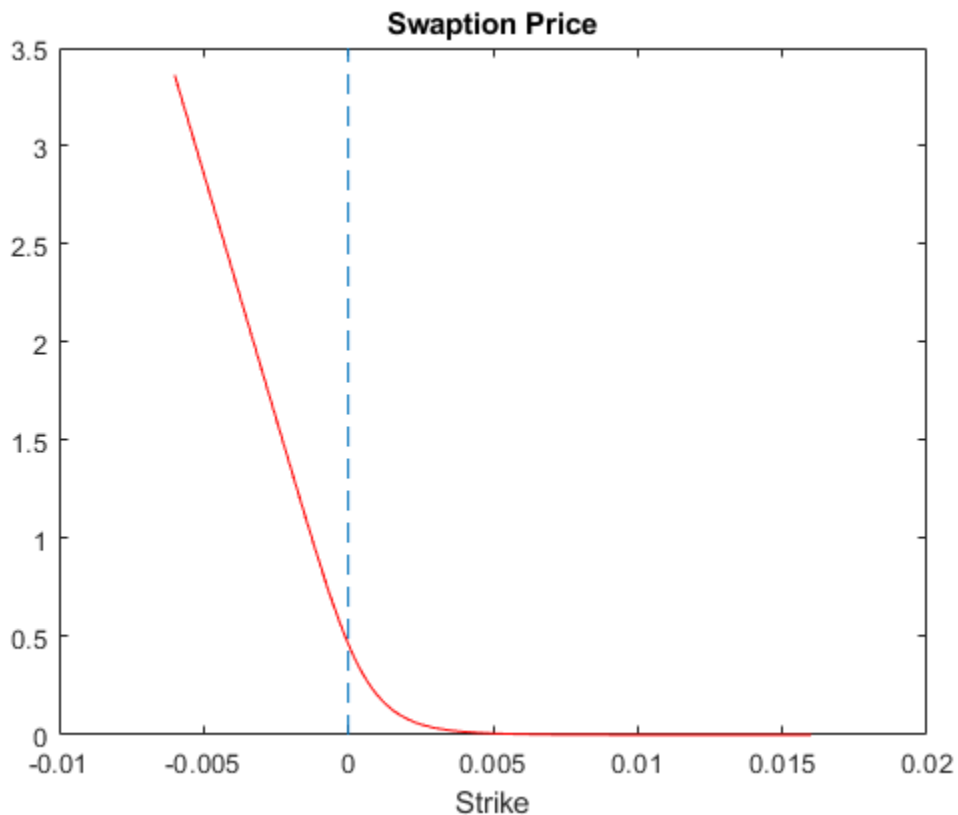

figure;

```

```

plot(SwaptionStrikes, SwaptionPrices, 'r');
h = gca;
line([0,0],[min(h.YLim),max(h.YLim)],'LineStyle','--');
xlabel('Strike');
title('Swaption Price');

```

## More About

### Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

### Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

**Introduced in R2020a**

# Vanilla

Vanilla instrument object

## Description

Create and price a Vanilla instrument object using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a BlackScholes, Heston, Bates, Merton, or Dupire model for the Vanilla instrument.
- 3 Use `finpricer` to specify a FiniteDifference, NumericalIntegration, FFT, BlackScholes, BjerksundStensland, or RollGeskeWhaley pricing method for the Vanilla instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
VanillaObj = fininstrument(InstrumentType, 'Strike', strike_value, '
ExerciseDate', exercise_date)
VanillaObj = fininstrument( ____, Name, Value)
```

### Description

`VanillaObj = fininstrument(InstrumentType, 'Strike', strike_value, 'ExerciseDate', exercise_date)` creates a Vanilla object by specifying `InstrumentType` and sets the properties on page 11-2277 for the required name-value pair arguments `Strike` and `ExerciseDate`. For more information on a Vanilla instrument, see “More About” on page 11-2288.

`VanillaObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2277 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `VanillaObj = fininstrument("Vanilla", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'OptionType', "put", 'ExerciseStyle', "American", 'Name', "vanilla_instrument")` creates a Vanilla put option with an American exercise. You can specify multiple name-value pair arguments.

### Input Arguments

#### **InstrumentType** — Instrument type

string with value "Vanilla" | character vector with value 'Vanilla'

Instrument type, specified as a string with the value of "Vanilla" or a character vector with the value of 'Vanilla'.

Data Types: char | string

### **Vanilla Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: VanillaObj =

```
fininstrument("Vanilla", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'OptionType', "put", 'ExerciseStyle', "American", 'Name', "vanilla_instrument")
```

### **Required Vanilla Name-Value Pair Arguments**

#### **Strike — Option strike price value**

nonnegative numeric

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative numeric value.

Data Types: double

#### **ExerciseDate — Option exercise date**

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For a European option, there is only one ExerciseDate on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

### **Optional Vanilla Name-Value Pair Arguments**

#### **OptionType — Option type**

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

---

**Note** When you use a RollGeskeWhaley pricer with a Vanilla option, OptionType must be 'call'.

---

Data Types: char | string

#### **ExerciseStyle — Option exercise style**

"European" (default) | string with value "European" or "American" | character vector with value 'European' or 'American'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

---

### Note

- When you use a BlackScholes pricer with a Vanilla option, the 'American' option type is not supported.
- When you use a RollGeskeWhaley or a BjerksundStensland pricer with a Vanilla option, you must specify an 'American' option.
- When you use a NumericalIntegration pricer with a Bates, Merton, or Heston model for a Vanilla option, the ExerciseStyle must be 'European'.
- When you use a FFT pricer with a Bates, Merton, or Heston model for a Vanilla option, the ExerciseStyle must be 'European'.

For more information on ExerciseStyle, see “Supported Exercise Styles” on page 1-45.

---

Data Types: string | char

### Name — User-defined name for instrument

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### Strike — Option strike price value

nonnegative numeric

Option strike price value, returned as a scalar nonnegative numeric value.

Data Types: double

### ExerciseDate — Option exercise date

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

### OptionType — Option type

"call" (default) | string with value "call" or "put"

Option type, returned as a string with a value of "call" or "put".

Data Types: string

### ExerciseStyle — Option type

"European" (default) | string with value "European" or "American"

Option exercise style, returned as a string with a value of "European" or "American".

Data Types: string

### **Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## **Examples**

### **Price Vanilla Instrument Using Black-Scholes Model and Black-Scholes Pricer**

This example shows the workflow to price a Vanilla instrument when you use a BlackScholes model and a BlackScholes pricing method.

#### **Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2018,5,1), 'Strike', 29, 'OptionType', 'put')
```

```
VanillaOpt =  
  Vanilla with properties:  
  
      OptionType: "put"  
  ExerciseStyle: "european"  
  ExerciseDate: 01-May-2018  
      Strike: 29  
      Name: "vanilla_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.25)
```

```
BlackScholesModel =  
  BlackScholes with properties:  
  
      Volatility: 0.2500  
      Correlation: 1
```

#### **Create ratecurve Object**

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);  
Maturity = datetime(2019,1,1);  
Rate = 0.05;  
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1)  
  
myRC =  
  ratecurve with properties:
```

```

        Type: "zero"
    Compounding: -1
        Basis: 1
        Dates: 01-Jan-2019
        Rates: 0.0500
        Settle: 01-Jan-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create BlackScholes Pricer Object

Use `finpricer` to create a BlackScholes pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', 30, 'I
```

```

outPricer =
    BlackScholes with properties:

        DiscountCurve: [1x1 ratecurve]
           Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 30
        DividendType: "continuous"
        DividendValue: 0.0450

```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 1.2046
```

```

outPR =
    pricerresult with properties:

```

```

        Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Rho	Theta
1.2046	-0.36943	0.086269	-9.3396	6.4702	-4.0959	-2.3107

### Price American Option for Vanilla Instrument Using Black-Scholes Model and Roll-Geske-Whaley Pricer

This example shows the workflow to price an American option for a Vanilla instrument when you use a BlackScholes model and a RollGeskeWhaley pricing method.

### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'Strike', 105, 'ExerciseDate', datetime(2022, 9, 15), 'OptionType', 'call')
VanillaOpt =
  Vanilla with properties:
      OptionType: "call"
      ExerciseStyle: "american"
      ExerciseDate: 15-Sep-2022
      Strike: 105
      Name: "vanilla_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", "Volatility", 0.2)
BlackScholesModel =
  BlackScholes with properties:
      Volatility: 0.2000
      Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018, 9, 15);
Maturity = datetime(2023, 9, 15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create RollGeskeWhaley Pricer Object

Use `finpricer` to create a RollGeskeWhaley pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', 100,
```

```

outPricer =
  RollGeskeWhaley with properties:

    DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 100
    DividendValue: [1x1 timetable]
    DividendType: "cash"

```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 19.9066
```

```

outPR =
  pricerresult with properties:

    Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
19.907	0.66568	0.0090971	3.344	72.805	-3.4537	186.68

### Price a Vanilla Instrument for Foreign Exchange Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a Vanilla instrument for foreign exchange (FX) when you use a `BlackScholes` model and a `BlackScholes` pricing method. Assume that the current exchange rate is \$0.52 and has a volatility of 12% per annum. The annualized continuously compounded foreign risk-free rate is 8% per annum.

#### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', .50, 'OptionType
```

```

VanillaOpt =
  Vanilla with properties:

    OptionType: "put"
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
    Strike: 0.5000
    Name: "vanilla_fx_option"

```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
Sigma = .12;
BlackScholesModel = finmodel("BlackScholes", "Volatility", Sigma)

BlackScholesModel =
  BlackScholes with properties:

    Volatility: 0.1200
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)

myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 12
    Dates: 15-Sep-2023
    Rates: 0.0350
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create BlackScholes Pricer Object

Use `finpricer` to create a BlackScholes pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument. When pricing currencies using a Vanilla instrument, the `DividendType` must be 'continuous' and `DividendValue` is the annualized risk-free interest rate in the foreign country.

```
ForeignRate = 0.08;
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', .52,

outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 0.5200
    DividendType: "continuous"
    DividendValue: 0.0800
```

## Price Vanilla FX Instrument

Use price to compute the price and sensitivities for the Vanilla FX instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 0.0738
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x7 table]
  PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Rho	Theta
0.073778	-0.49349	2.0818	-4.7899	0.27021	-1.3216	-0.013019

## Price Vanilla Instrument Using Heston Model and Multiple Different Pricers

This example shows the workflow to price a Vanilla instrument when you use a Heston model and various pricing methods.

### Create Vanilla Instrument Object

Use fininstrument to create a Vanilla instrument object.

```
Settle = datetime(2017,6,29);
```

```
Maturity = datemnth(Settle,6);
```

```
Strike = 80;
```

```
VanillaOpt = fininstrument('Vanilla', 'ExerciseDate', Maturity, 'Strike', Strike, 'Name', "vanilla_opt");
```

```
VanillaOpt =
```

```
  Vanilla with properties:
```

```
    OptionType: "call"
  ExerciseStyle: "european"
    ExerciseDate: 29-Dec-2017
        Strike: 80
        Name: "vanilla_option"
```

### Create Heston Model Object

Use finmodel to create a Heston model object.

```
V0 = 0.04;
```

```
ThetaV = 0.05;
```

```
Kappa = 1.0;
```

```
SigmaV = 0.2;
```

```
RhoSV = -0.7;
```

```
HestonModel = finmodel("Heston", 'V0', V0, 'ThetaV', ThetaV, 'Kappa', Kappa, 'SigmaV', SigmaV, 'RhoSV', RhoSV);
HestonModel =
    Heston with properties:
        V0: 0.0400
        ThetaV: 0.0500
        Kappa: 1
        SigmaV: 0.2000
        RhoSV: -0.7000
```

### Create ratecurve object

Create a ratecurve object using ratecurve.

```
Rate = 0.03;
ZeroCurve = ratecurve('zero', Settle, Maturity, Rate);
```

### Create NumericalIntegration, FFT, and FiniteDifference Pricer Objects

Use finpricer to create a NumericalIntegration, FFT, and FiniteDifference pricer objects and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
SpotPrice = 80;
Strike = 80;
DividendYield = 0.02;
```

```
NIPricer = finpricer("NumericalIntegration", 'Model', HestonModel, 'SpotPrice', SpotPrice, 'DiscountCurve', ZeroCurve, 'DividendYield', DividendYield, 'DividendValue', DividendValue, 'NumFFT', 8192);
```

```
NIPricer =
    NumericalIntegration with properties:
        Model: [1x1 finmodel.Heston]
        DiscountCurve: [1x1 ratecurve]
        SpotPrice: 80
        DividendType: "continuous"
        DividendValue: 0.0200
        AbsTol: 1.0000e-10
        RelTol: 1.0000e-10
        IntegrationRange: [1.0000e-09 Inf]
        CharacteristicFcn: @characteristicFcnHeston
        Framework: "heston1993"
        VolRiskPremium: 0
        LittleTrap: 1
```

```
FFTPricer = finpricer("FFT", 'Model', HestonModel, 'SpotPrice', SpotPrice, 'DiscountCurve', ZeroCurve, 'DividendYield', DividendYield, 'DividendValue', DividendValue, 'NumFFT', 8192);
```

```
FFTPricer =
    FFT with properties:
        Model: [1x1 finmodel.Heston]
        DiscountCurve: [1x1 ratecurve]
        SpotPrice: 80
        DividendType: "continuous"
```

```

        DividendValue: 0.0200
            NumFFT: 8192
CharacteristicFcnStep: 0.0100
    LogStrikeStep: 0.0767
CharacteristicFcn: @characteristicFcnHeston
    DampingFactor: 1.5000
        Quadrature: "simpson"
VolRiskPremium: 0
    LittleTrap: 1

```

```
FDPricer = finpricer("FiniteDifference", 'Model', HestonModel, 'SpotPrice', SpotPrice, 'DiscountCurve
```

```

FDPricer =
    FiniteDifference with properties:

        DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.Heston]
        SpotPrice: 80
    GridProperties: [1x1 struct]
        DividendType: "continuous"
        DividendValue: 0.0200

```

### Price Vanilla Instrument

Use the following sensitivities when pricing the Vanilla instrument.

```
InpSensitivity = ["delta", "gamma", "theta", "rho", "vega", "vegalt"];
```

Use price to compute the price and sensitivities for the Vanilla instrument that uses the NumericalIntegration pricer.

```
[PriceNI, outPR_NI] = price(NIPricer, VanillaOpt, InpSensitivity)
```

```
PriceNI = 4.7007
```

```

outPR_NI =
    pricerresult with properties:

        Results: [1x7 table]
        PricerData: []

```

Use price to compute the price and sensitivities for the Vanilla instrument that uses the FFT pricer.

```
[PriceFFT, outPR_FFT] = price(FFTPricer, VanillaOpt, InpSensitivity)
```

```
PriceFFT = 4.7007
```

```

outPR_FFT =
    pricerresult with properties:

        Results: [1x7 table]
        PricerData: []

```

Use price to compute the price and sensitivities for the Vanilla instrument that uses the FiniteDifference pricer.

```
[PriceFD, outPR_FD] = price(FDPricer, VanillaOpt, InpSensitivity)
```

```
PriceFD = 4.7003
```

```
outPR_FD =
  pricerresult with properties:
```

```
    Results: [1x7 table]
  PricerData: [1x1 struct]
```

Aggregate the price results.

```
[outPR_NI.Results; outPR_FFT.Results; outPR_FD.Results]
```

```
ans=3x7 table
```

Price	Delta	Gamma	Theta	Rho	Vega	VegaLT
4.7007	0.57747	0.03392	-4.8474	20.805	17.028	5.2394
4.7007	0.57747	0.03392	-4.8474	20.805	17.028	5.2394
4.7003	0.57722	0.035254	-4.8483	20.801	17.046	5.2422

### Compute Option Price Surfaces

Use the price function for the NumericalIntegration pricer and the price function for the FFT pricer to compute the prices for a range of Vanilla instruments.

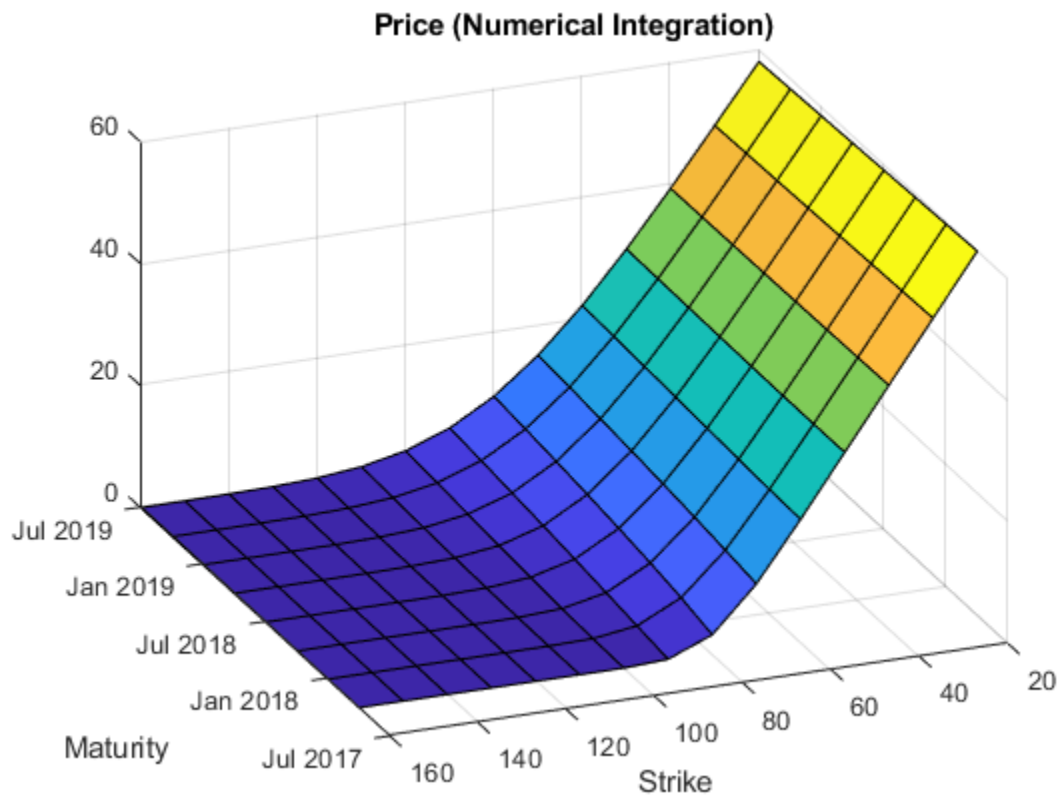

```
Maturities = datemnth(Settle, (3:3:24)');
NumMaturities = length(Maturities);
Strikes = (20:10:160)';
NumStrikes = length(Strikes);

[Maturities_Full, Strikes_Full] = meshgrid(Maturities, Strikes);

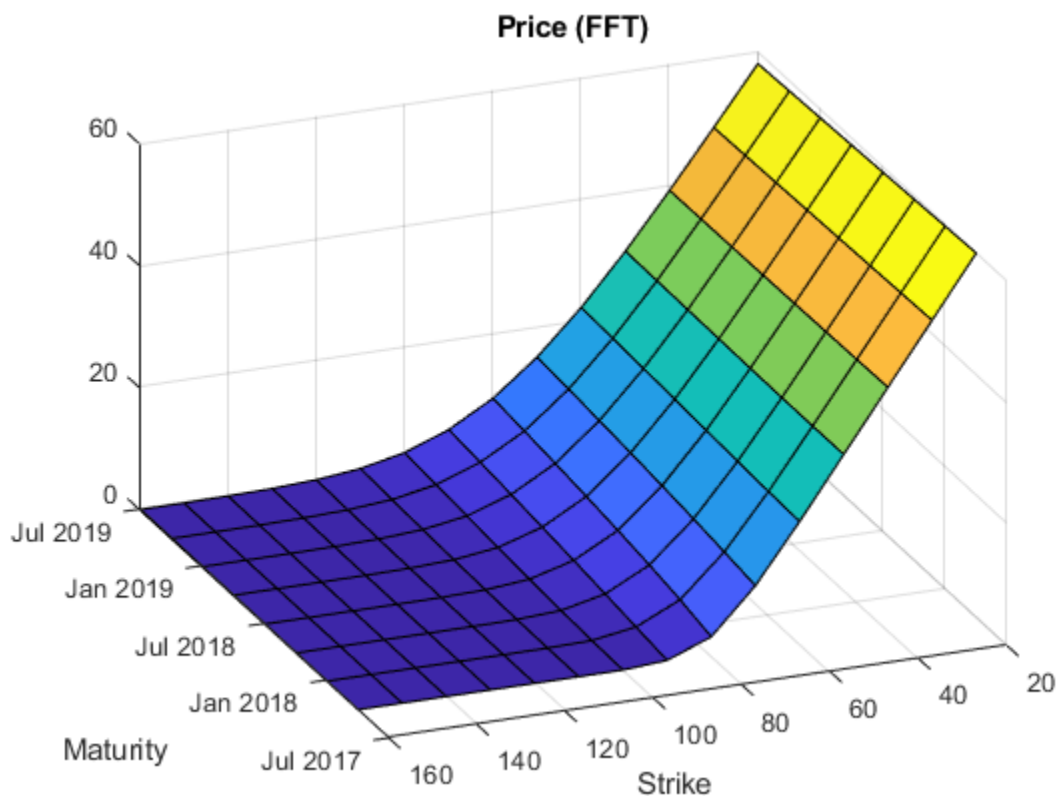

NumInst = numel(Strikes_Full);
VanillaOptions(NumInst, 1) = fininstrument("vanilla", ...
    "ExerciseDate", Maturities_Full(1), "Strike", Strikes_Full(1));
for instidx=1:NumInst
    VanillaOptions(instidx) = fininstrument("vanilla", ...
        "ExerciseDate", Maturities_Full(instidx), "Strike", Strikes_Full(instidx));
end

Prices_NI = price(NIPricer, VanillaOptions);
Prices_FFT = price(FFTPricer, VanillaOptions);

figure;
surf(Maturities_Full, Strikes_Full, reshape(Prices_NI, [NumStrikes, NumMaturities]));
title('Price (Numerical Integration)');
view(-112, 34);
xlabel('Maturity')
ylabel('Strike')
```

```
figure;  
surf(Maturities_Full, Strikes_Full, reshape(Prices_FFT, [NumStrikes, NumMaturities]));  
title('Price (FFT)');  
view(-112, 34);  
xlabel('Maturity');  
ylabel('Strike');
```

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see "Vanilla Option" on page 3-26.

## Tips

After creating an `Vanilla` instrument object with an "American" `ExerciseStyle`, you can modify the `ExerciseStyle` property to change it to "European" using dot notation.

```
Vanilla.ExerciseStyle = "European"
```

Because a European option has a scalar `Strike` and `ExerciseDate` value and an American option has a 2-element vector for `Strike` and `ExerciseDate` values, when you change to `ExerciseStyle` from "American" to "European", the `Strike` and `ExerciseDate` values become the last element in the 2-element vector for `Strike` and `ExerciseDate` values.

### Introduced in R2020a

# Deposit

Deposit instrument object

## Description

Create and price a `Deposit` instrument object using this workflow:

- 1 Use `fininstrument` to create a `Deposit` instrument object.
- 2 Use `ratecurve` to specify an interest-rate model for the `Deposit` instrument.
- 3 Use `finpricer` to specify a `Discount` pricing method for the `Deposit` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Deposit` instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
DepositObj = fininstrument(InstrumentType, 'Maturity', maturity_date, '
Rate', rate_value)
DepositObj = fininstrument( ____, Name, Value)
```

### Description

`DepositObj = fininstrument(InstrumentType, 'Maturity', maturity_date, 'Rate', rate_value)` creates a `Deposit` object by specifying `InstrumentType` and sets the properties on page 11-2293 for the required name-value pair arguments `Maturity` and `Rate`.

`DepositObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2293 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `DepositObj = fininstrument("Deposit", 'Maturity', datetime(2019,1,30), 'Rate', 0.027, 'Period', 2, 'Basis', 1, 'Principal', 100, 'BusinessDayConvention', "follow", 'Name', "deposit_instrument")` creates a `Deposit` instrument with an interest rate of .027 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Deposit" | character vector with value 'Deposit'

Instrument type, specified as a string with the value of "Deposit" or a character vector with the value of 'Deposit'.

Data Types: char | string

### Deposit Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: DepositObj =
fininstrument("Deposit", 'Maturity', datetime(2019,1,30), 'Rate', 0.027, 'Period',
2, 'Basis', 1, 'Principal', 100, 'BusinessDayConvention', "follow", 'Name', "deposit_
instrument")
```

### Required Deposit Name-Value Pair Arguments

#### Maturity — Maturity date

`datetime` | serial date number | date character vector | date string

Maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a `datetime`, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a `datetime`.

Data Types: `char` | `double` | `string` | `datetime`

#### Rate — Deposit interest rate

decimal

Deposit interest rate, specified as the comma-separated pair consisting of `'Rate'` and a scalar decimal.

Data Types: `double`

### Optional Deposit Name-Value Pair Arguments

#### Period — Frequency of payments per year

1 (default) | numeric value of 0, 1, 2, 3, 4, 6, or 12

Frequency of payments per year, specified as the comma-separated pair consisting of `'Period'` and scalar integer. Values for `Period` are: 0, 1, 2, 3, 4, 6, or 12.

Data Types: `double`

#### Basis — Day count basis

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer using one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)

- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

### **Principal — Principal amount**

100 (default) | `numeric`

Principal amount, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric.

Data Types: `double`

### **BusinessDayConvention — Business day convention**

"actual" (default) | `string` | `character vector`

Business day convention, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a string or character vector. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `string`

### **Holidays — Holidays used in computing business days**

NaT (default) | `datetime` | `cell array of character vectors` | `date string array` | `serial date numbers`

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));  
DepositObj = fininstrument("deposit", 'Maturity', datetime(2025,12,15), 'Rate', 0.027, 'Holidays', H)
```

Data Types: double | cell | datetime | string

### **Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## **Properties**

### **Maturity — Maturity date**

datetime

Maturity date, returned as a datetime.

Data Types: datetime

### **Rate — Deposit interest rate**

decimal

Deposit interest rate, returned as a scalar decimal.

Data Types: double

### **Period — Frequency of payments per year**

1 (default) | integer

Frequency of payments per year, returned as a scalar integer.

Data Types: double

### **Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as a scalar integer.

Data Types: double

### **Principal — Principal amount**

100 (default) | numeric

Principal amount, returned as a scalar numeric.

Data Types: double

### **BusinessDayConvention — Business day convention**

"actual" (default) | string

Business day convention, returned as a string.

Data Types: string

### **Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Object Functions

cashflows Computes cash flow for FixedBond, FloatBond, Swap, FRA, Swap, or Deposit instrument

## Examples

### Price Deposit Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a Deposit instrument when using a ratecurve and a Discount pricing method.

#### Create Deposit Instrument Object

Use `fininstrument` to create a Deposit instrument object.

```
DepositObj = fininstrument("Deposit", 'Maturity', datetime(2019,3,15), 'Rate', 0.0195, 'Period', 2, 'Ba
```

```
DepositObj =
```

```
Deposit with properties:
```

```

        Rate: 0.0195
        Period: 2
        Basis: 1
        Maturity: 15-Mar-2019
        Principal: 100
        BusinessDayConvention: "actual"
        Holidays: NaT
        Name: "deposit_instrument"

```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
```

```
Type = 'zero';
```

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
```

```
ratecurve with properties:
```

```
    Type: "zero"
```

```

    Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
    InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"

```

## Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```

outPricer =
  Discount with properties:
    DiscountCurve: [1x1 ratecurve]

```

## Price Deposit Instrument

Use `price` to compute the price and sensitivities for the Deposit instrument.

```
[Price, outPR] = price(outPricer, DepositObj,["all"])
```

```
Price = 0.9725
```

```

outPR =
  pricerresult with properties:

```

```

    Results: [1x2 table]
  PricerData: []

```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
0.97249	4.8225e-05

## More About

### Deposit Instrument

A deposit instrument is an over-the-counter contract between banks for interbank lending.

# Bates

Create Bates model object for Vanilla instrument

## Description

Create and price a Vanilla instrument object with a Bates model using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a Bates model object for the Vanilla instrument.
- 3 Use `finpricer` to specify a FiniteDifference, NumericalIntegration, or FFT pricing method for the Vanilla instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
BatesObj = finmodel(ModelType,'V0',V0_value,'ThetaV',thetav_value,'
Kappa',kappa_value,'SigmaV',sigmav_value,'RhoSV',rhosv_value,'
MeanJ',meanj_value,'JumpVol',jumpvol_value,'JumpFreq',jumpfreq_value)
```

### Description

`BatesObj = finmodel(ModelType,'V0',V0_value,'ThetaV',thetav_value,'Kappa',kappa_value,'SigmaV',sigmav_value,'RhoSV',rhosv_value,'MeanJ',meanj_value,'JumpVol',jumpvol_value,'JumpFreq',jumpfreq_value)` creates an Bates object by specifying `ModelType` and the required name-value pair arguments `V0`, `ThetaV`, `Kappa`, `SigmaV`, `RhoSV`, `MeanJ`, `JumpVol`, and `JumpFreq`. The required name-value pair arguments set properties on page 11-2299. For example, `BatesObj = finmodel("Bates",'V0',0.032,'ThetaV',0.1,'Kappa',0.003,'SigmaV',0.2,'RhoSV',0.9,'MeanJ',0.11,'JumpVol',.023,'JumpFreq',0.02)` creates a Bates model object.

### Input Arguments

#### ModelType — Model type

string with value "Bates" | character vector with value 'Bates'

Model type, specified as a string with the value of "Bates" or a character vector with the value of 'Bates'.

Data Types: char | string

**Bates Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: Bates =  
finmodel("Bates", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0  
.9, 'MeanJ', 0.11, 'JumpVol', .023, 'JumpFreq', 0.02)
```

**V0 — Initial variance of underlying asset**

numeric

Initial variance of the underlying asset, specified as the comma-separated pair consisting of 'V0' and a scalar numeric value.

Data Types: double

**ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underlying asset, specified as the comma-separated pair consisting of 'ThetaV' and a scalar numeric value.

Data Types: double

**Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, specified as the comma-separated pair consisting of 'Kappa' and a scalar numeric value.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, specified as the comma-separated pair consisting of 'SigmaV' and a scalar numeric value.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as the comma-separated pair consisting of 'RhoSV' and a scalar numeric value.

Data Types: double

**MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), specified as the comma-separated pair consisting of 'MeanJ' and a scalar decimal value where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$** 

decimal

Standard deviation of  $\log(1+J)$ , where  $J$  is the random percentage jump size, specified as the comma-separated pair consisting of 'JumpVol' and a scalar decimal value.

Data Types: double

**JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of the Poisson jump process, specified as the comma-separated pair consisting of 'JumpFreq' and a scalar numeric value.

Data Types: double

**Properties****V0 — Initial variance of underlying asset**

numeric

Initial variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

**ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

**Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, returned as a scalar numeric value.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

**RhoSV — Correlation between Wiener processes for underlying asset and its variance**

numeric

Correlation between the Wiener processes for the underlying asset and its variance, returned as a scalar numeric value.

Data Types: double

**MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), returned as a scalar decimal value.

Data Types: double

### JumpVol — Standard deviation of $\log(1+J)$

decimal

Standard deviation of  $\log(1+J)$ , where J is the random percentage jump size, returned as a scalar decimal value.

Data Types: double

### JumpFreq — Annual frequency of Poisson jump process

numeric

Annual frequency of the Poisson jump process, returned as a scalar numeric value.

Data Types: double

## Examples

### Use a Bates Model and Numerical Integration Pricer to Price Vanilla Instrument

This example shows the workflow to price a Vanilla instrument when you use a Bates model and a NumericalIntegration pricing method.

#### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType
```

```
VanillaOpt =
```

```
  Vanilla with properties:
```

```
      OptionType: "put"
      ExerciseStyle: "european"
      ExerciseDate: 15-Sep-2022
      Strike: 105
      Name: "vanilla_option"
```

#### Create Bates Model Object

Use `finmodel` to create a Bates model object.

```
BatesModel = finmodel("Bates", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9, 'Mea
```

```
BatesModel =
```

```
  Bates with properties:
```

```
      V0: 0.0320
      ThetaV: 0.1000
      Kappa: 0.0030
      SigmaV: 0.2000
      RhoSV: 0.9000
      MeanJ: 0.1100
      JumpVol: 0.0230
```

```
JumpFreq: 0.0200
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create NumericalIntegration Pricer Object

Use finpricer to create a NumericalIntegration pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("numericalintegration",'DiscountCurve',myRC,'Model',BatesModel,'SpotPrice')
```

```
outPricer =
  NumericalIntegration with properties:
      Model: [1x1 finmodel.Bates]
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 100
      DividendType: "continuous"
      DividendValue: 0
      AbsTol: 1.0000e-10
      RelTol: 1.0000e-10
      IntegrationRange: [1.0000e-09 Inf]
      CharacteristicFcn: @characteristicFcnBates
      Framework: "heston1993"
      VolRiskPremium: 0
      LittleTrap: 1
```

### Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 6.4007
```

```
outPR =
  pricerresult with properties:
```

```
Results: [1x7 table]
PricerData: []
```

outPR.Results

ans=1x7 table

Price	Delta	Gamma	Theta	Rho	Vega	VegaLT
6.4007	-0.53541	0.02006	1.106	-239.77	94.257	1.3059

# Black

Create Black model object for Cap, Floor, or Swaption instrument

## Description

Create and price a Cap, Floor, or Swaption instrument object with a Black model using this workflow:

- 1 Use `fininstrument` to create a Cap, Floor, or Swaption instrument object.
- 2 Use `finmodel` to specify a Black model object for the Cap, Floor, or Swaption instrument.
- 3 Use `finpricer` to specify a Black pricing method for the Cap, Floor, or Swaption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Cap, Floor, or Swaption instrument when using a Black model, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
BlackModelObj = finmodel(ModelType,'Volatility',volatility_value)
BlackModelObj = finmodel( ___,Name,Value)
```

### Description

`BlackModelObj = finmodel(ModelType,'Volatility',volatility_value)` creates a Black model object by specifying `ModelType` and sets the properties on page 11-2304 for the required name-value pair argument `Volatility`. For more information on a Black model, see “More About” on page 11-2306 and “Algorithms” on page 11-2306.

`BlackModelObj = finmodel( ___,Name,Value)` sets optional properties on page 11-2304 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BlackModelObj = finmodel("Black",'Volatility',0.032,'Shift',0.002)` creates a Black model object. You can specify multiple name-value pair arguments.

### Input Arguments

#### ModelType — Model type

string with value "Black" | character vector with value 'Black'

Model type, specified as a string with the value of "Black" or a character vector with the value of 'Black'.

Data Types: char | string

### Black Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `BlackModelObj = finmodel("Black", 'Volatility', 0.032, 'Shift', 0.002)`

### Required Black Name-Value Pair Arguments

#### **Volatility – Volatility value for the underlying asset**

nonnegative numeric

Volatility value for the underlying asset, specified as the comma-separated pair consisting of `'Volatility'` and a scalar nonnegative numeric.

Data Types: `double`

### Optional Black Name-Value Pair Argument

#### **Shift – Shift in decimals for shifted Black model**

0 (no shift) (default) | positive decimal

Shift in decimals for the shifted Black model, specified as the comma-separated pair consisting of `'Shift'` and a scalar rate shift in positive decimals. Set this parameter to a positive rate shift in decimals to add a positive shift to the forward rate and strike, which effectively sets a negative lower bound for the forward rate. For example, a `Shift` value of `0.01` is equal to a 1% shift.

Data Types: `double`

## Properties

#### **Volatility – Volatility value**

nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: `double`

#### **Shift – Shift in decimals for shifted Black model**

0 (no shift) (default) | positive decimal

Shift in decimals for the shifted Black model, returned as a scalar rate shift in a positive decimal.

Data Types: `double`

## Examples

### **Use Black Model and Black Pricer to Price Cap Instrument**

This example shows the workflow to price a Cap instrument when you use a Black model and a Black pricing method.

#### **Create Cap Instrument Object**

Use `fininstrument` to create a Cap instrument object.

```
CapOpt = fininstrument("Cap", 'Strike', .001, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Principal', ...)
```

```
CapOpt =
  Cap with properties:
      Strike: 1.0000e-03
      Maturity: 30-Jan-2019
      ResetOffset: 0
      Reset: 4
      Basis: 8
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "cap_option"
```

### Create Black Model Object

Use `finmodel` to create a Black model object.

```
BlackModel = finmodel("Black", 'Volatility', 0.032, 'Shift', 0.002)
```

```
BlackModel =
  Black with properties:
      Volatility: 0.0320
      Shift: 0.0020
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create Black Pricer Object

Use `finpricer` to create a Black pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackModel, 'DiscountCurve', myRC)

outPricer =
    Black with properties:
        Model: [1x1 finmodel.Black]
        DiscountCurve: [1x1 ratecurve]
```

### Price Cap Instrument

Use `price` to compute the price for the Cap instrument.

```
Price = price(outPricer, CapOpt)

Price = 0.1575
```

## More About

### Shifted Black Model

The shifted Black model is the same as the Black model, except that it models the movements of ( $F + \text{Shift}$ ) as the underlying asset, instead of  $F$  (which is the forward rate in the case of caplets).

This model allows negative rates, with a fixed negative lower bound defined by the amount of shift; that is, the zero lower bound of the Black model is shifted.

## Algorithms

### Black Model

$$dF = \sigma_{Black} F dw$$

$$call = e^{-vT} [FN(d_1) - KN(d_2)]$$

$$put = e^{-vT} [KN(-d_2) - FN(-d_1)]$$

$$d_1 = \frac{\ln\left(\frac{F}{K}\right) + \left(\frac{\sigma_B^2}{2}\right)T}{\sigma_B \sqrt{T}}, \quad d_2 = d_1 - \sigma_B \sqrt{T}$$

$$\sigma_B = \sigma_{Black}$$

Here,  $F$  is the forward value and  $K$  is the strike.

**Shifted Black Model**

$$dF = \sigma_{\text{Shifted\_Black}}(F + \text{Shift})dw$$

$$\text{call} = e^{-\nu T}[(F + \text{Shift})N(d_{s1}) - (K + \text{Shift})N(d_{s2})]$$

$$\text{put} = e^{-\nu T}[(K + \text{Shift})N(-d_{s2}) - (F + \text{Shift})N(-d_{s1})]$$

$$d_{s1} = \frac{\ln\left(\frac{F + \text{Shift}}{K + \text{Shift}}\right) + \left(\frac{\sigma_{sB}^2}{2}\right)T}{\sigma_{sB}\sqrt{T}}, \quad d_{s2} = d_{s1} - \sigma_{sB}\sqrt{T}$$

$$\sigma_{sB} = \sigma_{\text{Shifted\_Black}}$$

Here,  $F + \text{Shift}$  is the forward value and  $K + \text{Shift}$  is the strike for the shifted version.

# CDSBlack

Create CDSBlack model object for CDSOption instrument

## Description

Create and price a CDSOption instrument object with a CDSBlack model using this workflow:

- 1 Use `fininstrument` to create a CDSOption instrument object.
- 2 Use `finmodel` to specify a CDSBlack model object for the CDSOption instrument.
- 3 Use `finpricer` to specify a CDSBlack pricing method for the CDSOption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a CDSOption instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
CDSBlackModelObj = finmodel(ModelType, 'SpreadVolatility', spreadvolatility_value)
```

### Description

`CDSBlackModelObj = finmodel(ModelType, 'SpreadVolatility', spreadvolatility_value)` creates a CDSBlack model object by specifying `ModelType` and the required name-value pair argument `SpreadVolatility` to set the properties on page 11-2309 using name-value pair arguments. For example, `CDSBlackModelObj = finmodel("CDSBlack", 'SpreadVolatility', 0.052)` creates a CDSBlack model object.

### Input Arguments

#### ModelType — Model type

string with value "CDSBlack" | character vector with value 'CDSBlack'

Model type, specified as a string with the value of "CDSBlack" or a character vector with the value of 'CDSBlack'.

Data Types: char | string

#### CDSBlack Name-Value Pair Arguments

Specify required comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `CDSBlackModelObj = finmodel("CDSBlack", 'SpreadVolatility', 0.052)`

**SpreadVolatility — Spread volatility value**

nonnegative numeric

Spread volatility value, specified as the comma-separated pair consisting of 'SpreadVolatility' and a scalar nonnegative numeric.

Data Types: double

**Properties****SpreadVolatility — Spread volatility value**

nonnegative numeric

Spread volatility value, returned as a scalar nonnegative numeric.

Data Types: double

**Examples****Use CDS Black Model and CDS Black Pricer to Price CDSOption Instrument**

This example shows the workflow to price a CDSOption instrument when you use a CDSBlack model and a CDSBlack pricing method.

**Create CDS Instrument Object**

Use `fininstrument` to create a CDS instrument object as the underlying instrument.

```
CDS = fininstrument("CDS", 'Maturity', datetime(2021,9,15), 'ContractSpread', 150, 'Notional', 100, 'Name', 'CDS')
```

```
CDS =
```

```
  CDS with properties:
```

```
      ContractSpread: 150
      Maturity: 15-Sep-2021
      Period: 4
      Basis: 2
      RecoveryRate: 0.4000
      BusinessDayConvention: "actual"
      Holidays: NaT
      PayAccruedPremium: 1
      Notional: 100
      Name: "CDS_instrument"
```

**Create defprobcurve Object**

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities, 'Basis', 5)
```

```
DefaultProbCurve =
```

```
  defprobcurve with properties:
```

```
Settle: 20-Sep-2020
Basis: 5
Dates: [10x1 datetime]
DefaultProbabilities: [10x1 double]
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 15-Sep-2020
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create CDSOption Instrument Object

Use `fininstrument` to create a CDSOption instrument object.

```
CDSOptionInst = fininstrument("CDSOption", 'ExerciseDate', datetime(2021,8,15), 'Strike', 20, 'CDS', CDS)
```

```
CDSOptionInst =
  CDSOption with properties:
    OptionType: "put"
    Strike: 20
    Knockout: 0
    ExerciseDate: 15-Aug-2021
    CDS: [1x1 fininstrument.CDS]
    Name: "CDSOption_option"
```

### Create CDSBlack Model Object

Use `finmodel` to create a CDSBlack model object.

```
CDSBlackModel = finmodel("CDSBlack", 'SpreadVolatility', .2)
```

```
CDSBlackModel =
  CDSBlack with properties:
    SpreadVolatility: 0.2000
```

## Create CDSBlack Pricer Object

Use `finpricer` to create a CDSBlack pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', CDSBlackModel, 'DefaultProbabilityCurve', DefaultProbCurve)
outPricer =
    CDSBlack with properties:
        Model: [1x1 finmodel.CDSBlack]
        DiscountCurve: [1x1 ratecurve]
        DefaultProbabilityCurve: [1x1 defprobcurve]
```

## Price CDSOption Instrument

Use `price` to compute the price for the CDSOption instrument.

```
Price = price(outPricer, CDSOptionInst)
```

```
Price = 3.3016e-04
```

# BlackScholes

Create BlackScholes model object for an Asian, Barrier, Lookback, Spread, or Vanilla instrument

## Description

Create and price a Vanilla, Lookback, Barrier, Asian, or Spread instrument object with a BlackScholes model using this workflow:

- 1 Use `fininstrument` to create a Vanilla, Lookback, Barrier, Asian, or Spread instrument object.
- 2 Use `finmodel` to specify the BlackScholes model object for a Vanilla, Lookback, Barrier, Asian, or Spread instrument.
- 3 Use `finpricer` to specify a supported pricing method. For more information on the available pricing methods for the Vanilla, Lookback, Barrier, Asian, or Spread instrument when using a BlackScholes model, see “Choose Instruments, Models, and Pricers” on page 1-42.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla, Lookback, Barrier, Asian, or Spread instrument when using a BlackScholes model, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
BlackScholesModelObj = finmodel(ModelType, 'Volatility', volatility_value)
BlackScholesModelObj = finmodel( ___, Name, Value)
```

### Description

`BlackScholesModelObj = finmodel(ModelType, 'Volatility', volatility_value)` creates a BlackScholes model object by specifying `ModelType` and sets the properties on page 11-2313 for the required name-value pair argument `Volatility`.

`BlackScholesModelObj = finmodel( ___, Name, Value)` sets optional properties on page 11-2313 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BlackScholesModelObj = finmodel("BlackScholes", 'Volatility', 0.032)` creates a BlackScholes model object. You can specify multiple name-value pair arguments.

### Input Arguments

#### ModelType — Model type

string with value "BlackScholes" | character vector with value 'BlackScholes'

Model type, specified as a string with the value of "BlackScholes" or a character vector with the value of 'BlackScholes'.

Data Types: char | string

### BlackScholes Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `BlackScholesModelObj = finmodel("BlackScholes", 'Volatility', 0.032)`

### Required BlackScholes Name-Value Pair Arguments

#### Volatility — Volatility value

nonnegative numeric

Volatility value, specified as the comma-separated pair consisting of 'Volatility' and a scalar nonnegative numeric.

Data Types: double

### Optional BlackScholes Name-Value Pair Arguments

#### Corr — Correlation between underlying asset prices

numeric

Correlation between the underlying asset prices, specified as the comma-separated pair consisting of 'Corr' and a scalar numeric.

Data Types: double

## Properties

#### Volatility — Volatility value

nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: double

#### Corr — Correlation between underlying asset prices

numeric

Correlation between underlying asset prices, returned as a scalar numeric.

Data Types: double

## Examples

### Use Black-Scholes Model and Turnbull-Wakeman Pricer to Price Asian Instrument

This example shows the workflow to price an Asian instrument when you use a BlackScholes model and a TurnbullWakeman pricing method.

### Create Asian Instrument Object

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType', "put")
```

```
AsianOpt =  
Asian with properties:  
  
    OptionType: "put"  
        Strike: 105  
    AverageType: "arithmetic"  
    AveragePrice: 0  
    AverageStartDate: NaT  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Sep-2022  
        Name: "asian_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.28)
```

```
BlackScholesModel =  
BlackScholes with properties:  
  
    Volatility: 0.2800  
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =  
ratecurve with properties:  
  
    Type: "zero"  
    Compounding: -1  
    Basis: 12  
    Dates: 15-Sep-2023  
    Rates: 0.0350  
    Settle: 15-Sep-2018  
    InterpMethod: "linear"  
    ShortExtrapMethod: "next"  
    LongExtrapMethod: "previous"
```

### Create TurnbullWakeman Pricer Object

Use `finpricer` to create a TurnbullWakeman pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', 100,
outPricer =
  TurnbullWakeman with properties:
    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 100
    DividendValue: 0
    DividendType: "continuous"

```

## Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer, AsianOpt, ["all"])
```

```
Price = 11.2249
```

```
outPR =
  pricerresult with properties:
```

```

    Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
11.225	-0.38072	0.01087	-3.3917	44.242	-0.5256	-116.88

## BlackKarasinski

Create BlackKarasinski model object for a FloatBond, FixedBond, FixedBondOption, or OptionEmbeddedFixedBond instrument

### Description

Create and price a FloatBond, FixedBond, FixedBondOption, or OptionEmbeddedFixedBond instrument object with a BlackKarasinski model using this workflow:

- 1 Use `fininstrument` to create a FloatBond, FixedBond, FixedBondOption, or OptionEmbeddedFixedBond instrument object.
- 2 Use `finmodel` to specify a BlackKarasinski model object for the FixedBond, FloatBond, FixedBondOption, or OptionEmbeddedFixedBond instrument.
- 3 Use `finpricer` to specify a IRTree pricing method for the FixedBond, FloatBond, FixedBondOption or OptionEmbeddedFixedBond instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a FixedBond, FloatBond, FixedBondOption, or OptionEmbeddedFixedBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
BlackKarasinskiModelObj = finmodel(ModelType, 'Alpha', alpha_value, 'Sigma', sigma_value)
```

#### Description

`BlackKarasinskiModelObj = finmodel(ModelType, 'Alpha', alpha_value, 'Sigma', sigma_value)` creates a BlackKarasinski model object by specifying `ModelType` and the required name-value pair arguments `Alpha` and `Sigma` to set properties on page 11-2317 using required name-value pair arguments. For example, `BlackKarasinskiModelObj = finmodel("BlackKarasinski", 'Alpha', 0.052, 'Sigma', 0.34)` creates a BlackKarasinski model object.

#### Input Arguments

##### ModelType — Model type

string with value "BlackKarasinski" | character vector with value 'BlackKarasinski'

Model type, specified as a string with the value of "BlackKarasinski" or a character vector with the value of 'BlackKarasinski'.

Data Types: char | string

### BlackKarasinski Name-Value Pair Arguments

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: BlackKarasinskiModelObj =
finmodel("BlackKarasinski", 'Alpha', 0.052, 'Sigma', 0.34)
```

#### Alpha — Mean reversion speed

numeric | timetable

Mean reversion speed, specified as the comma-separated pair consisting of 'Alpha' and a scalar numeric value or timetable.

Alpha accepts a `timetable`, where the first column is dates and the second column is the associated Alpha value.

Data Types: double | timetable

#### Sigma — Volatility

numeric | timetable

Volatility, specified as the comma-separated pair consisting of 'Sigma' and a scalar numeric value or timetable.

Sigma accepts a `timetable`, where the first column is dates and the second column is the associated Sigma value.

Data Types: double | timetable

## Properties

#### Alpha — Mean reversion speed

numeric

Mean reversion speed, returned as a scalar numeric value or timetable.

Data Types: double | timetable

#### Sigma — Volatility

numeric

Volatility, returned as a scalar numeric value or timetable.

Data Types: double | timetable

## Examples

### Use Black-Karasinski Model and Black-Karasinski Tree Pricer to Price FixedBondOption Instrument

This example shows the workflow to price a `FixedBondOption` instrument when you use a `BlackKarasinski` model and an `IRTree` pricing method.

### Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond", 'Maturity', datetime(2029,9,15), 'CouponRate', .024, 'Principal', 100)
```

```
BondInst =
    FixedBond with properties:
        CouponRate: 0.0240
        Period: 1
        Basis: 1
        EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
        Maturity: 15-Sep-2029
        Name: "fixed_bond"
```

### Create FixedBondOption Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object.

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 800, 'Bond', BondInst)
```

```
FixedBOption =
    FixedBondOption with properties:
        OptionType: "put"
        ExerciseStyle: "american"
        ExerciseDate: 15-Sep-2025
        Strike: 800
        Bond: [1x1 fininstrument.FixedBond]
        Name: "fixed_bond_option"
```

### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates, 'Basis', 5)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
```

```

        Basis: 5
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2019
    InterpMethod: "linear"
ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create BlackKarasinski Model Object

Use `finmodel` to create a BlackKarasinski model object.

```
BlackKarasinskiModel = finmodel("BlackKarasinski", 'Alpha', 0.02, 'Sigma', 0.34)
```

```
BlackKarasinskiModel =
    BlackKarasinski with properties:

```

```

    Alpha: 0.0200
    Sigma: 0.3400

```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
BKTreePricer = finpricer("IRTree", 'Model', BlackKarasinskiModel, 'DiscountCurve', myRC, 'TreeDates', ...)
```

```
BKTreePricer =
    HWBKTree with properties:

```

```

        Tree: [1x1 struct]
    TreeDates: [10x1 datetime]
        Model: [1x1 finmodel.BlackKarasinski]
    DiscountCurve: [1x1 ratecurve]

```

`BKTreePricer.Tree`

```
ans = struct with fields:
    FinObj: 'BKFwdTree'
    tObs: [0 1 2 3 4 5 6 7 8 9]
    dObs: [1x10 datetime]
    CFlowT: {1x10 cell}
    Probs: {1x9 cell}
    Connect: {1x9 cell}
    FwdTree: {1x10 cell}

```

### Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the FixedBondOption instrument.

```
[Price, outPR] = price(BKTreePricer, FixedBOption, ["all"])
```

```
Price = 705.2729
```

```
outPR =
    pricerresult with properties:

```

```
Results: [1x4 table]
PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
```

Price	Vega	Gamma	Delta
705.27	-1.1369e-09	-8084.8	844.75

# Heston

Create Heston model object for Vanilla instrument

## Description

Create and price a Vanilla instrument object with a Heston model using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a Heston model object for the Vanilla instrument.
- 3 Use `finpricer` to specify a FiniteDifference, NumericalIntegration, or FFT pricing method for the Vanilla instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
HestonModelObj = finmodel(ModelType, 'V0'v0_value, 'ThetaV', thetav_value, 'Kappa', kappa_value, 'SigmaV', sigmav_value, 'RhoSV', rhosv_value)
```

### Description

`HestonModelObj = finmodel(ModelType, 'V0'v0_value, 'ThetaV', thetav_value, 'Kappa', kappa_value, 'SigmaV', sigmav_value, 'RhoSV', rhosv_value)` creates a Black model object by specifying `ModelType` and the required name-value pair arguments `V0`, `ThetaV`, `Kappa`, `SigmaV`, and `RhoSV` to set properties on page 11-2322 using required name-value pair arguments. For example, `HestonModelObj = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)` creates a Heston model object.

### Input Arguments

#### ModelType — Model type

string with value "Heston" | character vector with value 'Heston'

Model type, specified as a string with the value of "Heston" or a character vector with the value of 'Heston'.

Data Types: char | string

**Heston Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: HestonModelObj =  
finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV',  
0.9)
```

**V0 — Initial variance of underlying asset**

numeric

Initial variance of the underlying asset, specified as the comma-separated pair consisting of 'V0' and a scalar numeric value.

Data Types: double

**ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underlying asset, specified as the comma-separated pair consisting of 'ThetaV' and a scalar numeric value.

Data Types: double

**Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, specified as the comma-separated pair consisting of 'Kappa' and a scalar numeric value.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, specified as the comma-separated pair consisting of 'SigmaV' and a scalar numeric value.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as the comma-separated pair consisting of 'RhoSV' and a scalar numeric value.

Data Types: double

**Properties****V0 — Initial variance of underlying asset**

numeric

Initial variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

**ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

**Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, returned as a scalar numeric value.

Data Types: double

**SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, returned as a scalar numeric value.

Data Types: double

**Examples****Use Heston Model and FFT Pricer to Price Vanilla Instrument**

This example shows the workflow to price a Vanilla instrument when you use a Heston model and an FFT pricing method.

**Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'ExerciseSty
```

```
VanillaOpt =
```

```
  Vanilla with properties:
```

```
    OptionType: "call"
  ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
        Strike: 105
        Name: "vanilla_option"
```

**Create Heston Model Object**

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)
```

```
HestonModel =
  Heston with properties:

      V0: 0.0320
    ThetaV: 0.1000
      Kappa: 0.0030
    SigmaV: 0.2000
      RhoSV: 0.9000
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

      Type: "zero"
    Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create FFT Pricer Object

Use `finpricer` to create an FFT pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("FFT", 'DiscountCurve', myRC, 'Model', HestonModel, 'SpotPrice', 100, 'CharacteristicFcn', @characteristicFcnHeston)
```

```
outPricer =
  FFT with properties:

      Model: [1x1 finmodel.Heston]
    DiscountCurve: [1x1 ratecurve]
      SpotPrice: 100
    DividendType: "continuous"
    DividendValue: 0
      NumFFT: 8192
    CharacteristicFcnStep: 0.2000
      LogStrikeStep: 0.0038
    CharacteristicFcn: @characteristicFcnHeston
      DampingFactor: 1.5000
      Quadrature: "simpson"
    VolRiskPremium: 0
      LittleTrap: 1
```

## Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 14.7545
```

```
outPR =  
  pricerresult with properties:
```

```
    Results: [1x7 table]  
  PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Theta	Rho	Vega	VegaLT
14.754	0.44868	0.021649	-0.20891	120.45	88.192	1.3248

## HullWhite

Create HullWhite model object for Cap, Floor, Swaption, FixedBond, FloatBond, FixedBondOption, or OptionEmbeddedFixedBond instrument

### Description

Create and price a Cap, Floor, Swaption, FloatBond, FixedBond, FixedBondOption, or OptionEmbeddedFixedBond instrument object with a HullWhite model using this workflow:

- 1 Use `fininstrument` to create a Cap, Floor, Swaption, FixedBond, FloatBond, FixedBondOption, or OptionEmbeddedFixedBond instrument object.
- 2 Use `finmodel` to specify a HullWhite model object for the Cap, Floor, Swaption, FixedBond, FloatBond, FixedBondOption, or OptionEmbeddedFixedBond instrument.
- 3 Use `finpricer` to specify a HullWhite pricing method for a Cap, Floor, or Swaption and use an IRTree pricing method for the FixedBond, FloatBond, FixedBondOption, or OptionEmbeddedFixedBond instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Cap, Floor, Swaption, FixedBond, FloatBond, FixedBondOption, or OptionEmbeddedFixedBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
HullWhiteModelObj = finmodel(ModelType, 'Alpha'alpha_value, 'Sigma', sigma_value)
```

#### Description

`HullWhiteModelObj = finmodel(ModelType, 'Alpha'alpha_value, 'Sigma', sigma_value)` creates a HullWhite model object by specifying `ModelType` and the required name-value pair arguments `Alpha` and `Sigma` to set properties on page 11-2327 using name-value pair arguments. For example, `HullWhiteModelObj = finmodel("HullWhite", 'Alpha', 0.052, 'Sigma', 0.34)` creates a HullWhite model object.

#### Input Arguments

##### ModelType — Model type

string with value "HullWhite" | character vector with value 'HullWhite'

Model type, specified as a string with the value of "HullWhite" or a character vector with the value of 'HullWhite'.

Data Types: char | string

**HullWhite Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `HullWhiteModelObj = finmodel("HullWhite", 'Alpha', 0.052, 'Sigma', 0.34)`

**Alpha — Mean reversion speed**

numeric

Mean reversion speed, specified as the comma-separated pair consisting of `'Alpha'` and a scalar numeric or timetable.

`Alpha` accepts a timetable, where the first column is dates and the second column is the associated `Alpha` value.

Data Types: double | timetable

**Sigma — Volatility**

numeric | timetable

Volatility, specified as the comma-separated pair consisting of `'Sigma'` and a scalar numeric or timetable.

`Sigma` accepts a timetable, where the first column is dates and the second column is the associated `Sigma` value.

Data Types: double | timetable

**Properties****Alpha — Mean reversion speed**

numeric

Mean reversion speed, returned as a scalar numeric or timetable.

Data Types: double | timetable

**Sigma — Volatility**

numeric | timetable

Volatility, returned as a scalar numeric value or timetable.

Data Types: double | timetable

**Examples****Use Hull-White Model and Hull-White Pricer to Price Floor Instrument**

This example shows the workflow to price a `Floor` instrument when you use a `HullWhite` model and a `HullWhite` pricing method.

**Create Floor Instrument Object**

Use `fininstrument` to create a `Floor` instrument object.

```
FloorOpt = fininstrument("Floor", 'Strike', 0.045, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Principi
FloorOpt =
  Floor with properties:
      Strike: 0.0450
      Maturity: 30-Jan-2019
      ResetOffset: 0
      Reset: 4
      Basis: 1
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "floor_option"
```

### Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.032, 'Sigma', 0.04)
```

```
HullWhiteModel =
  HullWhite with properties:
```

```
    Alpha: 0.0320
    Sigma: 0.0400
```

### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
  ratecurve with properties:
```

```
    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

## Create HullWhite Pricer Object

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', HullWhiteModel, 'DiscountCurve', myRC)

outPricer =
    HullWhite with properties:

        DiscountCurve: [1x1 ratecurve]
        Model: [1x1 finmodel.HullWhite]
```

## Price Floor Instrument

Use `price` to compute the price for the `Floor` instrument.

```
Price = price(outPricer, FloorOpt)
```

```
Price = 1.4917
```

## Merton

Create Merton model object for Vanilla instrument

### Description

Create and price a Vanilla instrument object with a Merton model using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a Merton model object for the Vanilla instrument.
- 3 Use `finpricer` to specify a FiniteDifference, NumericalIntegration, or FFT pricing method for the Vanilla instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
MertonModelObj = finmodel(ModelType, 'Volatility', volatility_value, 'MeanJ', meanj_value, 'JumpVol', jumpvol_value, 'JumpFreq', jumpfreq_value)
```

#### Description

`MertonModelObj = finmodel(ModelType, 'Volatility', volatility_value, 'MeanJ', meanj_value, 'JumpVol', jumpvol_value, 'JumpFreq', jumpfreq_value)` creates a Merton model object by specifying `ModelType` and the required name-value pair arguments `MeanJ`, `JumpVol`, and `JumpFreq` to set properties on page 11-2331 using name-value pair arguments. For example, `MertonModelObj = finmodel("Merton", 'Volatility', 0.03, 'MeanJ', 0.22, 'JumpVol', 0.007, 'JumpFreq', 0.009)` creates a Merton model object.

#### Input Arguments

##### **ModelType** — Model type

string with value "Merton" | character vector with value 'Merton'

Model type, specified as a string with the value of "Merton" or a character vector with the value of 'Merton'.

Data Types: char | string

**Merton Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: MertonModelObj =
finmodel("Merton", 'Volatility', 0.03, 'MeanJ', 0.22, 'JumpVol', 0.007, 'JumpFreq', 0.009)
```

**Volatility — Volatility value for the underlying asset**

nonnegative numeric

Volatility value for the underlying asset, specified as the comma-separated pair consisting of `'Volatility'` and a scalar nonnegative numeric.

Data Types: double

**MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), specified as the comma-separated pair consisting of `'MeanJ'` and a scalar decimal value, where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation `JumpVol`.

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$** 

decimal

Standard deviation of  $\log(1+J)$ , where  $J$  is the random percentage jump size, specified as the comma-separated pair consisting of `'JumpVol'` and a scalar decimal value.

Data Types: double

**JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of the Poisson jump process, specified as the comma-separated pair consisting of `'JumpFreq'` and a scalar numeric value.

Data Types: double

**Properties****Volatility — Volatility value**

nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: double

**MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), returned as a scalar decimal value.

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$** 

decimal

Standard deviation of  $\log(1+J)$ , where J is the random percentage jump size, returned as a scalar decimal value.

Data Types: double

**JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of the Poisson jump process, returned as a scalar numeric value.

Data Types: double

**Examples****Use Merton Model and Numerical Integration Pricer to Price Vanilla Instrument**

This example shows the workflow to price a Vanilla instrument when you use a Merton model and a NumericalIntegration pricing method.

**Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType'
```

```
VanillaOpt =
```

```
Vanilla with properties:
```

```
    OptionType: "put"  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Sep-2022  
    Strike: 105  
    Name: "vanilla_option"
```

**Create Merton Model Object**

Use `finmodel` to create a Merton model object.

```
MertonModel = finmodel("Merton", 'Volatility', 0.45, 'MeanJ', 0.02, 'JumpVol', 0.07, 'JumpFreq', 0.09)
```

```
MertonModel =
```

```
Merton with properties:
```

```
    Volatility: 0.4500  
    MeanJ: 0.0200  
    JumpVol: 0.0700  
    JumpFreq: 0.0900
```

**Create ratecurve Object**

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create NumericalIntegration Pricer Object

Use `finpricer` to create a `NumericalIntegration` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("numericalintegration", 'DiscountCurve', myRC, 'Model', MertonModel, 'SpotPrice
```

```
outPricer =
  NumericalIntegration with properties:
      Model: [1x1 finmodel.Merton]
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 100
      DividendType: "continuous"
      DividendValue: 0.4500
      AbsTol: 0.5000
      RelTol: 0.0400
      IntegrationRange: [1.0000e-09 Inf]
      CharacteristicFcn: @characteristicFcnMerton76
      Framework: "lewis2001"
      VolRiskPremium: 0.0900
      LittleTrap: 0
```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 75.1139
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x6 table]
    PricerData: []
```

```
outPR.Results
```

ans=1x6 table

Price	Delta	Gamma	Theta	Rho	Vega
75.114	-0.15305	0.00025732	-3.9836	-361.67	4.6317

# Normal

Create `Normal` model object for `Cap`, `Floor`, or `Swaption` instrument

## Description

Create and price a `Cap`, `Floor`, or `Swaption` instrument object with a `Normal` model using this workflow:

- 1 Use `fininstrument` to create a `Cap`, `Floor`, or `Swaption` instrument object.
- 2 Use `finmodel` to specify a `Normal` model object for the `Cap`, `Floor`, or `Swaption` instrument.
- 3 Use `finpricer` to specify a `Normal` pricing method for the `Cap`, `Floor`, or `Swaption` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Cap`, `Floor`, or `Swaption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
NormalModelObj = finmodel(ModelType, 'Volatility', volatility_value)
```

### Description

`NormalModelObj = finmodel(ModelType, 'Volatility', volatility_value)` creates a `Normal` model object by specifying `ModelType` and the required name-value pair argument `Volatility` to set properties on page 11-2336 using name-value pair arguments. For example, `NormalModelObj = finmodel("Normal", 'Volatility', 0.063)` creates a `Normal` model object.

### Input Arguments

#### ModelType — Model type

string with value "Normal" | character vector with value 'Normal'

Model type, specified as a string with the value of "Normal" or a character vector with the value of 'Normal'.

Data Types: char | string

#### Normal Name-Value Pair Arguments

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: NormalModelObj = finmodel("Normal",'Volatility',0.063)
```

**Volatility – Volatility value**

nonnegative numeric

Volatility value, specified as the comma-separated pair consisting of 'Volatility' and a scalar nonnegative numeric.

Data Types: double

**Properties****Volatility – Volatility value**

nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: double

**Examples****Use Normal Model and Normal Pricer to Price Cap Instrument**

This example shows the workflow to price a Cap instrument when you use a Normal model and a Normal pricing method.

**Create Cap Instrument Object**

Use `fininstrument` to create a Cap instrument object.

```
CapOpt = fininstrument("Cap", 'Strike', 0.51, 'Maturity', datetime(2019,6,25), 'Reset', 4, 'Principal', ...)
```

```
CapOpt =  
    Cap with properties:
```

```
        Strike: 0.5100  
        Maturity: 25-Jun-2019  
    ResetOffset: 0  
         Reset: 4  
         Basis: 8  
    Principal: 100  
    ProjectionCurve: [0x0 ratecurve]  
DaycountAdjustedCashFlow: 0  
    BusinessDayConvention: "actual"  
        Holidays: NaT  
         Name: "cap_option"
```

**Create Normal Model Object**

Use `finmodel` to create a Normal model object.

```
NormalModel = finmodel("normal", 'Volatility', 0.063)
```

```
NormalModel =  
    Normal with properties:
```

```
Volatility: 0.0630
```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307];
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:

        Type: "zero"
    Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create Normal Pricer Object

Use finpricer to create a Normal pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',NormalModel,'DiscountCurve',myRC)
```

```
outPricer =
    Normal with properties:

        DiscountCurve: [1x1 ratecurve]
        Shift: 0
        Model: [1x1 finmodel.Normal]
```

### Price Cap Instrument

Use price to compute the price for the Cap instrument.

```
Price = price(outPricer,CapOpt)
```

```
Price = 9.3325e-30
```

# Dupire

Create Dupire model object for local volatility for Vanilla instrument

## Description

Create and price a Vanilla instrument object with a Dupire model using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a Dupire model object for the Vanilla instrument.
- 3 Use `finpricer` to specify a FiniteDifference pricing method for the Vanilla instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
DupireObj = finmodel(ModelType,'ImpliedVolData',impliedvoldata_value)
```

### Description

`DupireObj = finmodel(ModelType,'ImpliedVolData',impliedvoldata_value)` creates a Dupire model object by specifying `ModelType` and the required name-value pair argument `ImpliedVolData` to set properties on page 11-2340 using name-value pair arguments. For example, `DupireObj = finmodel("Dupire",'ImpliedVolData',voldata_table)` creates a Dupire model object.

### Input Arguments

#### ModelType — Model type

string with value "Dupire" | character vector with value 'Dupire'

Model type, specified as the string with the value "Dupire" or the character vector with the value 'Dupire'.

Data Types: char | string

#### Dupire Name-Value Pair Arguments

Specify required comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `DupireObj = finmodel("Dupire",'ImpliedVolData',voldata_table)`

**ImpliedVolData — Table of maturity dates, strike or exercise prices, and corresponding implied volatilities**

table

Table of maturity dates, strike or exercise prices, and their corresponding implied volatilities, specified as the comma-separated pair consisting of 'ImpliedVolData' and an NVOL-by-3 table.

Data Types: table

**Properties****ImpliedVolData — Table of maturity dates, strike or exercise prices, and corresponding implied volatilities**

table

Table of maturity dates, strike or exercise prices, and corresponding implied volatilities, returned as an NVOL-by-3 table.

Data Types: table

**Examples****Use Dupire Model and Finite Difference Pricer to Price Vanilla Instrument**

This example shows the workflow to price a Vanilla instrument when you use a Dupire model and a FiniteDifference pricing method.

**Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2020,1,1), 'Strike', 105, 'ExerciseStyle', 'american');
```

```
VanillaOpt =  
    Vanilla with properties:  
  
        OptionType: "call"  
        ExerciseStyle: "american"  
        ExerciseDate: 01-Jan-2020  
        Strike: 105  
        Name: "vanilla_option"
```

**Create Dupire Model Object**

Define the implied volatility surface data.

```
AssetPrice = 590;  
Maturity = ["06-Mar-2018" "05-Jun-2018" "12-Sep-2018" "10-Dec-2018" "01-Jan-2019" ...  
"02-Jul-2019" "01-Jan-2020" "01-Jan-2021" "01-Jan-2022" "01-Jan-2023"];  
Maturity = repmat(Maturity,10,1);  
Maturity = Maturity(:);  
  
ExercisePrice = AssetPrice.*[0.85 0.90 0.95 1.00 1.05 1.10 1.15 1.20 1.30 1.40];  
ExercisePrice = repmat(ExercisePrice,1,10)';
```

```

ImpliedVol = [...
    0.190; 0.168; 0.133; 0.113; 0.102; 0.097; 0.120; 0.142; 0.169; 0.200; ...
    0.177; 0.155; 0.138; 0.125; 0.109; 0.103; 0.100; 0.114; 0.130; 0.150; ...
    0.172; 0.157; 0.144; 0.133; 0.118; 0.104; 0.100; 0.101; 0.108; 0.124; ...
    0.171; 0.159; 0.149; 0.137; 0.127; 0.113; 0.106; 0.103; 0.100; 0.110; ...
    0.171; 0.159; 0.150; 0.138; 0.128; 0.115; 0.107; 0.103; 0.099; 0.108; ...
    0.169; 0.160; 0.151; 0.142; 0.133; 0.124; 0.119; 0.113; 0.107; 0.102; ...
    0.169; 0.161; 0.153; 0.145; 0.137; 0.130; 0.126; 0.119; 0.115; 0.111; ...
    0.168; 0.161; 0.155; 0.149; 0.143; 0.137; 0.133; 0.128; 0.124; 0.123; ...
    0.168; 0.162; 0.157; 0.152; 0.148; 0.143; 0.139; 0.135; 0.130; 0.128; ...
    0.168; 0.164; 0.159; 0.154; 0.151; 0.147; 0.144; 0.140; 0.136; 0.132];

```

```
ImpliedVolData = table(Maturity, ExercisePrice, ImpliedVol);
```

Use `finmodel` to create a Dupire model object.

```
DupireModel = finmodel("Dupire", 'ImpliedVolData', ImpliedVolData)
```

```

DupireModel =
    Dupire with properties:
        ImpliedVolData: [100x3 table]

```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018,1,1);
Maturity = datetime(2020,9,1);
Rate = 0.06;
myRC = ratecurve('zero', Settle, Maturity, Rate)

```

```

myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: 01-Sep-2020
        Rates: 0.0600
        Settle: 01-Jan-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create FiniteDifference Pricer Object

Use `finpricer` to create a FiniteDifference pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("FiniteDifference", 'Model', DupireModel, 'DiscountCurve', myRC, 'SpotPrice', 100)
```

```

outPricer =
    FiniteDifference with properties:
        DiscountCurve: [1x1 ratecurve]

```

```

        Model: [1x1 finmodel.Dupire]
        SpotPrice: 100
    GridProperties: [1x1 struct]
        DividendType: "continuous"
        DividendValue: 0.0262

```

## Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 15.5930
```

```
outPR =
    pricerresult with properties:
```

```

        Results: [1x7 table]
        PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Theta	Rho	Vega
15.593	0.55004	0.0091484	3.5275	-3.3431	78.792	49.33

## More About

### Local Volatility Model

A local volatility model treats volatility as a function both of the current asset level and of time.

The local volatility can be estimated by using the Dupire formula [2]:

$$\sigma_{loc}^2(K, \tau) = \frac{\sigma_{imp}^2 + 2\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial\tau} + 2(\tau - d)K\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial K}}{\left(1 + Kd_1\sqrt{\tau}\frac{\partial\sigma_{imp}}{\partial K}\right)^2 + K^2\tau\sigma_{imp}\left(\frac{\partial^2\sigma_{imp}}{\partial K^2} - d_1\sqrt{\tau}\left(\frac{\partial\sigma_{imp}}{\partial K}\right)^2\right)}$$

$$d_1 = \frac{\ln(S_0/K) + ((\tau - d) + \sigma_{imp}^2/2)\tau}{\sigma_{imp}\sqrt{\tau}}$$

# SABR

Create SABR model object for Swaption instrument

## Description

Create and price a Swaption instrument object with a SABR model using this workflow:

- 1 Use `fininstrument` to create a Swaption instrument object.
- 2 Use `finmodel` to specify a SABR model object for the Swaption instrument.
- 3 Use `finpricer` to specify a SABR pricing method for the Swaption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
SabrModelObj = finmodel(ModelType,'Alpha',alpha_value,'Beta',beta_value,'
Rho',rho_value,'Nu',nu_value)
SabrModelObj = finmodel(____,Name,Value)
```

### Description

`SabrModelObj = finmodel(ModelType,'Alpha',alpha_value,'Beta',beta_value,'Rho',rho_value,'Nu',nu_value)` creates a SABR model object by specifying `ModelType` and sets the properties on page 11-2346 for the required name-value pair arguments `Alpha`, `Beta`, `Rho`, and `Nu`.

`SabrModelObj = finmodel(____,Name,Value)` sets optional properties on page 11-2346 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `SabrModelObj = finmodel("SABR",'Alpha',0.22,'Beta',0.007,'Rho',0.009,'Nu',0.03,'Shift',0.002,'VolatilityType','black')` creates a SABR model object. You can specify multiple name-value pair arguments.

### Input Arguments

#### ModelType — Model type

string with value "SABR" | character vector with value 'SABR'

Model type, specified as a string with the value of "SABR" or a character vector with the value of 'SABR'.

Data Types: char | string

**SABR Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: SabrModelObj =
finmodel("SABR", 'Alpha', 0.22, 'Beta', 0.007, 'Rho', 0.009, 'Nu', 0.03, 'Shift', 0.002
, 'VolatilityType', "black")
```

**Required SABR Name-Value Pair Arguments****Alpha — Current SABR volatility**

scalar numeric

Current SABR volatility, specified as the comma-separated pair consisting of 'Alpha' and a scalar numeric.

Data Types: double

**Beta — SABR constant elasticity of variance (CEV) exponent**

scalar numeric

SABR constant elasticity of variance (CEV) exponent, specified as the comma-separated pair consisting of 'Beta' and a scalar numeric.

---

**Note** Set the Beta parameter to 0 to allow a negative ForwardValue and Strike.

---

Data Types: double

**Rho — Correlation between forward value and volatility**

scalar numeric

Correlation between the forward value and volatility, specified as the comma-separated pair consisting of 'Rho' and a scalar numeric.

Data Types: double

**Nu — Volatility of volatility**

scalar numeric

Volatility of volatility, specified as the comma-separated pair consisting of 'Nu' and a scalar numeric.

Data Types: double

**Optional SABR Name-Value Pair Arguments****Shift — Shift in decimals for shifted SABR model**

0 (no shift) (default) | scalar positive decimal

Shift in decimals for the shifted SABR model (to be used with the shifted Black model), specified as the comma-separated pair consisting of 'Shift' and a scalar positive decimal value. For example, a Shift value of 0.01 is equal to a 1% positive shift.

---

**Note** If you set VolatilityType to 'normal', the Shift value must be 0.

---

Data Types: double

**VolatilityType — Model used by the implied volatility sigma**

"black" (default) | string with value "black" or "normal" | character vector with value 'black' or 'normal'

Model used by the implied volatility sigma, specified as the comma-separated pair consisting of 'VolatilityType' and a scalar string or character vector.

---

**Note** The value of VolatilityType affects the interpretation of the implied volatility ("sigma").

- If you set VolatilityType to 'black' (default), "sigma" can be either implied Black (no shift) or implied shifted Black volatility.
  - If you set VolatilityType to 'normal', "sigma" is the implied Normal (Bachelier) volatility and you must also set Shift to zero.
- 

Data Types: char | string

**Properties****Alpha — Current SABR volatility**

scalar numeric

Current SABR volatility, returned as a scalar numeric.

Data Types: double

**Beta — SABR constant elasticity of variance (CEV) exponent**

scalar numeric

SABR constant elasticity of variance (CEV) exponent, returned as a scalar numeric.

Data Types: double

**Rho — Correlation between forward value and volatility**

scalar numeric

Correlation between forward value and volatility, returned as a scalar numeric.

Data Types: double

**Nu — Volatility of volatility**

scalar numeric

Volatility of volatility, returned as a scalar numeric.

Data Types: double

**Shift — Shift in decimals for shifted SABR model**

0 (no shift) (default) | scalar positive decimal

Shift in decimals for the shifted SABR model (to be used with the Shifted Black model), returned as a scalar positive decimal value.

Data Types: double

### VolatilityType — Model used by the implied volatility sigma

"black" (default) | string with value "black" or "normal"

Model used by the implied volatility sigma, returned as a string with a value of "black" or "normal".

Data Types: string

## Examples

### Use SABR Model and SABR Pricer to Price Swaption Instrument

This example shows the workflow to price a Swaption instrument when you use a SABR model and a SABR pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307];
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
```

```
ratecurve with properties:
```

```

        Type: "zero"
    Compounding: -1
        Basis: 0
        Dates: [10×1 datetime]
        Rates: [10×1 double]
        Settle: 15-Sep-2018
    InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"
```

#### Create Swap Instrument Object

Use fininstrument to create the underlying Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2023,1,30), 'LegRate', [0.018 0.24], 'LegType', ["fi
```

```
Swap =
```

```
Swap with properties:
```

```

        LegRate: [0.0180 0.2400]
        LegType: ["fixed"    "float"]
        Reset: [2 2]
        Basis: [5 5]
```

```

        Notional: 1000
    LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [1 1]
        ProjectionCurve: [1x2 ratecurve]
    BusinessDayConvention: ["follow" "follow"]
        Holidays: NaT
    EndMonthRule: [1 1]
        StartDate: 30-Mar-2020
        Maturity: 30-Jan-2023
        Name: "swap_instrument"

```

### Create Swaption Instrument Object

Use `fininstrument` to create a Swaption instrument object.

```
Swaption = fininstrument("swaption", 'Strike', 0.25, 'ExerciseDate', datetime(2021, 7, 30), 'Swap', Swap)
```

```
Swaption =
    Swaption with properties:

        OptionType: "put"
    ExerciseStyle: "european"
    ExerciseDate: 30-Jul-2021
        Strike: 0.2500
        Swap: [1x1 fininstrument.Swap]
        Name: "swaption_instrument"

```

### Create SABR Model Object

Use `finmodel` to create a SABR model object.

```
SabrModel = finmodel("SABR", 'Alpha', 0.032, 'Beta', 0.04, 'Rho', .08, 'Nu', 0.49, 'Shift', 0.002)
```

```
SabrModel =
    SABR with properties:

        Alpha: 0.0320
        Beta: 0.0400
        Rho: 0.0800
        Nu: 0.4900
        Shift: 0.0020
    VolatilityType: "black"

```

### Create SABR Pricer Object

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', SabrModel, 'DiscountCurve', myRC)
```

```
outPricer =
    SABR with properties:

        DiscountCurve: [1x1 ratecurve]

```

---

Model: [1x1 finmodel.SABR]

### **Price Swaption Instrument**

Use price to compute the price for the Swaption instrument.

```
Price = price(outPricer,Swaption)
```

```
Price = 55.8596
```

# BjersundStensland

Create BjersundStensland pricer object for Vanilla or Spread using BlackScholes model

## Description

Create and price a Vanilla or Spread instrument object with a BlackScholes model and a BjersundStensland pricing method using this workflow:

- 1 Use `fininstrument` to create a Vanilla or Spread instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Vanilla or Spread instrument.
- 3 Use `finpricer` to specify a BjersundStensland pricer object for the Vanilla instrument (American exercise) or Spread instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Vanilla or Spread instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
BjersundStenslandPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj, 'SpotPrice', spotprice_value)
BjersundStenslandPricerObj = finpricer( ___, Name, Value)
```

### Description

`BjersundStenslandPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj, 'SpotPrice', spotprice_value)` creates a BjersundStensland pricer object by specifying `PricerType` and sets the properties on page 11-2352 for the required name-value pair arguments `Model`, `DividendType`, and `SpotPrice`.

`BjersundStenslandPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2352 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BjersundStenslandPricerObj = finpricer("Analytic", 'Model', 'BSModel', 'DiscountCurve', ratecurve_obj, 'SpotPrice', [100;105], 'DividendValue', [2.5,2.8], 'PricingMethod', "BjersundStensland")` creates a BjersundStensland pricer object.

### Input Arguments

#### PricerType – Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### **Bjerk SundStensland Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Bjerk SundStenslandPricerObj = finpricer("Analytic", 'Model', 'BSModel', 'DiscountCurve', ratecurve_obj, 'SpotPrice', [100;105], 'DividendValue', [2.5,2.8], 'PricingMethod', "Bjerk SundStensland")`

### **Required Bjerk SundStensland Name-Value Pair Arguments**

#### **Model — Model object**

object

Model object, specified as the comma-separated pair consisting of `'Model'` and the name of the previously created BlackScholes model object using `finmodel`.

Data Types: object

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of the previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for `DiscountCurve`. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at `Maturity` and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### **SpotPrice — Current price of underlying asset**

scalar nonnegative numeric | vector of nonnegative numerics

Current price of the underlying asset, specified as the comma-separated pair consisting of `'SpotPrice'` and a scalar or vector of nonnegative numeric values. Use a vector for `SpotPrice` when pricing a Spread instrument.

Data Types: double

### **Optional Bjerk SundStensland Name-Value Pair Arguments**

#### **DividendValue — Dividend yield**

[0,0] (default) | scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar or vector of nonnegative numeric values. Use a 1-by-2 vector of nonnegative values for `DividendValue` when pricing a Spread instrument.

Data Types: double

**DividendType — Dividend type**

"continuous" (default) | string with value "continuous" | character vector with value 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and string or character vector.

Data Types: char | string

**PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "BjerksundStensland" | character vector with value 'BjerksundStensland'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a character vector or string.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: string | char

**Properties****Model — Model**

model object

Model, returned as a model object.

Data Types: object

**DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric | vector of nonnegative numerics

Current price of the underlying asset, returned as a scalar or vector of nonnegative numeric values.

Data Types: double

**DividendValue — Dividend yield**

scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield, returned as a scalar or vector of nonnegative numeric.

Data Types: double

**DividendType — Dividend type**

"continuous" (default) | string with value "continuous"

This property is read-only.

Dividend type, returned as a string.

Data Types: string

### PricingMethod — Analytic pricing method

default pricer associated with BlackScholes model (default) | string with value "Bjerk SundStensland"

Analytic pricing method, returned as a string.

Data Types: string

## Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## Examples

### Use Bjerk Sund-Stensland Pricer and Black-Scholes Model to Price Spread Instrument

This example shows the workflow to price a European exercise Spread instrument when you use a BlackScholes model and a Bjerk SundStensland pricing method.

#### Create Spread Instrument Object

Use `fininstrument` to create a Spread instrument object.

```
SpreadOpt = fininstrument("Spread", 'Strike', 5, 'ExerciseDate', datetime(2021, 9, 15), 'OptionType', "put")
```

```
SpreadOpt =
```

```
Spread with properties:
```

```

    OptionType: "put"
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2021
    Strike: 5
    Name: "spread_option"

```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', [.2;.1])
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```

    Volatility: [2x1 double]
    Correlation: [2x2 double]

```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create BjerksundStensland Pricer Object

Use `finpricer` to create a BjerksundStensland pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',[100

```

```

outPricer =
  BjerksundStensland with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: [2x1 double]
      DividendValue: [0.0900 0.1700]
      DividendType: "continuous"

```

### Price Spread Instrument

Use `price` to compute the price and sensitivities for the Spread instrument.

```

[Price, outPR] = price(outPricer,SpreadOpt,["all"])

```

```

Price = 7.0596

```

```

outPR =
  pricerresult with properties:

```

```

      Results: [1x7 table]
      PricerData: []

```

```

outPR.Results

```

```

ans=1x7 table

```

Price	Delta	Gamma	Lambda	Vega
-------	-------	-------	--------	------

7.0596    -0.23249    0.27057    0.0069887    0.0055319    -3.2932    3.8327    41.938

## Use Bjerk SundStensland Pricer and Black-Scholes Model to Price an American Exercise Vanilla Instrument

This example shows the workflow to price an American exercise Vanilla instrument when you use a BlackScholes model and a Bjerk SundStensland pricing method.

### Create Vanilla Instrument Object

Use `fininstrument` to create an American exercise Vanilla instrument object.

```
VanillaObj = fininstrument("Vanilla", 'Strike', 120, 'ExerciseDate', datetime(2019,1,30), 'OptionType'
```

```
VanillaObj =
  Vanilla with properties:

      OptionType: "put"
      ExerciseStyle: "american"
      ExerciseDate: 30-Jan-2019
      Strike: 120
      Name: "vanilla_instrument"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .2)
```

```
BlackScholesModel =
  BlackScholes with properties:

      Volatility: 0.2000
      Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =
  ratecurve with properties:

      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
```

```
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"
```

### Create BjerksundStensland Pricer Object

Use `finpricer` to create a BjerksundStensland pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', 120,
outPricer =
    BjerksundStensland with properties:

        DiscountCurve: [1x1 ratecurve]
           Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 120
    DividendValue: 0.0500
    DividendType: "continuous"
```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaObj, ["all"])
```

```
Price = 6.1080
```

```
outPR =
    pricerresult with properties:
```

```
    Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
6.108	-0.48471	0.026611	-9.5227	28.781	-8.3418	-24.115

# Black

Create Black pricer object for Cap, Floor, or Swaption instrument using Black model

## Description

Create and price a Cap, Floor, or Swaption instrument object with a Black model and a Black pricing method using this workflow:

- 1 Use `fininstrument` to create a Cap, Floor, or Swaption instrument object.
- 2 Use `finmodel` to specify a Black model for the Cap, Floor, or Swaption instrument.
- 3 Use `finpricer` to specify a Black pricer object for the Cap, Floor, or Swaption instrument.

---

**Note** If you do not specify `ProjectionCurve` when you create a Cap, Floor, or Swaption instrument with the Black pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

---

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Cap, Floor, or Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
BlackPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)
```

### Description

`BlackPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)` creates a Black pricer object by specifying `PricerType` and the required name-value pair arguments for `DiscountCurve` and `Model` to set properties on page 11-2358 using name-value pairs. For example, `BlackPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BlackModel)` creates a Black pricer object.

### Input Arguments

#### **PricerType** — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### Black Name-Value Pair Arguments

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: BlackPricerObj =  
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BlackModel)
```

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

Data Types: object

### Model — Model

Black model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created Black model object using `finmodel`.

Data Types: object

## Properties

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object

Data Types: object

### Model — Model

Black model object

Model, returned as a Black model object.

Data Types: object

## Object Functions

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## Examples

### Use Black Pricer and Black Model to Price Cap Instrument

This example shows the workflow to price a Cap instrument when you use a Black model and a Black pricing method.

#### Create Cap Instrument Object

Use `fininstrument` to create a Cap instrument object.

```
CapOpt = fininstrument("Cap", 'Strike', .02, 'Maturity', datetime(2021,12,30), 'Reset', 4, 'Principal', ...
```

```
CapOpt =
  Cap with properties:
      Strike: 0.0200
      Maturity: 30-Dec-2021
      ResetOffset: 0
      Reset: 4
      Basis: 12
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "cap_option"
```

### Create Black Model Object

Use `finmodel` to create a Black model object.

```
BlackModel = finmodel("Black", 'Volatility', 0.09, 'Shift', 0.002)
```

```
BlackModel =
  Black with properties:
      Volatility: 0.0900
      Shift: 0.0020
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2020,9,14);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 14-Sep-2020
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create Black Pricer Object

Use `finpricer` to create a Black pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackModel, 'DiscountCurve', myRC)

outPricer =
    Black with properties:
        Model: [1x1 finmodel.Black]
        DiscountCurve: [1x1 ratecurve]
```

### Price Cap Instrument

Use `price` to compute the price for the Cap instrument.

```
Price = price(outPricer, CapOpt)
```

```
Price = 4.6412e-29
```

# BlackScholes

Create BlackScholes pricer object for Vanilla, Lookback, Barrier, Asian, or Spread instrument using BlackScholes model

## Description

Create and price a Vanilla, Lookback, Barrier, Asian, or Spread instrument object with a BlackScholes model and a BlackScholes pricing method using this workflow:

- 1 Use `fininstrument` to create a Vanilla, Lookback, Barrier, Asian, or Spread instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Vanilla, Lookback, Barrier, Asian, or Spread instrument.
- 3 Use `finpricer` to specify a BlackScholes pricer object for the Vanilla, Lookback, Barrier, Asian, or Spread instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Vanilla, Lookback, Barrier, Asian, or Spread instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
BlackScholesPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value, )
BlackScholesPricerObj = finpricer( ____, Name, Value)
```

### Description

`BlackScholesPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value, )` creates a BlackScholes pricer object by specifying `PricerType` and sets the properties on page 11-2363 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`BlackScholesPricerObj = finpricer( ____, Name, Value)` to set optional properties on page 11-2363 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BlackScholesPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100)` creates a BlackScholes pricer object.

**Input Arguments****PricerType — Pricer type**

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

**BlackScholes Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: BlackScholesPricerObj =

```
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100)
```

**Required BlackScholes Name-Value Pair Arguments****DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

**Model — Model**

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

**Optional BlackScholes Name-Value Pair Arguments****DividendType — Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and character vector or string. The DividendType must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

---

**Note** When you price currencies using a Vanilla instrument, the DividendType must be "continuous" and DividendValue is the annualized risk-free interest rate in the foreign country.

---

Data Types: char | string

### **DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar numeric | timetable

Dividend amount for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

DividendValue must be a scalar for a "continuous" DividendType or a timetable for "cash" DividendType.

---

**Note** When you price currencies using a Vanilla instrument, the DividendType must be "continuous" and DividendValue is the annualized risk-free interest rate in the foreign country.

---

Data Types: double | timetable

## **Properties**

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object.

Data Types: object

### **Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

### **DividendType — Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous"

This property is read-only.

Stock dividend type, returned as a string. The `DividendType` must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: string

### **DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend amount or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend amount or a timetable for a dividend schedule.

Data Types: double | timetable

## **Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Price Vanilla Instrument Using Black-Scholes Model and Black-Scholes Pricer**

This example shows the workflow to price a Vanilla instrument when you use a `BlackScholes` model and a `BlackScholes` pricing method.

#### **Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2018,5,1), 'Strike', 29, 'OptionType', 'put')
```

```
VanillaOpt =
```

```
  Vanilla with properties:
```

```
      OptionType: "put"
      ExerciseStyle: "european"
      ExerciseDate: 01-May-2018
      Strike: 29
      Name: "vanilla_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.25)
```

```
BlackScholesModel =
```

```
  BlackScholes with properties:
```

```
      Volatility: 0.2500
      Correlation: 1
```

#### **Create ratecurve Object**

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2019,1,1);
Rate = 0.05;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 1
      Dates: 01-Jan-2019
      Rates: 0.0500
      Settle: 01-Jan-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create BlackScholes Pricer Object

Use `finpricer` to create a BlackScholes pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',30,'DividendValue',0.0450)
```

```
outPricer =
  BlackScholes with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 30
      DividendType: "continuous"
      DividendValue: 0.0450
```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 1.2046
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x7 table]
      PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Rho	Theta
-------	-------	-------	--------	------	-----	-------

```
1.2046    -0.36943    0.086269    -9.3396    6.4702    -4.0959    -2.3107
```

## Use Black-Scholes Pricer and Black-Scholes Model to Price Vanilla Instrument for Foreign Exchange

This example shows the workflow to price a Vanilla instrument for foreign exchange (FX) when you use a BlackScholes model and a BlackScholes pricing method. Assume that the current exchange rate is \$0.52 and has a volatility of 12% per annum. The annualized continuously compounded foreign risk-free rate is 8% per annum.

### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', .50, 'OptionType
```

```
VanillaOpt =
  Vanilla with properties:

    OptionType: "put"
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
    Strike: 0.5000
    Name: "vanilla_fx_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
Sigma = .12;
BlackScholesModel = finmodel("BlackScholes", 'Volatility', Sigma)
```

```
BlackScholesModel =
  BlackScholes with properties:

    Volatility: 0.1200
    Correlation: 1
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)

myRC =
  ratecurve with properties:

    Type: "zero"
```

```

    Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
    InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"

```

## Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument. When you price currencies using a `Vanilla` instrument, the `DividendType` must be 'continuous' and the `DividendValue` is the annualized risk-free interest rate in the foreign country.

```

ForeignRate = 0.08;
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', .52,
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 0.5200
    DividendType: "continuous"
    DividendValue: 0.0800

```

## Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` FX instrument.

```

[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
Price = 0.1123
outPR =
  pricerresult with properties:

    Results: [1x7 table]
    PricerData: []

```

outPR.Results

ans=1x7 table

Price	Delta	Gamma	Lambda	Vega	Rho	Theta
0.11229	-0.59114	1.5562	-3.7706	0.20212	-1.6799	-0.023676

# ConzeViswanathan

Create ConzeViswanathan pricer object for Lookback instrument using BlackScholes model

## Description

Create and price a Lookback instrument object with a BlackScholes model and a ConzeViswanathan pricing method using this workflow:

- 1 Use `fininstrument` to create a Lookback instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Lookback instrument.
- 3 Use `finpricer` to specify a ConzeViswanathan pricer object for the Lookback instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Lookback instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
ConzeViswanathanPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)
ConzeViswanathanPricerObj = finpricer( ___, Name, Value)
```

### Description

`ConzeViswanathanPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)` creates a ConzeViswanathan pricer object by specifying `PricerType` and sets the properties on page 11-2371 for the required name-value pair argument `Model`, `DiscountCurve`, and `SpotPrice`.

`ConzeViswanathanPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2371 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `ConzeViswanathanPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "ConzeViswanathan")` creates a ConzeViswanathan pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### ConzeViswanathan Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, . . . , `NameN`, `ValueN`.

Example: `ConzeViswanathanPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "ConzeViswanathan")`

### Required ConzeViswanathan Name-Value Pair Arguments

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for `DiscountCurve`. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at `Maturity` and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### Model — Model

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using `finmodel`.

Data Types: object

#### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### Optional ConzeViswanathan Name-Value Pair Arguments

#### DividendType — Stock dividend type

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and character vector or string. `DividendType` must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

**DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar numeric | timetable

Dividend amount for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

---

**Note** Specify a scalar if DividendType is "continuous" and a timetable if DividendType is "cash".

---

Data Types: double | timetable

**PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "ConzeViswanathan" | character vector with value 'ConzeViswanathan'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a string or character vector.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

**Properties****DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object.

Data Types: object

**Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

**DividendType — Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous"

This property is read-only.

Stock dividend type, returned as a string. DividendType is "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: string

### **DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend amounts or dividend schedule for underlying stock, returned as a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: double | timetable

### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "ConzeViswanathan"

Analytic pricing method, returned as a string.

Data Types: string

## **Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use Conze-Viswanathan Pricer and Black-Scholes Model to Price Lookback Instrument**

This example shows the workflow to price a fixed strike Lookback instrument when you use a BlackScholes model and a ConzeViswanathan pricing method.

#### **Create Lookback Instrument Object**

Use `fininstrument` to create a fixed strike Lookback instrument object.

```
LookbackOpt = fininstrument("Lookback", 'Strike', 90, 'ExerciseDate', datetime(2021,9,15), 'OptionType', 'put')
```

```
LookbackOpt =  
    Lookback with properties:  
  
        OptionType: "put"  
        Strike: 90  
        AssetMinMax: NaN  
        ExerciseStyle: "european"  
        ExerciseDate: 15-Sep-2021  
        Name: "lookback_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .358)
```

```
BlackScholesModel =  
    BlackScholes with properties:  
  
        Volatility: 0.3580
```

```
Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create ConzeViswanathan Pricer Object

Use finpricer to create a ConzeViswanathan pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',95,'I
```

```
outPricer =
  ConzeViswanathan with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 95
      DividendValue: 0.0250
      DividendType: "continuous"
```

### Price Lookback Instrument

Use price to compute the price and sensitivities for the Lookback instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])
```

```
Price = 29.6209
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x7 table]
      PricerData: []
```

```
outPR.Results
```

ans=1x7 table

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
29.621	-0.49834	0.0085048	-1.5983	78.573	-3.4045	-163.55

# Credit

Create `Credit` pricer object for CDS instrument using `defprobcurve`

## Description

Create and price a CDS instrument object with a `defprobcurve` and a `Credit` pricing method using this workflow:

- 1 Create a default probability curve object using `defprobcurve`.
- 2 Use `finpricer` to specify a `Credit` pricer object for the CDS instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a CDS instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
CreditPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, '
DefaultProbabilityCurve', defprobcurve_object)
```

### Description

`CreditPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'DefaultProbabilityCurve', defprobcurve_object)` creates a `Credit` pricer object by specifying `PricerType` and the required name-value pair arguments `DiscountCurve` and `DefaultProbabilityCurve` to set properties on page 11-2376 using name-value pairs. For example, `CreditPricerObj = finpricer("Credit", 'DiscountCurve', ratecurve_obj, 'DefaultProbabilityCurve', defprobcurve_obj)` creates a `Credit` pricer object.

### Input Arguments

#### **PricerType** – Pricer type

string with value "Credit" | character vector with value 'Credit'

Pricer type, specified as a string with the value of "Credit" or a character vector with the value of 'Credit'.

Data Types: char | string

#### **Credit Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: CreditPricerObj =
finpricer("Credit", 'DiscountCurve', ratecurve_obj, 'DefaultProbabilityCurve', de
fprobcurve_obj)
```

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object

Data Types: object

### **DefaultProbabilityCurve — Default probability curve**

defprobcurve object

Default probability curve, specified as the comma-separated pair consisting of 'DefaultProbabilityCurve' and the name of a previously created defprobcurve object.

Data Types: object

## **Properties**

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object

Data Types: object

### **DefaultProbabilityCurve — Default probability curve**

defprobcurve object

Default probability curve, returned as a defprobcurve object.

Data Types: object

## **Object Functions**

price Compute price for credit derivative instrument with Credit pricer

## **Examples**

### **Use Credit Pricer and Default Probability Curve to Price CDS Instrument**

This example shows the workflow to price a CDS instrument when you use a defprobcurve model and a Credit pricing method.

#### **Create CDS Instrument Object**

Use fininstrument to create a CDS instrument object.

```
CDS = fininstrument("cds", 'Maturity', datetime(2027,9,20), 'ContractSpread', 50, 'Name', "CDS_instrum
```

```
CDS =
    CDS with properties:
```

```

ContractSpread: 50
Maturity: 20-Sep-2027
Period: 4
Basis: 2
RecoveryRate: 0.4000
BusinessDayConvention: "actual"
Holidays: NaT
PayAccruedPremium: 1
Notional: 10000000

### Create defprobcurve Object

Create a defprobcurve object using defprobcurve.

```

Settle = datetime(2017, 9, 20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities)

```

```

DefaultProbCurve =
  defprobcurve with properties:

      Settle: 20-Sep-2017
      Basis: 2
      Dates: [10x1 datetime]
  DefaultProbabilities: [10x1 double]

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero", Settle, ZeroDates, ZeroRates)

```

```

ZeroCurve =
  ratecurve with properties:

      Type: "zero"
  Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 20-Sep-2017
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"

```

### Create Credit Pricer Object

Use finpricer to create a Credit pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
CDSpricer = finpricer("credit", 'DiscountCurve', ZeroCurve, 'DefaultProbabilityCurve', DefaultProbCu
CDSpricer =
  Credit with properties:
      DiscountCurve: [1x1 ratecurve]
      TimeStep: 10
      DefaultProbabilityCurve: [1x1 defprobcurve]
```

### **Price CDS Instrument**

Use price to compute the price for the CDS instrument.

```
outPrice = price(CDSpricer, CDS)
```

```
outPrice = 6.9363e+04
```

# CDSBlack

Create CDSBlack pricer object for CDSOption instrument using CDSBlack model

## Description

Create and price a CDSOption instrument object with a CDSBlack model and a CDSBlack pricing method using this workflow:

- 1 Use `fininstrument` to create the CDSOption instrument object.
- 2 Use `finmodel` to specify the CDSBlack model for the CDSOption instrument.
- 3 Use `finpricer` to specify the CDSBlack pricer object for the CDSOption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a CDSOption instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
CDSBlackPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'DefaultProbabilityCurve', defaultprobabilitycurve_obj)
```

### Description

`CDSBlackPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'DefaultProbabilityCurve', defaultprobabilitycurve_obj)` creates a CDSBlack pricer object by specifying `PricerType` and the required name-value pair arguments for `DiscountCurve`, `Model`, and `DefaultProbabilityCurve` to set properties on page 11-2380 using name-value pairs. For example, `CDSBlackPricerObj = finpricer("Analytic", 'Model', CDSBlack, 'DiscountCurve', ratecurve_obj, 'DefaultProbabilityCurve', defaultprobabilitycurve_obj)` creates a CDSBlack pricer object.

### Input Arguments

#### **PricerType** — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or the character vector with a value of 'Analytic'.

Data Types: char | string

**CDSBlack Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: CDSBlackPricerObj =  
finpricer("Analytic", 'Model', CDSBlack, 'DiscountCurve', ratecurve_obj, 'DefaultP  
robabilityCurve', defaultprobabilitycurve_obj)
```

**Required CDSBlack Name-Value Pair Arguments****DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

Data Types: object

**Model — Model**

CDSBlack model object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of a previously created CDSBlack model object using `finmodel`.

Data Types: object

**DefaultProbabilityCurve — Default probability curve**

defprobcurve object

Default probability curve, specified as the comma-separated pair consisting of 'DefaultProbabilityCurve' and a name of a previously created defprobcurve.

Data Types: object

**Properties****DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object.

Data Types: object

**Model — Model**

CDSBlack model object

Model, returned as a CDSBlack model object.

Data Types: object

**DefaultProbabilityCurve — Default probability curve**

object

Default probability curve, returned as a defprobcurve object.

Data Types: object

## Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## Examples

### Use CDS Black Pricer and CDS Black Model to Price CDSOption Instrument

This example shows the workflow to price a CDSOption instrument when you use a CDSBlack model and a CDSBlack pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2017,9,20);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero", Settle, ZeroDates ,ZeroRates)
```

ZeroCurve =

ratecurve with properties:

```

    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 20-Sep-2017
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

#### Create defprobcurve Object

Create a defprobcurve object using defprobcurve.

```
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities)
```

DefaultProbCurve =

defprobcurve with properties:

```

    Settle: 20-Sep-2017
    Basis: 2
    Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

#### Create CDS Instrument Object

Use fininstrument to create an underlying CDS instrument object.

```

ContractSpreadBP = 0; % Contractual spread is determined on ExerciseDate
CDS = fininstrument("CDS", 'Maturity', datetime(2027,9,20), 'ContractSpread', ContractSpreadBP)

CDS =
  CDS with properties:
      ContractSpread: 0
      Maturity: 20-Sep-2027
      Period: 4
      Basis: 2
      RecoveryRate: 0.4000
  BusinessDayConvention: "actual"
      Holidays: NaT
  PayAccruedPremium: 1
      Notional: 10000000
      Name: ""

```

### Create CDSOption Instrument Object

Use `fininstrument` to create a `CDSOption` instrument object.

```

ExerciseDate = datetime(2017, 12, 20);
Strike = 50;
CDSOption = fininstrument("CDSOption", 'Strike', Strike, 'ExerciseDate', ExerciseDate, 'OptionType', "put")

CDSOption =
  CDSOption with properties:
      OptionType: "put"
      Strike: 50
      Knockout: 0
  ExerciseDate: 20-Dec-2017
      CDS: [1x1 fininstrument.CDS]
      Name: ""

```

### Create CDSBlack Model Object

Use `finmodel` to create a `CDSBlack` model object.

```

SpreadVolatility = 0.3;
CDSOptionModel = finmodel("CDSBlack", 'SpreadVolatility', SpreadVolatility)

CDSOptionModel =
  CDSBlack with properties:
      SpreadVolatility: 0.3000

```

### Create CDSBlack Pricer Object

Use `finpricer` to create a `CDSBlack` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

CDSOptionpricer = finpricer("analytic", 'Model', CDSOptionModel, 'DiscountCurve', ZeroCurve, 'Default')

CDSOptionpricer =
  CDSBlack with properties:

```

```
Model: [1x1 finmodel.CDSBlack]
DiscountCurve: [1x1 ratecurve]
DefaultProbabilityCurve: [1x1 defprobcurve]
```

### **Price CDSOption Instrument**

Use `price` to compute the price for the CDSOption instrument.

```
outPrice = price(CDSOptionpricer,CDSOption)
```

```
outPrice = 6.5054
```

## NumericalIntegration

Create NumericalIntegration pricer object for Vanilla instrument using Heston, Bates, or Merton model

### Description

Create and price a Vanilla instrument object with a Heston, Bates, or Merton model and a NumericalIntegration pricing method using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a Heston, Bates, or Merton model for the Vanilla instrument.
- 3 Use `finpricer` to specify a NumericalIntegration pricer object for the Vanilla instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
NumericalIntegrationPricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)
NumericalIntegrationPricerObj = finpricer( ___,Name,Value)
```

#### Description

`NumericalIntegrationPricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)` creates a NumericalIntegration pricer object by specifying `PricerType` and sets the properties on page 11-2387 for the required name-value pair arguments `Model`, `DiscountCurve`, and `SpotPrice`.

`NumericalIntegrationPricerObj = finpricer( ___,Name,Value)` sets optional properties on page 11-2387 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `NumericalIntegrationPricerObj = finpricer("NumericalIntegration",'Model',NIModel,'DiscountCurve',ratecurve_obj,'SpotPrice',1000,'DividendValue',100,'VolRiskPremium',0.9)` creates a NumericalIntegration pricer object. You can specify multiple name-value pair arguments.

#### Input Arguments

##### PricerType — Pricer type

string with value "NumericalIntegration" | character vector with value 'NumericalIntegration'

Pricer type, specified as a string with the value of "NumericalIntegration" or a character vector with the value of 'NumericalIntegration'.

Data Types: char | string

### **NumericalIntegration Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: NumericalIntegrationPricerObj =  
 finpricer("NumericalIntegration", 'Model', NIModel, 'DiscountCurve', ratecurve\_obj, 'SpotPrice', 1000, 'DividendValue', 100, 'VolRiskPremium', 0.9)

### **Required NumericalIntegration Name-Value Pair Arguments**

#### **Model — Model**

model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created Merton, Bates, or Heston model object using finmodel.

Data Types: object

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### **Optional NumericalIntegration Name-Value Pair Arguments**

#### **DividendValue — Dividend yield**

0 (default) | scalar numeric

Dividend yield, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric.

Data Types: double

**VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

**LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with values true or false

Flag indicating Little Heston Trap formulation by Albrecher et al., specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- `true` — Use the Albrecher et al. formulation.

For more information on the `LittleTrap`, see [1] and also the Little Trap formulation is defined by  $C_j$  and  $D_j$ , see “Heston Stochastic Volatility Model” on page 11-2390 and “Bates Stochastic Volatility Jump Diffusion Model” on page 11-2392.

- `false` — Use the original Heston formation.

---

**Note** `LittleTrap` is supported only for Heston and Bates models.

---

Data Types: logical

**AbsTol — Absolute error tolerance for numerical integration**

1e-10 (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of 'AbsTol' and a scalar numeric value.

Data Types: double

**RelTol — Relative error tolerance for numerical integration**

1e-6 (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of 'RelTol' and a scalar numeric value.

Data Types: double

**IntegrationRange — Numerical integration range used to approximate continuous integral over [0 Inf]**

[1e-9 Inf] (default) | vector

Numerical integration range used to approximate the continuous integral over  $[0 \text{ Inf}]$ , specified as the comma-separated pair consisting of 'IntegrationRange' and a 1-by-2 vector representing `[LowerLimit UpperLimit]`.

Data Types: double

**Framework — Framework for computing option prices and sensitivities using numerical integration of models**

"heston1993" (default) | string with values "heston1993" or "lewis2001" | character vector with values 'heston1993' or 'lewis2001'

Framework for computing option prices and sensitivities using the numerical integration of models, specified as the comma-separated pair consisting of 'Framework' and a scalar string or character vector with the following values:

- "heston1993" or 'heston1993' — Method used in Heston (1993)
- "lewis2001" or 'lewis2001' — Method used in Lewis (2001)

Data Types: char | string

## Properties

### **Model — Model**

model object

Model, returned as a model object.

Data Types: object

### **DiscountCurve — ratecurve object for discounting cash flows**

object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

### **DividendValue — Dividend yield**

0 (default) | scalar numeric

Dividend yield, returned as a scalar numeric.

Data Types: double

### **VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, returned as a scalar numeric value.

Data Types: double

### **LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with value true or false

Flag indicating Little Heston Trap formulation by Albrecher et al., returned as a logical.

Data Types: logical

### **AbsTol — Absolute error tolerance for numerical integration**

1e-10 (default) | numeric

Absolute error tolerance for numerical integration, returned as a scalar numeric value.

Data Types: double

### **RelTol — Relative error tolerance for numerical integration**

1e-6 (default) | numeric

Relative error tolerance for numerical integration, returned as a scalar numeric value.

Data Types: double

### **IntegrationRange — Numerical integration range used to approximate continuous integral over [0 Inf]**

[1e-9 Inf] (default) | vector

Numerical integration range used to approximate the continuous integral over [0 Inf], returned as a 1-by-2 vector representing [LowerLimit UpperLimit].

Data Types: double

### **Framework — Framework for computing option prices and sensitivities using numerical integration of models**

"heston1993" (default) | string with value "heston1993" or "lewis2001"

Framework for computing option prices and sensitivities using the numerical integration of models, returned as a scalar string.

Data Types: string

## **Object Functions**

price Compute price for equity instrument with NumericalIntegration pricer

## **Examples**

### **Use Numerical Integration Pricer and Merton Model to Price Vanilla Instrument**

This example shows the workflow to price a Vanilla instrument when you use a Merton model and a NumericalIntegration pricing method.

#### **Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2020,3,15), 'ExerciseStyle', "european")
```

```
VanillaOpt =
```

```
    Vanilla with properties:
```

```
    OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Mar-2020
    Strike: 105
    Name: "vanilla_option"
```

#### **Create Merton Model Object**

Use `finmodel` to create a Merton model object.

```

MertonModel = finmodel("Merton", 'Volatility', 0.45, 'MeanJ', 0.02, 'JumpVol', 0.07, 'JumpFreq', 0.09)
MertonModel =
  Merton with properties:

    Volatility: 0.4500
      MeanJ: 0.0200
      JumpVol: 0.0700
      JumpFreq: 0.0900

```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```

myRC = ratecurve('zero', datetime(2019,9,15), datetime(2020,3,15), 0.02)
myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: 15-Mar-2020
    Rates: 0.0200
    Settle: 15-Sep-2019
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create NumericalIntegration Pricer Object

Use finpricer to create a NumericalIntegration pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("numericalintegration", 'Model', MertonModel, 'DiscountCurve', myRC, 'SpotPrice')
outPricer =
  NumericalIntegration with properties:

    Model: [1x1 finmodel.Merton]
    DiscountCurve: [1x1 ratecurve]
    SpotPrice: 100
    DividendType: "continuous"
    DividendValue: 0.0100
    AbsTol: 0.5000
    RelTol: 0.4000
    IntegrationRange: [1.0000e-09 Inf]
    CharacteristicFcn: @characteristicFcnMerton76
    Framework: "lewis2001"
    VolRiskPremium: 0.9000
    LittleTrap: 0

```

### Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
Price = 10.7325
outPR =
  pricerresult with properties:
      Results: [1x6 table]
  PricerData: []

outPR.Results
ans=1x6 table
  Price      Delta      Gamma      Theta      Rho      Vega
  _____  _____  _____  _____  _____  _____
  10.732     0.5058     0.012492   -12.969    19.815    27.954
```

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

Here:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is

$$dS_t = (r - q)S_t dt + \sqrt{v_t}S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v\sqrt{v_t}dW_t^\nu$$

$$E[dW_t dW_t^\nu] = \rho dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$v_0$  is the initial variance of the asset price at  $t = 0$  for ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for the variance for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of the variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

The characteristic function  $f_{Heston_j}(\phi)$  for  $j = 1$  (asset price measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - \rho\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - \rho\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}} \right)$$

$$g_j = \frac{b_j - \rho\sigma_v i\phi + d_j}{b_j - \rho\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - \rho\sigma_v i\phi)^2 - \sigma_v^2(2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - \rho\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  for the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates 1996) is an extension of the Heston model where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) are also added to model sudden asset price movements.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_J)S_t dt + \sqrt{v_t}S_t dW_t + JS_t dP_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t$$

$$E[dW_t dW_t^y] = \rho dt$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ -\frac{\left[ \ln(1 + J) - \left( \ln(1 + \mu_J) - \frac{\delta^2}{2} \right) \right]^2}{2\delta^2} \right\}$$

$v_0$  is the initial variance of the asset price at  $t = 0$  ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

$\mu_j$  is the mean of  $J$  for ( $\mu_j > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

The characteristic function  $f_{Bates_j(\phi)}$  for  $j = 1$  (asset price mean measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t) \exp(\lambda_p \tau (1 + \mu_j)^{m_j + \frac{1}{2}} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 (m_j i\phi + \frac{(i\phi)^2}{2})} - 1 \right] - \lambda_p \tau \mu_j i\phi)$$

$$m_j = \begin{cases} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{cases}$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j \tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j \tau}}{1 - g_j e^{d_j \tau}} \right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - p\sigma_v i\phi)^2 - \sigma_v^2 (2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity for ( $\tau = T - t$ ).

$i$  is the unit imaginary number for ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  for the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j \tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j \tau}}{1 - \varepsilon_j e^{-d_j \tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Merton Jump Diffusion Model

The Merton jump diffusion model (Merton 1976) is an extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + JS_t dP_t$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$W_t$  is the Weiner process.

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

$\sigma$  is the volatility of the asset price for ( $\sigma > 0$ ).

The characteristic function  $f_{Merton76,j}(\phi)$  for  $j = 1$  (asset prices measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Merton76,j} = f_{BS_j} \exp\left(\lambda_p \tau (1 + \mu_j)^{m_j} + \frac{1}{2} \left[ (1 + \mu_j)^i e^{\delta^2 \left(m_j i \phi + \frac{(i\phi)^2}{2}\right)} - 1 \right] - \lambda_p \tau \mu_j i \phi\right)$$

where for  $j = 1, 2$ :

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS_2}(\phi) = \exp\left(i\phi \left[\ln S_t + \left(r - q - \frac{\sigma^2}{2}\right)\tau\right] - \frac{\phi^2 \sigma^2}{2} \tau\right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

Here:

$\phi$  is the characteristic function variable

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

### Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \text{Re} \left[ \frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T - t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$f_j(\phi)$  is the characteristic function for  $P_j$  ( $j = 1, 2$ ).

$P_1$  is the probability of  $S_t > K$  under the asset price measure for the model.

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

Where  $j = 1, 2$  so that  $f_1(\phi)$  and  $f_2(\phi)$  are the characteristic functions for probabilities  $P_1$  and  $P_2$ , respectively.

Choose this framework by specifying the default value "Heston1993" for the Framework name-value pair argument.

### Numerical Integration Method Under Lewis Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K} e^{-\tau t}}{\pi} \int_0^{\infty} \operatorname{Re} \left[ K^{-iu} f_2 \left( \phi = \left( u - \frac{i}{2} \right) \frac{1}{u^2 + \frac{1}{4}} \right) \right] du$$

$$Put(K) = Call(K) = K e^{-\tau t} - S_t e^{-q\tau}$$

Here

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$u$  is the characteristic function variable for integration, where  $\phi = \left( u - \frac{i}{2} \right)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

Choose this framework by specifying the value "Lewis2001" for the Framework name-value pair argument.

**Introduced in R2020a**

## Discount

Create `Discount` pricer object for `Deposit`, `FRA`, `Swap`, `FixedBond`, or `FloatBond` using `ratecurve` object

## Description

Create and price a `Deposit`, `FRA`, `Swap`, `FixedBond`, or `FloatBond` instrument object with a `ratecurve` and a `Discount` pricing method using this workflow:

- 1 Create an interest-rate curve object using `ratecurve`.
- 2 Use `finpricer` to specify a `Discount` pricer object for the `Deposit`, `FRA`, `Swap`, `FixedBond`, or `FloatBond` instrument.

---

**Note** If you do not specify `ProjectionCurve` when you create a `Swap` or `FloatBond` instrument with the `Discount` pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

---

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Deposit`, `FRA`, `Swap`, `FixedBond`, or `FloatBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
DiscountPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_object)
```

### Description

`DiscountPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_object)` creates a `Discount` pricer object by specifying `PricerType` and the required name-value pair argument `DiscountCurve` to set properties on page 11-2399 using name-value pairs. For example, `DiscountPricerObj = finpricer("Discount", 'DiscountCurve', ratecurve_obj)` creates a `Discount` pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Discount" | character vector with value 'Discount'

Pricer type, specified as a string with the value of "Discount" or a character vector with the value of 'Discount'.

Data Types: char | string

### Discount Name-Value Pair Arguments

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: DiscountPricerObj =
finpricer("Discount", 'DiscountCurve', ratecurve_obj)
```

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object

Data Types: object

## Properties

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object.

Data Types: object

## Object Functions

`price` Compute price for interest-rate instrument with Discount pricer

## Examples

### Use Discount Pricer and ratecurve to Price Swap Instrument

This example shows the workflow to price a Swap instrument when using a ratecurve and a Discount pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve for the underlying interest-rate curve for the Swap instrument.

```
Settle = datetime(2022,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
```

```

        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Jan-2022
    InterpMethod: "linear"
ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Swap Instrument Object

Use `fininstrument` to create a Swap instrument object.

```
SwapOpt = fininstrument("Swap", 'Maturity', datetime(2023,6,15), 'LegRate', [0.024 0.015], 'LegType',
```

```
SwapOpt =
    Swap with properties:
```

```

        LegRate: [0.0240 0.0150]
        LegType: ["fixed" "float"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
    LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
        ProjectionCurve: [1x2 ratecurve]
    BusinessDayConvention: ["actual" "actual"]
        Holidays: NaT
    EndMonthRule: [1 1]
        StartDate: NaT
        Maturity: 15-Jun-2023
        Name: "swap_instrument"

```

### Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
outPricer =
    Discount with properties:

        DiscountCurve: [1x1 ratecurve]

```

### Price Swap Instrument

Use `price` to compute the price and sensitivities for the Swap instrument.

```
[Price, outPR] = price(outPricer, SwapOpt, ["all"])
```

```
Price = 0.2845
```

```
outPR =
    pricerresult with properties:
```

```
Results: [1x2 table]
PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
0.28451	0.0075236

## FFT

Create FFT pricer object for Vanilla instrument using Merton, Heston, or Bates model

### Description

Create and price a Vanilla instrument object with a Heston, Bates, or Merton model and an FFT pricing method using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a Heston, Bates, or Merton model for the Vanilla instrument.
- 3 Use `finpricer` to specify an FFT pricer object for the Vanilla instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
FFTPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj)
FFTPricerObj = finpricer( ___, Name, Value)
```

#### Description

`FFTPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj)` creates an FFT pricer object by specifying `PricerType` and sets the properties on page 11-2405 for the required name-value pair arguments `Model` and `DiscountCurve`.

`FFTPricerObj = finpricer( ___, Name, Value)` sets optional properties on page 11-2405 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FFTPricerObj = finpricer("FFT", 'Model', FFTModel, 'DiscountCurve', ratecurve_obj, 'SpotPrice', 1000, 'DividendValue', 0.01, 'VolRiskPremium', 0.9)` creates an FFT pricer object. You can specify multiple name-value pair arguments.

#### Input Arguments

##### **PricerType** — Pricer type

string with value "FFT" | character vector with value 'FFT'

Pricer type, specified as a string with the value of "FFT" or a character vector with the value of 'FFT'.

Data Types: char | string

### FFT Name-Value Pair Arguments

Specify required and optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

```
Example: FFTPricerObj = finpricer("FFT", 'Model', FFTModel,
'DiscountCurve', ratecurve_obj, 'SpotPrice', 1000, 'DividendValue', 0.01, 'VolRiskP
remium', 0.9)
```

### Required FFT Name-Value Pair Arguments

#### **Model** — Model

model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of the previously created Merton, Bates, or Heston model object using `finmodel`.

Data Types: object

#### **DiscountCurve** — ratecurve object for discounting cash flows

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the ratecurve object.

---

**Note** Specify a flat ratecurve object for **DiscountCurve**. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at **Maturity** and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### **SpotPrice** — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### Optional FFT Name-Value Pair Arguments

#### **DividendValue** — Dividend yield

0 (default) | scalar nonnegative numeric

Dividend yield, specified as the comma-separated pair consisting of 'DividendValue' and a scalar nonnegative numeric in decimals.

Data Types: double

#### **VolRiskPremium** — Volatility risk premium

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

**LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with value true or false

Flag indicating Little Heston Trap formulation by Albrecher et al., specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- true — Use the Albrecher et al. formulation.

For more information on the LittleTrap, see [1] and also the Little Trap formulation is defined by  $C_j$  and  $D_j$  in “Heston Stochastic Volatility Model” on page 11-2408 and “Bates Stochastic Volatility Jump Diffusion Model” on page 11-2410.

- false — Use the original Heston formation.

---

**Note** LittleTrap is supported only for Heston and Bates models.

---

Data Types: logical

**NumFFT — Number of grid points in characteristic function variable**

4096 (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of 'NumFFT' and a scalar numeric value.

Data Types: double

**CharacteristicFcnStep — Characteristic function variable grid spacing**

0.01 (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of 'CharacteristicFcnStep' and a scalar numeric value.

Data Types: double

**LogStrikeStep — Log-strike grid spacing**

$2\pi/\text{NumFFT}/\text{CharacteristicFcnStep}$  (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of 'LogStrikeStep' and a scalar numeric value.

---

**Note** If  $(\text{LogStrikeStep} \times \text{CharacteristicFcnStep})$  is  $2\pi/\text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

---

Data Types: double

**DampingFactor — Damping factor for Carr-Madan formulation**

1.5 (default) | numeric

Damping factor for the Carr-Madan formulation, specified as the comma-separated pair consisting of 'DampingFactor' and a scalar numeric value.

Data Types: double

### **Quadrature — Type of quadrature**

"simpson" (default) | string with value "simpson" or "trapezoidal" | character vector with value 'simpson' or 'trapezoidal'

Type of quadrature, specified as the comma-separated pair consisting of 'Quadrature' and a scalar string or character vector.

Data Types: char | string

## **Properties**

### **Model — Model**

model object

Model, returned as a model object.

Data Types: object

### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

### **DividendValue — Dividend yield**

0 (default) | scalar nonnegative numeric

Dividend yield, returned as a scalar nonnegative numeric in decimals.

Data Types: double

### **VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, returned as a scalar numeric value.

Data Types: double

### **LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with value true or false

Flag indicating Little Heston Trap formulation by Albrecher et al., returned as a logical.

Data Types: logical

### **NumFFT — Number of grid points in the characteristic function variable**

4096 (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, returned as a scalar numeric value.

Data Types: double

**CharacteristicFcnStep — Characteristic function variable grid spacing**

0.01 (default) | numeric

Characteristic function variable grid spacing, returned as a scalar numeric value.

Data Types: double

**LogStrikeStep — Log-strike grid spacing** $2\pi/\text{NumFFT}/\text{CharacteristicFcnStep}$  (default) | numeric

Log-strike grid spacing, returned as a scalar numeric value.

Data Types: double

**DampingFactor — Damping factor for Carr-Madan formulation**

1.5 (default) | numeric

Damping factor for the Carr-Madan formulation, returned as a scalar numeric value.

Data Types: double

**Quadrature — Type of quadrature**

"simpson" (default) | string with value "simpson" or "trapezoidal"

Type of quadrature, returned as a string.

Data Types: string

**Object Functions**

price Compute price for equity instrument with FFT pricer

**Examples****Use FFT Pricer and Heston Model to Price Vanilla Instrument**

This example shows the workflow to price a Vanilla instrument when you use a Heston model and an FFT pricing method.

**Create Vanilla Instrument Object**Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'ExerciseSty
```

```
VanillaOpt =
```

```
Vanilla with properties:
```

```
    OptionType: "call"  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Sep-2022  
    Strike: 105  
    Name: "vanilla_option"
```

### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)
```

```
HestonModel =
  Heston with properties:
```

```
    V0: 0.0320
  ThetaV: 0.1000
    Kappa: 0.0030
  SigmaV: 0.2000
  RhoSV: 0.9000
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =
  ratecurve with properties:
```

```
    Type: "zero"
  Compounding: -1
    Basis: 12
    Dates: 15-Sep-2023
    Rates: 0.0350
    Settle: 15-Sep-2018
  InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"
```

### Create FFT Pricer Object

Use `finpricer` to create an FFT pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("fft", 'DiscountCurve', myRC, 'Model', HestonModel, 'SpotPrice', 100, 'CharacteristicFcn', @characteristicFcnHeston)
```

```
outPricer =
  FFT with properties:
```

```
    Model: [1x1 finmodel.Heston]
  DiscountCurve: [1x1 ratecurve]
    SpotPrice: 100
    DividendType: "continuous"
  DividendValue: 0
    NumFFT: 8192
  CharacteristicFcnStep: 0.2000
    LogStrikeStep: 0.0038
  CharacteristicFcn: @characteristicFcnHeston
  DampingFactor: 1.5000
```

```

    Quadrature: "simpson"
  VolRiskPremium: 0
  LittleTrap: 1

```

### Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

Here:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (the square root of the variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This process allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is

$$dS_t = (r - q)S_t dt + \sqrt{v_t}S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$E[dW_t dW_t^v] = \rho dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$v_0$  is the initial variance of the asset price at  $t = 0$  for ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for the variance for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of the variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

The characteristic function  $f_{Heston_j}(\phi)$  for  $j = 1$  (asset price measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}} \right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - p\sigma_v i\phi)^2 - \sigma_v^2 (2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  in the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates 1996) is an extension of the Heston model where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) are also added to model sudden asset price movements.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_J)S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t$$

$$E[dW_t dW_t^v] = \rho dt$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ -\frac{\left[ \ln(1 + J) - \left( \ln(1 + \mu_J) - \frac{\delta^2}{2} \right) \right]^2}{2\delta^2} \right\}$$

Here:

$v_0$  is the initial variance of the asset price at  $t = 0$  ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

$\mu_j$  is the mean of  $J$  for ( $\mu_j > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

The characteristic function  $f_{Bates_j(\phi)}$  for  $j = 1$  (asset price mean measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t) \exp(\lambda_p \tau (1 + \mu_j)^{m_j + \frac{1}{2}} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 (m_j i\phi + \frac{(i\phi)^2}{2})} - 1 \right] - \lambda_p \tau \mu_j i\phi)$$

$$m_j = \begin{cases} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{cases}$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - \rho\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j \tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - \rho\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j \tau}}{1 - g_j e^{d_j \tau}} \right)$$

$$g_j = \frac{b_j - \rho\sigma_v i\phi + d_j}{b_j - \rho\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - \rho\sigma_v i\phi)^2 - \sigma_v^2 (2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - \rho\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity for ( $\tau = T - t$ ).

$i$  is the unit imaginary number for ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  in the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Merton Jump Diffusion Model

The Merton jump diffusion model (Merton 1976) is an extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + JS_t dP_t$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$W_t$  is the Weiner process.

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{ -\frac{\left[ \ln(1+J) - \left( \ln(1 + \mu_J) - \frac{\delta^2}{2} \right) \right]^2}{2\delta^2} \right\}$$

Here:

$\mu_J$  is the mean of  $J$  for  $(\mu_J > -1)$ .

$\delta$  is the standard deviation of  $\ln(1+J)$  for  $(\delta \geq 0)$ .

$\lambda_p$  is the annual frequency (intensity) of the Poisson process  $P_t$  for  $(\lambda_p \geq 0)$ .

$\sigma$  is the volatility of the asset price for  $(\sigma > 0)$ .

The characteristic function  $f_{Merton76,j}(\phi)$  for  $j = 1$  (asset price measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Merton76j} = f_{BSj} \exp \left( \lambda_p \tau (1 + \mu_j)^{mj} + \frac{1}{2} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 \left( m_j i \phi + \frac{(i\phi)^2}{2} \right)} - 1 \right] - \lambda_p \tau \mu_j i \phi \right)$$

where for  $j = 1, 2$ :

$$f_{BS1}(\phi) = \frac{f_{BS2}(\phi - i)}{f_{BS2}(-i)}$$

$$f_{BS2}(\phi) = \exp \left( i\phi \left[ \ln S_t + \left( r - q - \frac{\sigma^2}{2} \right) \tau \right] - \frac{\phi^2 \sigma^2 \tau}{2} \right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

Here:

$\phi$  is the characteristic function variable.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

### Carr-Madan Formulation

The Carr-Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities  $P_1$  and  $P_2$  as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi} \int_0^{\infty} \text{Re} \left[ e^{-iuk} \psi(u) \right] du$$

$$\psi(u) = \frac{e^{-r\tau} f_2(\phi = (u - (\alpha + 1)i))}{\alpha^2 + \alpha - u^2 + iu(2\alpha + 1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$\tau$  is time to maturity ( $\tau = T - t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$

$i$  is a unit imaginary number ( $i^2 = -1$ )

$\phi$  is the characteristic function variable.

$\alpha$  is the damping factor.

$u$  is the characteristic function variable for integration, where  $\phi = (u - (\alpha+1)i)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration  $u$  is discretized into NumFFT( $N$ ) points with the step size CharacteristicFcnStep ( $\Delta u$ ), and the log-strike  $k$  is discretized into  $N$  points with the step size LogStrikeStep( $\Delta k$ ).

The discretized characteristic function variable for integration  $u_j$ (for  $j = 1, 2, 3, \dots, N$ ) has a minimum value of 0 and a maximum value of  $(N-1) (\Delta u)$ , and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid  $k_n$ (for  $n = 1, 2, 3, N$ ) is approximately centered around  $\ln(S_t)$ , with a minimum value of

$$\ln(S_t) - \frac{N}{2}\Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^N \operatorname{Re}\left[e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iu_j \left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j)\right] w_j$$

Here:

$\Delta u$  is the step size of the discretized characteristic function variable for integration.

$\Delta k$  is the step size of the discretized log strike.

$N$  is the number of FFT or FRFT points.

$w_j$  is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if  $\Delta k$  and  $\Delta u$  are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

Otherwise, the functions use the FRFT method described in Chourdakis (2005).

# GoldmanSosinGatto

Create GoldmanSosinGatto pricer object for Lookback instrument using BlackScholes model

## Description

Create and price a Lookback instrument object with a BlackScholes model and a GoldmanSosinGatto pricing method using this workflow:

- 1 Use `fininstrument` to create a Lookback instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Lookback instrument.
- 3 Use `finpricer` to specify a GoldmanSosinGatto pricer object for the Lookback instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Lookback instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
GoldmanSosinGattoPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)
GoldmanSosinGattoPricerObj = finpricer( ___, Name, Value)
```

### Description

`GoldmanSosinGattoPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)` creates a GoldmanSosinGatto pricer object by specifying `PricerType` and sets the properties on page 11-2418 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`GoldmanSosinGattoPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2418 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `GoldmanSosinGattoPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 500, 'PricingMethod', "GoldmanSosinGatto")` creates a GoldmanSosinGatto pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### GoldmanSosinGatto Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

```
Example: GoldmanSosinGattoPricerObj =
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice',
1000, 'DividendType', "continuous", 'DividendValue', 500, 'PricingMethod', "GoldmanSosinGatto")
```

### Required GoldmanSosinGatto Name-Value Pair Arguments

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### Model — Model

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

#### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### Optional GoldmanSosinGatto Name-Value Pair Arguments

#### DividendType — Stock dividend type

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and a character vector or string. DividendType must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

**DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar numeric | timetable

Dividend amount for underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

---

**Note** Specify a scalar if DividendType is "continuous" and a timetable if DividendType is "cash".

---

Data Types: double | timetable

**PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "GoldmanSosinGatto" | character vector with value 'GoldmanSosinGatto'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a character vector or string.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

**Properties****DiscountCurve — ratecurve object for discounting cash flows**

object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

**Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

**DividendType — Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous"

This property is read-only.

Stock dividend type, returned as a string. DividendType is either "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: string

### **DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend amount or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend amount or a timetable for a dividend schedule.

Data Types: double | timetable

### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "GoldmanSosinGatto"

Analytic pricing method, returned as a string.

Data Types: string

## **Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use Goldman-Sosin-Gatto Pricer and Black-Scholes Model to Price Lookback Instrument**

This example shows the workflow to price a floating-strike Lookback instrument when you use a BlackScholes model and a GoldmanSosinGatto pricing method.

#### **Create Lookback Instrument Object**

Use `fininstrument` to create a floating-strike Lookback instrument object where the `Strike` argument is specified as `NaN`.

```
LookbackOpt = fininstrument("lookback", 'Strike', NaN, 'ExerciseDate', datetime(2021,9,15), 'OptionType', 'put')
```

```
LookbackOpt =
  Lookback with properties:
    OptionType: "put"
    Strike: NaN
    AssetMinMax: NaN
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2021
    Name: "lookback_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .358)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```

    Volatility: 0.3580
    Correlation: 1

```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```

myRC =
    ratecurve with properties:

        Type: "zero"
        Compounding: -1
        Basis: 12
        Dates: 15-Sep-2023
        Rates: 0.0350
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create GoldmanSosinGatto Pricer Object

Use finpricer to create a GoldmanSosinGatto pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,

```

```

outPricer =
    GoldmanSosinGatto with properties:

        DiscountCurve: [1x1 ratecurve]
        Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
        DividendType: "continuous"
        DividendValue: 0.0250

```

### Price Lookback Instrument

Use price to compute the price and sensitivities for the floating-strike Lookback instrument.

```

[Price, outPR] = price(outPricer,LookbackOpt,["all"])

```

```

Price = 53.3720

```

```

outPR =
    pricerresult with properties:

```

```

        Results: [1x7 table]
        PricerData: []

```

```

outPR.Results

```

ans=1x7 table

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
53.372	0.53372	-1.4211e-06	1	181.37	-8.7793	-213.01

## HullWhite

Create HullWhite pricer object for Cap, Floor, or Swaption instrument using HullWhite model

### Description

Create and price a Cap, Floor, or Swaption instrument object with a HullWhite model and a HullWhite pricing method using this workflow:

- 1 Use `fininstrument` to create a Cap, Floor, or Swaption instrument object.
- 2 Use `finmodel` to specify the HullWhite model for the Cap, Floor, or Swaption instrument.
- 3 Use `finpricer` to specify the HullWhite pricer object for the Cap, Floor, or Swaption instrument.

---

**Note** If you do not specify `ProjectionCurve` when you create a Cap, Floor, or Swaption instrument with the HullWhite pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

---

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Cap, Floor, or Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
HullWhitePricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)
```

### Description

`HullWhitePricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)` creates a HullWhite pricer object by specifying `PricerType` and the required name-value pair arguments `DiscountCurve` and `Model` to set properties on page 11-2423 using name-value pairs. For example, `HullWhitePricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', HWMModel)` creates a HullWhite pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### HullWhite Name-Value Pair Arguments

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `HullWhitePricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', HWModel)`

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Data Types: object

### Model — Model

HullWhite model object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of the previously created HullWhite model object using `finmodel`.

Data Types: object

## Properties

### DiscountCurve — ratecurve object for discounting cash flows

object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### Model — Model

HullWhite model object

Model, returned as a HullWhite model object.

Data Types: object

## Object Functions

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## Examples

### Use Hull-White Pricer and Hull-White Model to Price a Floor Instrument

This example shows the workflow to price a Floor instrument when you use a HullWhite model and a HullWhite pricing method.

### Create Floor Instrument Object

Use `fininstrument` to create a Floor instrument object.

```
FloorOpt = fininstrument("Floor", 'Strike', 0.02, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Princip
```

```
FloorOpt =
  Floor with properties:
      Strike: 0.0200
      Maturity: 30-Jan-2019
      ResetOffset: 0
      Reset: 4
      Basis: 8
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "floor_option"
```

### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.032, 'Sigma', 0.04)
```

```
HullWhiteModel =
  HullWhite with properties:
      Alpha: 0.0320
      Sigma: 0.0400
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
```

```
LongExtrapMethod: "previous"
```

### Create HullWhite Pricer Object

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', HullWhiteModel, 'DiscountCurve', myRC)
```

```
outPricer =
```

```
  HullWhite with properties:
```

```
    DiscountCurve: [1x1 ratecurve]
           Model: [1x1 finmodel.HullWhite]
```

### Price Floor Instrument

Use `price` to compute the price for the `Floor` instrument.

```
Price = price(outPricer, FloorOpt)
```

```
Price = 0.5809
```

## See Also

### Functions

`fininstrument` | `finmodel` | `ratecurve`

### Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-42

### Introduced in R2020a

## IRTree

Create `IRTree` pricer object for `FloatBond`, `FixedBond`, `FixedBondOption`, or `OptionEmbeddedFixedBond` instrument

### Description

Create and price a `FloatBond`, `FixedBond`, `FixedBondOption`, or `OptionEmbeddedFixedBond` instrument object with a `HullWhite` or `BlackKarasinski` model and an `IRTree` pricing method using this workflow:

- 1 Use `fininstrument` to create a `FloatBond`, `FixedBond`, `FixedBondOption`, or `OptionEmbeddedFixedBond` instrument object.
- 2 Use `finmodel` to specify a `HullWhite` or `BlackKarasinski` model for the `FixedBond`, `FloatBond`, `FixedBondOption`, or `OptionEmbeddedFixedBond` instrument.
- 3 Use `finpricer` to specify an `IRTree` pricer object for a BK or HW trinomial tree model for the `FixedBond`, `FloatBond`, `FixedBondOption`, or `OptionEmbeddedFixedBond` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `FixedBond`, `FloatBond`, `OptionEmbeddedFixedBond`, or `FixedBondOption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
IRTreePricerObj = finpricer(PricerType, 'Model', model_type, 'DiscountCurve', ratecurve_obj, 'TreeDates', tree_dates)
```

### Description

`IRTreePricerObj = finpricer(PricerType, 'Model', model_type, 'DiscountCurve', ratecurve_obj, 'TreeDates', tree_dates)` creates a `IRTree` pricer object by specifying `PricerType` and the required name-value pair arguments for `Model`, `DiscountCurve`, and `TreeDates` to set properties on page 11-2427 using name-value pair arguments. For example, `IRTreePricerObj = finpricer("IRTree", 'Model', HullWhite, 'DiscountCurve', ratecure_obj, 'TreeDates', ['jan-30-2018'; 'jan-30-2019'])` creates an `IRTree` pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "IRTree" | character vector with value 'IRTree'

Pricer type, specified as a string with the value of "IRTree" or a character vector with the value of 'IRTree'.

Data Types: char | string

### IRTree Name-Value Pair Arguments

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

```
Example: IRTreePricerObj =
finpricer("IRTree", 'Model', HullWhite, 'DiscountCurve', ratecurve_obj, 'TreeDates'
, ['jan-30-2018'; 'jan-30-2019'])
```

### Model — Model type

string with value of "HullWhite" or "BlackKarasinski" | character vector with value of 'HullWhite' or 'BlackKarasinski'

Model type, specified as the comma-separated pair consisting of 'Model' and a character vector or string.

---

**Note** When you use a "HullWhite" model, the IRTree pricer uses the HW2000 algorithm [1].

---

Data Types: char | string

### DiscountCurve — ratecurve object for creating IRTree and discounting cash flows

ratecurve object

This property is read-only.

ratecurve object for creating IRTree and discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a ratecurve object.

Data Types: object

### TreeDates — Dates marking the cash flow dates of the tree

vector

Dates marking the cash flow dates of the tree, specified as the comma-separated pair consisting of 'TreeDates' and an NLEVELS-by-1 vector of dates. Cash flows with these dates will fall on tree nodes. The TreeDates argument determines the number of levels, or depth, of the tree. List dates in increasing order.

Data Types: double | cell | datetime

## Properties

### Tree — HW or BK trinomial tree

struct for HW or BK tree

HW or BK trinomial tree, returned as a struct with the following properties:

- `tObs` contains the time factor of each level of the tree.
- `dObs` contains the date of each level of the tree.
- `Probs` contains a cell array of 3-by-N numeric arrays with the up, mid, down probabilities of each node of the tree except for the last level. The cells in the cell array are ordered from root node.

The arrays are 3-by-N with the first row corresponding to an up move, the mid row to a mid-move, and so on. Each column of the array represents a node starting from the top node of a given level.

- `CFlowT` is a cell array with as many elements as levels of the tree. Each cell array element contains the time factors (`tObs`) corresponding to its level of the tree and those levels ahead of it.
- `Connect` contains a cell array with connectivity information for each node of the tree. The arrangement is similar to `Probs`, with the exception that it has only one row in each cell. The number represents the node in the next level to which the middle branch connects to. The top branch connects to the value above (minus one) and the lower branch connects to the value below (plus one).
- `FwdTree` contains the forward spot rate from one node to the next. The forward spot rate is defined as the inverse of the discount factor.

Data Types: `struct`

### **TreeDates — Tree dates**

`datetime`

Tree dates, returned as a scalar `datetime` or `datetime` array.

Data Types: `datetime`

### **Model — Model type**

string with value of "HullWhite" or "BlackKarasinski"

Model type, returned as a string.

Data Types: `string`

### **DiscountCurve — ratecurve object for creating IRTree and discounting cash flows**

`ratecurve` object

This property is read-only.

`ratecurve` object for creating the `IRTree` object and discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

## **Object Functions**

`price` Compute price for interest-rate instrument with `IRTree` pricer

## **Examples**

### **Use Hull-White Tree Pricer and Hull-White Model to Price FixedBondOption Instrument**

This example shows the workflow to price a `FixedBondOption` instrument when you use a `HullWhite` model and an `IRTree` pricing method.

#### **Create FixedBond Instrument Object**

Use `fininstrument` to create a `FixedBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond", 'Maturity', datetime(2029,9,15), 'CouponRate', 0.025, 'Period',
```

```

BondInst =
  FixedBond with properties:
      CouponRate: 0.0250
      Period: 1
      Basis: 0
      EndMonthRule: 1
      Principal: 100
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      IssueDate: NaT
      FirstCouponDate: NaT
      LastCouponDate: NaT
      StartDate: NaT
      Maturity: 15-Sep-2029
      Name: "fixed_bond_instrument"

```

### Create FixedBondOption Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object.

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 98, 'B
```

```

FixedBOption =
  FixedBondOption with properties:
      OptionType: "call"
      ExerciseStyle: "european"
      ExerciseDate: 15-Sep-2025
      Strike: 98
      Bond: [1x1 fininstrument.FixedBond]
      Name: "fixed_bond_option_instrument"

```

### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```

Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2019
      InterpMethod: "linear"
      ShortExtrapMethod: "next"

```

```
LongExtrapMethod: "previous"
```

### Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.01, 'Sigma', 0.05)
```

```
HullWhiteModel =  
HullWhite with properties:
```

```
Alpha: 0.0100  
Sigma: 0.0500
```

### Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
HWTreepricer = finpricer("irtree", 'Model', HullWhiteModel, 'DiscountCurve', myRC, 'TreeDates', ZeroData)
```

```
HWTreepricer =  
HWBKTree with properties:
```

```
Tree: [1x1 struct]  
TreeDates: [10x1 datetime]  
Model: [1x1 finmodel.HullWhite]  
DiscountCurve: [1x1 ratecurve]
```

```
HWTreepricer.Tree
```

```
ans = struct with fields:  
FinObj: 'HWFwdTree'  
tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]  
dObs: [1x10 datetime]  
CFlowT: {1x10 cell}  
Probs: {1x9 cell}  
Connect: {1x9 cell}  
FwdTree: {1x10 cell}
```

### Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(HWTreepricer, FixedBOption, ["all"])
```

```
Price = 11.1370
```

```
outPR =  
pricerresult with properties:
```

```
Results: [1x4 table]  
PricerData: [1x1 struct]
```

```
outPR.Results
```

ans=1x4 table

Price	Vega	Gamma	Delta
11.137	242.76	3662.6	-271.74

## Use Black-Karasinski Tree Pricer and Black-Karasinski Model to Price FixedBondOption Instrument

This example shows the workflow to price a FixedBondOption instrument when you use a BlackKarasinski model and an IRTree pricing method.

### Create FixedBond Instrument Object

Use `fininstrument` to create a FixedBond instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond", 'Maturity', datetime(2029,9,15), 'CouponRate', 0.025, 'Period', 1)
```

```
BondInst =
    FixedBond with properties:
        CouponRate: 0.0250
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2029
        Name: "fixed_bond_instrument"
```

### Create FixedBondOption Instrument Object

Use `fininstrument` to create a FixedBondOption instrument object.

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 100, 'OptionType', 'call')
```

```
FixedBOption =
    FixedBondOption with properties:
        OptionType: "call"
        ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2025
        Strike: 100
        Bond: [1x1 fininstrument.FixedBond]
        Name: "fixed_bond_option"
```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2019
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create BlackKarasinski Model Object

Use finmodel to create a BlackKarasinski model object.

```
BlackKarasinskiModel = finmodel("BlackKarasinski", 'Alpha',0.02, 'Sigma',0.34)
```

```
BlackKarasinskiModel =
    BlackKarasinski with properties:
        Alpha: 0.0200
        Sigma: 0.3400
```

### Create IRTree Pricer Object

Use finpricer to create an IRTree pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
BKTreePricer = finpricer("IRTree", 'Model',BlackKarasinskiModel, 'DiscountCurve',myRC, 'TreeDates', ...)
```

```
BKTreePricer =
    HWBKTree with properties:
        Tree: [1x1 struct]
        TreeDates: [10x1 datetime]
        Model: [1x1 finmodel.BlackKarasinski]
        DiscountCurve: [1x1 ratecurve]
```

```
BKTreePricer.Tree
```

```
ans = struct with fields:
    FinObj: 'BKFwdTree'
```

```

tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
dObs: [1x10 datetime]
CFlowT: {1x10 cell}
Probs: {1x9 cell}
Connect: {1x9 cell}
FwdTree: {1x10 cell}

```

### Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(BKTreePricer,FixedBOption,["all"])
```

```
Price = 0.5810
```

```
outPR =
    pricerresult with properties:
```

```

    Results: [1x4 table]
    PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x4 table
    Price      Vega      Gamma      Delta
    _____  _____  _____  _____
    0.58103    2.797    45.967    -15.872
```

### Use Hull-White Tree Pricer and Hull-White Model to Price Vanilla FixedBond Instrument

This example shows the workflow to price a vanilla `FixedBond` instrument when you use a `HullWhite` model and an `IRTree` pricing method.

#### Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```

Maturity = datetime(2024,1,1);
Period = 1;
VBond = fininstrument("FixedBond", 'Maturity', Maturity, 'CouponRate', 0.025, 'Period', Period)

```

```

VBond =
    FixedBond with properties:
        CouponRate: 0.0250
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT

```

```

FirstCouponDate: NaT
LastCouponDate: NaT
StartDate: NaT
Maturity: 01-Jan-2024
Name: ""

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);

```

### Create HullWhite Model Object

Use finmodel to create a HullWhite model object.

```

VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite",'alpha',AlphaCurve,'sigma',VolCurve);

```

### Create IRTree Pricer Object

Use finpricer to create an IRTree pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

HWTrePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates);

HWTrePricer =
    HWBKTree with properties:

        Tree: [1x1 struct]
    TreeDates: [10x1 datetime]
        Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]

```

### Price FixedBond Instrument

Use price to compute the price and sensitivities for the vanilla FixedBond instrument.

```
[Price, outPR] = price(HWTrePricer, VBond,["all"])
```

```
Price = 107.7023
```

```
outPR =
    pricerresult with properties:
```

```

    Results: [1x4 table]
    PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x4 table
   Price      Vega      Gamma      Delta
   _____  _____  _____  _____
   107.7      1.4211e-10    4086.4     -602.56
```

## Use Hull-White Tree Pricer and Hull-White Model to Price Vanilla FloatBond Instrument

This example shows the workflow to price a vanilla FloatBond instrument when you use a HullWhite model and an IRTree pricing method.

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

### Create FloatBond Instrument Object

Use fininstrument to create a vanilla FloatBond instrument object.

```
Spread = 0.03;
Reset = 1;
Maturity = datetime(2024,1,1);
Period = 1;
Float = fininstrument("FloatBond", 'Maturity',Maturity, 'Spread',Spread, 'Reset',Reset, 'ProjectionC
```

```
Float =
  FloatBond with properties:
      Spread: 0.0300
  ProjectionCurve: [1x1 ratecurve]
  ResetOffset: 0
      Reset: 1
      Basis: 0
  EndMonthRule: 1
  Principal: 100
  DaycountAdjustedCashFlow: 0
  BusinessDayConvention: "actual"
  LatestFloatingRate: NaN
  Holidays: NaT
  IssueDate: NaT
  FirstCouponDate: NaT
  LastCouponDate: NaT
  StartDate: NaT
  Maturity: 01-Jan-2024
  Name: ""
```

### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite", 'alpha', AlphaCurve, 'sigma', VolCurve);
```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
HWTreepricer = finpricer("IRTree", 'Model', HWModel, 'DiscountCurve', ZeroCurve, 'TreeDates', ZeroDates);

HWTreepricer =
    HWBKTree with properties:

        Tree: [1x1 struct]
    TreeDates: [10x1 datetime]
        Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

### Price FloatBond Instrument

Use `price` to compute the price and sensitivities for the vanilla FloatBond instrument.

```
[Price, outPR] = price(HWTreepricer, Float, ["all"]);

Price = 117.4768

outPR =
    pricerresult with properties:

        Results: [1x4 table]
    PricerData: [1x1 struct]
```

outPR.Results

```
ans=1x4 table
    Price      Vega      Gamma      Delta
    _____  _____  _____  _____
    117.48    -0.00014296    315.14    -60.024
```

## KemnaVorst

Create KemnaVorst pricer object for Asian instrument using BlackScholes model

### Description

Create and price a Asian instrument object with a BlackScholes model and a KemnaVorst pricing method using this workflow:

- 1 Use `fininstrument` to create an Asian instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Asian instrument.
- 3 Use `finpricer` to specify a KemnaVorst pricer object for the Asian instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an Asian instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
KemnaVorstPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, '
Model', model, 'SpotPrice', spotprice_value)
KemnaVorstPricerObj = finpricer( ___, Name, Value)
```

#### Description

`KemnaVorstPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)` creates a KemnaVorst pricer object by specifying `PricerType` and sets the properties on page 11-2440 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`KemnaVorstPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2440 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `KemnaVorstPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "KemnaVorst")` creates a KemnaVorst pricer object.

#### Input Arguments

##### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### **KemnaVorst Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: `KemnaVorstPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "KemnaVorst")`

### **Required KemnaVorst Name-Value Pair Arguments**

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for **DiscountCurve**. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at **Maturity** and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### **Model — Model**

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using `finmodel`.

Data Types: object

#### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### **Optional KemnaVorst Name-Value Pair Arguments**

#### **DividendType — Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and a string or character vector. **DividendType** must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

**DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar numeric | timetable

Dividend amount for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

---

**Note** DividendValue must be a scalar for a "continuous" DividendType or a timetable for "cash" DividendType.

---

Data Types: double | timetable

**PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "KemnaVorst" | character vector with value 'KemnaVorst'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a string or character vector.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

**Properties****DiscountCurve — ratecurve object for discounting cash flows**

object

This property is read-only.

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

**Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

**DividendType — Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous"

This property is read-only.

Stock dividend type, returned as a string. `DividendType` is either "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: string

### **DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend amount or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: double | timetable

### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "KemnaVorst"

Analytic pricing method, returned as a string.

Data Types: string

## **Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use Kemna-Vorst Pricer and Black-Scholes Model to Price Asian Instrument**

This example shows the workflow to price an Asian instrument when you use a BlackScholes model and a KemnaVorst pricing method.

#### **Create Asian Instrument Object**

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType', "put")
```

```
AsianOpt =
```

```
Asian with properties:
```

```

    OptionType: "put"
        Strike: 105
    AverageType: "geometric"
    AveragePrice: 0
AverageStartDate: NaT
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
        Name: "asian_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.32)
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```
Volatility: 0.3200  
Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =  
  ratecurve with properties:  
  
      Type: "zero"  
  Compounding: -1  
      Basis: 12  
      Dates: 15-Sep-2023  
      Rates: 0.0350  
      Settle: 15-Sep-2018  
  InterpMethod: "linear"  
ShortExtrapMethod: "next"  
LongExtrapMethod: "previous"
```

### Create KemnaVorst Pricer Object

Use finpricer to create a KemnaVorst pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =  
  KemnaVorst with properties:  
  
  DiscountCurve: [1x1 ratecurve]  
      Model: [1x1 finmodel.BlackScholes]  
  SpotPrice: 100  
  DividendValue: 0.0500  
  DividendType: "continuous"
```

### Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 18.1186
```

```
outPR =  
  pricerresult with properties:  
  
      Results: [1x7 table]  
  PricerData: []
```

outPR.Results

ans=1x7 table

Price	Delta	Gamma	Lambda	Vega	Rho	Theta
18.119	-0.44689	0.0087391	-3.025	64.582	-251.23	-1.5738

## Kirk

Create Kirk pricer object for Spread instrument using BlackScholes model

### Description

Create and price a Spread instrument object with a BlackScholes model and a Kirk pricing method using this workflow:

- 1 Use `fininstrument` to create a Spread instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Spread instrument.
- 3 Use `finpricer` to specify a Kirk pricer object for the Spread instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Spread instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
KirkPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, '
Model', model, 'SpotPrice', spotprice_value)
KirkPricerObj = finpricer( ___, Name, Value)
```

#### Description

`KirkPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)` creates a Kirk pricer object by specifying `PricerType` and sets the properties on page 11-2446 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`KirkPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2446 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `KirkPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', [100;105], 'DividendValue', [2.5,2.8], 'PricingMethod', "Kirk")` creates a Kirk pricer object.

#### Input Arguments

##### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### Kirk Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `KirkPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', [100;105], 'DividendValue', [2.5,2.8], 'PricingMethod', "Kirk")`

### Required Kirk Name-Value Pair Arguments

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for `DiscountCurve`. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at `Maturity` and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### Model — Model

BlackScholes model object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using `finmodel`.

Data Types: object

#### SpotPrice — Current price of underlying asset

scalar nonnegative numeric | cell array of nonnegative numerics

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar or cell array of nonnegative numerics.

Data Types: double

### Optional Kirk Name-Value Pair Arguments

#### DividendType — Dividend type

"continuous" (default) | string with value "continuous" | character vector with value 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and a string or character vector.

Data Types: char | string

#### DividendValue — Dividend yield for underlying asset

[0, 0] (default) | scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield for the underlying asset, specified as the comma-separated pair consisting of 'DividendValue' and a scalar or a vector of nonnegative numerics. Use a vector of nonnegative values for DividendValue when pricing a Spread instrument.

Data Types: double

**PricingMethod – Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "Kirk" | character vector with value 'Kirk'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a string or character vector.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

**Properties****DiscountCurve – ratecurve object for discounting cash flows**

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

**Model – Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

**SpotPrice – Current price of underlying asset**

required input (default) | scalar nonnegative numeric | vector of nonnegative numerics

Current price of the underlying asset, returned as a scalar or vector of nonnegative numeric values.

Data Types: double

**DividendType – Dividend type**

"continuous" (default) | string with value "continuous"

This property is read-only.

Dividend type, returned as a string.

Data Types: string

**DividendValue – Dividend yield for underlying stock**

[0, 0] (default) | scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield for the underlying stock, returned as a scalar or vector of nonnegative numerics.

Data Types: double

### PricingMethod — Analytic pricing method

default pricer associated with BlackScholes model (default) | string with value "Kirk"

Analytic pricing method, returned as a string.

Data Types: string

## Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## Examples

### Use Kirk Pricer and Black-Scholes Model to Price Spread Instrument

This example shows the workflow to price a Spread instrument when you use a BlackScholes model and a Kirk pricing method.

#### Create Spread Instrument Object

Use `fininstrument` to create a Spread instrument object.

```
SpreadOpt = fininstrument("Spread", 'Strike', 5, 'ExerciseDate', datetime(2021,9,15), 'OptionType', "p
```

```
SpreadOpt =
```

```
Spread with properties:
```

```
    OptionType: "put"
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2021
    Strike: 5
    Name: "spread_option"
```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', [0.2 ; 0.1])
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```
    Volatility: [2x1 double]
    Correlation: [2x2 double]
```

#### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create Kirk Pricer Object

Use `finpricer` to create a Kirk pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', [103
```

```

outPricer =
  Kirk with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: [2x1 double]
      DividendValue: [2x1 double]
      DividendType: "continuous"

```

### Price Spread Instrument

Use `price` to compute the price and sensitivities for the Spread instrument.

```
[Price, outPR] = price(outPricer, SpreadOpt, ["all"])
```

```
Price = 17.8614
```

```

outPR =
  pricerresult with properties:
      Results: [1x7 table]
      PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta		Gamma		Lambda		Vega
17.861	-0.44663	0.58229	0.0093493	0.008195	-2.5756	3.3578	59.518

### See Also

#### Functions

`fininstrument` | `finmodel` | `ratecurve` | `timetable`

## Levy

Create Levy pricer object for Asian instrument using BlackScholes model

### Description

Create and price a Asian instrument object with a BlackScholes model and a Levy pricing method using this workflow:

- 1 Use `fininstrument` to create an Asian instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Asian instrument.
- 3 Use `finpricer` to specify a Levy pricer object for the Asian instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an Asian instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
LevyPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, '
Model', model, 'SpotPrice', spotprice_value)
LevyPricerObj = finpricer( ___, Name, Value)
```

#### Description

`LevyPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)` creates a Levy pricer object by specifying `PricerType` and sets the properties on page 11-2452 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`LevyPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2452 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `LevyPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "Levy")` creates a Levy pricer object.

#### Input Arguments

##### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### Levy Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

```
Example: LevyPricerObj =
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice',
1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "Levy"
)
```

### Required Levy Name-Value Pair Arguments

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### Model — Model

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

#### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### Optional Levy Name-Value Pair Arguments

#### DividendType — Dividend type

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and a string or character vector. DividendType must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

**DividendValue — Dividend yield or dividend schedule for underlying stock**

0 (default) | scalar numeric | timetable

Dividend yield for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend yield or a timetable for a dividend schedule.

---

**Note** Specify a scalar if DividendType is "continuous" and a timetable if DividendType is "cash".

---

Data Types: double | timetable

**PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "Levy" | character vector with value 'Levy'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a character vector or string.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

**Properties****DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

**Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

**DividendType — Dividend type**

"continuous" (default) | string with value "cash" or "continuous"

This property is read-only.

Dividend type, returned as a string. DividendType is either "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: string

### **DividendValue — Dividend yield or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend yield or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: double | timetable

### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "Levy"

Analytic pricing method, returned as a string.

Data Types: string

## **Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use Levy Pricer and Black-Scholes Model to Price Asian Instrument**

This example shows the workflow to price an Asian instrument when you use a BlackScholes model and a Levy pricing method.

#### **Create Asian Instrument Object**

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType', "p
```

```
AsianOpt =
  Asian with properties:
      OptionType: "put"
      Strike: 105
      AverageType: "arithmetic"
      AveragePrice: 0
      AverageStartDate: NaT
      ExerciseStyle: "european"
      ExerciseDate: 15-Sep-2022
      Name: "asian_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.32)
```

```
BlackScholesModel =
  BlackScholes with properties:
      Volatility: 0.3200
```

```
Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
  Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
  InterpMethod: "linear"
ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create Levy Pricer Object

Use `finpricer` to create a Levy pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  Levy with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
      DividendValue: 0
      DividendType: "continuous"
```

### Price Asian Instrument

Use `price` to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 13.0014
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x7 table]
      PricerData: []
```

```
outPR.Results
```

ans=1x7 table

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
13.001	-0.3749	0.0094403	-2.8836	44.587	-0.71607	-121.97

## Use Levy Pricer and Black-Scholes Model to Price Asian Instrument for Foreign Exchange

This example shows the workflow to price an Asian instrument for an arithmetic average currency option when you use a BlackScholes model and a Levy pricing method. Assume that the current exchange rate is \$0.52 and has a volatility of 12% per annum. The annualized continuously compounded foreign risk-free rate is 8% per annum.

### Create Asian Instrument Object

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', .50, 'OptionType', "put")
```

```
AsianOpt =
```

```
Asian with properties:
```

```

    OptionType: "put"
        Strike: 0.5000
    AverageType: "arithmetic"
    AveragePrice: 0
    AverageStartDate: NaT
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
        Name: "asian_fx_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
Sigma = .12;
```

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', Sigma)
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```

    Volatility: 0.1200
    Correlation: 1
```

### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
```

```
Type = 'zero';
```

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307];
```

```
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
  Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create Levy Pricer Object

Use `finpricer` to create a Levy pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument. When you price currencies using an Asian instrument for an arithmetic average currency option, `DividendType` must be "continuous" and `DividendValue` is the annualized risk-free interest rate in the foreign country.

```
ForeignRate = 0.08;
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',.52,
outPricer =
  Levy with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 0.5200
      DividendValue: 0.0800
      DividendType: "continuous"
```

### Price Asian FX Instrument

Use `price` to compute the price and sensitivities for the Asian FX instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 0.0535
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x7 table]
  PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
-------	-------	-------	--------	------	-------	-----

---

0.053516   -0.62792   3.8371   -6.1014   0.15616   -0.010917   -0.82694

## Normal

Create `Normal` pricer object for `Cap`, `Floor`, or `Swaption` instrument using `Normal` model

## Description

Create and price a `Cap`, `Floor`, or `Swaption` instrument object with a `Normal` model and a `Normal` pricing method using this workflow:

- 1 Use `fininstrument` to create a `Cap`, `Floor`, or `Swaption` instrument object.
- 2 Use `finmodel` to specify a `Normal` model for the `Cap`, `Floor`, or `Swaption` instrument.
- 3 Use `finpricer` to specify a `Normal` pricer object for the `Cap`, `Floor`, or `Swaption` instrument.

---

**Note** If you do not specify `ProjectionCurve` when you create a `Cap`, `Floor`, or `Swaption` instrument with the `HullWhite` pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

---

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Cap`, `Floor`, or `Swaption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
NormalPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)
```

### Description

`NormalPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)` creates a `Normal` pricer object by specifying `PricerType` and the required name-value pair arguments `DiscountCurve` and `Model` to set properties on page 11-2459 using name-value pair arguments. For example, `NormalPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', NormModel)` creates a `Normal` pricer object.

### Input Arguments

#### **PricerType** — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

**Normal Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: NormalPricerObj =
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', NormModel)
```

**DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Data Types: object

**Model — Model**

Normal model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created Normal model object using `finmodel`.

Data Types: object

**Properties****DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

**Model — Model**

Normal model object

Model, returned as a Normal model object.

Data Types: object

**Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

**Examples****Use Normal Pricer and Normal Model to Price Cap Instrument**

This example shows the workflow to price a Cap instrument when you use a Normal model and a Normal pricing method.

**Create Cap Instrument Object**

Use `fininstrument` to create a Cap instrument object.

```

CapOpt = fininstrument("Cap", 'Strike', 0.02, 'Maturity', datetime(2019, 6, 25), 'Reset', 4, 'Principal', ...
CapOpt =
    Cap with properties:
        Strike: 0.0200
        Maturity: 25-Jun-2019
        ResetOffset: 0
        Reset: 4
        Basis: 8
        Principal: 100
        ProjectionCurve: [0x0 ratecurve]
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        Name: "cap_option"

```

### Create Normal Model Object

Use `finmodel` to create a Normal model object.

```
NormalModel = finmodel("Normal", 'Volatility', 0.063)
```

```

NormalModel =
    Normal with properties:
        Volatility: 0.0630

```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```

Settle = datetime(2018, 9, 15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```

myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

## Create Normal Pricer Object

Use `finpricer` to create a `Normal` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', NormalModel, 'DiscountCurve', myRC)

outPricer =
    Normal with properties:
        DiscountCurve: [1x1 ratecurve]
        Shift: 0
        Model: [1x1 finmodel.Normal]
```

## Price Cap Instrument

Use `price` to compute the price for the Cap instrument.

```
Price = price(outPricer, CapOpt)
```

```
Price = 0.4828
```

## RollGeskeWhaley

Create RollGeskeWhaley pricer object for American exercise Vanilla instrument using BlackScholes model

### Description

Create and price a Vanilla instrument object with a BlackScholes model and a RollGeskeWhaley pricing method using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Vanilla instrument.
- 3 Use `finpricer` to specify a RollGeskeWhaley pricer object for the Vanilla instrument (American exercise).

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

### Creation

#### Syntax

```
RollGeskeWhaleyPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj, 'SpotPrice', spotrate_value, 'DividendType', dividendtype, 'DividendValue', dividendvalue)
RollGeskeWhaleyPricerObj = finpricer( ____, Name, Value)
```

#### Description

`RollGeskeWhaleyPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj, 'SpotPrice', spotrate_value, 'DividendType', dividendtype, 'DividendValue', dividendvalue)` creates a RollGeskeWhaley pricer object by specifying `PricerType` and sets the properties on page 11-2464 for the required name-value pair arguments `Model`, `DiscountCurve`, and `SpotPrice`.

`RollGeskeWhaleyPricerObj = finpricer( ____, Name, Value)` to set optional properties on page 11-2464 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `RollGeskeWhaleyPricerObj = finpricer("Analytic", 'Model', BSMModel, 'DiscountCurve', ratecurve_obj, 'SpotPrice', 1000, 'DividendValue', timetable(datetime(2021,6,15),2.5), 'DividendType', "cash", 'PricingMethod', "RollGeskeWhaley")` creates a RollGeskeWhaley pricer object. You can specify multiple name-value pair arguments.

## Input Arguments

### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### RollGeskeWhaley Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: RollGeskeWhaleyPricerObj =  
finpricer("Analytic", 'Model', BSMModel, 'DiscountCurve', ratecurve\_obj, 'SpotPrice', 1000, 'DividendValue', timetable(datetime(2021,6,15), 2.5), 'DividendType', "cash", 'PricingMethod', "RollGeskeWhaley")

### Required RollGeskeWhaley Name-Value Pair Arguments

#### Model — Model

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

#### DividendValue — Cash dividend for underlying stock

timetable

Cash dividend for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a timetable.

Data Types: timetable

#### **Optional RollGeskeWhaley Name-Value Pair Arguments**

##### **DividendType — Stock dividend type**

"cash" (default) | string with value "cash" | character vector with value 'cash'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and a string or character vector.

Data Types: char | string

##### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "RollGeskeWhaley" | character vector with value 'RollGeskeWhaley'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a string or character vector.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

## **Properties**

##### **Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

##### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as a ratecurve object

Data Types: object

##### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

##### **DividendValue — Cash dividend for underlying stock**

timetable

Cash dividend for the underlying stock, returned as a timetable.

Data Types: timetable

##### **DividendType — Stock dividend type**

"cash" (default) | string with value "cash"

Stock dividend type, returned as a string.

Data Types: char | string

### **PricingMethod – Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "RollGeskeWhaley"

Analytic pricing method, returned as a string.

Data Types: string

## **Object Functions**

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use a Roll-Geske-Whaley Pricer and Black-Scholes Model to Price Vanilla Instrument**

This example shows the workflow to price an American exercise Vanilla instrument when you use a BlackScholes model and a RollGeskeWhaley pricing method.

#### **Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'ExerciseStyle', 'american')
```

```
VanillaOpt =  
    Vanilla with properties:
```

```
        OptionType: "call"  
        ExerciseStyle: "american"  
        ExerciseDate: 15-Sep-2022  
        Strike: 105  
        Name: "vanilla_american_instrument"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.07)
```

```
BlackScholesModel =  
    BlackScholes with properties:
```

```
        Volatility: 0.0700  
        Correlation: 1
```

#### **Create ratecurve Object**

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
myRC = ratecurve("zero",Settle,datetime(2023,9,15),.05,'Basis',12);
```

### Create RollGeskeWhaley Pricer Object

Use `finpricer` to create a `RollGeskeWhaley` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
    RollGeskeWhaley with properties:

    DiscountCurve: [1x1 ratecurve]
           Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 100
    DividendValue: [1x1 timetable]
    DividendType: "cash"
```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 14.9582
```

```
outPR =
    pricerresult with properties:

    Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
14.958	0.87494	0.01471	5.8493	41.218	-3.9873	290.2

# SABR

Create SABR pricer object for Swaption instrument using SABR model

## Description

Create and price a Swaption instrument object with a SABR model and a SABR pricing method using this workflow:

- 1 Use `fininstrument` to create a Swaption instrument object.
- 2 Use `finmodel` to specify a SABR model for the Swaption instrument.
- 3 Use `finpricer` to specify a SABR pricer object for the Swaption instrument.

---

**Note** If you do not specify `ProjectionCurve` when you create a Swaption instrument with the SABR pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

---

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
SABRPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)
```

### Description

`SABRPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)` creates a SABR pricer object by specifying `PricerType` and the required name-value pair argument `Model` to set properties on page 11-2468 using name-value pairs. For example, `SABRPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', SABRModel)` creates a SABR pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### **SABR Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: SABRPricerObj =  
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', SABRModel)
```

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Data Types: object

### **Model — Model**

SABR model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created SABR model object using `finmodel`.

Data Types: object

## **Properties**

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as a ratecurve object

Data Types: object

### **Model — Model object**

SABR model object

Model, returned as a SABR model object.

Data Types: object

## **Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use SABR Pricer and SABR Model to Price Swaption Instrument**

This example shows the workflow to price a Swaption instrument when you use a SABR model and a SABR pricing method.

#### **Create ratecurve Object**

Create a ratecurve object using `ratecurve`.

```

Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307];
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
    ratecurve with properties:

        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create Swap Instrument Object

Use `fininstrument` to create the underlying Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2023,1,30), 'LegRate', [0.018 0.24], 'LegType', ["fi
```

```

Swap =
    Swap with properties:

        LegRate: [0.0180 0.2400]
        LegType: ["fixed" "float"]
        Reset: [2 2]
        Basis: [1 1]
        Notional: 100
        LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
        DaycountAdjustedCashFlow: [0 0]
        ProjectionCurve: [1x2 ratecurve]
        BusinessDayConvention: ["actual" "actual"]
        Holidays: NaT
        EndMonthRule: [1 1]
        StartDate: 30-Mar-2020
        Maturity: 30-Jan-2023
        Name: "swap_instrument"

```

### Create Swaption Instrument Object

Use `fininstrument` to create a Swaption instrument object.

```
Swaption = fininstrument("Swaption", 'Strike', 0.275, 'ExerciseDate', datetime(2021,7,30), 'Swap', Swap
```

```

Swaption =
    Swaption with properties:

        OptionType: "put"
        ExerciseStyle: "european"

```

```
ExerciseDate: 30-Jul-2021
Strike: 0.2750
Swap: [1x1 fininstrument.Swap]
Name: "swaption_instrument"
```

### Create SABR Model Object

Use `finmodel` to create a SABR model object.

```
SABRModel = finmodel("SABR", 'Alpha', 0.032, 'Beta', 0.04, 'Rho', .08, 'Nu', 0.49, 'Shift', 0.002)
```

```
SABRModel =
  SABR with properties:
    Alpha: 0.0320
    Beta: 0.0400
    Rho: 0.0800
    Nu: 0.4900
    Shift: 0.0020
    VolatilityType: "black"
```

### Create SABR Pricer Object

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', SABRModel, 'DiscountCurve', myRC)
```

```
outPricer =
  SABR with properties:
    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.SABR]
```

### Price Swaption Instrument

Use `price` to compute the price for the Swaption instrument.

```
Price = price(outPricer, Swaption)
```

```
Price = 10.3771
```

## FiniteDifference

Create `FiniteDifference` pricer object for `Barrier` or `Vanilla` instrument using a `BlackScholes`, `Heston`, `Merton`, or `Bates` model

### Description

Create and price a `Vanilla` or `Barrier` instrument object with a `BlackScholes`, `Heston`, `Bates`, `Merton`, or `Dupire` model and a `FiniteDifference` pricing method using this workflow:

- 1 Use `fininstrument` to create the `Barrier` or `Vanilla` instrument object.
- 2 Use `finmodel` to specify the `BlackScholes` model for the `Barrier` instrument or a `Heston`, `Bates`, `Dupire`, or `Merton` model for the `Vanilla` instrument.
- 3 Use `finpricer` to specify the `FiniteDifference` pricer object for the `Barrier` or `Vanilla` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Vanilla` or `Barrier` instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
FiniteDifferencePricerObj = finpricer(PricerType,'Model',model,'
DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)
FiniteDifferencePricerObj = finpricer( ___,Name,Value)
```

### Description

`FiniteDifferencePricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)` creates a `FiniteDifference` pricer object by specifying `PricerType` and sets the properties on page 11-2475 for the required name-value pair arguments `Model`, `DiscountCurve`, and `SpotPrice`.

`FiniteDifferencePricerObj = finpricer( ___,Name,Value)` sets optional properties on page 11-2475 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FiniteDifferencePricerObj = finpricer("FiniteDifference",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',100,'DividendValue',.025,'DividendType',"cash")` creates a `FiniteDifference` pricer object. You can specify multiple name-value pair arguments.

### Input Arguments

#### PricerType — Pricer type

string with value "FiniteDifference" | character vector with value 'FiniteDifference'

Pricer type, specified as a string with the value of "FiniteDifference" or the character vector with a value of 'FiniteDifference'.

Data Types: char | string

### FiniteDifference Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `FiniteDifferencePricerObj = finpricer("FiniteDifference", 'Model', BSMModel, 'DiscountCurve', ratecurve_obj, 'SpotPrice', 100, 'DividendValue', .025, 'DividendType', "cash")`

### Required FiniteDifference Name-Value Pair Arguments

#### Model — Model object

object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of the previously created Merton, Bates, or Heston model object using `finmodel`.

Data Types: object

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### Optional FiniteDifference Name-Value Pair Arguments

#### DividendValue — Dividend yield or dividend schedule

0 (default) | scalar | timetable

Dividend yield or dividend schedule, specified as the comma-separated pair consisting of 'DividendValue' and a scalar for a dividend yield or a timetable for a dividend schedule.

Data Types: double | timetable

**DividendType – Dividend type**

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and a character vector or string. DividendType must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

---

**Note** When you use a Barrier instrument, you must set DividendType to "cash".

---

Data Types: char | string

**SpotGridSize – Size of spot grid for finite difference grid**

400 (default) | scalar numeric

Size of the spot grid for the finite difference grid, specified as the comma-separated pair consisting of 'SpotGridSize' and a scalar numeric.

Data Types: double

**SpotPriceMax – Maximum price for price grid boundary**

if unspecified, SpotPrice values are calculated using asset distributions at maturity (default) | positive scalar

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of 'SpotPriceMax' and a positive scalar.

Data Types: single | double

**VarianceGridSize – Number of nodes of variance grid for finite difference grid**

200 (default) | scalar numeric

Number of nodes of the variance grid for the finite difference grid, specified as the comma-separated pair consisting of 'VarianceGridSize' and a scalar numeric.

---

**Note** VarianceGridSize is supported only when you use a Heston or Bates model.

---

Data Types: double

**VarianceMax – Maximum variance for variance grid boundary**

1.0 (default) | scalar numeric

Maximum variance for the variance grid boundary, specified as the comma-separated pair consisting of 'VarianceMax' as a scalar numeric.

---

**Note** VarianceMax is supported only when you use a Heston or Bates model.

---

Data Types: double

**TimeGridSize – Number of nodes of time grid for finite difference grid**

100 (default) | positive numeric scalar

Number of nodes of the time grid for the finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive numeric scalar.

Data Types: double

### **InterpMethod — Method of interpolation for estimating the implied volatility surface from ImpliedVolData**

'linear' (default) | string with value "linear", "makima", "spline", or "tpaps" | character vector with value 'linear', 'makima', 'spline', or 'tpaps'

Method of interpolation for estimating the implied volatility surface from ImpliedVolData for use only with a Dupire model, specified as the comma-separated pair consisting of 'InterpMethod' and a string or character vector with one of the following values:

- 'linear' — Linear interpolation
- 'makima' — Modified Akima cubic Hermite interpolation
- 'spline' — Cubic spline interpolation
- 'tpaps' — Thin-plate smoothing spline interpolation

---

**Note** The 'tpaps' method uses the thin-plate smoothing spline functionality from Curve Fitting Toolbox.

The 'makima' and 'spline' methods work only for gridded data. For scattered data, use the 'linear' or 'tpaps' methods.

---

For more information on gridded or scattered data and details on interpolation methods, see “Gridded and Scattered Sample Data” (MATLAB) and “Interpolating Gridded Data” (MATLAB).

Data Types: char | string

## **Properties**

### **Model — Model**

object

Model, returned as a model object.

Data Types: object

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, returned as the ratecurve object.

Data Types: object

### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

**DividendValue — Dividend yield or dividend schedule**

0 (default) | scalar | timetable

Dividend yield or dividend schedule, returned as a scalar for a dividend yield or a timetable for a dividend schedule.

Data Types: double | timetable

**DividendType — Dividend type**

"continuous" (default) | string with value "cash" or "continuous"

This property is read-only.

Dividend type, returned as a string. The `DividendType` is either "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: string

**GridProperties — Grid properties**

400 (default) | scalar numeric

Grid properties, returned as a struct.

For a Dupire model, `GridProperties` contains the following fields:

- `SpotGridSize` — Size of the spot grid for the finite difference grid, returned as a scalar numeric.
- `SpotPriceMax` — Maximum price for price grid boundary, returned as a positive scalar.
- `TimeGridSize` — Number of nodes of the time grid for the finite difference grid, returned as a positive numeric scalar.
- `InterpMethod` — Method of interpolation for estimating the implied volatility surface, returned as a string.

For a Heston or Bates model, `GridProperties` contains the following fields:

- `VarianceGridSize` — Size of the variance grid for the finite difference grid, returned as a scalar numeric.
- `VarianceMax` — Maximum variance for the variance grid boundary, returned as a scalar numeric.

Data Types: struct

**Object Functions**

price Compute price for equity instrument with `FiniteDifference` pricer

**Examples****Use Finite Difference Pricer and Black-Scholes Model to Price Barrier Instrument**

This example shows the workflow to price a Barrier instrument when you use a `BlackScholes` model and a `FiniteDifference` pricing method.

**Create Barrier Instrument Object**

Use `fininstrument` to create a Barrier instrument object.

```
BarrierOpt = fininstrument("Barrier", 'Strike', 105, 'ExerciseDate', datetime(2019,1,1), 'OptionType', 'call')
```

```
BarrierOpt =
  Barrier with properties:
    OptionType: "call"
    Strike: 105
    BarrierType: "do"
    BarrierValue: 40
    Rebate: 0
    ExerciseStyle: "american"
    ExerciseDate: 01-Jan-2019
    Name: "barrier_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:
    Volatility: 0.3000
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1)
```

```
myRC =
  ratecurve with properties:
    Type: "zero"
    Compounding: -1
    Basis: 1
    Dates: 01-Jan-2023
    Rates: 0.0350
    Settle: 01-Jan-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create FiniteDifference Pricer Object

Use `finpricer` to create a FiniteDifference pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("FiniteDifference", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPricer')
```

```
outPricer =
  FiniteDifference with properties:
```

```

DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
GridProperties: [1x1 struct]
      DividendType: "continuous"
      DividendValue: 0

```

### Price Barrier Instrument

Use `price` to compute the price and sensitivities for the `Barrier` instrument.

```
[Price, outPR] = price(outPricer,BarrierOpt,["all"])
```

```
Price = 11.3230
```

```
outPR =
  pricerresult with properties:
```

```

      Results: [1x7 table]
      PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Theta	Rho	Vega
11.323	0.54126	0.0132	4.7802	-7.4408	42.766	39.627

# TurnbullWakeman

Create TurnbullWakeman pricer object for Asian instrument using BlackScholes model

## Description

Create and price a Asian instrument object with a BlackScholes model and a TurnbullWakeman pricing method using this workflow:

- 1 Use `fininstrument` to create an Asian instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Asian instrument.
- 3 Use `finpricer` to specify a TurnbullWakeman pricer object for the Asian instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an Asian instrument, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
TurnbullWakemanPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)
TurnbullWakemanPricerObj = finpricer( ___, Name, Value)
```

### Description

`TurnbullWakemanPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)` creates a TurnbullWakeman pricer object by specifying `PricerType` and sets the properties on page 11-2481 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`TurnbullWakemanPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2481 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `TurnbullWakemanPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100)` creates a TurnbullWakeman pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### TurnbullWakeman Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `TurnbullWakemanPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', 'TurnbullWakeman')`

### Required TurnbullWakeman Name-Value Pair Arguments

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

Data Types: object

#### Model — Model

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using `finmodel`.

Data Types: object

#### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### Optional TurnbullWakeman Name-Value Pair Arguments

#### DividendType — Stock dividend type

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and a character vector or string. `DividendType` must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

#### DividendValue — Dividend yield or dividend schedule for underlying stock

0 (default) | scalar numeric | timetable

Dividend yield for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend yield or a timetable for a dividend schedule.

---

**Note** DividendValue must be a scalar for a "continuous" DividendType or a timetable for a "cash" DividendType.

---

Data Types: double | timetable

### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "TurnbullWakeman" | character vector with value 'TurnbullWakeman'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a string or character vector.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

## **Properties**

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### **Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

### **DividendType — Stock dividend type**

'continuous' (default) | string with value "cash" or "continuous"

This property is read-only.

Stock dividend type, returned as a string. DividendType is either "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: string

**DividendValue — Dividend yield or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend yield or dividend schedule for the underlying stock, returned as a scalar nonnegative numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: double | timetable

**PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "TurnbullWakeman"

Analytic pricing method, returned as a string.

Data Types: string

**Object Functions**

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

**Examples****Use Turnbull-Wakeman Pricer and Black-Scholes Model to Price Asian Instrument**

This example shows the workflow to price an Asian instrument when you use a BlackScholes model and a TurnbullWakeman pricing method.

**Create Asian Instrument Object**Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType', "put")
```

AsianOpt =

Asian with properties:

```

    OptionType: "put"
    Strike: 105
    AverageType: "arithmetic"
    AveragePrice: 0
    AverageStartDate: NaT
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
    Name: "asian_option"

```

**Create BlackScholes Model Object**Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.35)
```

BlackScholesModel =

BlackScholes with properties:

```
Volatility: 0.3500
```

```
Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create TurnbullWakeman Pricer Object

Use finpricer to create a TurnbullWakeman pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  TurnbullWakeman with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
      DividendValue: 0
      DividendType: "continuous"
```

### Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 14.3431
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x7 table]
      PricerData: []
```

```
outPR.Results
```

ans=1x7 table

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
14.343	-0.37004	0.0085706	-2.5799	44.864	-0.86257	-125.73

# defprobcurve

Create defprobcurve object for credit instrument

## Description

Create a defprobcurve object for a credit instrument.

After creating a defprobcurve object, you can use the associated functions `survprobs`, `hazardrates`, and `defprobstrip`.

To price a CDS instrument, you must create a defprobcurve object and then create a `Credit` pricer object.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-42.

## Creation

### Syntax

```
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities)
DefaultProbCurve = defprobcurve( ____, Name, Value)
```

### Description

`DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities)` creates a defprobcurve object.

`DefaultProbCurve = defprobcurve( ____, Name, Value)` sets properties on page 11-2486 using name-value pairs and any of the arguments in the previous syntax. For example, `DefaultProbCurve = defprobcurve(datetime(2017,1,30), [datetime(2018,1,30); datetime(2019,1,30)], [0.005 0.007], 'Basis', 2)` creates a default probability curve object. You can specify multiple name-value pair arguments.

### Input Arguments

#### Settle — Settle date for curve

serial date number | date character vector | date string | datetime

Settle date for curve, specified as a scalar serial date number, date character vector, date string, or datetime.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Settle` property is stored as a datetime.

Data Types: `char` | `string` | `double` | `datetime`

#### ProbDates — Dates corresponding to DefaultProbabilities

serial date number | cell array of date character vectors | date string | datetime

Dates corresponding to `DefaultProbabilities`, specified as an `NPOINTS`-by-1 vector of serial date numbers, cell array of date character vectors, string array, or datetime array.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `ProbDates` property is stored as a datetime.

Data Types: `string` | `datetime` | `double` | `char` | `cell`

### **DefaultProbabilities — Default probability data for the curve** vector

Default probability data for the curve, specified as a numeric vector.

Data Types: `double`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `defprobcurve = defprobcurve(datetime(2017,1,30), [datetime(2018,1,30);datetime(2019,1,30)], [0.005 0.007], 'Basis', 2)`

### **Basis — Day-count basis**

2 (actual/360) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-129.

Data Types: `double`

## **Properties**

### **Settle — Settlement date**

`datetime`

Settlement date, returned as a datetime.

Data Types: datetime

### **Basis — Day-count basis**

2 (actual/360) (default) | integer from 0 to 13

This property is read-only.

Day-count basis of the instrument, returned as a scalar integer.

Data Types: double

### **Dates — Dates corresponding to rate data**

datetime

Dates corresponding to the rate data, returned as a datetime.

Data Types: datetime

### **DefaultProbabilities — Default probabilities for the curve**

vector

Default probabilities for the curve, returned as a vector.

Data Types: double

## **Object Functions**

survprobs      Compute survival probability based on default probability curve  
 hazardrates    Compute hazard rates based on default probability curve  
 defprobstrip   Bootstrap defprobcurve object from market CDS instruments

## **Examples**

### **Create defprobcurve Object**

Create a defprobcurve object using defprobcurve.

```
Settle = datetime(2017,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
```

```
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',2)
```

```
DefaultProbCurve =
  defprobcurve with properties:
```

```
        Settle: 20-Sep-2017
        Basis: 2
        Dates: [10x1 datetime]
  DefaultProbabilities: [10x1 double]
```

# survprobs

Compute survival probability based on default probability curve

## Syntax

```
outSurvProbs = survprobs(obj,inDates)
```

## Description

`outSurvProbs = survprobs(obj,inDates)` computes the survival probability based on the default probability curve object.

## Examples

### Calculate Survival Probability Based on Default Probability Curve

Create a `defprobcurve` object using `defprobcurve` and then use `survprobs` to calculate the survival probability.

```
Settle = datetime(2017,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
DefProbDates = Settle + DefProbTimes;

DefaultProbCurve = defprobcurve(Settle,DefProbDates,DefaultProbabilities,'Basis',5)

DefaultProbCurve =
    defprobcurve with properties:

        Settle: 20-Sep-2017
        Basis: 5
        Dates: [10x1 datetime]
        DefaultProbabilities: [10x1 double]

SurvProbTimes = [calmonths([6 12 18])];
SurvProbDates = Settle + SurvProbTimes;
outSurvProb = survprobs(DefaultProbCurve, SurvProbDates)

outSurvProb = 3×1

    0.9950
    0.9930
    0.9915
```

## Input Arguments

**obj** — **defprobcurve** object  
defprobcurve object

defprobcurve object, specified as a previously created defprobcurve object.

Data Types: object

**inDates — Survival probability dates**

datetime | serial date number | date character vector | date string

Survival probability dates, specified as a scalar datetime, serial date number, date character vector, or date string.

Data Types: double | char | string | datetime

**Output Arguments****outSurvProbs — Survival probability**

numeric

Survival probability, returned as a numeric.

**See Also**

defprobstrip | hazardrates

# hazardrates

Compute hazard rates based on default probability curve

## Syntax

```
OutRates = hazardrates(obj)
```

## Description

OutRates = hazardrates(obj) computes hazard rates based on a defprobcurve object.

## Examples

### Calculate Hazard Rates Based on Default Probability Curve

Create a defprobcurve object using defprobcurve and then use hazardrates to calculate the hazard rates.

```
Settle = datetime(2017,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
```

```
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',5)
```

```
DefaultProbCurve =
    defprobcurve with properties:
        Settle: 20-Sep-2017
        Basis: 5
        Dates: [10x1 datetime]
        DefaultProbabilities: [10x1 double]
```

```
hazardrates(DefaultProbCurve)
```

```
ans = 10x1
    0.0100
    0.0040
    0.0030
    0.0051
    0.0112
    0.0145
    0.0197
    0.0058
    0.0065
    0.0061
```

## Input Arguments

### **obj — defprobcurve object**

defprobcurve object

defprobcurve object, specified as a previously created defprobcurve object.

Data Types: object

## Output Arguments

### **OutRates — Hazard rates**

numeric

Hazard rates, returned as a numeric.

## See Also

# defprobstrip

Bootstrap defprobcurve object from market CDS instruments

## Syntax

```
OutCurve = defprobstrip(ZeroCurve,MarketInstruments,MarketQuotes)
OutCurve = defprobstrip( ____,Name,Value)
```

## Description

OutCurve = defprobstrip(ZeroCurve,MarketInstruments,MarketQuotes) bootstraps a defprobcurve object from market CDS instruments.

OutCurve = defprobstrip( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntax.

## Examples

### Bootstrap Default Probability Curve from Market CDS Instruments

This example shows how to use defprobstrip to bootstrap a defprobcurve object based on market CDS instruments.

#### Create ratecurve Object for Zero-Rate Curve

Create a ratecurve object using ratecurve.

```
Settle = datetime(2017,9,15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates);
```

### Market CDS Spreads and Vector of Market CDS Instruments

Define the market CDS spreads and use fininstrument to create a vector of market CDS instrument objects.

```
SpreadTimes = [1 2 3 4 5 7 10 20 30]';
Spread = [140 175 210 265 310 360 410 460 490]';
MarketDates = datemnth(Settle,12*SpreadTimes);

NumMarketInst = length(MarketDates);
ContractSpreadBP = zeros(NumMarketInst,1);

MarketCDSInstruments(NumMarketInst,1) = fininstrument("cds", ...
    'ContractSpread', ContractSpreadBP(end), 'Maturity', MarketDates(end));
for k = 1:NumMarketInst
    MarketCDSInstruments(k,1) = fininstrument("cds", ...
        'ContractSpread', ContractSpreadBP(k), 'Maturity', MarketDates(k));
end
```

Use `defprobstrip` to create a `defprobcurve` object.

```
DefaultProbCurve = defprobstrip(ZeroCurve,MarketCDSInstruments, Spread)
```

```
DefaultProbCurve =  
  defprobcurve with properties:  
  
          Settle: 15-Sep-2017  
          Basis: 2  
          Dates: [9x1 datetime]  
  DefaultProbabilities: [9x1 double]
```

## Input Arguments

### **ZeroCurve — Zero-rate curve**

ratecurve object

Zero-rate curve, specified by a previously created ratecurve.

Data Types: object

### **MarketInstruments — Market CDS instruments**

vector

Market CDS instruments, specified as an NINST-by-1 vector.

Data Types: double

### **MarketQuotes — Market spread**

vector

Market quotes, specified as an NINST-by-1 vector.

Data Types: double

### **Name-Value Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `DefaultProbCurve = defprobstrip(ZeroCurve, MarketInstruments, MarketQuotes, 'QuoteType', "upfront")`

### **QuoteType — Market quote type**

"fairspread" (default) | string with value of "fairspread" or "upfront" | character vector with value of 'fairspread' or 'upfront'

Frequency of payments per year, specified as the comma-separated pair consisting of 'QuoteType' and a scalar character vector or string.

- "fairspread" — CDS break-even spread for zero upfront price
- "upfront" — CDS upfront price for a given contractual spread

Data Types: char | string

## Output Arguments

### **OutCurve — Default probability curve**

defprobcurve object

Default probability curve, returned as a defprobcurve object with the following properties:

- `Settle`
- `Basis`
- `Dates`
- `DefaultProbabilities`

### **See Also**

`hazardrates` | `survprobs`

# **Derivatives Pricing Options**

## Pricing Options Structure

### In this section...

“Introduction” on page B-2

“Default Structure” on page B-2

“Customizing the Structure” on page B-3

### Introduction

The MATLAB Options structure provides additional input to most pricing functions. The Options structure

- Tells pricing functions how to use the interest-rate tree to calculate instrument prices.
- Determines what additional information the Command Window displays along with instrument prices.
- Tells pricing functions which method to use in pricing barrier options.

The pricing options structure is primarily used in the pricing of interest-rate-based financial derivatives. However, the `BarrierMethod` field in the structure allows you to use it in pricing equity barrier options as well.

You provide pricing options in an optional `Options` argument passed to a pricing function. (See, for example, `bondbyhjm`, `bdtprice`, `barrierbycrr`, `barrierbyeqp`, or `barrierbyitt`.)

### Default Structure

If you do not specify the `Options` argument in the call to a pricing function, the function uses a default structure. To observe the default structure, use `derivset` without any arguments.

```
Options = derivset
```

```
Options =
```

```
    Diagnostics: 'off'  
      Warnings: 'on'  
    ConstRate: 'on'  
BarrierMethod: 'unenhanced'
```

The `Options` structure has four fields: `Diagnostics` on page B-2, `Warnings` on page B-2, `ConstRate` on page B-3, and `BarrierMethod` on page B-3.

### Diagnostics Field

`Diagnostics` indicates whether additional information is displayed if the tree is modified. The default value for this option is 'off'. If `Diagnostics` is set to 'on' and `ConstRate` is set to 'off', the pricing functions display information such as the number of nodes in the last level of the tree generated for pricing purposes.

### Warnings Field

`Warnings` indicates whether to display warning messages when the input tree is not adequate for accurately pricing the instruments. The default value for this option is 'on'. If both `ConstRate` and

Warnings are 'on', a warning is displayed if any of the instruments in the input portfolio have a cash flow date between tree dates. If `ConstRate` is 'off', and `Warnings` is 'on', a warning is displayed if the tree is modified to match the cash flow dates on the instruments in the portfolio.

### ConstRate Field

`ConstRate` indicates whether the interest rates should be assumed constant between tree dates. By default this option is 'on', which is not an arbitrage-free assumption. So the pricing functions return an approximate price for instruments featuring cash flows between tree dates. Instruments featuring cash flows only on tree nodes are not affected by this option and return exact (arbitrage-free) prices. When `ConstRate` is 'off', the pricing function finds the cash flow dates for all instruments in the portfolio. If these cash flows do not align exactly with the tree dates, a new tree is generated and used for pricing. This new tree features the same volatility and initial rate specifications of the input tree but contains tree nodes for each date in which at least one instrument in the portfolio has a cash flow. Keep in mind that the number of nodes in a tree grows exponentially with the number of tree dates. So, setting `ConstRate` 'off' dramatically increases the memory and processor demands on the computer.

### BarrierMethod Field

When using binomial trees to price barrier options, this may require many tree steps to achieve an accurate result when tree nodes do not align with the barrier level. With the `BarrierMethod` field, the toolbox provides an enhancement method that improves the accuracy of the results without having to use large trees.

The `BarrierMethod` field can be set to 'unenhanced' (default) or 'interp'. If you specify 'unenhanced', no correction calculation is used. Otherwise, if you specify 'interp', the toolbox provides an enhanced valuation by interpolating between nodes on barrier boundaries.

You specify the barrier method in the last input argument, `Options`, of the functions `barrierbycrr`, `barrierbyeqp`, `barrierbyitt`, `crrprice`, `eqpprice`, `ittprice`, `crrsens`, `eqpsens`, or `ittsens`. `Options` is a structure that you create with the function `derivset`. Using `derivset`, you specify whether to use the enhanced or the unenhanced method.

For more information about this algorithm, see Derman, E., I. Kani, D. Ergener and I. Bardhan, "Enhanced Numerical Methods for Options with Barriers," *Financial Analysts Journal*, (Nov. - Dec. 1995), pp. 65-74.

## Customizing the Structure

Customize the `Options` structure by passing property name/property value pairs to the `derivset` function.

As an example, consider an `Options` structure with `ConstRate` 'off' and `Diagnostics` 'on'.

```
Options = derivset('ConstRate', 'off', 'Diagnostics', 'on')
```

```
Options =
```

```
    Diagnostics: 'on'
      Warnings: 'on'
     ConstRate: 'off'
BarrierMethod: 'unenhanced'
```

To obtain the value of a specific property from the `Options` structure, use `derivget`.

```
CR = derivget(Options, 'ConstRate')
```

```
CR =  
Off
```

---

**Note** Use `derivset` and `derivget` to construct the Options structure. These functions are guaranteed to remain unchanged, while the implementation of the structure itself may be modified in the future.

---

Now observe the effects of setting `ConstRate` 'off'. Obtain the tree dates from the HJM tree.

```
TreeDates = [HJMTree.TimeSpec.ValuationDate;...  
HJMTree.TimeSpec.Maturity]
```

```
TreeDates =
```

```
    730486  
    730852  
    731217  
    731582  
    731947
```

```
datedisp(TreeDates)
```

```
01-Jan-2000  
01-Jan-2001  
01-Jan-2002  
01-Jan-2003  
01-Jan-2004
```

All instruments in `HJMInstSet` settle on January 1, 2000, and all have cash flows once a year, except for the second bond, which features a period of 2. This bond has cash flows twice a year, with every other cash flow consequently falling between tree dates. You can extract this bond from the portfolio to compare how its price differs by setting `ConstRate` to 'on' and 'off'.

```
BondPort = instselect(HJMInstSet, 'Index', 2);
```

```
instdisp(BondPort)
```

```
Index Type CouponRate Settle      Maturity      Period Basis...  
1      Bond 0.04          01-Jan-2000 01-Jan-2004  2      NaN...
```

First price the bond with `ConstRate` 'on' (default).

```
format long  
[BondPrice, BondPriceTree] = hjmprice(HJMTree, BondPort)  
Warning: Not all cash flows are aligned with the tree. Result will  
be approximated.
```

```
BondPrice =
```

```
    97.52801411736377
```

```
BondPriceTree =
```

```
FinObj: 'HJMPriceTree'  
PBush: {1x5 cell}  
AIBush: {[0] [1x1x2 double] ... [1x4x2 double] [1x8 double]}  
tobs: [0 1 2 3 4]
```

Now recalculate the price of the bond setting `ConstRate` 'off'.

```
OptionsNoCR = derivset('ConstR', 'off')

OptionsNoCR =

Diagnostics: 'off'
  Warnings: 'on'
  ConstRate: 'off'

[BondPriceNoCR, BondPriceTreeNoCR] = hjmprice(HJMTree,...
BondPort, OptionsNoCR)
Warning: Not all cash flows are aligned with the tree. Rebuilding
tree.

BondPriceNoCR =

    97.53342361674437

BondPriceTreeNoCR =

FinObj: 'HJMPriceTree'
PBush: {1x9 cell}
AIBush: {1x9 cell}
tObs: [0 0.5000 1 1.5000 2 2.5000 3 3.5000 4]
```

As indicated in the last warning, because the cash flows of the bond did not align with the tree dates, a new tree was generated for pricing the bond. This pricing method returns more accurate results since it guarantees that the process is arbitrage-free. It also takes longer to calculate and requires more memory. The `tObs` field of the price tree structure indicates the increased memory usage. `BondPriceTree.tObs` has only five elements, while `BondPriceTreeNoCR.tObs` has nine. While this may not seem like a large difference, it has a dramatic effect on the number of states in the last node.

```
size(BondPriceTree.PBush{end})

ans =

    1 8

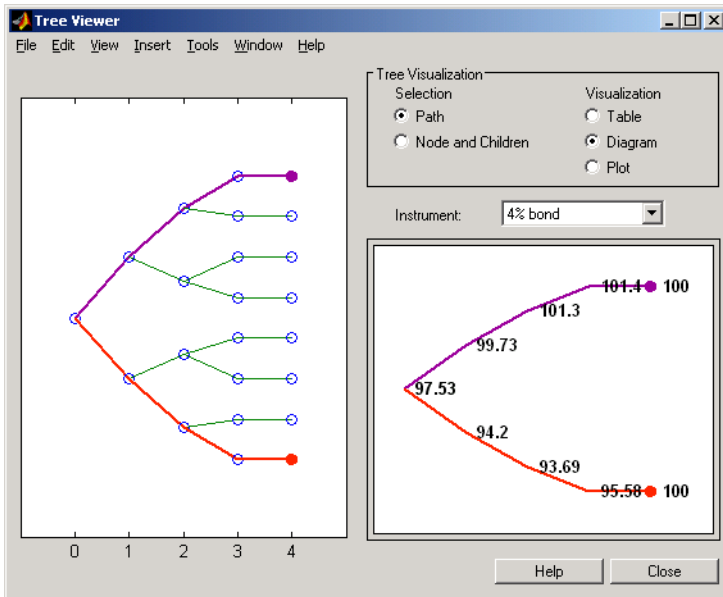

size(BondPriceTreeNoCR.PBush{end})

ans =

    1 128
```

The differences become more obvious by examining the price trees with `treeviewer`.

```
treeviewer(BondPriceTree, BondPort)
```

`treeviewer(BondPriceTreeNoCR, BondPort)`

`All = [Delta ./ Price, Gamma ./ Price, Vega ./ Price, Price]`

`All =`

## Glossary

### **basis**

Day count basis determines how interest accrues over time for various instruments and the amount transferred on interest payment dates. The calculation of accrued interest for dates between payments also uses day count basis. Day count basis is a fraction of Number of interest accrual days / Days in the relevant coupon period. Supported day count conventions and basis values are:

<b>Basis Value</b>	<b>Day Count Convention</b>
0	actual/actual (default) — Number of days in both a period and a year is the actual number of days.
1	30/360 SIA — Year fraction is calculated based on a 360 day year with 30-day months, after applying the following rules: If the first date and the second date are the last day of February, the second date is changed to the 30th. If the first date falls on the 31st or is the last day of February, it is changed to the 30th. If after the preceding test, the first day is the 30th and the second day is the 31st, then the second day is changed to the 30th.
2	actual/360 — Number of days in a period is equal to the actual number of days, however the number of days in a year is 360.
3	actual/365 — Number of days in a period is equal to the actual number of days, however the number of days in a year is 365 (even in a leap year).

Basis Value	Day Count Convention
4	30/360 PSA — Number of days in every month is set to 30 (including February). If the start date of the period is either the 31st of a month or the last day of February, the start date is set to the 30th, while if the start date is the 30th of a month and the end date is the 31st, the end date is set to the 30th. The number of days in a year is 360.
5	30/360 ISDA — Number of days in every month is set to 30, except for February where it is the actual number of days. If the start date of the period is the 31st of a month, the start date is set to the 30th while if the start date is the 30th of a month and the end date is the 31st, the end date is set to the 30th. The number of days in a year is 360.
6	30E /360 — Number of days in every month is set to 30 except for February where it is equal to the actual number of days. If the start date or the end date of the period is the 31st of a month, that date is set to the 30th. The number of days in a year is 360.
7	actual/365 Japanese — Number of days in a period is equal to the actual number of days, except for leap days (29th February) which are ignored. The number of days in a year is 365 (even in a leap year).
8	actual/actual ICMA — Number of days in both a period and a year is the actual number of days and the compounding frequency is annual.

<b>Basis Value</b>	<b>Day Count Convention</b>
9	actual/360 ICMA — Number of days in a period is equal to the actual number of days, however the number of days in a year is 360 and the compounding frequency is annual.
10	actual/365 ICMA — Number of days in a period is equal to the actual number of days, however the number of days in a year is 365 (even in a leap year) and the compounding frequency is annual.
11	30/360 ICMA — Number of days in every month is set to 30, except for February where it is equal to the actual number of days. If the start date or the end date of the period is the 31st of a month, that date is set to the 30th. The number of days in a year is 360 and the compounding frequency is annual.
12	actual/365 ISDA — The day count fraction is calculated using the following formula: (Actual number of days in period that fall in a leap year / 366) + (Actual number of days in period that fall in a normal year / 365 ).
13	bus/252 — The number of days in a period is equal to the actual number of business days. The number of business days in a year is 252.
