| <code>width</code> | Width of the bars and separation of bars within a group. (Default = 0.8.) If width is 1, the bars within a group touch one another. Values > 1 produce overlapping bars. |
| <code>style</code> | 'detached' (default), 'grouped', or 'stacked'.                                                                                                                           |

### Description

`bar3`, `bar3h` draw three-dimensional vertical and horizontal bar charts.

`bar3(tsobj)` draws the columns of data series of the object `tsobj`. The number of data series dictates the number of vertical bars per group. Each group is the data for one particular date.

`bar3(tsobj,width)` specifies the width of the bars.

`bar3(..., 'style')` changes the style of the bar chart.

`hbar3 = bar3(...)` returns a vector of bar handles.

Use the MATLAB command `shading faceted` to put edges on the bars. Use `shading flat` to turn edges off.

### Examples

## Create a Three-Dimensional Bar Chart

This example shows how to create a three-dimensional bar chart for Disney stock showing high, low, opening, and closing prices.

```
load disney
bar3(q_dis, 'stacked')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [matlab.com/help/finance/stock\\_prices.html](#).

```
title('Three-Dimensional Bar Chart of Disney Prices')
```

## Create a Three-Dimensional (Stacked) Bar Chart

This example shows how to create a three-dimensional, stacked bar chart for Disney stock showing high, low, opening, and closing prices.

```
load disney
bar3(q_dis, 'stacked')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [matlab.com/help/finance/stock\\_prices.html](#).

```
title('Three-Dimensional Bar Chart of Disney Prices (Stacked)')
```

# beytbill

Bond equivalent yield for Treasury bill

## Syntax

```
Yield = beytbill(Settle,Maturity,Discount)
```

## Description

`Yield = beytbill(Settle,Maturity,Discount)` returns the bond equivalent yield for a Treasury bill.

## Examples

### Find the Bond Equivalent Yield for a Treasury Bill

This example shows how to find the bond equivalent yield for a Treasury bill that has a settlement date of February 11, 2000, a maturity date of August 7, 2000, and a discount rate is 5.77.

```
Yield = beytbill('2/11/2000', '8/7/2000', 0.0577)
```

```
Yield = 0.0602
```

### Find the Bond Equivalent Yield for a Treasury Bill Using datetime Inputs

This example shows how to use `datetime` inputs to find the bond equivalent yield for a Treasury bill that has a settlement date of February 11, 2000, a maturity date of August 7, 2000, and the discount rate is 5.77.

```
Yield = beytbill(datetime('11-Feb-2000','Locale','en_US'), datetime('7-Aug-2000','Locale','en_US'), 0.0577)
```

```
Yield = 0.0602
```

## Input Arguments

### Settle — Settlement date of Treasury bill

serial date number | date character vector | datetime

Settlement date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays. `Settle` must be earlier than `Maturity`.

Data Types: double | char | datetime

### Maturity — Maturity date of Treasury bill

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `char` | `datetime`

**Discount – Discount rate of Treasury bill**

decimal

Discount rate of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of decimal fraction values.

Data Types: `double`

**Output Arguments****Yield – Treasury bill yield**

decimal

Treasury bill yield, returned as a scalar or NTBILLS-by-1 vector.

---

**Note** The number of days to maturity is typically quoted as: `md - sd - 1`. A NaN is returned for all cases in which negative prices are implied by the discount rate, `Discount`, and the number of days between `Settle` and `Maturity`.

---

# binprice

Binomial put and call American option pricing using Cox-Ross-Rubinstein model

## Syntax

```
[AssetPrice,OptionValue] = binprice(Price,Strike,Rate,Time,Increment,
Volatility,Flag)
[AssetPrice,OptionValue] = binprice( ____,DividendRate,Dividend,ExDiv)
```

## Description

[AssetPrice,OptionValue] = binprice(Price,Strike,Rate,Time,Increment, Volatility,Flag) prices an American option using the Cox-Ross-Rubinstein binomial pricing model. An American option can be exercised any time until its expiration date.

[AssetPrice,OptionValue] = binprice( \_\_\_\_,DividendRate,Dividend,ExDiv) adds optional arguments for DividendRate,Dividend, and ExDiv.

## Examples

### Price an American Option Using the Cox-Ross-Rubinstein Binomial Pricing Model

This example shows how to price an American put option with an exercise price of \$50 that matures in 5 months. The current asset price is \$52, the risk-free interest rate is 10%, and the volatility is 40%. There is one dividend payment of \$2.06 in 3-1/2 months. When specifying the input argument ExDiv in terms of number of periods, divide the ex-dividend date, specified in years, by the time Increment.

$$\text{ExDiv} = (3.5/12) / (1/12) = 3.5$$

```
[Price, Option] = binprice(52, 50, 0.1, 5/12, 1/12, 0.4, 0, 0, 2.06, 3.5)
```

Price = 6×6

|         |         |         |         |         |         |
|---------|---------|---------|---------|---------|---------|
| 52.0000 | 58.1367 | 65.0226 | 72.7494 | 79.3515 | 89.0642 |
| 0       | 46.5642 | 52.0336 | 58.1706 | 62.9882 | 70.6980 |
| 0       | 0       | 41.7231 | 46.5981 | 49.9992 | 56.1192 |
| 0       | 0       | 0       | 37.4120 | 39.6887 | 44.5467 |
| 0       | 0       | 0       | 0       | 31.5044 | 35.3606 |
| 0       | 0       | 0       | 0       | 0       | 28.0688 |

Option = 6×6

|        |        |         |         |         |         |
|--------|--------|---------|---------|---------|---------|
| 4.4404 | 2.1627 | 0.6361  | 0       | 0       | 0       |
| 0      | 6.8611 | 3.7715  | 1.3018  | 0       | 0       |
| 0      | 0      | 10.1591 | 6.3785  | 2.6645  | 0       |
| 0      | 0      | 0       | 14.2245 | 10.3113 | 5.4533  |
| 0      | 0      | 0       | 0       | 18.4956 | 14.6394 |
| 0      | 0      | 0       | 0       | 0       | 21.9312 |

The output returned is the asset price and American option value at each node of the binary tree.

## Input Arguments

### **Price — Current price of underlying asset**

numeric

Current price of underlying asset, specified as a scalar numeric value.

Data Types: `double`

### **Strike — Exercise price of the option**

numeric

Exercise price of the option, specified as a scalar numeric value.

Data Types: `double`

### **Rate — Risk-free interest rate**

decimal

Risk-free interest rate, specified as scalar decimal fraction.

Data Types: `double`

### **Time — Option time until maturity**

numeric

Option time until maturity, specified as a scalar for the number of years.

Data Types: `double`

### **Increment — Time increment**

numeric

Time increment, specified as a scalar numeric. `Increment` is adjusted so that the length of each interval is consistent with the maturity time of the option. (`Increment` is adjusted so that `Time` divided by `Increment` equals an integer number of increments.)

Data Types: `double`

### **Volatility — Asset volatility**

numeric

Asset volatility, specified as a scalar numeric.

Data Types: `double`

### **Flag — Flag indicating whether option is a call or put**

integer with values 0 or 1

Flag indicating whether option is a call or put, specified as a scalar `Flag = 1` for a call option, or `Flag = 0` for a put option.

Data Types: `logical`

**DividendRate — Dividend rate**

0 (default) | decimal

(Optional) Dividend rate, specified as a scalar decimal. If you enter a value for `DividendRate`, set `Dividend` and `ExDiv = 0` or do not enter them. If you enter values for `Dividend` and `ExDiv`, set `DividendRate = 0`

Data Types: double

**Dividend — Dividend payment**

0 (default) | numeric

(Optional) Dividend payment at an ex-dividend date (`ExDiv`), specified as a 1-by-N row vector. For each dividend payment, there must be a corresponding ex-dividend date. If you enter values for `Dividend` and `ExDiv`, set `DividendRate = 0`.

Data Types: double

**ExDiv — Ex-dividend date**

0 (default) | numeric

(Optional) Ex-dividend date, specified as a 1-by-N vector row vector for the number of periods.

Data Types: double

**Output Arguments****AssetPrice — Asset price**

vector

Asset price, returned as a vector that represents each node of the Cox-Ross-Rubinstein (CRR) binary tree.

**OptionValue — Option value**

vector

Option value, returned as a vector that represents each node of the Cox-Ross-Rubinstein (CRR) binary tree.

# blkimpv

Implied volatility for futures options from Black model

## Syntax

```
Volatility = blkimpv(Price,Strike,Rate,Time,Value)
Volatility = blkimpv( ____,Name,Value)
```

## Description

`Volatility = blkimpv(Price,Strike,Rate,Time,Value)` computes the implied volatility of a futures price from the market value of European futures options using Black's model. If the `Class` name-value argument is empty or unspecified, the default is a call option

---

**Note** Any input argument can be a scalar, vector, or matrix. When a value is a scalar, that value is used to compute the implied volatility of all the options. If more than one input is a vector or matrix, the dimensions of all nonscalar inputs must be identical.

Ensure that `Rate` and `Time` are expressed in consistent units of time.

---

`Volatility = blkimpv( ____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Find Implied Volatility for Futures Options from Black's Model

This example shows how to find the implied volatility for a European call futures option that expires in four months, trades at \$1.1166, and has an exercise price of \$20. Assume that the current underlying futures price is also \$20 and that the risk-free rate is 9% per annum. Furthermore, assume that you are interested in implied volatilities no greater than 0.5 (50% per annum). Under these conditions, the following commands all return an implied volatility of 0.25, or 25% per annum.

```
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5);
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5,'Class',{'Call'});
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5,'Class',true);
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5,'Class',true,'Method','jackel2016')

Volatility = 0.2500
```

## Input Arguments

### Price — Current price of underlying asset

scalar numeric

Current price of the underlying asset (that is, a futures contract), specified as a scalar numeric.

Data Types: double

**Strike — Exercise price of the futures option**

scalar numeric

Exercise price of the futures option, specified as a scalar numeric.

Data Types: double

**Rate — Annualized continuously compounded risk-free rate of return over life of the option**

scalar positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a scalar positive decimal.

Data Types: double

**Time — Time to expiration of the futures option**

scalar numeric

Time to expiration of the futures option, specified as the number of years using a scalar numeric.

Data Types: double

**Value — Price of a European option from which implied volatility of underlying asset is derived**

scalar numeric

Price of a European futures option from which the implied volatility of the underlying asset is derived, specified as a scalar numeric.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Volatility =`

```
blkimpv(Yield, CouponRate, Settle, Maturity, 'Method', 'jackel2016')
```

**Limit — Upper bound of implied volatility search interval**

10 (1000% per annum) (default) | positive scalar numeric

Upper bound of the implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a positive scalar numeric. If `Limit` is empty or unspecified, the default is 10, or 1000% per annum.

---

**Note** If you are using `Method` with a value of `'jackel2016'`, the `Limit` argument is ignored.

---

Data Types: double

**Tolerance — Implied volatility termination tolerance**

1e-6 (default) | positive scalar numeric

Implied volatility termination tolerance, specified as the comma-separated pair consisting of 'Tolerance' and a positive scalar numeric. If empty or missing, the default is 1e-6.

---

**Note** If you are using Method with a value of 'jackel2016', the Tolerance argument is ignored.

---

Data Types: double

### **Class — Option class from which implied volatility is derived**

true (call option) (default) | logical | cell array of character vectors | string array

Option class indicating option type (call or put) from which implied volatility is derived, specified as the comma-separated pair consisting of 'Class' and a logical indicator, cell array of character vectors, or string array.

To specify call options, set Class = true or Class = {'call'}. To specify put options, set Class = false or Class = {'put'} or Class = ["put"]. If Class is empty or unspecified, the default is a call option.

Data Types: logical | cell | string

### **Method — Method for computing implied volatility**

'jackel2016' (default) | character vector with values 'search' or 'jackel2016' | string with values "search" or "jackel2016"

Method for computing implied volatility, specified as the comma-separated pair consisting of 'Method' and a character vector with a value of 'search' or 'jackel2016' or a string with a value of "search" or "jackel2016".

Data Types: char | string

## **Output Arguments**

### **Volatility — Implied volatility of underlying asset derived from European futures option prices**

decimal

Implied volatility of the underlying asset derived from European futures option prices, returned as a decimal. If no solution is found, blkimpv returns NaN.

# blkprice

Black model for pricing futures options

## Syntax

```
[Call,Put] = blkprice(Price,Strike,Rate,Time,Volatility)
```

## Description

[Call,Put] = blkprice(Price,Strike,Rate,Time,Volatility) computes European put and call futures option prices using Black's model.

---

**Note** Any input argument can be a scalar, vector, or matrix. If a scalar, then that value is used to price all options. If more than one input is a vector or matrix, then the dimensions of those non-scalar inputs must be the same.

Ensure that Rate, Time, and Volatility are expressed in consistent units of time.

---

## Examples

### Compute European Put and Call Futures Option Prices Using Black's Model

This example shows how to price European futures options with exercise prices of \$20 that expire in four months. Assume that the current underlying futures price is also \$20 with a volatility of 25% per annum. The risk-free rate is 9% per annum.

```
[Call, Put] = blkprice(20, 20, 0.09, 4/12, 0.25)
```

```
Call = 1.1166
```

```
Put = 1.1166
```

## Input Arguments

### Price — Current price of underlying asset

numeric

Current price of the underlying asset (that is, a futures contract), specified as a numeric value.

Data Types: double

### Strike — Exercise price of the futures option

numeric

Exercise price of the futures option, specified as a numeric value.

Data Types: double

**Rate — Annualized continuously compounded risk-free rate of return over life of the option**  
positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal number.

Data Types: double

**Time — Time to expiration of option**  
numeric

Time to expiration of the option, specified as the number of years. Time must be greater than 0.

Data Types: double

**Volatility — Annualized asset price volatility**  
positive decimal

Annualized futures price volatility, specified as a positive decimal number.

Data Types: double

## Output Arguments

**Call — Price of a European call futures option**  
matrix

Price of a European call futures option, returned as a matrix.

**Put — Price of a European put futures option**  
matrix

Price of a European put futures option, returned as a matrix.

## blsdelta

Black-Scholes sensitivity to underlying price change

### Syntax

```
[CallDelta,PutDelta] = blsdelta(Price,Strike,Rate,Time,Volatility)
[CallDelta,PutDelta] = blsdelta(___,Yield)
```

### Description

[CallDelta,PutDelta] = blsdelta(Price,Strike,Rate,Time,Volatility) returns delta, the sensitivity in option value to change in the underlying asset price. Delta is also known as the hedge ratio. blsdelta uses normcdf, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

---

**Note** blsdelta can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

Yield = Rate

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate

where ForeignRate is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

[CallDelta,PutDelta] = blsdelta(\_\_\_,Yield) adds an optional argument for Yield.

### Examples

#### Find the Sensitivity in Option Value to Change in the Underlying Asset Price

This example shows how to find the Black-Scholes delta sensitivity for an underlying asset price change.

```
[CallDelta, PutDelta] = blsdelta(50, 50, 0.1, 0.25, 0.3, 0)
```

```
CallDelta = 0.5955
```

```
PutDelta = -0.4045
```

### Input Arguments

#### Price — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

**Strike — Exercise price of option**

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

**Rate — Annualized, continuously compounded risk-free rate of return over life of option**

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

**Time — Time (in years) to expiration of the option**

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

**Volatility — Annualized asset price volatility**

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

**Yield — Annualized, continuously compounded yield of the underlying asset over life of option**

0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

**Output Arguments****CallDelta — Delta of call option**

numeric

Delta of the call option, returned as a numeric value.

**PutDelta — Delta of put option**

numeric

Delta of the put option, returned as a numeric.

**References**

## blsgamma

Black-Scholes sensitivity to underlying delta change

### Syntax

```
Gamma = blsgamma(Price,Strike,Rate,Time,Volatility)
Gamma = blsgamma( ____,Yield)
```

### Description

Gamma = blsgamma(Price,Strike,Rate,Time,Volatility) returns gamma, the sensitivity of delta to change in the underlying asset price. blsgamma uses normpdf, the probability density function in the Statistics and Machine Learning Toolbox.

---

**Note** blsgamma can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

```
Yield = ForeignRate
```

where ForeignRate is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

Gamma = blsgamma( \_\_\_\_,Yield) adds an optional argument for Yield.

### Examples

#### Find Gamma for a Change in the Underlying Asset Price

This example shows how to find the gamma, the sensitivity of delta to a change in the underlying asset price.

```
Gamma = blsgamma(50, 50, 0.12, 0.25, 0.3, 0)
```

```
Gamma = 0.0512
```

### Input Arguments

#### Price — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

**Strike — Exercise price of option**

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

**Rate — Annualized, continuously compounded risk-free rate of return over life of option**

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

**Time — Time (in years) to expiration of the option**

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

**Volatility — Annualized asset price volatility**

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

**Yield — Annualized, continuously compounded yield of the underlying asset over life of option**

0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

**Output Arguments****Gamma — Delta to change in underlying security price**

numeric

Delta to change in underlying security price, returned as a numeric value.

# blsimpv

Black-Scholes implied volatility

## Syntax

```
Volatility = blsimpv(Price,Strike,Rate,Time,Value)
Volatility = blsimpv( ____,Name,Value)
```

## Description

`Volatility = blsimpv(Price,Strike,Rate,Time,Value)` using a Black-Scholes model computes the implied volatility of an underlying asset from the market value of European options. If the `Class` name-value argument is empty or unspecified, the default is a call option

---

**Note** The input arguments `Price`, `Strike`, `Rate`, `Time`, `Value`, `Yield`, and `Class` can be scalars, vectors, or matrices. If scalars, then that value is used to compute the implied volatility from all options. If more than one of these inputs is a vector or matrix, then the dimensions of all non-scalar inputs must be the same.

Also, ensure that `Rate`, `Time`, and `Yield` are expressed in consistent units of time.

---

`Volatility = blsimpv( ____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Implied Volatility of an Underlying Asset Using a Black-Scholes Model

This example shows how to compute the implied volatility for a European call option trading at \$10 with an exercise price of \$95 and three months until expiration. Assume that the underlying stock pays no dividend and trades at \$100. The risk-free rate is 7.5% per annum. Furthermore, assume that you are interested in implied volatilities no greater than 0.5 (50% per annum). Under these conditions, the following statements all compute an implied volatility of 0.3130, or 31.30% per annum.

```
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit', 0.5);
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit',0.5,'Yield',0,'Class', {'Call'});
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit',0.5,'Yield',0, 'Class', true);
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit',0.5,'Yield',0, 'Class', true,'Method','ja

Volatility = 0.3130
```

## Input Arguments

### Price — Current price of underlying asset

scalar numeric

Current price of the underlying asset, specified as a scalar numeric.

Data Types: double

**Strike — Exercise price of the option**

scalar numeric

Exercise price of the option, specified as a scalar numeric.

Data Types: double

**Rate — Annualized continuously compounded risk-free rate of return over life of the option**

scalar positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a scalar positive decimal.

Data Types: double

**Time — Time to expiration of option**

scalar numeric

Time to expiration of the option, specified as the number of years using a scalar numeric.

Data Types: double

**Value — Price of a European option from which implied volatility of underlying asset is derived**

scalar numeric

Price of a European option from which the implied volatility of the underlying asset is derived, specified as a scalar numeric.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Volatility = blsimpv(Yield, CouponRate, Settle, Maturity, 'Method', 'jackel2016')`

**Limit — Upper bound of implied volatility search interval**

10 (1000% per annum) (default) | positive scalar numeric

Upper bound of the implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a positive scalar numeric. If `Limit` is empty or unspecified, the default is 10, or 1000% per annum.

---

**Note** If you are using `Method` with a value of `'jackel2016'`, the `Limit` argument is ignored.

---

Data Types: double

**Yield — Annualized continuously compounded yield of underlying asset over life of the option**

0 (default) | decimal

Annualized continuously compounded yield of the underlying asset over the life of the option, specified as the comma-separated pair consisting of 'Yield' and a decimal number. If Yield is empty or missing, the default value is 0.

For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

---

**Note** blsimpv can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

Yield = Rate

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate

where ForeignRate is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

Data Types: double

**Tolerance — Implied volatility termination tolerance**

1e-6 (default) | positive scalar numeric

Implied volatility termination tolerance, specified as the comma-separated pair consisting of 'Tolerance' and a positive scalar numeric. If empty or missing, the default is 1e-6.

---

**Note** If you are using Method with a value of 'jackel2016', the Tolerance argument is ignored.

---

Data Types: double

**Class — Option class from which implied volatility is derived**

true (call option) (default) | logical | cell array of character vectors | string array

Option class indicating option type (call or put) from which implied volatility is derived, specified as the comma-separated pair consisting of 'Class' and a logical indicator, cell array of character vectors, or string array.

To specify call options, set Class = true or Class = {'call'}. To specify put options, set Class = false or Class = {'put'} or Class = ["put"]. If Class is empty or unspecified, the default is a call option.

Data Types: logical | cell | string

**Method — Method for computing implied volatility**

'jackel2016' (default) | character vector with values 'search' or 'jackel2016' | string with values "search" or "jackel2016"

Method for computing implied volatility, specified as the comma-separated pair consisting of 'Method' and a character vector with a value of 'search' or 'jackel2016' or a string with a value of "search" or "jackel2016".

Data Types: char | string

## Output Arguments

**Volatility** — Implied volatility of underlying asset derived from European option prices  
decimal

Implied volatility of the underlying asset derived from European option prices, returned as a decimal. If no solution is found, `blsimpv` returns NaN.

## blslambda

Black-Scholes elasticity

### Syntax

```
[CallEl,PutEl] = blslambda(Price,Strike,Rate,Time,Volatility)
[CallEl,PutEl] = blslambda( ____,Yield)
```

### Description

[CallEl,PutEl] = blslambda(Price,Strike,Rate,Time,Volatility) returns the elasticity of an option. CallEl is the call option elasticity or leverage factor, and PutEl is the put option elasticity or leverage factor. Elasticity (the leverage of an option position) measures the percent change in an option price per 1 percent change in the underlying asset price. blslambda uses normcdf, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

---

**Note** blslambda can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

Yield = Rate

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate

where ForeignRate is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

[CallEl,PutEl] = blslambda( \_\_\_\_,Yield) adds an optional argument for Yield.

### Examples

#### Find the Black-Scholes Elasticity (Lambda) for an Option

This example shows how to find the Black-Scholes elasticity, or leverage, of an option position.

```
[CallEl, PutEl] = blslambda(50, 50, 0.12, 0.25, 0.3)
```

```
CallEl = 8.1274
```

```
PutEl = -8.6466
```

### Input Arguments

#### Price — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

**Strike — Exercise price of option**

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

**Rate — Annualized, continuously compounded risk-free rate of return over life of option**

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

**Time — Time (in years) to expiration of the option**

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

**Volatility — Annualized asset price volatility**

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

**Yield — Annualized, continuously compounded yield of the underlying asset over life of option**

0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

## Output Arguments

**CallEL — Call option elasticity**

numeric

Call option elasticity or leverage factor, returned as a numeric value.

**PutEL — Put option elasticity**

numeric

Put option elasticity or leverage factor, returned as a numeric value.

## blsprice

Black-Scholes put and call option pricing

### Syntax

```
[Call,Put] = blsprice(Price,Strike,Rate,Time,Volatility)
[Call,Put] = blsprice( ____,Yield)
```

### Description

[Call,Put] = blsprice(Price,Strike,Rate,Time,Volatility) computes European put and call option prices using a Black-Scholes model.

---

**Note** Any input argument can be a scalar, vector, or matrix. If a scalar, then that value is used to price all options. If more than one input is a vector or matrix, then the dimensions of those non-scalar inputs must be the same.

---

Ensure that Rate, Time, Volatility, and Yield are expressed in consistent units of time.

---

[Call,Put] = blsprice( \_\_\_\_,Yield) adds an optional an argument for Yield.

### Examples

#### Compute European Put and Call Option Prices Using a Black-Scholes Model

This example shows how to price European stock options that expire in three months with an exercise price of \$95. Assume that the underlying stock pays no dividend, trades at \$100, and has a volatility of 50% per annum. The risk-free rate is 10% per annum.

```
[Call, Put] = blsprice(100, 95, 0.1, 0.25, 0.5)
```

```
Call = 13.6953
```

```
Put = 6.3497
```

#### Compute European Put and Call Option Prices on a Stock Index Using a Black-Scholes Model

The S&P 100 index is at 910 and has a volatility of 25% per annum. The risk-free rate of interest is 2% per annum and the index provides a dividend yield of 2.5% per annum. Calculate the value of a three-month European call and put with a strike price of 980.

```
[Call,Put] = blsprice(910,980,.02,.25,.25,.025)
```

```
Call = 19.6863
```

```
Put = 90.4683
```

## Price a European Call Option with the Garman-Kohlhagen Model

Price an FX option on buying GBP with USD.

```
S = 1.6; % spot exchange rate
X = 1.6; % strike
T = .3333;
r_d = .08; % USD interest rate
r_f = .11; % GBP interest rate
sigma = .2;
```

```
Price = blsprice(S,X,r_d,T,sigma,r_f)
```

```
Price = 0.0639
```

## Input Arguments

### Price — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

### Strike — Exercise price of the option

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

### Rate — Annualized continuously compounded risk-free rate of return over life of the option

positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal number.

Data Types: double

### Time — Time to expiration of option

numeric

Time to expiration of the option, specified as the number of years.

Data Types: double

### Volatility — Annualized asset price volatility

positive decimal

Annualized asset price volatility (that is, annualized standard deviation of the continuously compounded asset return), specified as a positive decimal number.

Data Types: double

**Yield — Annualized continuously compounded yield of underlying asset over life of the option** $\theta$  (default) | decimal

(Optional) Annualized continuously compounded yield of the underlying asset over the life of the option, specified as a decimal number. If `Yield` is empty or missing, the default value is  $\theta$ .

For example, `Yield` could represent the dividend yield (annual dividend rate expressed as a percentage of the price of the security) or foreign risk-free interest rate for options written on stock indices and currencies.

---

**Note** `blsprice` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

`Yield = Rate`

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

`Yield = ForeignRate`

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

Data Types: `double`

**Output Arguments****Call — Price of a European call option**

matrix

Price of a European call option, returned as a matrix.

**Put — Price of a European put option**

matrix

Price of a European put option, returned as a matrix.

## blsrho

Black-Scholes sensitivity to interest-rate change

### Syntax

```
[CallRho,PutRho] = blsrho(Price,Strike,Rate,Time,Volatility)
[CallRho,PutRho] = blsrho( ____,Yield)
```

### Description

[CallRho,PutRho] = blsrho(Price,Strike,Rate,Time,Volatility) returns the call option rho CallRho, and the put option rho PutRho. Rho is the rate of change in value of derivative securities with respect to interest rates. blsrho uses normcdf, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

---

**Note** blsrho can also handle an underlying asset such as currencies. When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate

where ForeignRate is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

[CallRho,PutRho] = blsrho( \_\_\_\_,Yield) adds an optional argument for Yield.

### Examples

#### Find the Black-Scholes Sensitivity (Rho) to Interest-Rate Change

This example shows how to find the Black-Scholes sensitivity, rho, to interest-rate change.

```
[CallRho, PutRho] = blsrho(50, 50, 0.12, 0.25, 0.3, 0)
```

```
CallRho = 6.6686
```

```
PutRho = -5.4619
```

### Input Arguments

#### Price — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

#### Strike — Exercise price of option

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

**Rate — Annualized, continuously compounded risk-free rate of return over life of option**

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

**Time — Time (in years) to expiration of the option**

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

**Volatility — Annualized asset price volatility**

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

**Yield — Annualized, continuously compounded yield of the underlying asset over life of option**

0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

## Output Arguments

**CallRho — Call option rho**

numeric

Call option rho, returned as a numeric value.

**PutRho — Put option rho**

numeric

Put option rho, returned as a numeric value.

# blstheta

Black-Scholes sensitivity to time-until-maturity change

## Syntax

```
[CallTheta,PutTheta] = blstheta(Price,Strike,Rate,Time,Volatility)
[CallTheta,PutTheta] = blstheta( ____,Yield)
```

## Description

[CallTheta,PutTheta] = blstheta(Price,Strike,Rate,Time,Volatility) returns the call option theta CallTheta, and the put option theta PutTheta.

Theta is the sensitivity in option value with respect to time and is measured in years. CallTheta or PutTheta can be divided by 365 to get Theta per calendar day or by 252 to get Theta by trading day.

blstheta uses normcdf, the normal cumulative distribution function, and normpdf, the normal probability density function, in the Statistics and Machine Learning Toolbox.

---

**Note** blstheta can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

Yield = Rate

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate

where ForeignRate is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

[CallTheta,PutTheta] = blstheta( \_\_\_\_,Yield) adds an optional argument for Yield.

## Examples

### Compute the Black-Scholes Sensitivity to Time-Until-Maturity Change (Theta)

This example shows how to compute theta, the sensitivity in option value with respect to time.

```
[CallTheta, PutTheta] = blstheta(50, 50, 0.12, 0.25, 0.3, 0)
```

```
CallTheta = -8.9630
```

```
PutTheta = -3.1404
```

## Input Arguments

### Price — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

### Strike — Exercise price of option

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

### Rate — Annualized, continuously compounded risk-free rate of return over life of option

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

### Time — Time (in years) to expiration of the option

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

### Volatility — Annualized asset price volatility

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

### Yield — Annualized, continuously compounded yield of the underlying asset over life of option

0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

## Output Arguments

### CallTheta — Call option theta

numeric

Call option theta, returned as a numeric value.

**PutTheta – Put option theta**

numeric

Put option theta, returned as a numeric value.

**References**

## blsvega

Black-Scholes sensitivity to underlying price volatility

### Syntax

```
Vega = blsvega(Price,Strike,Rate,Time,Volatility)
Vega = blsvega( ____,Yield)
```

### Description

`Vega = blsvega(Price,Strike,Rate,Time,Volatility)` rate of change of the option value with respect to the volatility of the underlying asset. `blsvega` uses `normpdf`, the normal probability density function in the Statistics and Machine Learning Toolbox.

---

**Note** `blsvega` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

```
Yield = ForeignRate
```

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

`Vega = blsvega( ____,Yield)` adds an optional argument for `Yield`.

### Examples

#### Compute Black-Scholes Sensitivity to Underlying Price Volatility (Vega)

This example shows how to compute vega, the rate of change of the option value with respect to the volatility of the underlying asset.

```
Vega = blsvega(50, 50, 0.12, 0.25, 0.3, 0)
```

```
Vega = 9.6035
```

### Input Arguments

#### Price — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

**Strike — Exercise price of option**

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

**Rate — Annualized, continuously compounded risk-free rate of return over life of option**

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

**Time — Time (in years) to expiration of the option**

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

**Volatility — Annualized asset price volatility**

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

**Yield — Annualized, continuously compounded yield of the underlying asset over life of option**

0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

**Output Arguments****Vega — Rate of change of option value with respect to volatility of underlying asset**

numeric

Rate of change of the option value with respect to the volatility of the underlying asset, returned as a numeric value.

# bondDefaultBootstrap

Bootstrap default probability curve from bond prices

## Syntax

```
[ProbabilityData,HazardData] = bondDefaultBootstrap(ZeroData,MarketData,
Settle)
[ProbabilityData,HazardData] = bondDefaultBootstrap( ____,Name,Value)
```

## Description

[ProbabilityData,HazardData] = bondDefaultBootstrap(ZeroData,MarketData,Settle) bootstraps the default probability curve from bond prices.

Using bondDefaultBootstrap, you can:

- Extract discrete default probabilities for a certain period from market bond data.
- Interpolate these default probabilities to get the default probability curve for pricing and risk management purposes.

[ProbabilityData,HazardData] = bondDefaultBootstrap( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Determine the Default Probability and Hazard Rate Values for Treasury Bonds

Use the following bond data.

```
Settle = datenum('08-Jul-2016');
MarketDate = datenum({'06/15/2018', '01/08/2019', '02/01/2021', '03/18/2021', '08/04/2025'}','mm/dd/yyyy');
CouponRate = [2.240 2.943 5.750 3.336 4.134]/100;
MarketPrice = [101.300 103.020 115.423 104.683 108.642]';
MarketData = [MarketDate,MarketPrice,CouponRate];
```

Calculate the ProbabilityData and HazardData.

```
TreasuryParYield = [0.26 0.28 0.36 0.48 0.61 0.71 0.95 1.19 1.37 1.69 2.11]'/100;
TreasuryDates = datemnth(Settle, [[1 3 6], 12 * [1 2 3 5 7 10 20 30]]');
[ZeroRates, CurveDates] = pyld2zero(TreasuryParYield, TreasuryDates, Settle);
ZeroData = [CurveDates, ZeroRates];
format longg
[ProbabilityData,HazardData]=bondDefaultBootstrap(ZeroData,MarketData,Settle)
```

ProbabilityData = 5×2

|        |                    |
|--------|--------------------|
| 737226 | 0.0299675399937611 |
| 737433 | 0.0418832295824674 |
| 738188 | 0.090518332884262  |
| 738233 | 0.101248065083713  |

```
739833      0.233002708031915
```

```
HazardData = 5×2
```

```
737226      0.0157077745460244
737433      0.0217939816590403
738188      0.025184912824721
738233      0.0962608718640789
739833      0.0361632398787917
```

```
format
```

### Reprice a Bond Listed on the Default Probability Curve

Reprice one of the bonds from bonds list based on the default probability curve. The expected result of this repricing is a perfect match with the market quote.

Use the following Treasury data from US Department of the Treasury.

```
Settle = datetime('08-Jul-2016','Locale','en_US');
TreasuryParYield = [0.26 0.28 0.36 0.48 0.61 0.71 0.95 1.19 1.37 1.69 2.11]'/100;
TreasuryDates = datemnth(Settle, [[1 3 6], 12 * [1 2 3 5 7 10 20 30]]');

## Input Arguments

### ZeroData — Zero rate data

matrix | IRDataCurve object

Zero rate data, specified as an M-by-2 matrix of dates and zero rates or an IRDataCurve object of zero rates. For array input, the dates must be entered as serial date numbers, and discount rate must be in decimal form.

When ZeroData is an IRDataCurve object, ZeroCompounding and ZeroBasis are implicit in ZeroData and are redundant inside this function. In this case, specify these optional parameters when constructing the IRDataCurve object before using this bondDefaultBootstrap function.

For more information on an IRDataCurve object, see “Creating an IRDataCurve Object” (Financial Instruments Toolbox).

Data Types: double

### MarketData — Bond market data

matrix

Bond market data, specified as an N-by-3 matrix of maturity dates, market prices, and coupon rates for bonds. The dates must be entered as serial date numbers, market prices must be numeric values, and coupon rate must be in decimal form.

---

**Note** A warning is displayed when MarketData is not sorted in ascending order by time.

---

Data Types: double

### Settle — Settlement date

serial date number | date character vector | datetime object | date string object

Settlement date, specified as a serial date number, a date character vector, a datetime object, or a date string object. `Settle` must be earlier than or equal to the maturity dates in `MarketData`.

Data Types: double | char | datetime | string

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

---

**Note** Any optional input of size N-by-1 is also acceptable as an array of size 1-by-N, or as a single value applicable to all contracts.

---

Example: `[ProbabilityData,HazardData] = bondDefaultBootstrap(ZeroData,MarketData,Settle,'RecoveryRate',Recovery,'ZeroCompounding',-1)`

### RecoveryRate — Recovery rate

0.4 (default) | decimal

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a N-by-1 vector of recovery rates, expressed as a decimal from 0 through 1.

Data Types: double

### ProbabilityDates — Dates for output of default probability data

column of dates in `MarketData` (default) | serial date number | date character vector | datetime object | date string object

Dates for the output of default probability data, specified as the comma-separated pair consisting of `'ProbabilityDates'` and a P-by-1 vector, given as serial date numbers, datetime objects, date character vectors, or date string objects.

Data Types: double | char | datetime | string

### ZeroCompounding — Compounding frequency of the zero curve

2 (semiannual) (default) | integer with value of 1,2,3,4,6,12, or -1

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of `'ZeroCompounding'` and a N-by-1 vector. Values are:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding

- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: double

### **ZeroBasis — Basis of the zero curve**

0 (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and the same values listed for Basis.

Data Types: double

### **RecoveryMethod — Recovery method**

'facevalue' (default) | character vector with value of 'presentvalue' or 'facevalue' | string object with value of 'presentvalue' or 'facevalue'

Recovery method, specified as the comma-separated pair consisting of 'RecoveryMethod' and a character vector or a string with a value of 'presentvalue' or 'facevalue'.

- 'presentvalue' assumes that upon default, a bond is valued at a given fraction to the hypothetical present value of its remaining cash flows, discounted at risk-free rate.
- 'facevalue' assumes that a bond recovers a given fraction of its face value upon recovery.

Data Types: char | string

### **Face — Face or par value**

100 (default) | numeric

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector of bonds.

Data Types: double

### **Period — Payment frequency**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Payment frequency, specified as the comma-separated pair consisting of 'Period' and a N-by-1 vector with values of 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer, 0 or 1, using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

### **IssueDate — Bond issue date**

if IssueDate not specified, cash flow payment dates determined from other inputs (default) | serial date number | date character vector | datetime object | date string object

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a N-by-1 vector, given as serial date numbers, datetime objects, date character vectors, or date string objects.

Data Types: double | char | datetime | string

### **FirstCouponDate — First actual coupon date**

if you do not specify a FirstCouponDate, cash flow payment dates are determined from other inputs (default) | serial date number

First actual coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a serial date number. FirstCouponDate is used when a bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Data Types: double

### **LastCouponDate — Last actual coupon date**

if you do not specify a LastCouponDate, cash flow payment dates are determined from other inputs (default) | scalar for serial date number

Last actual coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a serial date number. LastCouponDate is used when a bond has an irregular last coupon period.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Data Types: `double`

### **StartDate — Forward starting date of payments**

if you do not specify `StartDate`, effective start date is `Settle` date (default) | serial date number

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a serial date number. `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

Data Types: `double`

### **BusinessDayConvention — Business day conventions**

`'actual'` (default) | character vector or string object with values `'actual'`, `'follow'`, `'modifiedfollow'`, `'previous'` or `'modifiedprevious'`

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a string object. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `'actual'` — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `'follow'` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `'modifiedfollow'` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `'previous'` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `'modifiedprevious'` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

## **Output Arguments**

### **ProbabilityData — Default probability values**

`matrix`

Default probability values, returned as a P-by-2 matrix with dates and corresponding cumulative default probability values. The dates match those in `MarketData`, unless the optional input parameter `ProbabilityDates` is provided.

### **HazardData — Hazard rate values**

`matrix`

Hazard rate values, returned as an N-by-2 matrix with dates and corresponding hazard rate values for the survival probability model. The dates match those in `MarketData`.

---

**Note** A warning is displayed when nonmonotone default probabilities (that is, negative hazard rates) are found.

---

## Topics

"Creating an `IRDataCurve` Object" (Financial Instruments Toolbox)

**Introduced in R2017a**

# bndconvp

Bond convexity given price

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

## Syntax

```
[YearConvexity,PerConvexity] = bndconvp(Price,CouponRate,Settle,Maturity)
[YearConvexity,PerConvexity] = bndconvp( ____,Name,Value)
```

## Description

`[YearConvexity,PerConvexity] = bndconvp(Price,CouponRate,Settle,Maturity)` computes the convexity of `NUMBONDS` fixed income securities given a clean price for each bond. The clean price of a bond excludes any interest that has accrued since issue or the most recent coupon payment.

`bndconvp` determines the convexity for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bndconvp` also determines the convexity of a zero coupon bond. Convexity is a measure of the rate of change in duration; measured in time. The greater the rate of change, the more the duration changes as yield changes.

`[YearConvexity,PerConvexity] = bndconvp( ____,Name,Value)` adds optional name-value pair arguments.

## Examples

### Find Bond Convexity Given Price

This example shows how to compute the convexity of three bonds given their prices.

```
Price = [106; 100; 98];
CouponRate = 0.055;
Settle = '02-Aug-1999';
Maturity = '15-Jun-2004';
Period = 2;
Basis = 0;
```

```
[YearConvexity, PerConvexity] = bndconvp(Price,...
CouponRate,Settle, Maturity, Period, Basis)
```

```
YearConvexity = 3×1
```

```
21.4447
21.0363
20.8951
```

```
PerConvexity = 3×1
```

```
85.7788
84.1454
83.5803
```

### Find Bond Convexity Given Price Using datetime Inputs

This example shows how to compute the convexity of three bonds given their prices using datetime inputs.

```
Price = [106; 100; 98];
CouponRate = 0.055;
Period = 2;
Basis = 0;
Settle = datetime('02-Aug-1999','Locale','en_US');
Maturity = datetime('15-Jun-2004','Locale','en_US');
[YearConvexity, PerConvexity] = bndconvp(Price,...
CouponRate, Settle, Maturity, Period, Basis)
```

```
YearConvexity = 3×1
```

```
21.4447
21.0363
20.8951
```

```
PerConvexity = 3×1
```

```
85.7788
84.1454
83.5803
```

## Input Arguments

### Price — Clean price (excludes accrued interest)

numeric

Clean price (excludes accrued interest), specified as numeric value using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### CouponRate — Annual percentage rate used to determine coupons payable on a bond

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

Data Types: `double`

### **Settle — Settlement date for certificate of deposit**

serial date number | date character vector | `datetime`

Settlement date for the certificate of deposit, specified as a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or `datetime` arrays. The `Settle` date must be before the `Maturity` date.

Data Types: `double` | `char` | `datetime`

### **Maturity — Maturity date for certificate of deposit**

serial date number | date character vector | `datetime`

Maturity date for the certificate of deposit, specified as a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or `datetime` arrays.

Data Types: `double` | `char` | `datetime`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `[YearConvexity, PerConvexity] = bndconvp(Price, CouponRate, Settle, Maturity, 'Period', 4, 'Basis', 7)`

### **Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: `double`

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)

- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `double`

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

### **IssueDate — Bond issue date**

serial date number | date character vector | `datetime`

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or `datetime` arrays.

If you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | `datetime`

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or `datetime` arrays.

If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | `datetime`

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or `datetime` arrays.

If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **StartDate — Forward starting date of payments**

serial date number | date character vector | `datetime`

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or `datetime` arrays. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

Data Types: `double` | `char` | `datetime`

### **Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

Data Types: `double`

### **CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of `'CompoundingFrequency'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: `double`

### **DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of `'DiscountBasis'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector. Values are:

- 0 = actual/actual

- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

---

Data Types: double

### **LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. LastCouponInterest is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## **Output Arguments**

### **YearConvexity — Yearly (annualized) convexity**

numeric

Yearly (annualized) convexity, returned as a NUMBONDS-by-1 vector.

### **PerConvexity — Periodic convexity reported on semiannual bond basis**

numeric

Periodic convexity reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

## bndconvy

Bond convexity given yield

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

### Syntax

```
[YearConvexity,PerConvexity] = bndconvy(Yield,CouponRate,Settle,Maturity)
[YearConvexity,PerConvexity] = bndconvy( ____,Name,Value)
```

### Description

`[YearConvexity,PerConvexity] = bndconvy(Yield,CouponRate,Settle,Maturity)` computes the convexity of NUMBONDS fixed income securities given a clean price for each bond.

`bndconvy` determines the convexity for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bndconvy` also determines the convexity of a zero coupon bond.

`[YearConvexity,PerConvexity] = bndconvy( ____,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Find Bond Convexity Given Yield

This example shows how to compute the convexity of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];
CouponRate = 0.055;
Settle = '02-Aug-1999';
Maturity = '15-Jun-2004';
Period = 2;
Basis = 0;
```

```
[YearConvexity, PerConvexity]=bndconvy(Yield, CouponRate,...
Settle, Maturity, Period, Basis)
```

```
YearConvexity = 3×1
```

```
21.4825
21.0358
20.8885
```

```
PerConvexity = 3×1
    85.9298
    84.1434
    83.5541
```

## Find Bond Convexity Given Yield Using datetime Inputs

This example shows how to use `datetime` inputs to compute the convexity of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];
CouponRate = 0.055;
Settle = datetime('02-Aug-1999','Locale','en_US');
Maturity = datetime('15-Jun-2004','Locale','en_US');
Period = 2;
Basis = 0;
[YearConvexity, PerConvexity]=bndconvy(Yield, CouponRate,...
Settle, Maturity, Period, Basis)
```

```
YearConvexity = 3×1
    21.4825
    21.0358
    20.8885
```

```
PerConvexity = 3×1
    85.9298
    84.1434
    83.5541
```

## Input Arguments

### Yield — Yield to maturity on semiannual basis

numeric

Yield to maturity on a semiannual basis, specified as numeric value using a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

Data Types: double

### CouponRate — Annual percentage rate used to determine coupons payable on a bond

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

Data Types: double

**Settle — Settlement date for certificate of deposit**

serial date number | date character vector | datetime

Settlement date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The `Settle` date must be before the `Maturity` date.

Data Types: double | char | datetime

**Maturity — Maturity date for certificate of deposit**

serial date number | date character vector | datetime

Maturity date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[YearConvexity, PerConvexity] = bndconvy(Yield, CouponRate, Settle, Maturity, 'Period', 4, 'Basis', 7)`

**Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

### **IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The StartDate is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a StartDate, the effective start date is the Settle date.

Data Types: double | char | datetime

**Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

---

Data Types: double

### **LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. LastCouponInterest is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## **Output Arguments**

### **YearConvexity — Yearly (annualized) convexity**

numeric

Yearly (annualized) convexity, returned as a NUMBONDS-by-1 vector.

### **PerConvexity — Periodic convexity reported on semiannual bond basis**

numeric

Periodic convexity reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

# bnddurp

Bond duration given price

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

## Syntax

```
[ModDuration, YearDuration, PerDuration] = bnddurp(Price, CouponRate, Settle,
Maturity)
[ModDuration, YearDuration, PerDuration] = bnddurp( ____, Name, Value)
```

## Description

`[ModDuration, YearDuration, PerDuration] = bnddurp(Price, CouponRate, Settle, Maturity)` computes the Macaulay and modified duration of NUMBONDS fixed-income securities given a clean price for each bond.

`bnddurp` determines the Macaulay and modified duration for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bnddurp` also determines the Macaulay and modified duration for a zero coupon bond.

`[ModDuration, YearDuration, PerDuration] = bnddurp( ____, Name, Value)` adds optional name-value pair arguments.

## Examples

### Find Bond Duration Given Price

This example shows how to compute the duration of three bonds given their prices.

```
Price = [106; 100; 98];
CouponRate = 0.055;
Settle = '02-Aug-1999';
Maturity = '15-Jun-2004';
Period = 2;
Basis = 0;
```

```
[ModDuration, YearDuration, PerDuration] = bnddurp(Price, ...
CouponRate, Settle, Maturity, Period, Basis)
```

```
ModDuration = 3×1
```

```
4.2400
```

```
4.1925
4.1759
```

```
YearDuration = 3×1
```

```
4.3275
4.3077
4.3007
```

```
PerDuration = 3×1
```

```
8.6549
8.6154
8.6014
```

### Find Bond Duration Given Price Using datetime Inputs

This example shows how to use `datetime` inputs to compute the duration of three bonds given their prices.

```
Price = [106; 100; 98];
CouponRate = 0.055;
Settle = datetime('02-Aug-1999','Locale','en_US');
Maturity = datetime('15-Jun-2004','Locale','en_US');
Period = 2;
Basis = 0;
[ModDuration, YearDuration, PerDuration] = bnddurp(Price,...
CouponRate, Settle, Maturity, Period, Basis)
```

```
ModDuration = 3×1
```

```
4.2400
4.1925
4.1759
```

```
YearDuration = 3×1
```

```
4.3275
4.3077
4.3007
```

```
PerDuration = 3×1
```

```
8.6549
8.6154
8.6014
```

## Input Arguments

### Price — Clean price (excludes accrued interest)

numeric

Clean price (excludes accrued interest), specified as numeric value using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### CouponRate — Annual percentage rate used to determine coupons payable on a bond

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### Settle — Settlement date for certificate of deposit

serial date number | date character vector | datetime

Settlement date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

### Maturity — Maturity date for certificate of deposit

serial date number | date character vector | datetime

Maturity date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: [ModDuration, YearDuration, PerDuration] =  
bnddurp(Price, CouponRate, Settle, Maturity, 'Period', 4, 'Basis', 7)

### Period — Number of coupon payments per year

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### Basis — Day-count basis of instrument

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `double`

#### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

#### **IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

#### **FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | `datetime`

Irregular or normal last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or `datetime` arrays.

If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **StartDate — Forward starting date of payments**

serial date number | date character vector | `datetime`

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or `datetime` arrays. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

Data Types: `double` | `char` | `datetime`

### **Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

Data Types: `double`

### **CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of `'CompoundingFrequency'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If a SIA day-count basis is defined in the Basis input argument and there is no value assigned for DiscountBasis, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the Basis input argument and there is no value assigned for DiscountBasis, the specified bases from the Basis input argument are used.

---

Data Types: double

**LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. LastCouponInterest is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## Output Arguments

### **ModDuration — Modified duration in years**

numeric

Modified duration in years reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

### **YearDuration — Macaulay duration in years**

numeric

Macaulay duration in years, returned as a NUMBONDS-by-1 vector.

### **PerDuration — Periodic Macaulay duration**

numeric

Periodic Macaulay duration reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

## bnddury

Bond duration given yield

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

### Syntax

```
[ModDuration,YearDuration,PerDuration] = bnddury(Yield,CouponRate,Settle,
Maturity)
[ModDuration,YearDuration,PerDuration] = bnddury( ____,Name,Value)
```

### Description

`[ModDuration,YearDuration,PerDuration] = bnddury(Yield,CouponRate,Settle,Maturity)` computes the Macaulay and modified duration of NUMBONDS fixed income securities given yield to maturity for each bond.

`bnddury` determines the Macaulay and modified duration for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bnddury` also determines the Macaulay and modified duration for a zero coupon bond.

`[ModDuration,YearDuration,PerDuration] = bnddury( ____,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Find Bond Duration Given Yield

This example shows how to compute the duration of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];
CouponRate = 0.055;
Settle = '02-Aug-1999';
Maturity = '15-Jun-2004';
Period = 2;
Basis = 0;
```

```
[ModDuration,YearDuration,PerDuration]=bnddury(Yield,...
CouponRate, Settle, Maturity, Period, Basis)
```

```
ModDuration = 3×1
```

```
4.2444
```

```
4.1924
4.1751
```

```
YearDuration = 3×1
```

```
4.3292
4.3077
4.3004
```

```
PerDuration = 3×1
```

```
8.6585
8.6154
8.6007
```

### Find Bond Duration Given Yield Using datetime Inputs

This example shows how to use `datetime` inputs to compute the duration of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];
CouponRate = 0.055;
Settle = datetime('02-Aug-1999','Locale','en_US');
Maturity = datetime('15-Jun-2004','Locale','en_US');
Period = 2;
Basis = 0;
[ModDuration,YearDuration,PerDuration]=bnddury(Yield,...
CouponRate, Settle, Maturity, Period, Basis)
```

```
ModDuration = 3×1
```

```
4.2444
4.1924
4.1751
```

```
YearDuration = 3×1
```

```
4.3292
4.3077
4.3004
```

```
PerDuration = 3×1
```

```
8.6585
8.6154
8.6007
```

## Input Arguments

### Yield — Yield to maturity on a semiannual basis

decimal

Yield to maturity on a semiannual basis, specified as a decimal value using a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

Data Types: `double`

### CouponRate — Annual percentage rate used to determine coupons payable on a bond

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

Data Types: `double`

### Settle — Settlement date for certificate of deposit

serial date number | date character vector | datetime

Settlement date for the certificate of deposit, specified as a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or datetime arrays. The `Settle` date must be before the `Maturity` date.

Data Types: `double` | `char` | `datetime`

### Maturity — Maturity date for certificate of deposit

serial date number | date character vector | datetime

Maturity date for the certificate of deposit, specified as a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `char` | `datetime`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[ModDuration, YearDuration, PerDuration] = bnddury(Yield, CouponRate, Settle, Maturity, 'Period', 4, 'Basis', 7)`

### Period — Number of coupon payments per year

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: `double`

### Basis — Day-count basis of instrument

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `double`

#### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

#### **IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

#### **FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | `datetime`

Irregular or normal last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or `datetime` arrays.

If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **StartDate — Forward starting date of payments**

serial date number | date character vector | `datetime`

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or `datetime` arrays. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

Data Types: `double` | `char` | `datetime`

### **Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

Data Types: `double`

### **CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of `'CompoundingFrequency'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If a SIA day-count basis is defined in the Basis input argument and there is no value assigned for DiscountBasis, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the Basis input argument and there is no value assigned for DiscountBasis, the specified bases from the Basis input argument are used.

---

Data Types: double

**LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. LastCouponInterest is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## Output Arguments

### **ModDuration** — Modified duration in years

numeric

Modified duration in years reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

### **YearDuration** — Macaulay duration in years

numeric

Macaulay duration in years, returned as a NUMBONDS-by-1 vector.

### **PerDuration** — Periodic Macaulay duration

numeric

Periodic Macaulay duration reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

## bndkrdur

Bond key rate duration given zero curve

### Syntax

```
KeyRateDuration = bndkrdur(ZeroData,CouponRate,Settle,Maturity)
KeyRateDuration = bndkrdur( ____,Name,Value)
```

### Description

KeyRateDuration = bndkrdur(ZeroData,CouponRate,Settle,Maturity) computes the key rate durations for one or more bonds given a zero curve and a set of key rates.

KeyRateDuration = bndkrdur( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Find the Bond Key Rate Duration Given the Zero Curve

This example shows how to compute the key rate duration of a bond for key rate times of 2, 5, 10, and 30 years.

```
ZeroRates = [0.0476 .0466 .0465 .0468 .0473 .0478 ...
             .0493 .0539 .0572 .0553 .0530]';

ZeroDates = daysadd('31-Dec-1998',[30 360 360*2 360*3 360*5 ...
             360*7 360*10 360*15 360*20 360*25 360*30],1);

ZeroData = [ZeroDates ZeroRates];

krdur = bndkrdur(ZeroData,.0525,'12/31/1998',...
             '11/15/2028','KeyRates',[2 5 10 30])

krdur = 1×4

    0.2986    0.8791    4.1353    9.5814
```

#### Find the Bond Key Rate Duration Given the Zero Curve Using datetime Inputs

This example shows how to use datetime inputs for Settle and Maturity and also use a table for ZeroData to compute the key rate duration of a bond for key rate times of 2, 5, 10, and 30 years.

```
ZeroRates = [0.0476 .0466 .0465 .0468 .0473 .0478 ...
             .0493 .0539 .0572 .0553 .0530]';

ZeroDates = daysadd('31-Dec-1998',[30 360 360*2 360*3 360*5 ...
             360*7 360*10 360*15 360*20 360*25 360*30],1);
```

```
ZeroData = table(datetime(ZeroDates, 'ConvertFrom', 'datenum', 'Locale', 'en_US'), ZeroRates);
krdur = bndkrdur(ZeroData, .0525, datetime('12/31/1998', 'Locale', 'en_US'), ...
datetime('11/15/2028', 'Locale', 'en_US'), 'KeyRates', [2 5 10 30])
krdur = 1×4
    0.2986    0.8791    4.1353    9.5814
```

## Input Arguments

### ZeroData — Zero curve

matrix | table

Zero Curve, specified as a numRates-by-2 matrix or a numRates-by-2 table.

If ZeroData is represented as a numRates-by-2 matrix, the first column is a MATLAB serial date number and the second column is the accompanying zero rates.

If ZeroData is a table, the first column can be serial date numbers, date character vectors, or datetime arrays. The second column must be numeric data corresponding to the zero rates.

Data Types: double | table

### CouponRate — Annual percentage rate used to determine coupons payable on a bond

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a NUMBONDS-by-1 vector.

Data Types: double

### Settle — Settlement date for all bonds and zero curve

serial date number | date character vector | datetime

Settlement date for all bonds and zero curve, specified as a scalar using a serial date number, date character vector, or datetime array. Settle must be the same settlement date for all the bonds and the zero curve.

Data Types: double | char | datetime

### Maturity — Maturity date for bonds

serial date number | date character vector | datetime

Maturity date for bonds, specified as a scalar or a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `KeyRateDuration = bndkrdur(ZeroData, .0525, '12/31/1998', '11/15/2028', 'KeyRates', [2 5 10 30])`

### **InterpMethod — Interpolation method used to obtain points from zero curve**

'linear' (default) | 'cubic', 'pchip'

Interpolation method used to obtain points from the zero curve, specified as the comma-separated pair consisting of 'InterpMethod' and a character vector using one of the following values:

- 'linear' (default)
- 'cubic'
- 'pchip'

Data Types: char

### **ShiftValue — Value that zero curve is shifted up and down to compute duration**

.01 (100 basis points) (default) | numeric

Value that zero curve is shifted up and down to compute duration, specified as the comma-separated pair consisting of 'ShiftValue' and a scalar numeric value.

Data Types: double

### **KeyRates — Rates to perform the duration calculation**

set to each of the zero dates (default) | numeric

Rates to perform the duration calculation, specified as the comma-separated pair consisting of 'KeyRates' and a time to maturity using a scalar or a NUMBONDS-by-1 vector.

Data Types: double

### **CurveCompounding — Compounding frequency of curve**

2 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency of the curve, specified as the comma-separated pair consisting of 'CurveCompounding' and a scalar using one of the following values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

.

Data Types: double

### **CurveBasis — Basis of the curve**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Basis of the curve, specified as the comma-separated pair consisting of 'CurveBasis' and a scalar using one of the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

#### **Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

#### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

### **IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays. The StartDate is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a StartDate, the effective start date is the Settle date.

Data Types: double | char | datetime

### Face — Face value of bond

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 vector.

Data Types: double

## Output Arguments

### KeyRateDuration — Key rate durations

matrix

Key rate durations, returned as a numBonds-by-numRates matrix.

## Algorithms

bndkrdur computes the key rate durations for one or more bonds given a zero curve and a set of key rates. By default, the key rates are each of the zero curve rates. For each key rate, the duration is computed by shifting the zero curve up and down by a specified amount (ShiftValue) at that particular key rate, computing the present value of the bond in each case with the new zero curves, and then evaluating the following:

$$krdur_i = \frac{(PV_{down} - PV_{up})}{(PV \times ShiftValue \times 2)}$$

---

**Note** The shift to the curve is computed by shifting the particular key rate by the ShiftValue and then interpolating the values of the curve in the interval between the previous and next key rates. For the first key rate, any curve values before the date are equal to the ShiftValue; likewise, for the last key rate, any curve values after the date are equal to the ShiftValue.

---

**Introduced before R2006a**

## bndprice

Price fixed-income security from yield to maturity

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

### Syntax

```
[Price,AccruedInt] = bndprice(Yield,CouponRate,Settle,Maturity)
[Price,AccruedInt] = bndprice( ____,Name,Value)
```

### Description

`[Price,AccruedInt] = bndprice(Yield,CouponRate,Settle,Maturity)` given bonds with SIA date parameters and yields to maturity, returns the clean prices and accrued interest due.

`[Price,AccruedInt] = bndprice( ____,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Price a Treasury Bond from Yield to Maturity

This example shows how to price a treasury bond at three different yield values.

```
Yield = [0.04; 0.05; 0.06];
CouponRate = 0.05;
Settle = '20-Jan-1997';
Maturity = '15-Jun-2002';
Period = 2;
Basis = 0;
```

```
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle,...
Maturity, Period, Basis)
```

```
Price = 3×1
```

```
104.8106
99.9951
95.4384
```

```
AccruedInt = 3×1
```

```
0.4945
0.4945
```

```
0.4945
```

### Price a Treasury Bond from Yield to Maturity Using datetime Inputs

This example shows how to use `datetime` inputs to price a treasury bond at three different yield values.

```
Yield = [0.04; 0.05; 0.06];
CouponRate = 0.05;
Settle = datetime('20-Jan-1997','Locale','en_US');
Maturity = datetime('15-Jun-2002','Locale','en_US');
Period = 2;
Basis = 0;
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle,...
Maturity, Period, Basis)
```

```
Price = 3×1
```

```
104.8106
99.9951
95.4384
```

```
AccruedInt = 3×1
```

```
0.4945
0.4945
0.4945
```

### Price a Treasury Bond with Different Yield Values

This example shows how to price a Treasury bond at two different yield values that include parameter/value pairs for `CompoundingFrequency`, `DiscountBasis`, and `LastCouponPeriodInterest`.

```
bndprice(.04,0.08,'5/25/2004','4/21/2005','Period',1,'Basis',8, ...
'LastCouponInterest','simple')
```

```
ans = 103.4743
```

## Input Arguments

### Yield — Bond yield to maturity

numeric

Bond yield to maturity is specified as a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector. Yield is on a semiannual basis for `Basis` values 0 through 7 and 13 and an annual basis for `Basis` values 8 through 12.

Data Types: double

**CouponRate** — Annual percentage rate used to determine coupons payable on a bond  
decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**Settle** — Settlement date of bond

serial date number | date character vector | datetime

Settlement date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

**Maturity** — Maturity date of bond

serial date number | date character vector | datetime

Maturity date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: [Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, Maturity, 'Period', 4, 'Basis', 9)

**Period** — Number of coupon payments per year

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis** — Day-count basis of instrument

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

### **IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### StartDate — Forward starting date of payments

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a StartDate, the effective start date is the Settle date.

Data Types: double | char | datetime

### Face — Face value of bond

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### CompoundingFrequency — Compounding frequency for yield calculation

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

### DiscountBasis — Basis used to compute the discount factors for computing the yield

SIA bases uses 0 (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

---

Data Types: double

### **LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. LastCouponInterest is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## **Output Arguments**

### **Price — Clean price of bond**

numeric

Clean price of bond, returned as a NUMBONDS-by-1 vector. The dirty price of the bond is the clean price plus the accrued interest. It equals the present value of the bond cash flows of the yield to maturity with semiannual compounding.

**AccruedInt — Accrued interest payable at settlement**

numeric

accrued interest payable at settlement, returned as a NUMBONDS-by-1 vector.

**More About****Price and Yield Conventions**

The Price and Yield are related to different formulae for SIA and ICMA conventions.

For SIA conventions, Price and Yield are related by the formula:

$$\text{Price} + \text{Accrued Interest} = \text{sum}(\text{Cash\_Flow} * (1 + \text{Yield}/2)^{(-\text{Time})})$$

where the sum is over the bond's cash flows and corresponding times in units of semiannual coupon periods.

For ICMA conventions, the Price and Yield are related by the formula:

$$\text{Price} + \text{Accrued Interest} = \text{sum}(\text{Cash\_Flow} * (1 + \text{Yield})^{(-\text{Time})})$$

**Algorithms**

For SIA conventions, the following formula defines bond price and yield:

$$PV = \sum_{i=1}^n \left( \frac{CF}{\left(1 + \frac{z}{f}\right)^{TF}} \right),$$

where:

|        |                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $PV =$ | Present value of a cash flow.                                                                                                                                                                                                                                                                                                                                                                |
| $CF =$ | Cash flow amount.                                                                                                                                                                                                                                                                                                                                                                            |
| $z =$  | Risk-adjusted annualized rate or yield corresponding to a given cash flow. The yield is quoted on a semiannual basis.                                                                                                                                                                                                                                                                        |
| $f =$  | Frequency of quotes for the yield. Default is 2 for Basis values 0 to 7 and 13 and 1 for Basis values 8 to 12. The default can be overridden by specifying the CompoundingFrequency name-value pair.                                                                                                                                                                                         |
| $TF =$ | Time factor for a given cash flow. The time factor is computed using the compounding frequency and the discount basis. If these values are not specified, then the defaults are as follows: CompoundingFrequency default is 2 for Basis values 0 to 7 and 13 and 1 for Basis values 8 to 12. DiscountBasis is 0 for Basis values 0 to 7 and 13 and the input Basis for Basis values 8 to 12. |

**Note** The Basis is always used to compute accrued interest.

For ICMA conventions, the frequency of annual coupon payments determines bond price and yield.

## bndspread

Static spread over spot curve

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

### Syntax

```
Spread = bndspread(SpotInfo,Price,Coupon,Settle,Maturity)
Spread = bndspread( ___,Name,Value)
```

### Description

`Spread = bndspread(SpotInfo,Price,Coupon,Settle,Maturity)` computes the static spread (Z-spread) to benchmark in basis points.

`Spread = bndspread( ___,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Compute the Static Spread Over a Spot Curve

This example shows how to compute a Federal National Mortgage Association (FNMA) 4 3/8 spread over a Treasury spot curve and plot the results.

```
RefMaturity = [datenum('02/27/2003');
               datenum('05/29/2003');
               datenum('10/31/2004');
               datenum('11/15/2007');
               datenum('11/15/2012');
               datenum('02/15/2031')];
```

```
RefCpn = [0;
          0;
          2.125;
          3;
          4;
          5.375] / 100;
```

```
RefPrices = [99.6964;
             99.3572;
             100.3662;
             99.4511;
             99.4299;
             106.5756];
```

```

RefBonds = [RefPrices, RefMaturity, RefCpn];
Settle = datenum('26-Nov-2002');

ZeroRates*100+SpreadInBP/100, 'r--')
legend({'Treasury'; 'FNMA 4 3/8'})
xlabel('Curve Dates')
ylabel('Spot Rate [%]')
grid;

```

## Input Arguments

### SpotInfo — Spot-rates information

matrix | table | term structure

Spot-rates information, specified as matrix of two columns, an annualized term structure created by `intenvset`, or a table.

- Matrix of two columns— The first column is the `SpotDate`, and the second column, `ZeroRates`, is the zero-rate corresponding to maturities on the `SpotDate`. It is recommended that the spot-rates are spaced as evenly apart as possible, perhaps one that is built from 3-months deposit rates. For example, using the 3-month deposit rates:

```
SpotInfo = ...
[datetime('2-Jan-2004') , 0.03840;
 datetime('2-Jan-2005') , 0.04512;
 datetime('2-Jan-2006') , 0.05086];
```

- Annualized term structure — Refer to `intenvset` to create an annualized term structure. For example:

```
Settle = datetime('1-Jan-2004');
Rates = [0.03840; 0.04512; 0.05086];
EndDates = [datetime('2-Jan-2004'); datetime('2-Jan-2005');...
            datetime('2-Jan-2006')];
SpotInfo = intenvset('StartDates' , Settle , ...
```

```

'Rates'      , Rates , ...
'EndDates'   , EndDates, ...
'Compounding', 2     , ...
'Basis'      , 0);

```

- **Table** — If `SpotInfo` is a table, the first column can be either a serial date number, date character vector, or datetime array. The second column is numerical data representing zero rates. For example:

```

ZeroRates = ... [0.012067955808764;0.012730933424479;0.019360902068703;0.031704525214251;0.042306085224510;0.054987415342936];
CurveDates = [731639;731730;732251;733361;735188;741854];
Settle     = datenum('26-Nov-2002');
Price      = 105.484;
Coupon     = 0.04375;
Maturity   = datenum('15-Oct-2006');
Period     = 2;
Basis      = 1;
SpotInfo   = table(datestr(CurveDates), ZeroRates);

```

Data Types: double | table | struct

**Price** — Price for every \$100 notional amount of bonds whose spreads are computed  
numeric

Price for every \$100 notional amount of bonds whose spreads are computed, specified as numeric value using a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

Data Types: double

**Coupon** — Annual coupon rate of bonds whose spreads are computed  
decimal

Annual coupon rate of bonds whose spreads are computed, specified as decimal value using a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector.

Data Types: double

**Settle** — Settlement date of bond  
serial date number | date character vector | datetime

Settlement date of the bond, specified as a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or datetime arrays. The `Settle` date must be before the `Maturity` date.

Data Types: double | char | datetime

**Maturity** — Maturity date of bond  
serial date number | date character vector | datetime

Maturity date of the bond, specified as a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Spread = bndspread(SpotInfo, Price, Coupon, Settle, Maturity, 'Period', 4, 'Basis', 7)`

**Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The StartDate is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a StartDate, the effective start date is the Settle date.

Data Types: double | char | datetime

### **Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### **CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis** — Basis used to compute the discount factors for computing the yield

SIA uses 0 (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If a SIA day-count basis is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the specified bases from the **Basis** input argument are used.

---

Data Types: double

### **LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. LastCouponInterest is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

### **Output Arguments**

#### **Spread — Static spread to benchmark in basis points**

numeric

Static spread to benchmark, returned in basis points as a scalar or a NUMBONDS-by-1 vector.

## bndtotalreturn

Total return of fixed-coupon bond

### Syntax

```
[BondEquiv,EffectiveRate] = bndtotalreturn(Price,CouponRate,Settle,Maturity,
ReinvestRate)
[BondEquiv,EffectiveRate] = bndtotalreturn( ____,Name,Value)
```

### Description

[BondEquiv,EffectiveRate] = bndtotalreturn(Price,CouponRate,Settle,Maturity,ReinvestRate) calculates the total return for fixed-coupon bonds to maturity or to a specific investment horizon.

[BondEquiv,EffectiveRate] = bndtotalreturn( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute the Total Return of a Fixed-Coupon Bond

Use `bndtotalreturn` to compute the total return for a fixed-coupon bond, given an investment horizon date.

Define fixed-coupon bond.

```
Price = 101;
CouponRate = 0.05;
Settle = '15-Nov-2011';
Maturity = '15-Nov-2031';
ReinvestRate = 0.04;
```

Calculate the total return to maturity.

```
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
Settle, Maturity, ReinvestRate)
```

```
BondEquiv = 0.0460
```

```
EffectiveRate = 0.0466
```

Specify an investment horizon.

```
HorizonDate = '15-Nov-2021';
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
Settle, Maturity, ReinvestRate, 'HorizonDate', HorizonDate)
```

```
BondEquiv = 0.0521
```

```
EffectiveRate = 0.0528
```

Perform scenario analysis on the reinvestment rate.

```
ReinvestRate = [0.03; 0.035; 0.04; 0.045; 0.05];
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
Settle, Maturity, ReinvestRate, 'HorizonDate', HorizonDate)
```

```
BondEquiv = 5×1
```

```
0.0557
0.0538
0.0521
0.0505
0.0490
```

```
EffectiveRate = 5×1
```

```
0.0565
0.0546
0.0528
0.0511
0.0496
```

### Compute the Total Return of a Fixed-Coupon Bond Using datetime Inputs

Use `bndtotalreturn` with `datetime` inputs to compute the total return for a fixed-coupon bond, given an investment horizon date.

```
Price = 101;
CouponRate = 0.05;
Settle = datetime('15-Nov-2011','Locale','en_US');
Maturity = datetime('15-Nov-2031','Locale','en_US');
HorizonDate = datetime('15-Nov-2021','Locale','en_US');
ReinvestRate = 0.04;
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
Settle, Maturity, ReinvestRate, 'HorizonDate', HorizonDate)
```

```
BondEquiv = 0.0521
```

```
EffectiveRate = 0.0528
```

## Input Arguments

### Price — Clean price at settlement date

matrix

Clean price at the settlement date, specified as a scalar or a NINST-by-1 vector.

Data Types: double

### CouponRate — Coupon rate

decimal

Coupon rate, specified as a scalar or a NINST-by-1 vector of decimal values.

Data Types: double

### **Settle — Settlement date of fixed-coupon bond**

serial date number | date character vector | datetime

Settlement date of the fixed-coupon bond, specified as scalar or a NINST-by-1 vector of serial date numbers, date character vectors, or datetime arrays. If supplied as a NINST-by-1 vector of dates, settlement dates can be different, as long as they are before the Maturity date and HorizonDate.

Data Types: double | char | datetime

### **Maturity — Maturity date of fixed-coupon bond**

serial date number | date character vector | datetime

Maturity date of the fixed-coupon bond, specified as scalar or a NINST-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **ReinvestRate — Reinvestment rate**

decimal

Reinvestment rate (the rate earned by reinvesting the coupons), specified as scalar or a NINST-by-2 vector of decimal values.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: [BondEquiv, EffectiveRate] =  
bndtotalreturn(Price, CouponRate, Settle, Maturity, ReinvestRate, 'HorizonDate', '15-Nov-2021')

### **HorizonDate — Investment horizon date**

Maturity date (default) | serial date number | date character vector | datetime

Investment horizon date, specified as the comma-separated pair consisting of 'HorizonDate' and a scalar or a NINST-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If HorizonDate is unspecified, the total return is calculated to Maturity.

Data Types: double | char | datetime

### **HorizonPrice — Price at investment horizon date**

calculated based on ReinvestRate (default) | numeric

Price at investment horizon date, specified as the comma-separated pair consisting of 'HorizonPrice' and a scalar or a NINST-by-1 vector.

If HorizonPrice is unspecified, the price at the HorizonDate is calculated based on the ReinvestRate. If the HorizonDate equals the Maturity date, the HorizonPrice is ignored and the total return to maturity is calculated based on the Face value.

Data Types: double

**Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NINST-by-1 vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NINST-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NINST-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NINST-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NINST-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a StartDate, the effective start date is the Settle date.

Data Types: double | char | datetime

### **Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NINST-by-1 vector.

Data Types: double

### **CompoundingFrequency — Compounding frequency for yield calculation**

integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NINST-by-1 vector.

- 1 — Annual compounding

- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** The default behavior is for SIA bases (0-7) to use the actual/actual day count to compute discount factors, and for ICMA day counts (8 - 12) and BUS/252 to use the specified DiscountBasis.

---

Data Types: double

## Output Arguments

**BondEquiv — Total return in bond equivalent basis**

numeric

Total return in bond equivalent basis, returned as a NUMBONDS-by-1 vector.

**EffectiveRate — Total return in effective rate basis**

numeric

Total return in effective rate basis, returned as a NUMBONDS-by-1 vector.

“Yield Conventions” on page 2-22

**Introduced in R2012b**

# bndyield

Yield to maturity for fixed-income security

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

## Syntax

```
Yield = bndyield(Price,CouponRate,Settle,Maturity)
Yield = bndyield( ____,Name,Value)
```

## Description

`Yield = bndyield(Price,CouponRate,Settle,Maturity)` given `NUMBONDS` bonds with SIA date parameters and clean prices (excludes accrued interest), returns the bond equivalent yields to maturity.

`Yield = bndyield( ____,Name,Value)` adds optional name-value arguments.

## Examples

### Compute Yield to Maturity for a Treasury Bond

This example shows how to compute the yield of a Treasury bond at three different price values.

```
Price = [95; 100; 105];
CouponRate = 0.05;
Settle = '20-Jan-1997';
Maturity = '15-Jun-2002';
Period = 2;
Basis = 0;

Yield = bndyield(Price, CouponRate, Settle,...
Maturity, Period, Basis)

Yield = 3×1

    0.0610
    0.0500
    0.0396
```

### Compute Yield to Maturity for a Treasury Bond Using datetime Inputs

This example shows how to use `datetime` inputs to compute the yield of a Treasury bond at three different price values.

```
Price = [95; 100; 105];
CouponRate = 0.05;
Settle = datetime('20-Jan-1997','Locale','en_US');
Maturity = datetime('15-Jun-2002','Locale','en_US');
Period = 2;
Basis = 0;
Yield = bndyield(Price, CouponRate, Settle, ...
Maturity, Period, Basis)
```

```
Yield = 3×1
```

```
0.0610
0.0500
0.0396
```

### Compute the Yield of a Treasury Bond Using the Same Basis for Discounting and Generating the Cash Flows

Compute the yield of a Treasury bond.

```
Price = [95; 100; 105];
CouponRate = 0.0345;
Settle = '15-May-2016';
Maturity = '02-Feb-2026';
Period = 2;
Basis = 1;
format long
```

```
Yield = bndyield(Price,CouponRate,Settle,Maturity,Period,Basis)
```

```
Yield = 3×1
```

```
0.040764403932618
0.034482347625316
0.028554719853118
```

Using the same data, compute the yield of a Treasury bond using the same basis for discounting and generating the cash flows.

```
DiscountBasis = 1;
```

```
Yield = bndyield(Price,CouponRate,Settle,Maturity,'Period',Period,'Basis',Basis, ...
'DiscountBasis',DiscountBasis)
```

```
Yield = 3×1
```

```
0.040780176658036
0.034495592361619
```

0.028565614029497

## Input Arguments

### Price — Clean price of the bond

numeric

Clean price of the bond (current price without accrued interest), specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### CouponRate — Annual percentage rate used to determine coupons payable on a bond

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### Settle — Settlement date of bond

serial date number | date character vector | datetime

Settlement date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

### Maturity — Maturity date of bond

serial date number | date character vector | datetime

Maturity date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: Yield =

```
bndyield(Price,CouponRate,Settle,Maturity,'Period',4,'Basis',9)
```

### Period — Number of coupon payments per year

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### Basis — Day-count basis of instrument

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

#### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

#### **IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

#### **FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a StartDate, the effective start date is the Settle date.

Data Types: double | char | datetime

### **Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### **CompoundingFrequency — Compounding frequency for yield calculation**

SIA uses 2, ICMA uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If a SIA day-count basis is defined in the Basis input argument and there is no value assigned for DiscountBasis, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the Basis input argument and there is no value assigned for DiscountBasis, the specified bases from the Basis input argument are used.

---

Data Types: double

**LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## Output Arguments

### Yield — Yield to maturity with semiannual compounding

numeric

Yield to maturity with semiannual compounding, returned as a NUMBONDS-by-1 vector.

## More About

### Price and Yield Conventions

The Price and Yield are related to different formulae for SIA and ICMA conventions.

For SIA conventions, Price and Yield are related by the formula:

$$\text{Price} + \text{Accrued Interest} = \text{sum}(\text{Cash\_Flow} * (1 + \text{Yield}/2)^{(-\text{Time})})$$

where the sum is over the bond's cash flows and corresponding times in units of semiannual coupon periods.

For ICMA conventions, the Price and Yield are related by the formula:

$$\text{Price} + \text{Accrued Interest} = \text{sum}(\text{Cash\_Flow} * (1 + \text{Yield})^{(-\text{Time})})$$

## Algorithms

For SIA conventions, the following formula defines bond price and yield:

$$PV = \frac{CF}{\left(1 + \frac{z}{f}\right)^{TF}}$$

where:

|        |                                                                                                                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $PV =$ | Present value of a cash flow.                                                                                                                                                                                                      |
| $CF =$ | The cash flow amount.                                                                                                                                                                                                              |
| $z =$  | The risk-adjusted annualized rate or yield corresponding to a given cash flow. The yield is quoted on a semiannual basis.                                                                                                          |
| $f =$  | The frequency of quotes for the yield.                                                                                                                                                                                             |
| $TF =$ | Time factor for a given cash flow. Time is measured in semiannual periods from the settlement date to the cash flow date. In computing time factors, use SIA actual/actual day count conventions for all time factor calculations. |

For ICMA conventions, the frequency of annual coupon payments determines bond price and yield.

# bolling

Bollinger band chart

---

**Note** bolling is not recommended. Use bollinger instead.

---

## Syntax

```
bolling(Asset,Samples,Alpha,Width)
```

```
[Movavgv,UpperBand,LowerBand] = bolling(Asset,Samples,Alpha,Width)
```

## Arguments

|         |                                                                                                                                                                                      |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Asset   | Vector of asset data.                                                                                                                                                                |
| Samples | Number of samples to use in computing the moving average.                                                                                                                            |
| Alpha   | (Optional) Exponent used to compute the element weights of the moving average. Default = 0 (simple moving average).                                                                  |
| Width   | (Optional) Number of standard deviations to include in the envelope. A multiplicative factor specifying how tight the bands should be around the simple moving average. Default = 2. |

## Description

`bolling(Asset,Samples,Alpha,Width)` plots Bollinger bands for given Asset data. This form of the function does not return any data.

`[Movavgv,UpperBand,LowerBand] = bolling(Asset,Samples,Alpha,Width)` returns Movavgv with the moving average of the Asset data, UpperBand with the upper band data, and LowerBand with the lower band data. This form of the function does not plot any data.

---

**Note** The standard deviations are normalized by N-1, where N = the sequence length.

---

## Examples

If Asset is a column vector of closing stock prices

```
bolling(Asset, 20, 1)
```

plots linear 20-day moving average Bollinger bands based on the stock prices.

```
[Movavgv, UpperBand, LowerBand] = bolling(Asset, 20, 1)
```

returns Movavgv, UpperBand, and LowerBand as vectors containing the moving average, upper band, and lower band data, without plotting the data.

# bollinger

Time series Bollinger band

---

**Note** `bollinger` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
[middle,upper,lower] = bollinger(Data)
[middle,upper,lower] = bollinger( ___,Name,Value)
```

## Description

`[middle,upper,lower] = bollinger(Data)` calculates the middle, upper, and lower bands that make up the Bollinger bands from a series of data. A Bollinger band chart plots actual asset data along with three other bands of data: the upper band that is two standard deviations above a user-specified moving average; the lower band that is two standard deviations below that moving average; and the middle band that is the moving average itself.

`[middle,upper,lower] = bollinger( ___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Bollinger Bands for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
[middle,upper,lower]= bollinger(TMW);
CloseBolling = [middle.Close, upper.Close,...
lower.Close];
plot(middle.Time,CloseBolling)
title('Bollinger Bands for TMW Closing Prices')
```

## Input Arguments

### Data — Data for market prices

matrix | table | timetable

Data for market prices, specified as a matrix, table, or timetable. For matrix input, Data must be column-oriented.

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: [middle, upper, lower] = bollinger(TMW\_CLOSE, 'WindowSize', 10, 'Type', 1)

### WindowSize — Number of observations of input series to include in moving average in periods

10 (default) | positive integer

Number of observations of the input series to include in the moving average in periods, specified as the comma-separated pair consisting of 'WindowSize' and a scalar positive integer.

Data Types: double

**Type — Type of moving average to compute**

0 (simple) (default) | integer with value 0 or 1

Type of moving average to compute, specified as the comma-separated pair consisting of 'Type' and a scalar integer with a value of 0 (simple) or 1 (linear).

Data Types: double

**NumStd — Number of standard deviations for the upper and lower bounds**

2 (default) | positive integer

Number of standard deviations for the upper and lower bounds, specified as the comma-separated pair consisting of 'NumStd' and a scalar positive integer.

Data Types: double

**Output Arguments****middle — Moving average series representing the middle band**

matrix | table | timetable

Moving average series representing the middle band, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

**upper — Moving average series representing the upper band**

matrix | table | timetable

Moving average series representing the upper band, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

**lower — Moving average series representing the lower band**

matrix | table | timetable

Moving average series representing the lower band, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## boxcox

Box-Cox transformation

---

**Note** `boxcox` has been partially removed and will no longer accept a `fints` object (`tsobj`).

Replace all instances of a `fints` object (`tsobj`) for input with an array by using `fts2timetable` to convert a `fints` object to a `timetable` object and then use `timetable2table` and `table2array`.

---

### Syntax

```
[transdat,lambda] = boxcox(data)
```

```
[transfts,lambda] = boxcox(tsobj)
```

```
transdat = boxcox(lambda,data)
```

```
transfts = boxcox(lambda,tsobj)
```

### Arguments

|                    |                                                                      |
|--------------------|----------------------------------------------------------------------|
| <code>data</code>  | Data vector. Must be positive and specified as a column data vector. |
| <code>tsobj</code> | Financial time series object.                                        |

### Description

`boxcox` transforms nonnormally distributed data to a set of data that has approximately normal distribution. The Box-Cox transformation is a family of power transformations.

If  $\lambda$  is not = 0, then

$$data(\lambda) = \frac{data^\lambda - 1}{\lambda}$$

If  $\lambda$  is = 0, then

$$data(\lambda) = \log(data)$$

The logarithm is the natural logarithm (log base e). The algorithm calls for finding the  $\lambda$  value that maximizes the Log-Likelihood Function (LLF). The search is conducted using `fminsearch`.

`[transdat,lambda] = boxcox(data)` transforms the data vector `data` using the Box-Cox transformation method into `transdat`. It also estimates the transformation parameter  $\lambda$ .

`[transfts,lambda] = boxcox(tsobj)` transforms the financial time series object `tsobj` using the Box-Cox transformation method into `transfts`. It also estimates the transformation parameter  $\lambda$ .

If the input data is a vector, `lambda` is a scalar. If the input is a financial time series object, `lambda` is a structure with fields similar to the components of the object; for example, if the object contains series names `Open` and `Close`, `lambda` has fields `lambda.Open` and `lambda.Close`.

`transdat = boxcox(lambda, data)` and `transfts = boxcox(lambda, tsoj)` transform the data using a certain specified  $\lambda$  for the Box-Cox transformation. This syntax does not find the optimum  $\lambda$  that maximizes the LLF.

## Examples

### Transform a Data Series Contained in a Financial Times Series Object

Use `boxcox` to transform the data series contained in a financial time series object into another set of data series with relatively normal distributions.

Create a financial time series object from the supplied `whirlpool.dat` data file.

```
whrl = ascii2fts('whirlpool.dat', 1, 2, []);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

Fill any missing values denoted with NaN's in `whrl` with values calculated using the linear method.

```
f_whrl = fillts(whrl);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

Transform the nonnormally distributed filled data series `f_whrl` into a normally distributed one using Box-Cox transformation.

```
bc_whrl = boxcox(f_whrl);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

Compare the result of the `Close` data series with a normal (Gaussian) probability distribution function and the nonnormally distributed `f_whrl`.

```
subplot(2, 1, 1);  
hist(f_whrl.Close);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
grid; title('Nonnormally Distributed Data');  
subplot(2, 1, 2);  
hist(bc_whrl.Close);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
grid; title('Box-Cox Transformed Data');
```

The bar chart on the top represents the probability distribution function of the filled data series, `f_wlr`, which is the original data series `wlr` with the missing values interpolated using the linear method. The distribution is skewed toward the left (not normally distributed). The bar chart on the bottom is less skewed to the left. If you plot a Gaussian probability distribution function (PDF) with similar mean and standard deviation, the distribution of the transformed data is very close to normal (Gaussian). When you examine the contents of the resulting object `bc_wlr`, you find an identical object to the original object `wlr` but the contents are the transformed data series.

# busdate

Next or previous business day

## Syntax

```
Busday = busdate(Date)
Busday = busdate( ___, DirFlag, Holiday, Weekend)
```

## Description

`Busday = busdate(Date)` returns the scalar, vector, or matrix of the next or previous business days, depending on the definition for `Holiday`.

`Busday = busdate( ___, DirFlag, Holiday, Weekend)` returns the scalar, vector, or matrix of the next or previous business days, depending on the optional input arguments, including `Holiday`.

If both `Date` and `Holiday` are either serial date numbers or date character vectors, `Busday` is returned as a serial date number.

However, if either `Date` or `Holiday` are datetime arrays, `Busday` is returned as a datetime array.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

## Examples

### Determine Business Days

Determine the next business day when `Date` is a character vector.

```
Busday = busdate('3-Jul-2001', 1)
```

```
Busday = 731037
```

```
datestr(Busday)
```

```
ans =
'05-Jul-2001'
```

Indicate that Saturday is a business day by appropriately setting the `Weekend` argument. July 4, 2003 falls on a Friday. Use `busdate` to verify that Saturday, July 5, is actually a business day.

```
Weekend = [1 0 0 0 0 0 0];
Date = datestr(busdate('3-Jul-2003', 1, [], Weekend))
```

```
Date =
'05-Jul-2003'
```

If either `Date` or `Holiday` are datetime arrays, `Busday` is returned as a datetime array.

```
Busday = busdate(datetime('3-Jul-2001', 'Locale', 'en_US'), 1)
```

```
Busday = datetime
05-Jul-2001
```

## Input Arguments

### Date — Reference business date

serial date number | date character vector | datetime object

Reference business date, specified as a scalar, vector, or matrix using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### DirFlag — Business day convention

follow (default) | date character vector with values of follow, modifiedfollow, previous, or modifiedprevious | cell array of date character vectors with values of follow, modifiedfollow, previous, or modifiedprevious

Business day convention, specified date character vector or cell array of date character vectors with values of follow, modifiedfollow, previous, or modifiedprevious.

Also, DirFlag can be a scalar, vector, or matrix of search directions, where Next is DIREC = 1 (default) or Previous is DIREC = -1.

Data Types: double | char | datetime

### Holiday — Holidays and nontrading-day dates

non-trading day vector is determined by the routine holidays (default) | serial date number | date character vector | datetime object

Holidays and nontrading-day dates, specified as vector.

All dates in Holiday must be the same format: either serial date numbers, or date character vectors, or datetime arrays. (Using serial date numbers improves performance.)

Data Types: double | char | datetime

### Weekend — Weekend days

[1 0 0 0 0 0 1] (Saturday and Sunday form the weekend) (default) | vector of length 7, containing 0 and 1, where 1 indicates weekend days

Weekend days, specified as a vector of length 7, containing 0 and 1, where 1 indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: double

## Output Arguments

### Busday — Next or previous business day

scalar | vector | matrix

Next or previous business day, returned as a scalar, vector, or matrix depending on the definition for Holiday. If Date is a datetime array, Busday returns a datetime array. Otherwise, Busday returns a serial date numbers.

## **See Also**

datetime | holidays

## **Topics**

“Handle and Convert Dates” on page 2-2

“Trading Calendars User Interface” on page 16-2

**Introduced before R2006a**

## busdays

Business days for given period

### Syntax

```
bdates = busdays(sdate,edate)
bdates = busdays( ___,bdmode,Holiday)
```

### Description

`bdates = busdays(sdate,edate)` generates a vector of business days between the last business date of the period that contains the start date (`sdate`), and the last business date of period that contains the end date (`edate`).

`bdates = busdays( ___,bdmode,Holiday)` generates a vector of business days between the last business date of the period that contains the start date (`sdate`), and the last business date of period that contains the end date (`edate`) using optional input arguments. If `Holiday` is not supplied, the dates are generated based on United States holidays. If you do not supply `bdmode`, `bdates` generates a daily vector.

### Examples

#### Determine Business Days for a Given Period

Determine the business days for a weekly period.

```
bdates = datestr(busdays('1/2/01','1/9/01','weekly'))
bdates = 2x11 char array
    '05-Jan-2001'
    '12-Jan-2001'
```

The end of the week is considered to be a Friday. Between 1/2/01 (Monday) and 1/9/01 (Tuesday), there is only one end-of-week day, 1/5/01 (Friday). Because 1/9/01 is part of the following week, the following Friday (1/12/01) is also reported.

Determine the business days for a weekly period using a datetime input for `sdate`.

```
bdates = busdays(datetime('2-Jan-2001','Locale','en_US'),'9-Jan-2001','weekly')
bdates = 2x1 datetime
    05-Jan-2001
    12-Jan-2001
```

Determine the business days for a monthly period.

```
vec = datestr(busdays('1/8/16','3/1/16','monthly'))
vec = 3x11 char array
    '29-Jan-2016'
```

```
'29-Feb-2016'
'31-Mar-2016'
```

The start date (1/8/16) is in the month of January, 2016. The last business day for the month of January is 1/29/16 (Friday). The end date (3/1/16) is in the month of March, 2016. The last business day for the month of March is 3/31/16 (Thursday). The month of February, 2016 lies between the start date and the end date. The last business day for the month of February is 2/29/16 (Monday).

## Input Arguments

### **sdate** — Start date

serial date number | date character vector | datetime object

Start date, specified as a serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **edate** — End date

serial date number | date character vector | datetime object

End date, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **bdmode** — Frequency of business days

DAILY (1) (default) | nonnegative numeric with values 1 through 5 | date character vector with values DAILY, WEEKLY, MONTHLY, QUARTERLY, SEMIANNUAL or ANNUAL

Frequency of business days, specified as a nonnegative numeric with values 1 through 5 or date character vector with values of DAILY, WEEKLY, MONTHLY, QUARTERLY, SEMIANNUAL, or ANNUAL

Valid periodicities include:

- DAILY, Daily, daily, D, d, 1 (default)
- WEEKLY, Weekly, weekly, W, w, 2
- MONTHLY, Monthly, monthly, M, m, 3
- QUARTERLY, Quarterly, quarterly, Q, q, 4
- SEMIANNUAL, Semiannual, semiannual, S, s, 5
- ANNUAL, Annual, annual, A, a, 6

Character vectors must be enclosed in single quotation marks.

For example, if `bdmode` is set to `monthly`, `busdays` returns end-of-month business dates for all full or partial months between the start date and end date inclusive.

Data Types: double | char

### **holiday** — Holiday and nontrading-day dates

if `holiday` is [ ] holiday dates are based on United States holidays specified by `holidays` (default) | serial date number | date character vector | datetime object

Holiday and nontrading-day dates, specified as a vector in date character vector, serial date, or datetime array format. If you specify `Holiday`, you must also supply the frequency `bdmode`. Using a `Holiday` value of `NaN` uses a holiday list that has no dates.

Data Types: `double` | `char` | `datetime`

## Output Arguments

### **bdates** — Business days

column vector

Business days, returned as a column vector of business dates, in serial date format (default) or datetime format (if `sdate`, `edate`, or `Holiday` are in datetime format). Business dates can exist before and/or after the specified `sdate` and `edate`.

## See Also

`datetime` | `holidays` | `isbusday`

# candle

Candlestick chart

---

**Note** `candle` is updated to accept data input as a matrix, timetable, or table.

---

## Syntax

```
candle(Data)
candle(Data,Color)
h = candle(ax___)
```

## Description

`candle(Data)` plots a candlestick chart from a series of opening, high, low, and closing prices of a security. If the closing price is greater than the opening price, the body (the region between the open and close price) is unfilled; otherwise the body is filled.

`candle(Data,Color)` adds an optional argument for `Color`.

`h = candle(ax___)` adds an optional argument for `ax`.

## Examples

### Generate a Candlestick Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock. This is a candlestick chart with blue candles, for the most recent 21 days in `SimulatedStock.mat`.

```
load SimulatedStock.mat;
candle(TMW(end-20:end,:), 'b');
title('Candlestick chart for TMW')
```

## Input Arguments

### Data — Data for opening, high, low, and closing prices

matrix | table | timetable

Data for opening, high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, `Data` is an M-by-4 matrix of opening, high, low, and closing prices stored in the corresponding columns. Timetables and tables with M rows must contain variables named 'Open', 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

### Color — (Optional) Three element color vector

background color of figure window (default) | color vector [R G B] | string

Three element color vector, specified as a [R G B] color vector or a string specifying the color name. The default color differs depending on the background color of the figure window. For more information, see `colspec`.

Data Types: double | string

### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The candle plot is created in the axes specified by `ax` instead of in the current axes (`ax = gca`). The option `ax` can precede any of the input argument combinations.

Data Types: `object`

## Output Arguments

### **h** — Graphic handle of the figure

`handle object`

Graphic handle of the figure, returned as a handle object.

## See Also

`highlow` | `kagi` | `linebreak` | `movavg` | `pointfig` | `priceandvol` | `renko` | `table` | `timetable` | `volarea`

**Introduced before R2006a**

## candle (fts)

Time series candle plot

---

**Note** `candle (fts)` is not recommended. Use `candle` instead.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
candle(tsoobj)
```

```
candle(tsoobj,color)
```

```
candle(tsoobj,color,dateform)
```

```
candle(tsoobj,color,dateform,'ParameterName',ParameterValue,...)
```

```
hcdl = candle(tsoobj,color,dateform,'ParameterName',ParameterValue,...)
```

### Arguments

|                       |                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsoobj</code>   | Financial time series object                                                                                                                                                                                                                                                                                                               |
| <code>color</code>    | (Optional) A three-element row vector representing RGB or a color identifier. (See <code>plot</code> .)                                                                                                                                                                                                                                    |
| <code>dateform</code> | (Optional) Date character vector format used as the x-axis tick labels. (See <code>datetick</code> .) You can specify a <code>dateform</code> only when <code>tsoobj</code> does not contain time-of-day data. If <code>tsoobj</code> contains time-of-day data, <code>dateform</code> is restricted to <code>'dd-mmm-yyyy HH:MM'</code> . |

### Description

`candle(tsoobj)` generates a candle plot of the data in the financial time series object `tsoobj`. `tsoobj` must contain at least four data series representing the high, low, open, and closing prices. These series must have the names `High`, `Low`, `Open`, and `Close` (case-insensitive).

`candle(tsoobj,color)` additionally specifies the color of the candle box.

`candle(tsoobj,color,dateform)` additionally specifies the date character vector format used as the x-axis tick labels. See `datestr` for a list of date character vector formats.

`candle(tsoobj,color,dateform,'ParameterName',ParameterValue,...)` indicates the actual names of the required data series if the data series do not have the default names.

'ParameterName' can be

- `HighName`: high prices series name
- `LowName`: low prices series name
- `OpenName`: open prices series name

- `CloseName`: closing prices series name

`hcdl = candle(tsoobj, color, dateform, 'ParameterName', ParameterValue, ...)` returns the handle to the patch objects and the line object that make up the candle plot. `hcdl` is a three-element column vector representing the handles to the two patches and one line that forms the candle plot.

## Examples

### Create a Candle Plot for a Financial Time Series Object

This example shows how to create a candle plot for Disney stock for the dates March 31, 1998 through April 30, 1998.

```
load disney.mat
candle(dis('3/31/98::4/30/98'))
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

Warning: Low prices must be less than or equal to the corresponding opening prices.

```
title('Disney 3/31/98 to 4/30/98')
```

**See Also**

**Introduced before R2006a**

## cdai

Accrued interest on certificate of deposit

### Syntax

```
AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate)
AccrInt = cdai( ____, Basis)
```

### Description

`AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate)` computes the accrued interest on a certificate of deposit.

`cdai` assumes that the certificates of deposit pay interest at maturity. Because of the simple interest treatment of these securities, this function is best used for short-term maturities (less than 1 year). The default simple interest calculation uses the `Basis` for the actual/360 convention (2).

`AccrInt = cdai( ____, Basis)` adds an optional argument for `Basis`.

### Examples

#### Find the Accrued Interest on a Certificate of Deposit

This example shows how to compute the accrued interest due, given a certificate of deposit with the following characteristics.

```
CouponRate    = 0.05;
Settle         = '02-Jan-02';
Maturity       = '31-Mar-02';
IssueDate      = '1-Oct-01';
```

```
AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate)
```

```
AccrInt = 1.2917
```

#### Find the Accrued Interest on a Certificate of Deposit Using datetime Inputs

This example shows how to use `datetime` inputs to compute the accrued interest due, given a certificate of deposit with the following characteristics.

```
CouponRate = 0.05;
Settle = datetime('02-Jan-02', 'Locale', 'en_US');
Maturity = datetime('31-Mar-02', 'Locale', 'en_US');
IssueDate = datetime('1-Oct-01', 'Locale', 'en_US');
AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate)
```

```
AccrInt = 1.2917
```

## Input Arguments

### CouponRate — Annual interest rate

decimal

Annual interest rate, specified as decimal using a scalar or a NCDS-by-1 or 1-by-NCDS vector.

Data Types: double

### Settle — Settlement date for certificate of deposit

serial date number | date character vector | datetime

Settlement date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays. The `Settle` date must be before the `Maturity` date.

Data Types: double | char | datetime

### Maturity — Maturity date for certificate of deposit

serial date number | date character vector | datetime

Maturity date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### IssueDate — Issue date for certificate of deposit

serial date number | date character vector | datetime

Issue date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Basis — Day-count basis for certificate of deposit

2 (actual/360) (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

(Optional) Day-count basis for the certificate of deposit, specified as a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

## Output Arguments

### **AccrInt — Accrued interest per \$100 of face value**

numeric

Accrued interest per \$100 of face value, returned as a NCDS-by-1 or 1-by-NCDS vector.

## See Also

## cdprice

Price of certificate of deposit

### Syntax

```
[Price,AccrInt] = cdprice(Yield,CouponRate,Settle,Maturity,IssueDate)
[PriceAccrInt] = cdprice( ____,Basis)
```

### Description

`[Price,AccrInt] = cdprice(Yield,CouponRate,Settle,Maturity,IssueDate)` computes the price of a certificate of deposit given its yield.

`cdprice` assumes that the certificates of deposit pay interest at maturity. Because of the simple interest treatment of these securities, this function is best used for short-term maturities (less than 1 year). The default simple interest calculation uses the `Basis` for the actual/360 convention (2).

`[PriceAccrInt] = cdprice( ____,Basis)` adds an optional argument for `Basis`.

### Examples

#### Compute the Price and Accrued Interest for a Certificate of Deposit

This example shows how to compute the price and the accrued interest due on the settlement date, given a certificate of deposit with the following characteristics.

```
Yield          = 0.0525;
CouponRate     = 0.05;
Settle         = '02-Jan-02';
Maturity       = '31-Mar-02';
IssueDate      = '1-Oct-01';
```

```
[Price, AccruedInt] = cdprice(Yield, CouponRate, Settle, ...
Maturity, IssueDate)
```

```
Price = 99.9233
```

```
AccruedInt = 1.2917
```

#### Compute the Price and Accrued Interest for a Certificate of Deposit Using datetime Inputs

This example shows how to use `datetime` inputs to compute the price and the accrued interest due on the settlement date, given a certificate of deposit with the following characteristics.

```
Yield = 0.0525;
CouponRate = 0.05;
Settle = datetime('02-Jan-02','Locale','en_US');
Maturity = datetime('31-Mar-02','Locale','en_US');
```

```

IssueDate = datetime('1-Oct-01','Locale','en_US');

[Price, AccruedInt] = cdprice(Yield, CouponRate, Settle, ...
Maturity, IssueDate)

Price = 99.9233

AccruedInt = 1.2917

```

## Input Arguments

### Yield — Simple yield to maturity over basis denominator

numeric

Simple yield to maturity over the basis denominator, specified as a numeric value using a scalar or a NCDS-by-1 or 1-by-NCDS vector.

Data Types: double

### CouponRate — Coupon annual interest rate

decimal

Coupon annual interest rate, specified as decimal using a scalar or a NCDS-by-1 or 1-by-NCDS vector.

Data Types: double

### Settle — Settlement date for certificate of deposit

serial date number | date character vector | datetime

Settlement date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

### Maturity — Maturity date for certificate of deposit

serial date number | date character vector | datetime

Maturity date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### IssueDate — Issue date for certificate of deposit

serial date number | date character vector | datetime

Issue date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Basis — Day-count basis for certificate of deposit

2 (actual/360) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

(Optional) Day-count basis for the certificate of deposit, specified as a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

## Output Arguments

### **Price — Clean price of certificate of deposit per \$100**

numeric

Clean price of the certificate of deposit per \$100, returned as a NCDS-by-1 or 1-by-NCDS vector.

### **AccrInt — Accrued interest payable at settlement per unit of face value**

numeric

Accrued interest payable at settlement per unit of face value, returned as a NCDS-by-1 or 1-by-NCDS vector.

# cdsbootstrap

Bootstrap default probability curve from credit default swap market quotes

## Syntax

```
[ProbData,HazData] = cdsbootstrap(ZeroData,MarketData,Settle)
[ProbData,HazData] = cdsbootstrap( ____,Name,Value)
```

## Description

`[ProbData,HazData] = cdsbootstrap(ZeroData,MarketData,Settle)` bootstraps the default probability curve using credit default swap (CDS) market quotes. The market quotes can be expressed as a list of maturity dates and corresponding CDS market spreads, or as a list of maturities and corresponding upfronts and standard spreads for standard CDS contracts. The estimation uses the standard model of the survival probability.

`[ProbData,HazData] = cdsbootstrap( ____,Name,Value)` adds optional name-value pair arguments.

## Examples

### Bootstrap Default Probability Curve from Credit Default Swap Market Quotes

This example shows how to use `cdsbootstrap` with market quotes for CDS contracts to generate `ProbData` and `HazData` values.

```
Settle = '17-Jul-2009'; % valuation date for the CDS
Spread_Time = [1 2 3 5 7]';
Spread = [140 175 210 265 310]';
Market_Dates = daysadd(datenum(Settle),360*Spread_Time,1);
MarketData = [Market_Dates Spread];
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
Zero_Dates = daysadd(datenum(Settle),360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];

format long
[ProbData,HazData] = cdsbootstrap(ZeroData,MarketData,Settle)

ProbData = 5×2

```

## Input Arguments

### ZeroData — Zero rate data

vector | IRDataCurve object

Zero rate data, specified as a M-by-2 vector of dates and zero rates or an IRDataCurve object of zero rates.

When ZeroData is an IRDataCurve object, ZeroCompounding and ZeroBasis are implicit in ZeroData and are redundant inside this function. In this case, specify these optional parameters when constructing the IRDataCurve object before using the cdsbootstrap function.

For more information on an IRDataCurve object, see “Creating an IRDataCurve Object” (Financial Instruments Toolbox).

Data Types: double

### MarketData — Bond market data

matrix

Bond market data, specified as a N-by-2 matrix of dates and corresponding market spreads or N-by-3 matrix of dates, upfronts, and standard spreads of CDS contracts. The dates must be entered as serial date numbers, upfronts must be numeric values between 0 and 1, and spreads must be in basis points.

Data Types: double

### Settle — Settlement date

serial date number | date character vector

Settlement date, specified as a serial date number or a date character vector. The Settle date must be earlier than or equal to the dates in MarketData

Data Types: double | char

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

---

**Note** Any optional input of size N-by-1 is also acceptable as an array of size 1-by-N, or as a single value applicable to all contracts. Single values are internally expanded to an array of size N-by-1.

---

Example: [ProbData,HazData] =  
 cdsbootstrap(ZeroData,MarketData,Settle,'RecoveryRate',Recovery,'ZeroCompounding',-1)

### **RecoveryRate — Recovery rate**

0.4 (default) | decimal

Recovery rate, specified as the comma-separated pair consisting of 'RecoveryDate' and a N-by-1 vector of recovery rates, specified as a decimal from 0 to 1.

Data Types: double

### **Period — Premium payment frequency**

4 (default) | numeric with values 1, 2, 3, 4, 6 or 12

Premium payment frequency, specified as the comma-separated pair consisting of 'Period' and a N-by-1 vector with values of 1, 2, 3, 4, 6, or 12.

Data Types: double

### **Basis — Day-count basis of contract**

2 (actual/360) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Day-count basis of the contract, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

### **BusDayConvention — Business day conventions**

'actual' (default) | character vector

Business day conventions, specified as the comma-separated pair consisting of 'BusDayConvention' and a character vector. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char`

#### **PayAccruedPremium — Flag for accrued premiums paid upon default**

`true` (default) | integer with value 1 or 0

Flag for accrued premiums paid upon default, specified as the comma-separated pair consisting of 'PayAccruedPremium' and a N-by-1 vector of Boolean flags that is `true` (default) if accrued premiums are paid upon default, `false` otherwise.

Data Types: `logical`

#### **TimeStep — Number of days as time step for numerical integration**

10 (days) (default) | nonnegative integer

Number of days to take as time step for the numerical integration, specified as the comma-separated pair consisting of 'TimeStep' and a nonnegative integer.

Data Types: `double`

#### **ZeroCompounding — Compounding frequency of the zero curve**

2 (semiannual) (default) | integer with value of 1,2,3,4,6,12, or -1

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'ZeroCompounding' and an integer with values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: `double`

#### **ZeroBasis — Basis of the zero curve**

0 (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and an integer with values that are identical to Basis.

Data Types: double

### ProbDates — Dates for probability data

column of dates in MarketData (default) | serial date number | date character vector

Dates for probability data, specified as the comma-separated pair consisting of 'ProbDates' and a P-by-1 vector of dates, given as serial date numbers or date character vectors.

Data Types: double | char

## Output Arguments

### ProbData — Default probability values

matrix

Default probability values, returned as a P-by-2 matrix with dates and corresponding cumulative default probability values. The dates match those in MarketData, unless the optional input parameter ProbDates is provided.

### HazData — Hazard rate values

matrix

Hazard rate values, returned as a N-by-2 matrix with dates and corresponding hazard rate values for the survival probability model. The dates match those in MarketData.

---

**Note** A warning is displayed when non-monotone default probabilities (that is, negative hazard rates) are found.

---

## Algorithms

If the time to default is denoted by  $\tau$ , the default probability curve, or function,  $PD(t)$ , and its complement, the survival function  $Q(t)$ , are given by:

$$PD(t) = P[\tau \leq t] = 1 - P[\tau > t] = 1 - Q(t)$$

In the standard model, the survival probability is defined in terms of a piecewise constant hazard rate  $h(t)$ . For example, if  $h(t) =$

$$\lambda_1, \text{ for } 0 \leq t \leq t_1$$

$$\lambda_2, \text{ for } t_1 < t \leq t_2$$

$$\lambda_3, \text{ for } t_2 < t$$

then the survival function is given by  $Q(t) =$

$$e^{-\lambda_1 t}, \text{ for } 0 \leq t \leq t_1$$

$$e^{-\lambda_1 t - \lambda_2(t - t_1)}, \text{ for } t_1 < t \leq t_2$$

$$e^{-\lambda_1 t_1 - \lambda_2(t_2 - t_1) - \lambda_3(t - t_2)}, \text{ for } t_2 < t$$

Given  $n$  market dates  $t_1, \dots, t_n$  and corresponding market CDS spreads  $S_1, \dots, S_n$ , `cdsbootstrap` calibrates the parameters  $\lambda_1, \dots, \lambda_n$  and evaluates  $PD(t)$  on the market dates, or an optional user-defined set of dates.

# cdsprice

Determine price for credit default swap

## Syntax

```
[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice(ZeroData,
ProbData,Settle,Maturity,ContractSpread)
[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice( ____,
Name,Value)
```

## Description

[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice(ZeroData, ProbData,Settle,Maturity,ContractSpread) computes the price, or the mark-to-market value for CDS instruments.

[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice( \_\_\_\_, Name,Value) adds optional name-value pair arguments.

## Examples

### Determine the Price for a Credit Default Swap

This example shows how to use `cdsprice` to compute the clean price for a CDS contract using the following data.

```
Settle = '17-Jul-2009'; % valuation date for the CDS
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];
```

```
ProbData = [daysadd(datenum(Settle),360,1), 0.0247];
Maturity = '20-Sep-2010';
ContractSpread = 135;
```

```
[Price,AccPrem] = cdsprice(ZeroData,ProbData,Settle,Maturity,ContractSpread)
```

```
Price = 1.5461e+04
```

```
AccPrem = 10500
```

## Input Arguments

### ZeroData — Zero rate data

vector | IRDataCurve object

Zero rate data, specified as a M-by-2 vector of dates and zero rates or an IRDataCurve object of zero rates.

When `ZeroData` is an `IRDataCurve` object, `ZeroCompounding` and `ZeroBasis` are implicit in `ZeroData` and are redundant inside this function. In this case, specify these optional parameters when constructing the `IRDataCurve` object before using the `cdsprice` function.

For more information on an `IRDataCurve` object, see “Creating an `IRDataCurve` Object” (Financial Instruments Toolbox).

Data Types: `double` | `struct`

### **ProbData — Default probability values**

`matrix`

Default probability values, specified as a P-by-2 matrix with dates and corresponding cumulative default probability values.

Data Types: `double` | `char`

### **Settle — Settlement date**

`serial date number` | `date character vector`

Settlement date, specified as a scalar serial date number or date character vector. The `Settle` date must be earlier than or equal to the dates in `Maturity`.

Data Types: `double` | `char`

### **Maturity — Maturity date**

`serial date number` | `date character vector`

Maturity date, specified as a N-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char`

### **ContractSpread — Contract spreads**

`numeric`

Contract spreads, specified as a N-by-1 vector of spreads, expressed in basis points.

Data Types: `double`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

---

**Note** Any optional input of size N-by-1 is also acceptable as an array of size 1-by-N, or as a single value applicable to all contracts. Single values are internally expanded to an array of size N-by-1.

---

Example: `[Price, AccPrem] = cdsprice(ZeroData, ProbData, Settle, Maturity, ContractSpread, 'Basis', 7, 'BusDayConvention', 'previous')`

### **RecoveryRate — Recovery rate**

`0.4` (default) | `decimal`

Recovery rate, specified as the comma-separated pair consisting of 'RecoveryRate' and a N-by-1 vector of recovery rates, specified as a decimal from 0 to 1.

Data Types: double

### **Period — Premium payment frequency**

4 (default) | numeric with values 1, 2, 3, 4, 6 or 12

Premium payment frequency, specified as the comma-separated pair consisting of 'Period' and a N-by-1 vector with values of 1, 2, 3, 4, 6, or 12.

Data Types: double

### **Basis — Day-count basis of contract**

2 (actual/360) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis of the contract, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

### **BusDayConvention — Business day conventions**

actual (default) | character vector

Business day conventions, specified as the comma-separated pair consisting of 'BusDayConvention' and a character vector. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.

- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char`

### **PayAccruedPremium — Flag for accrued premiums paid upon default**

`true` (default) | integer with value 1 or 0

Flag for accrued premiums paid upon default, specified as the comma-separated pair consisting of 'PayAccruedPremium' and a N-by-1 vector of Boolean flags that is `true` (default) if accrued premiums are paid upon default, `false` otherwise.

Data Types: `logical`

### **Notional — Contract notional values**

10MM (default) | positive or negative integer

Contract notional values, specified as the comma-separated pair consisting of 'Notional' and a N-by-1 vector of integers. Use positive integer values for long positions and negative integer values for short positions.

Data Types: `double`

### **TimeStep — Number of days as time step for numerical integration**

10 (days) (default) | nonnegative integer

Number of days to take as time step for the numerical integration, specified as the comma-separated pair consisting of 'TimeStep' and a nonnegative integer.

Data Types: `double`

### **ZeroCompounding — Compounding frequency of the zero curve**

2 (semiannual) (default) | integer with value of 1,2,3,4,6,12, or -1

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'ZeroCompounding' and an integer with values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: `double`

**ZeroBasis — Basis of the zero curve**

0 (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and an integer with values that are identical to Basis.

Data Types: double

**Output Arguments****Price — CDS clean prices**

vector

CDS clean prices, returned as a N-by-1 vector.

**AccPrem — Accrued premiums**

vector

Accrued premiums, returned as a N-by-1 vector.

**PaymentDates — Payment dates**

matrix

Payment dates, returned as a N-by-numCF matrix.

**PaymentTimes — Payment times**

matrix

Payment times, returned as a N-by-numCF matrix of accrual fractions.

**PaymentCF — Payments**

matrix

Payments, returned as a N-by-numCF matrix.

**More About****CDS Price**

The price or mark-to-market (MtM) value of an existing CDS contract.

The CDS price is computed using the following formula:

$$\text{CDS price} = \text{Notional} * (\text{Current Spread} - \text{Contract Spread}) * \text{RPV01}$$

Current Spread is the current breakeven spread for a similar contract, according to current market conditions. RPV01 is the 'risky present value of a basis point,' the present value of the premium payments, considering the default probability. This formula assumes a long position, and the right side is multiplied by -1 for short positions.

**Algorithms**

The premium leg is computed as the product of a spread  $S$  and the risky present value of a basis point (RPV01). The RPV01 is given by:

$$RPV01 = \sum_{j=1}^N Z(t_j) \Delta(t_{j-1}, t_j, B) Q(t_j)$$

when no accrued premiums are paid upon default, and it can be approximated by

$$RPV01 \approx \frac{1}{2} \sum_{j=1}^N Z(t_j) \Delta(t_{j-1}, t_j, B) (Q(t_{j-1}) + Q(t_j))$$

when accrued premiums are paid upon default. Here,  $t_0 = \theta$  is the valuation date, and  $t_1, \dots, t_n = T$  are the premium payment dates over the life of the contract,  $T$  is the maturity of the contract,  $Z(t)$  is the discount factor for a payment received at time  $t$ , and  $\Delta(t_{j-1}, t_j, B)$  is a day count between dates  $t_{j-1}$  and  $t_j$  corresponding to a basis  $B$ .

The protection leg of a CDS contract is given by the following formula:

$$\begin{aligned} \text{ProtectionLeg} &= \int_0^T Z(\tau) (1 - R) dPD(\tau) \\ &\approx (1 - R) \sum_{i=1}^M Z(\tau_i) (PD(\tau_i) - PD(\tau_{i-1})) \\ &= (1 - R) \sum_{i=1}^M Z(\tau_i) (Q(\tau_{i-1}) - Q(\tau_i)) \end{aligned}$$

where the integral is approximated with a finite sum over the discretization  $\tau_0 = \theta, \tau_1, \dots, \tau_M = T$ .

If the spread of an existing CDS contract is  $S_C$ , and the current breakeven spread for a comparable contract is  $S_0$ , the current price, or mark-to-market value of the contract is given by:

$$\text{MtM} = \text{Notional} (S_0 - S_C) \text{RPV01}$$

This assumes a long position from the protection standpoint (protection was bought). For short positions, the sign is reversed.

## cdsspread

Determine spread of credit default swap

### Syntax

```
[Spread,PaymentDates,PaymentTimes,] = cdsspread(ZeroData,ProbData,Settle,
Maturity,)
```

```
[Spread,PaymentDates,PaymentTimes,] = cdsspread( ____,Name,Value)
```

### Description

[Spread,PaymentDates,PaymentTimes,] = cdsspread(ZeroData,ProbData,Settle, Maturity, ) computes the spread of the CDS.

[Spread,PaymentDates,PaymentTimes,] = cdsspread( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Determine the Spread of a Credit Default Swap

This example shows how to use `cdsspread` to compute the spread (in basis points) for a CDS contract with the following data.

```
Settle = '17-Jul-2009'; % valuation date for the CDS
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];
ProbData = [daysadd(datenum(Settle),360,1), 0.0247];
Maturity = '20-Sep-2010';
```

```
Spread = cdsspread(ZeroData,ProbData,Settle,Maturity)
```

```
Spread = 148.2705
```

### Input Arguments

#### ZeroData — Zero rate data

vector | IRDataCurve object

Zero rate data, specified as a M-by-2 vector of dates and zero rates or an `IRDataCurve` object of zero rates.

When `ZeroData` is an `IRDataCurve` object, `ZeroCompounding` and `ZeroBasis` are implicit in `ZeroData` and are redundant inside this function. In this case, specify these optional parameters when constructing the `IRDataCurve` object before using the `cdsspread` function.

For more information on an `IRDataCurve` object, see “Creating an `IRDataCurve` Object” (Financial Instruments Toolbox).

Data Types: `double` | `struct`

### **ProbData — Default probability values**

matrix

Default probability values, specified as a P-by-2 matrix with dates and corresponding cumulative default probability values.

Data Types: `double` | `char`

### **Settle — Settlement date**

serial date number | date character vector

Settlement date, specified as a scalar serial date number or date character vector. The `Settle` date must be earlier than or equal to the dates in `Maturity`.

Data Types: `double` | `char`

### **Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as a N-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

---

**Note** Any optional input of size N-by-1 is also acceptable as an array of size 1-by-N, or as a single value applicable to all contracts. Single values are internally expanded to an array of size N-by-1.

---

Example: `Spread = cdsspread(ZeroData, ProbData, Settle, Maturity, 'Basis', 7, 'BusDayConvention', 'previous')`

### **RecoveryRate — Recovery rate**

0.4 (default) | decimal

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a N-by-1 vector of recovery rates, specified as a decimal from 0 to 1.

Data Types: `double`

### **Period — Premium payment frequency**

4 (default) | numeric with values 1, 2, 3, 4, 6 or 12

Premium payment frequency, specified as the comma-separated pair consisting of `'Period'` and a N-by-1 vector with values of 1, 2, 3, 4, 6, or 12.

Data Types: `double`

**Basis — Day-count basis of contract**

2 (actual/360) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Day-count basis of the contract, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

**BusDayConvention — Business day conventions**

actual (default) | character vector

Business day conventions, specified as the comma-separated pair consisting of 'BusDayConvention' and a character vector. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char

**PayAccruedPremium — Flag for accrued premiums paid upon default**

true (default) | integer with value 1 or 0

Flag for accrued premiums paid upon default, specified as the comma-separated pair consisting of 'PayAccruedPremium' and a N-by-1 vector of Boolean flags that is true (default) if accrued premiums are paid upon default, false otherwise.

Data Types: logical

**TimeStep — Number of days as time step for numerical integration**

10 (days) (default) | nonnegative integer

Number of days to take as time step for the numerical integration, specified as the comma-separated pair consisting of 'TimeStep' and a nonnegative integer.

Data Types: double

**ZeroCompounding — Compounding frequency of the zero curve**

2 (semiannual) (default) | integer with value of 1,2,3,4,6,12, or -1

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'ZeroCompounding' and an integer with values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: double

**ZeroBasis — Basis of the zero curve**

0 (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and a positive integer with values that are identical to Basis.

Data Types: double

**Output Arguments****Spread — Spreads (in basis points)**

vector

Spreads (in basis points), returned as a N-by-1 vector.

**PaymentDates — Payment dates**

matrix

Payment dates, returned as a N-by-numCF matrix.

**PaymentTimes – Payment times**

matrix

Payment times, returned as a N-by-numCF matrix of accrual fractions.

**More About****CDS Spread**

The market, or breakeven, spread value of a CDS.

The CDS spread can be computed by equating the value of the protection leg with the value of the premium leg:

$$\text{Market Spread} * \text{RPV01} = \text{Value of Protection Leg}$$

The left side corresponds to the value of the premium leg, and this has been decomposed as the product of the market or breakeven spread times the RPV01 or 'risky present value of a basis point' of the contract. The latter is the present value of the premium payments, considering the default probability. The Market Spread can be computed as the ratio of the value of the protection leg, to the RPV01 of the contract. `cdspread` returns the resulting spread in basis points.

**Algorithms**

The premium leg is computed as the product of a spread  $S$  and the risky present value of a basis point (RPV01). The RPV01 is given by:

$$\text{RPV01} = \sum_{j=1}^N Z(t_j) \Delta(t_{j-1}, t_j, B) Q(t_j)$$

when no accrued premiums are paid upon default, and it can be approximated by

$$\text{RPV01} \approx \frac{1}{2} \sum_{j=1}^N Z(t_j) \Delta(t_{j-1}, t_j, B) (Q(t_{j-1}) + Q(t_j))$$

when accrued premiums are paid upon default. Here,  $t_0 = \theta$  is the valuation date, and  $t_1, \dots, t_n = T$  are the premium payment dates over the life of the contract,  $T$  is the maturity of the contract,  $Z(t)$  is the discount factor for a payment received at time  $t$ , and  $\Delta(t_{j-1}, t_j, B)$  is a day count between dates  $t_{j-1}$  and  $t_j$  corresponding to a basis  $B$ .

The protection leg of a CDS contract is given by the following formula:

$$\begin{aligned} \text{ProtectionLeg} &= \int_0^T Z(\tau) (1 - R) dPD(\tau) \\ &\approx (1 - R) \sum_{i=1}^M Z(\tau_i) (PD(\tau_i) - PD(\tau_{i-1})) \\ &= (1 - R) \sum_{i=1}^M Z(\tau_i) (Q(\tau_{i-1}) - Q(\tau_i)) \end{aligned}$$

where the integral is approximated with a finite sum over the discretization  $\tau_0 = \theta, \tau_1, \dots, \tau_M = T$ .

A breakeven spread  $S_0$  makes the value of the premium and protection legs equal. It follows that:

$$S_0 = \frac{\text{ProtectionLeg}}{RPV01}$$

## Introduced in R2010b

## cdsrpv01

Compute risky present value of a basis point for credit default swap

### Syntax

```
RPV01 = cdsrpv01(ZeroData,ProbData,Settle,Maturity)
RPV01 = cdsrpv01( ____,Name,Value)
```

```
[RPV01,PaymentDates,PaymentTimes] = cdsrpv01(ZeroData,ProbData,Settle,
Maturity)
[RPV01,PaymentDates,PaymentTimes] = cdsrpv01( ____,Name,Value)
```

### Description

`RPV01 = cdsrpv01(ZeroData,ProbData,Settle,Maturity)` computes the risky present value of a basis point (RPV01) for a credit default swap (CDS).

`RPV01 = cdsrpv01( ____,Name,Value)` adds optional name-value arguments.

`[RPV01,PaymentDates,PaymentTimes] = cdsrpv01(ZeroData,ProbData,Settle,Maturity)` computes the risky present value of a basis point (RPV01), PaymentDates, and PaymentTimes for a credit default swap (CDS).

`[RPV01,PaymentDates,PaymentTimes] = cdsrpv01( ____,Name,Value)` computes the risky present value of a basis point (RPV01), PaymentDates, and PaymentTimes for a credit default swap (CDS) using optional name-value pair arguments.

### Examples

#### Calculate the RPV01 Value for a CDS

Calculate the RPV01 value, given the following specification for a CDS.

```
Settle = '17-Jul-2009'; % valuation date for the CDS
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];
ProbData = [daysadd(datenum(Settle),360,1), 0.0247];
Maturity = '20-Sep-2010';
```

```
RPV01 = cdsrpv01(ZeroData,ProbData,Settle,Maturity)
```

```
RPV01 = 1.1651
```

### Input Arguments

#### ZeroData — Dates and zero rates

object from IRDataCurve or vector of dates and zero rates

Dates and zero rates, specified by an M-by-2 vector of dates and zero rates or the object `IRDataCurve` for zero rates. For more information on an `IRDataCurve` object, see “Creating an `IRDataCurve` Object” (Financial Instruments Toolbox).

Data Types: `struct` | `double`

### **ProbData — Dates and default probabilities**

vector of dates and default probabilities

Dates and default probabilities, specified by a P-by-2 array.

Data Types: `double`

### **Settle — Settlement date**

serial date number | character vector | cell array of character vectors

Settlement date, specified by a serial date number or date character vector. This must be earlier than or equal to the dates in `Maturity`.

Data Types: `char` | `cell` | `double`

### **Maturity — CDS maturity date**

serial date number | character vector | cell array of character vectors

CDS maturity date, specified by an N-by-1 vector of serial date numbers or date character vectors containing the maturity dates. The CDS premium payment dates occur at regular intervals, and the last payment occurs on these maturity dates.

Data Types: `char` | `cell` | `double`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, . . . , `NameN`, `ValueN`.

Example: `RPV01 = cdsrpv01(ZeroData,ProbData,Settle,Maturity,'Period',1,'StartDate','20-Sep-2010','Basis',1,'BusDayConvention','actual','CleanRPV01',true,'PayAccruedPremium',true,'ZeroCompounding',1,'ZeroBasis',1)`

### **Period — Number of premium payments per year**

4 (default) | positive integer from the set [1,2,3,4,6,12] | vector of positive integers from the set [1,2,3,4,6,12]

Number of premium payments per year, specified as the comma-separated pair consisting of `'Period'` and an N-by-1 vector. Values are 1, 2, 3, 4, 6, and 12.

Data Types: `double`

### **StartDate — Dates the CDS premium leg starts**

Settle date (default) | serial date number | character vector | cell array of character vectors

Dates when the CDS premium leg actually starts, specified as the comma-separated pair consisting of `'StartDate'` and an N-by-1 vector of serial date numbers or date character vectors. Must be on or between the `Settle` and `Maturity` dates. For a forward-starting CDS, specify this date as a future date after `Settle`.

Data Types: `double` | `char` | `cell`

### **Basis — Day-count basis of contract**

2 (actual/360) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis of the contract, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `double`

### **BusDayConvention — Business day conventions**

`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusDayConvention' and a character vector or N-by-1 cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

### **CleanRPV01 — Flag for premium accrual**

true (default) | boolean flag with value true or false

Flag for premium accrual, specified as the comma-separated pair consisting of 'CleanRPV01' and a N-by-1 vector of Boolean flags, which is true if the premium accrued at StartDate is excluded in the RPV01, and false otherwise.

Data Types: logical

### **PayAccruedPremium — Flag for accrued premium payment**

true (default) | boolean flag with value true or false

Flag for accrued premium payment, specified as the comma-separated pair consisting of 'PayAccruedPremium' and a N-by-1 vector of Boolean flags, true if accrued premiums are paid upon default, false otherwise.

Data Types: logical

### **ZeroCompounding — Compounding frequency of zero curve**

2 semiannual compounding (default) | integer with acceptable value [1, 2, 3, 4, 6, 12, -1]

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'ZeroCompounding' and an integer with values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

---

**Note** When ZeroData is an IRDataCurve object, the arguments ZeroCompounding and ZeroBasis are implicit in ZeroData and are redundant inside this function. In that case, specify these optional arguments when constructing the IRDataCurve object before calling this function.

---

Data Types: double

### **ZeroBasis — Basis of zero curve**

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and a positive integer using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

## Output Arguments

### **RPV01 — RPV01 value**

scalar | vector

RPV01 value, returned as an N-by-1 vector.

### **PaymentDates — Payment dates**

scalar | vector

Payment dates, returned as an N-by-numCF matrix of dates.

### **PaymentTimes — Payment times**

scalar | vector

Payment times, returned as an N-by-numCF matrix of accrual fractions.

## More About

### **RPV01**

RPV01, associated with a CDS, is the value of a stream of 1-basis-point premiums according to the payment structure of the CDS contract, and considering the default probability over time.

For more information, see [3] and [4] for details.

## creditexposures

Compute credit exposures from contract values

### Syntax

```
[exposures,exposurecpty] = creditexposures(values,counterparties)
[exposures,exposurecpty] = creditexposures( ___,Name,Value)
```

```
[exposures,exposurecpty,collateral] = creditexposures( ___,Name,Value)
```

### Description

`[exposures,exposurecpty] = creditexposures(values,counterparties)` computes the counterparty credit exposures from an array of mark-to-market OTC contract values. These exposures are used when calculating the CVA (credit value adjustment) for a portfolio.

`[exposures,exposurecpty] = creditexposures( ___,Name,Value)` adds optional name-value arguments.

`[exposures,exposurecpty,collateral] = creditexposures( ___,Name,Value)` computes the counterparty credit exposures from an array of mark-to-market OTC contract values using optional name-value pair arguments for `CollateralTable` and `Dates`, the `collateral` output is returned for the simulated collateral amounts available to counterparties at each simulation date and over each scenario.

### Examples

#### View Contract Values and Exposures Over Time for a Particular Counterparty

After computing the mark-to-market contract values for a portfolio of swaps over many scenarios, compute the credit exposure for a particular counterparty. View the contract values and credit exposure over time.

First, load data (`ccr.mat`) containing the mark-to-market contract values for a portfolio of swaps over many scenarios.

```
load ccr.mat
% Look at one counterparty.
cpID = 4;
cpValues = squeeze(sum(values(:,swaps.Counterparty == cpID,:),2));
subplot(2,1,1)
plot(simulationDates,cpValues);
title(sprintf('Mark-to-Market Contract Values for Counterparty: %d',cpID));
datetick('x','mmyy')
ylabel('Portfolio Value ($)')
% Compute the exposure by counterparty.
[exposures, expcpty] = creditexposures(values,swaps.Counterparty,...
'NettingID',swaps.NettingID);
% View the credit exposure over time for the counterparty.
subplot(2,1,2)
```

```

cpIdx = find(expcpty == cpID);
plot(simulationDates,squeeze(exposures(:,cpIdx,:)));
title(sprintf('Exposure for counterparty: %d',cpIdx));
datetick('x','mmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates')

```

### Compute the Credit Exposure and Determine the Incremental Exposure for a New Trade

Load the data (`ccr.mat`) containing the mark-to-market contract values for a portfolio of swaps over many scenarios.

```
load ccr.mat
```

Look at one counterparty.

```

cpID = 4;
cpIdx = swaps.Counterparty == cpID;
cpValues = values(:,cpIdx,:);
plot(simulationDates,squeeze(sum(cpValues,2)));
grid on;
title(sprintf('Potential Mark-to-Market Portfolio Values for Counterparty: %d',cpID));
datetick('x','mmyy')
ylabel('Portfolio Value ($)')

```

Compute the exposures.

```
netting = swaps.NettingID(cpIdx);
exposures = creditexposures(cpValues,cpID,'NettingID',netting);
```

View the credit exposure over time for the counterparty.

```
figure;
plot(simulationDates,squeeze(exposures));
grid on
title(sprintf('Exposure for counterparty: %d',cpID));
datetick('x','mmmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```

Compute the credit exposure profiles.

```
profilesBefore = exposureprofiles(simulationDates,exposures)
```

```
profilesBefore = struct with fields:
```

```
Dates: [37x1 double]
EE: [37x1 double]
PFE: [37x1 double]
MPFE: 2.1580e+05
EffEE: [37x1 double]
EPE: 2.8602e+04
EffEPE: 4.9579e+04
```

Consider a new trade with a counterparty. For this example, take another trade from the original swap portfolio and "copy" it for a new counterparty. This example is only for illustrative purposes.

```
newTradeIdx = 3;
newTradeValues = values(:,newTradeIdx,:);

% Append a new trade to your existing portfolio.
cpValues = [cpValues newTradeValues];
netting = [netting; cpID];
exposures = creditexposures(cpValues,cpID,'NettingID',netting);
```

Compute the new credit exposure profiles.

```
profilesAfter = exposureprofiles(simulationDates,exposures)
```

```
profilesAfter = struct with fields:
    Dates: [37x1 double]
    EE: [37x1 double]
    PFE: [37x1 double]
    MPFE: 2.4689e+05
    EffEE: [37x1 double]
    EPE: 3.1609e+04
    EffEPE: 5.6178e+04
```

Visualize the expected exposures and the new trade's incremental exposure. Use the incremental exposure to compute the incremental credit value adjustment (CVA) charge.

```
figure;
subplot(2,1,1)
plot(simulationDates,profilesBefore.EE,...
     simulationDates,profilesAfter.EE);
grid on;
legend({'EE before','EE with trade'})
datetick('x','mmyy','keeplimits')
title('Expected Exposure before and after new trade');
ylabel('Exposure ($)')

subplot(2,1,2)
incrementalEE = profilesAfter.EE - profilesBefore.EE;
plot(simulationDates,incrementalEE);
grid on;
legend('incremental EE')
datetick('x','mmyy','keeplimits')
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```

### Compute Exposures for Counterparties Under Collateral Agreement

Load the data (`ccr.mat`) containing the mark-to-market contract values for a portfolio of swaps over many scenarios.

```
load ccr.mat
```

Only look at a single counterparty for this example.

```
cpID = 4;
cpIdx = swaps.Counterparty == cpID;
cpValues = values(:,cpIdx,:);
```

Compute the uncollateralized exposures.

```
exposures = creditexposures(cpValues,swaps.Counterparty(cpIdx),...
'NettingID',swaps.NettingID(cpIdx));
```

View the credit exposure over time for the counterparty.

```
plot(simulationDates,squeeze(exposures));
expYLim = get(gca,'YLim');
title(sprintf('Exposures for Counterparty: %d',cpID));
datetick('x','mmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```

Add a collateral agreement for the counterparty. The 'CollateralTable' parameter is a MATLAB® table. You can create tables from spreadsheets or other data sources, in addition to building them inline as seen here. For more information, see [table](#).

```
collateralVariables = {'Counterparty'; 'PeriodOfRisk'; 'Threshold'; 'MinimumTransfer'};
periodOfRisk = 14;
threshold = 100000;
minTransfer = 10000;
collateralTable = table(cpID, periodOfRisk, threshold, minTransfer, ...
    'VariableNames', collateralVariables)
```

```
collateralTable=1×4 table
    Counterparty    PeriodOfRisk    Threshold    MinimumTransfer
    _____    _____    _____    _____
            4            14            1e+05            10000
```

Compute the collateralized exposures.

```
[collatExp, collatcpty, collateral] = creditexposures(cpValues, ...
    swaps.Counterparty(cpIdx), 'NettingID', swaps.NettingID(cpIdx), ...
    'CollateralTable', collateralTable, 'Dates', simulationDates);
```

Plot the collateral levels and collateralized exposures.

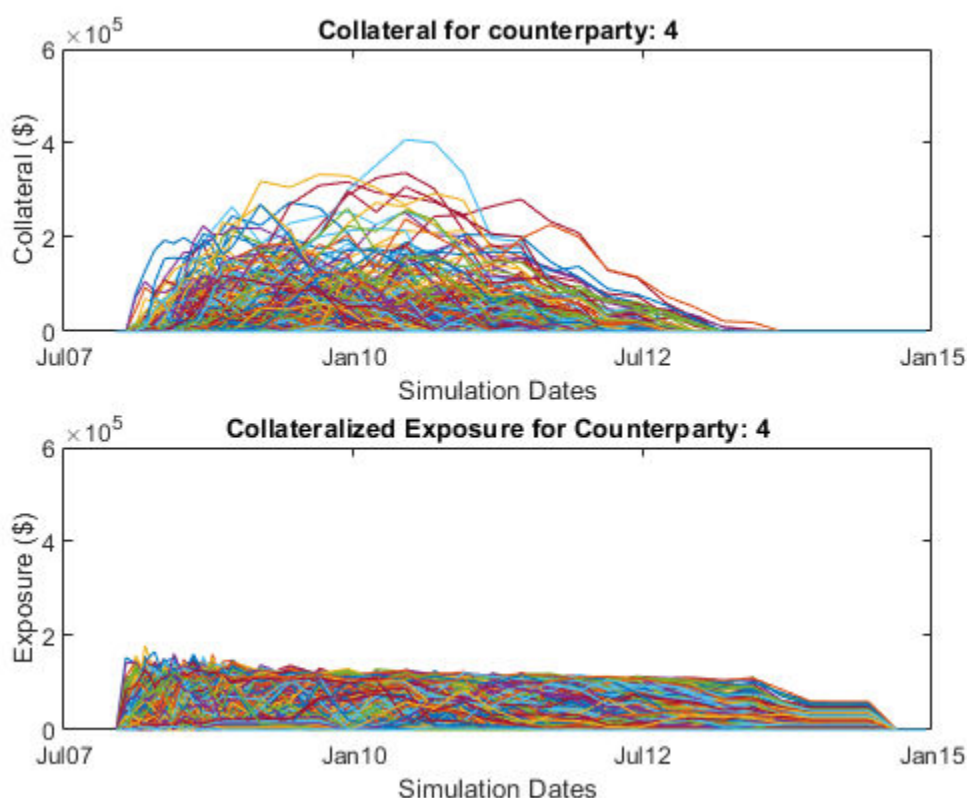

```
figure;
subplot(2,1,1)
```

```

plot(simulationDates,squeeze(collateral));
set(gca,'YLim',expYLim);
title(sprintf('Collateral for counterparty: %d',cpID));
datetick('x','mmyy')
ylabel('Collateral ($)')
xlabel('Simulation Dates')

subplot(2,1,2)
plot(simulationDates,squeeze(collatExp));
set(gca,'YLim',expYLim);
title(sprintf('Collateralized Exposure for Counterparty: %d',cpID));
datetick('x','mmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates');

```

## Input Arguments

**values** — 3-D array of simulated mark-to-market values of portfolio of contracts

array

3-D array of simulated mark-to-market values of a portfolio of contracts simulated over a series of simulation dates and across many scenarios, specified as a NumDates-by-NumContracts-by-NumScenarios "cube" of contract values. Each row represents a different simulation date, each column a different contract, and each "page" is a different scenario from a Monte-Carlo simulation.

Data Types: double

**counterparties — Counterparties corresponding to each contract**

vector | cell array

Counterparties corresponding to each contract in `values`, specified as a `NumContracts`-element vector of counterparties. Counterparties can be a vector of numeric IDs or a cell array of counterparty names. By default, each counterparty is assumed to have one netting set that covers all of its contracts. If counterparties are covered by multiple netting sets, then use the `NettingID` parameter. A value of `NaN` (or `''` in a cell array) indicates that a contract is not included in any netting set unless otherwise specified by `NettingID`. `counterparties` is case insensitive and leading or trailing white spaces are removed.

Data Types: double | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[exposures, exposurecpty] = creditexposures(values, counterparties, 'NettingID', '10', 'ExposureType', 'Additive')`

**NettingID — Netting set IDs indicate which netting set each contract belongs**

vector | cell array

Netting set IDs to indicate to which netting set each contract in `values` belongs, specified by a `NumContracts`-element vector of netting set IDs. `NettingID` can be a vector of numeric IDs or else a cell array of character vector identifiers. The `creditexposures` function uses `counterparties` and `NettingID` to define each unique netting set (all contracts in a netting set must be with the same counterparty). By default, each counterparty has a single netting set which covers all of their contracts. A value of `NaN` (or `''` in a cell array) indicates that a contract is not included in any netting set. `NettingID` is case insensitive and leading or trailing white spaces are removed.

Data Types: double | cell

**ExposureType — Calculation method for exposures**

'Counterparty' (default) | character vector with value of 'Counterparty' or 'Additive'

Calculation method for exposures, specified with values:

- 'Counterparty' — Compute exposures per counterparty.
- 'Additive' — Compute additive exposures at the contract level. Exposures are computed per contract and sum to the total counterparty exposure.

Data Types: char

**CollateralTable — Table containing information on collateral agreements of counterparties**

MATLAB table

Table containing information on collateral agreements of counterparties, specified as a MATLAB table. The table consists of one entry (row) per collateralized counterparty and must have the following variables (columns):

- 'Counterparty' — Counterparty name or ID. The Counterparty name or ID should match the parameter 'Counterparty' for the ExposureType argument.
- 'PeriodOfRisk' — Margin period of risk in days. The number of days from a margin call until the posted collateral is available from the counterparty.
- 'Threshold' — Collateral threshold. When counterparty exposures exceed this amount, the counterparty must post collateral.
- 'MinimumTransfer' — Minimum transfer amount. The minimum amount over/under the threshold required to trigger transfer of collateral.

---

**Note** When computing collateralized exposures, both the CollateralTable parameter and the Dates parameter must be specified.

---

Data Types: table

### Dates — Simulation dates corresponding to each row of the values array

vector of date numbers | cell array of character vectors

Simulation dates corresponding to each row of the values array, specified as a NUMDATES-by-1 vector of simulation dates. Dates is either a vector of MATLAB date numbers or else a cell array of character vectors in a known date format. See datenum for known date formats.

---

**Note** When computing collateralized exposures, both the CollateralTable parameter and the Dates parameter must be specified.

---

Data Types: double | cell

## Output Arguments

### exposures — 3-D array of credit exposures

array

3-D array of credit exposures representing the potential losses from each counterparty or contract at each date and over all scenarios. The size of exposures depends on the ExposureType input argument:

- When ExposureType is 'Counterparty', exposures returns a NumDates-by-NumCounterparties-by-NumScenarios “cube” of credit exposures representing potential losses that could be incurred over all dates, counterparties, and scenarios, if a counterparty defaulted (ignoring any post-default recovery).
- When ExposureType is 'Additive', exposures returns a NumDates-by-NumContracts-by-NumScenarios “cube,” where each element is the additive exposure of each contract (over all dates and scenarios). Additive exposures sum to the counterparty-level exposure.

### exposurecpty — Counterparties that correspond to columns of exposures array

vector

Counterparties that correspond to columns of the exposures array, returned as NumCounterparties or NumContracts elements depending on the ExposureType.

**collateral** — Simulated collateral amounts available to counterparties at each simulation date and over each scenario

3D array

Simulated collateral amounts available to counterparties at each simulation date and over each scenario, returned as a NumDates-by-NumCounterparties-by-NumScenarios 3D array. Collateral amounts are calculated using a Brownian bridge to estimate contract values between simulation dates. For more information, see “Brownian Bridge” on page 19-442. If the CollateralTable was not specified, this output is empty.

**More About****Brownian Bridge**

A Brownian bridge is used to simulate portfolio values at intermediate dates to compute collateral available at the subsequent simulation dates.

For example, to estimate collateral available at a particular simulation date,  $t_i$ , you need to know the state of the portfolio at time  $t_i - dt$ , where  $dt$  is the margin period of risk. Portfolio values are simulated at these intermediate dates by drawing from a distribution defined by the Brownian bridge between  $t_i$  and the previous simulation date,  $t_{i-1}$ .

If the contract values at time  $t_{i-1}$  and  $t_i$  are known and you want to estimate the contract value at time  $t_c$  (where  $t_c$  is  $t_i - dt$ ), then a sample from a normal distribution is used with variance:

$$\frac{(t_i - t_c)(t_c - t_{i-1})}{(t_i - t_{i-1})}$$

and with mean that is simply the linear interpolation of the contract values between the two simulation dates at time  $t_c$ . For more details, see References.

## exposureprofiles

Compute exposure profiles from credit exposures

### Syntax

```
profilestructs = exposureprofiles(dates,exposures)
profilestructs = exposureprofiles( ____,Name,Value)
```

### Description

`profilestructs = exposureprofiles(dates,exposures)` computes common counterparty credit exposures profiles from an array of exposures.

`profilestructs = exposureprofiles( ____,Name,Value)` adds optional name-value arguments.

### Examples

#### View Exposure Profiles of a Particular Counterparty

After computing the mark-to-market contract values for a portfolio of swaps over many scenarios, view the exposure profiles of a particular counterparty.

Load the data (`ccr.mat`) that contains the mark-to-market contract values for a portfolio of swaps over many scenarios.

```
load ccr.mat
```

Compute the exposure by counterparty.

```
[exposures, expcpty] = creditexposures(values,swaps.Counterparty,...
'NettingID',swaps.NettingID);
```

Compute the credit exposure profiles for all counterparties.

```
cpProfiles = exposureprofiles(simulationDates,exposures)
```

```
cpProfiles=5x1 struct array with fields:
```

```
Dates
EE
PFE
MPFE
EffEE
EPE
EffEPE
```

Visualize the exposure profiles for a particular counterparty.

```
cpIdx = find(expcpty == 4);
numDates = numel(simulationDates);
```

```

plot(simulationDates, cpProfiles(cpIdx).PFE, ...
     simulationDates, cpProfiles(cpIdx).MPFE * ones(numDates,1), ...
     simulationDates, cpProfiles(cpIdx).EE, ...
     simulationDates, cpProfiles(cpIdx).EPE * ones(numDates,1), ...
     simulationDates, cpProfiles(cpIdx).EffEE, ...
     simulationDates, cpProfiles(cpIdx).EffEPE * ones(numDates,1));
legend({'PFE (95%)', 'Max PFE', 'Exp Exposure (EE)', ...
       'Time-Avg EE (EPE)', 'Max past EE (EffEE)', ...
       'Time-Avg EffEE (EffEPE)'});
datetick('x', 'mmyy', 'keepLimits')
title(sprintf('Counterparty %d Exposure Profiles', cpIdx));
ylabel('Exposure ($)')
xlabel('Simulation Dates')

```

## Input Arguments

### dates — Simulation dates

vector of date numbers | cell array of character vectors

Simulation dates, specified as vector of date numbers or a cell array of character vectors in a known date format. For more information for known date formats, see the function `datenum`.

Data Types: `double` | `char` | `cell`

### exposures — 3-D array of potential losses due to counterparty default

array

3-D array of potential losses due to counterparty default on a set of instruments simulated over a series of simulation dates and across many scenarios, specified as a `NumDates-by-NumCounterParties-by-NumScenarios` “cube” of credit exposures. Each row represents a different simulation date, each column a different counterparty, and each “page” is a different scenario from a Monte-Carlo simulation.

Data Types: `double`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `profilestructs = exposureprofiles(dates, exposures, 'ProfileSpec', 'PFE', 'PFEProbabilityLevel', .9)`

### ProfileSpec — Exposure profiles

`All` (generate all profiles) (default) | character vector with possible values `EE`, `PFE`, `MPE`, `EffEE`, `EPE`, `EffEPE`, `All` | cell array of character vectors with possible values `EE`, `PFE`, `MPE`, `EffEE`, `EPE`, `EffEPE`

Exposure profiles, specified as a character vector or cell array of character vectors with the following possible values:

- `EE` — Expected Exposure. The mean of the distribution of exposures at each date. A [`NumDates-by-1`] vector.
- `PFE` — Potential Future Exposure. A high percentile (default 95%) of the distribution of possible exposures at each date. This is sometimes referred to as “Peak Exposure.” A [`NumDates-by-1`] vector.
- `MPFE` — Maximum Potential Future Exposure. The maximum potential future exposure (PFE) over all dates
- `EffEE` — Effective Expected Exposure. The maximum expected exposure (at a specific date) that occurs at that date or any prior date. This is the expected exposure, but constrained to be nondecreasing over time. A [`NumDates-by-1`] vector.
- `EPE` — Expected Positive Exposure. The weighted average over time of expected exposures. A scalar.
- `EffEPE` — Effective Expected Positive Exposure. The weighted average over time of the effective expected exposure (`EffEE`). A scalar.
- `All` — Generate all the previous profiles.

---

**Note** Exposure profiles are computed on a per-counterparty basis.

---

Data Types: `char` | `cell`

### PFEProbabilityLevel — Level for potential future exposure (PFE) and maximum potential future exposure (MPFE)

`.95` (the 95th percentile) (default) | scalar with value [`0 . . 1`]

Level for potential future exposure (PFE) and maximum potential future exposure (MPFE), specified as a scalar with value [`0 . . 1`].

Data Types: double

## Output Arguments

### **profilestructs** — Structure of credit exposure profiles

array of structs holding credit exposure profiles for each counterparty

Structure of credit exposure profiles, returned as an array of structs holding credit exposure profiles for each counterparty, returned as a struct, with the fields of the struct as the (abbreviated) names of every exposure profile. Profiles listed in the `ProfileSpec` (and their related profiles) are populated, while those not requested contain empty (`[]`). `profilestructs` contains the `dates` information as a vector of MATLAB date numbers requested in the `ProfileSpec` argument.

## cdyield

Yield on certificate of deposit (CD)

### Syntax

```
Yield = cdyield(Price,CouponRate,Settle,Maturity,IssueDate)
Yield = cdyield( ____,Basis)
```

### Description

`Yield = cdyield(Price,CouponRate,Settle,Maturity,IssueDate)` computes the yield to maturity of a certificate of deposit given its clean price.

`cdyield` assumes that the certificates of deposit pay interest at maturity. Because of the simple interest treatment of these securities, this function is best used for short-term maturities (less than 1 year). The default simple interest calculation uses the `Basis` for the actual/360 convention (2).

`Yield = cdyield( ____,Basis)` adds an optional argument for `Basis`.

### Examples

#### Compute the Yield to Maturity of a Certificate of Deposit

This example shows how to compute the yield on the certificate of deposit (CD), given a CD with the following characteristics.

```
Price      = 101.125;
CouponRate = 0.05;
Settle     = '02-Jan-02';
Maturity   = '31-Mar-02';
IssueDate  = '1-Oct-01';
```

```
Yield = cdyield(Price, CouponRate, Settle, Maturity, IssueDate)
```

```
Yield = 0.0039
```

#### Compute the Yield to Maturity of a Certificate of Deposit Using datetime Inputs

This example shows how to use `datetime` inputs to compute the yield on the certificate of deposit (CD), given a CD with the following characteristics.

```
Price      = 101.125;
CouponRate = 0.05;
Settle     = datetime('02-Jan-02','Locale','en_US');
Maturity   = datetime('31-Mar-02','Locale','en_US');
IssueDate  = datetime('1-Oct-01','Locale','en_US');
```

```
Yield = cdyield(Price, CouponRate, Settle, Maturity, IssueDate)
```

Yield = 0.0039

## Input Arguments

### Price — Clean price of certificate of deposit per \$100 face

numeric

Clean price of the certificate of deposit per \$100 face, specified as a numeric value using a scalar or a NCDS-by-1 or 1-by-NCDS vector.

Data Types: double

### CouponRate — Coupon annual interest rate

decimal

Coupon annual interest rate, specified as decimal using a scalar or a NCDS-by-1 or 1-by-NCDS vector.

Data Types: double

### Settle — Settlement date of certificate of deposit

serial date number | date character vector | datetime

Settlement date of the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays. The `Settle` date must be before the `Maturity` date.

Data Types: double | char | datetime

### Maturity — Maturity date of certificate of deposit

serial date number | date character vector | datetime

Maturity date of the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### IssueDate — Issue date for certificate of deposit

serial date number | date character vector | datetime

Issue date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Basis — Day-count basis for certificate of deposit

2 (actual/360) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

(Optional) Day-count basis for the certificate of deposit, specified as a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

## Output Arguments

### **Yield — Simple yield to maturity of certificate of deposit**

numeric

Simple yield to maturity of the certificate of deposit, returned as a NCDS-by-1 or 1-by-NCDS vector.

# cfamounts

Cash flow and time mapping for bond portfolio

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `AdjustCashFlowsBasis`, `BusinessDayConvention`, `CompoundingFrequency`, `DiscountBasis`, `Holidays`, and `PrincipalType`.

---

## Syntax

```
[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts(
CouponRate,Settle,Maturity)
[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts( __ ,
Name,Value)
```

## Description

`[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts(CouponRate,Settle,Maturity)` returns matrices of cash flow amounts, cash flow dates, time factors, and cash flow flags for a portfolio of NUMBONDS fixed-income securities.

The elements contained in the `cfamounts` outputs for the cash flow matrix, time factor matrix, and cash flow flag matrix correspond to the cash flow dates for each security. The first element of each row in the cash flow matrix is the accrued interest payable on each bond. This accrued interest is zero in the case of all zero coupon bonds. `cfamounts` determines all cash flows and time mappings for a bond whether or not the coupon structure contains odd first or last periods. All output matrices are padded with NaNs as necessary to ensure that all rows have the same number of elements.

`[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts( __ , Name,Value)` adds optional name-value arguments.

## Examples

### Compute the Cash Flow Structure and Time Factors for a Bond Portfolio

This example shows how to compute the cash flow structure and time factors for a bond portfolio that contains a corporate bond paying interest quarterly and a Treasury bond paying interest semiannually.

```
Settle = '01-Nov-1993';
Maturity = ['15-Dec-1994'; '15-Jun-1995'];
CouponRate= [0.06; 0.05];
Period = [4; 2];
Basis = [1; 0];
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ...
cfamounts(CouponRate,Settle, Maturity, Period, Basis)
```

```
CFlowAmounts = 2×6
```

```
-0.7667    1.5000    1.5000    1.5000    1.5000    101.5000
-1.8989    2.5000    2.5000    2.5000    102.5000    NaN
```

```
CFlowDates = 2×6
```

```
    728234    728278    728368    728460    728552    728643
    728234    728278    728460    728643    728825    NaN
```

```
TFactors = 2×6
```

```
    0    0.2404    0.7403    1.2404    1.7403    2.2404
    0    0.2404    1.2404    2.2404    3.2404    NaN
```

```
CFlowFlags = 2×6
```

```
    0    3    3    3    3    4
    0    3    3    3    4    NaN
```

### Compute the Cash Flow Structure and Time Factors for a Bond Portfolio and Return a datetime array for CFlowDates

This example shows how to compute the cash flow structure and time factors for a bond portfolio that contains a corporate bond paying interest quarterly and a Treasury bond paying interest semiannually and CFlowDates is returned as a datetime array.

```
Settle = datetime('01-Nov-1993','Locale','en_US');
Maturity = ['15-Dec-1994'; '15-Jun-1995'];
CouponRate = [0.06; 0.05];
Period = [4; 2];
Basis = [1; 0];
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = cfamounts(CouponRate, ...
Settle, Maturity, Period, Basis)
```

```
CFlowAmounts = 2×6
```

```
-0.7667    1.5000    1.5000    1.5000    1.5000    101.5000
-1.8989    2.5000    2.5000    2.5000    102.5000    NaN
```

```
CFlowDates = 2×6 datetime
Columns 1 through 5
```

```
    01-Nov-1993    15-Dec-1993    15-Mar-1994    15-Jun-1994    15-Sep-1994
    01-Nov-1993    15-Dec-1993    15-Jun-1994    15-Dec-1994    15-Jun-1995
```

```
Column 6
```

```
    15-Dec-1994
    NaT
```

TFactors = 2×6

|   |        |        |        |        |        |
|---|--------|--------|--------|--------|--------|
| 0 | 0.2404 | 0.7403 | 1.2404 | 1.7403 | 2.2404 |
| 0 | 0.2404 | 1.2404 | 2.2404 | 3.2404 | NaN    |

CFlowFlags = 2×6

|   |   |   |   |   |     |
|---|---|---|---|---|-----|
| 0 | 3 | 3 | 3 | 3 | 4   |
| 0 | 3 | 3 | 3 | 4 | NaN |

### Compute the Cash Flow Structure and Time Factors for a Bond Portfolio Using Optional Name-Value Pairs

This example shows how to compute the cash flow structure and time factors for a bond portfolio that contains a corporate bond paying interest quarterly and a Treasury bond paying interest semiannually. This example uses the following Name-Value pairs for `Period`, `Basis`, `BusinessDayConvention`, and `AdjustCashFlowsBasis`.

```
Settle = '01-Jun-2010';
Maturity = ['15-Dec-2011'; '15-Jun-2012'];
CouponRate = [0.06; 0.05];
Period = [4; 2];
Basis = [1; 0];
```

```
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ...
cfamounts(CouponRate, Settle, Maturity, 'Period', Period, ...
'Basis', Basis, 'AdjustCashFlowsBasis', true, ...
'BusinessDayConvention', 'modifiedfollow')
```

CFlowAmounts = 2×8

|         |        |        |        |        |          |        |          |
|---------|--------|--------|--------|--------|----------|--------|----------|
| -1.2667 | 1.5000 | 1.5000 | 1.5000 | 1.5000 | 1.5000   | 1.5000 | 101.5000 |
| -2.3077 | 2.4932 | 2.5068 | 2.4932 | 2.5000 | 102.5000 | NaN    | NaN      |

CFlowDates = 2×8

|        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|
| 734290 | 734304 | 734396 | 734487 | 734577 | 734669 | 734761 | 734852 |
| 734290 | 734304 | 734487 | 734669 | 734852 | 735035 | NaN    | NaN    |

TFactors = 2×8

|   |        |        |        |        |        |        |        |
|---|--------|--------|--------|--------|--------|--------|--------|
| 0 | 0.0778 | 0.5778 | 1.0778 | 1.5778 | 2.0778 | 2.5778 | 3.0778 |
| 0 | 0.0769 | 1.0769 | 2.0769 | 3.0769 | 4.0769 | NaN    | NaN    |

CFlowFlags = 2×8

|   |   |   |   |   |   |     |     |
|---|---|---|---|---|---|-----|-----|
| 0 | 3 | 3 | 3 | 3 | 3 | 3   | 4   |
| 0 | 3 | 3 | 3 | 3 | 4 | NaN | NaN |

### Use cfamounts With a CouponRate Schedule

This example shows how to use `cfamounts` with a `CouponRate` schedule. For `CouponRate` and `Face` that change over the life of the bond, schedules for `CouponRate` and `Face` can be specified with an `NINST`-by-1 cell array, where each element is a `NumDates`-by-2 matrix where the first column is dates and the second column is associated rates.

```
CouponSchedule = {[datenum('15-Mar-2012') .04;datenum('15- Mar -2013') .05;...
datenum('15- Mar -2015') .06]}
```

```
CouponSchedule = 1x1 cell array
                  {3x2 double}
```

```
cfamounts(CouponSchedule, '01-Mar-2011', '15-Mar-2015' )
```

```
ans = 1x10
```

```
-1.8453    2.0000    2.0000    2.0000    2.5000    2.5000    3.0000    3.0000    3.0000    103.0000
```

### Use cfamounts With a Face Schedule

This example shows how to use `cfamounts` with a `Face` schedule. For `CouponRate` and `Face` that change over the life of the bond, schedules for `CouponRate` and `Face` can be specified with an `NINST`-by-1 cell array, where each element is a `NumDates`-by-2 matrix where the first column is dates and the second column is associated rates.

```
FaceSchedule = {[datenum('15-Mar-2012') 100;datenum('15- Mar -2013') 90;...
datenum('15- Mar -2015') 80]}
```

```
FaceSchedule = 1x1 cell array
               {3x2 double}
```

```
cfamounts(.05, '01-Mar-2011', '15-Mar-2015', 'Face', FaceSchedule)
```

```
ans = 1x10
```

```
-2.3066    2.5000    2.5000    12.5000    2.2500    12.2500    2.0000    2.0000    2.0000    82.0000
```

### Use cfamounts to Generate the Cash Flows for a Sinking Bond

This example shows how to use `cfamounts` to generate the cash flows for a sinking bond.

```
[CFlowAmounts,CFDates,TFactors,CFFlags,CFPrincipal] = cfamounts(.05, '04-Nov-2010',...
{'15-Jul-2014'; '15-Jul-2015'}, 'Face', {[datenum('15-Jul-2013') 100;datenum('15-Jul-2014')...
90;datenum('15-Jul-2015') 80]}))
```

```
CFlowAmounts = 2x11
```

|         |        |        |        |        |        |         |        |         |     |
|---------|--------|--------|--------|--------|--------|---------|--------|---------|-----|
| -1.5217 | 2.5000 | 2.5000 | 2.5000 | 2.5000 | 2.5000 | 12.5000 | 2.2500 | 92.2500 |     |
| -1.5217 | 2.5000 | 2.5000 | 2.5000 | 2.5000 | 2.5000 | 12.5000 | 2.2500 | 12.2500 | 2.0 |

CFDates = 2×11

|        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|
| 734446 | 734518 | 734699 | 734883 | 735065 | 735249 | 735430 | 735614 |
| 734446 | 734518 | 734699 | 734883 | 735065 | 735249 | 735430 | 735614 |

TFactors = 2×11

|   |        |        |        |        |        |        |        |        |     |

| 0 | 0 | 0 | 0 | 0 | 0 | 10 | 0 | 90 | NaN | NaN |
| 0 | 0 | 0 | 0 | 0 | 0 | 10 | 0 | 10 | 0   | 80  |

## Input Arguments

**CouponRate** — Annual percentage rate used to determine coupons payable on a bond  
decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal using a scalar or a NBONDS-by-1 vector.

CouponRate is 0 for zero coupon bonds.

---

**Note** CouponRate and Face can change over the life of the bond. Schedules for CouponRate and Face can be specified with an NBONDS-by-1 cell array, where each element is a NumDates-by-2 matrix or cell array, where the first column is dates (serial date numbers or character vectors) and the second column is associated rates. The date indicates the last day that the coupon rate or face value is valid. This means that the corresponding CouponRate and Face value applies "on or before" the specified ending date.

---

Data Types: double | cell | char

**Settle** — Settlement date of bond

serial date number | date character vector | datetime

Settlement date of the bond, specified as a scalar or a NBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

**Maturity — Maturity date of bond**

serial date number | date character vector | datetime

Maturity date of the bond, specified as a scalar or a NBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

```
Example: [CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ...
cfamounts(CouponRate, Settle,
Maturity, 'Period', 4, 'Basis', 3, 'AdjustCashFlowsBasis', true, 'BusinessDayConvention', 'modifiedfollow')
```

**Period — Number of coupon payments per year for bond**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year for the bond, specified as the comma-separated pair consisting of 'Period' and a scalar or a NBONDS-by-1 vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis of bond**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the bond, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NBONDS-by-1 vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NBONDS-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond issue date (the date the bond begins to accrue interest), specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays. The IssueDate cannot be after the Settle date.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

**Note** When FirstCouponDate and LastCouponDate

are both specified, the FirstCouponDate takes precedence in determining the coupon payment structure. If FirstCouponDate is not specified, then LastCouponDate determines the coupon structure of the bond.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

**Note** When FirstCouponDate and LastCouponDate are both specified, the FirstCouponDate takes precedence in determining the coupon payment structure. If FirstCouponDate is not specified, then LastCouponDate determines the coupon structure of the bond.

Data Types: double | char | datetime

### **StartDate — Forward starting date of coupon payments**

serial date number | date character vector | datetime

Forward starting date of coupon payments after the `Settle` date, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or a NBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

---

**Note** To make an instrument forward starting, specify `StartDate` as a future date.

---

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

Data Types: double | char | datetime

### **Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar or a NBONDS-by-1 vector.

---

**Note** `CouponRate` and `Face` can change over the life of the bond. Schedules for `CouponRate` and `Face` can be specified with an NBONDS-by-1 cell array where each element is a NumDates-by-2 matrix or cell array, where the first column is dates (serial date numbers or character vectors) and the second column is associated rates. The date indicates the last day that the coupon rate or face value is valid. This means that the corresponding `CouponRate` and `Face` value applies "on or before" the specified ending date.

When the corresponding `Face` value is used to compute the coupon cashflow on the specified ending date. Three things happen on the specified ending date:

- 1 The last coupon corresponding to the current `Face` value is paid.
  - 2 The principal differential (between the current and the next `Face` value) is paid.
  - 3 The date marks the beginning of the period with the next `Face` value, for which the cashflow does not occur until later.
- 

Data Types: double | cell | char

### **AdjustCashFlowsBasis — Adjusts cash flows according to accrual amount based on actual period day count**

false (default) | logical with a value of true or false

Adjusts cash flows according to the accrual amount based on the actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a scalar or a NBONDS-by-1 vector.

Data Types: logical

### **BusinessDayConvention — Business day conventions**

'actual' (default) | character vector with values 'actual', 'follow', 'modifiedfollow', 'previous' or 'modifiedprevious'

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar or NBONDS-by-1 cell array of character vectors of business day conventions to be used in computing payment dates. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

### **CompoundingFrequency — Compounding frequency for yield calculation**

SIA uses 2, ICMA uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NBONDS-by-1 vector. Values are:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

### **DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NBONDS-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

---

Data Types: double

### Holidays — Dates for holidays

`holidays.m` used (default)

Dates for holidays, specified as the comma-separated pair consisting of 'Holidays' and a `NHOLIDAYS-by-1` vector of MATLAB dates using serial date numbers, date character vectors, or datetime arrays. Holidays are used in computing business days.

Data Types: double | char | datetime

### PrincipalType — Type of principal when a Face schedule is specified

`sinking` (default) | character vector with values 'sinking' or 'bullet'

Type of principal when a Face schedule, specified as the comma-separated pair consisting of 'PrincipalType' and a value of 'sinking' or 'bullet' using a scalar or a `NBONDS-by-1` vector.

If 'sinking', principal cash flows are returned throughout the life of the bond.

If 'bullet', principal cash flow is only returned at maturity.

Data Types: char | cell

## Output Arguments

### CFlowAmounts — Cash flow amounts

matrix

Cash flow amounts, returned as a NBONDS-by-NCFS (number of cash flows) matrix. The first entry in each row vector is the accrued interest due at settlement. This amount could be zero, positive or negative. If no accrued interest is due, the first column is zero. If the bond is trading ex-coupon then the accrued interest is negative.

### **CFlowDates — Cash flow dates for a portfolio of bonds**

matrix

Cash flow dates for a portfolio of bonds, returned as a NBONDS-by-NCFS matrix. Each row represents a single bond in the portfolio. Each element in a column represents a cash flow date of that bond.

If all the above inputs (Settle, Maturity, IssueDate, FirstCouponDate, LastCouponDate, and StartDate) are either serial date numbers or date character vectors, then CFlowDates is returned as a serial date number. If any of these inputs are datetime arrays, then CFlowDates is returned as a datetime array.

### **TFactors — Matrix of time factors for a portfolio of bonds**

matrix

Matrix of time factors for a portfolio of bonds, returned as a NBONDS-by-NCFS matrix. Each row corresponds to the vector of time factors for each bond. Each element in a column corresponds to the specific time factor associated with each cash flow of a bond.

Time factors are for price/yield conversion and time factors are in units of whole semiannual coupon periods plus any fractional period using an actual day count. For more information on time factors, see "Time Factors" on page 19-462.

### **CFlowFlags — Cash flow flags for a portfolio of bonds**

matrix

Cash flow flags for a portfolio of bonds, returned as a NBONDS-by-NCFS matrix. Each row corresponds to the vector of cash flow flags for each bond. Each element in a column corresponds to the specific flag associated with each cash flow of a bond. Flags identify the type of each cash flow (for example, nominal coupon cash flow, front, or end partial, or "stub" coupon, maturity cash flow).

| <b>Flag</b> | <b>Cash Flow Type</b>                                                                                                                                                           |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | Accrued interest due on a bond at settlement.                                                                                                                                   |
| 1           | Initial cash flow amount smaller than normal due to a "stub" coupon period. A stub period is created when the time from issue date to first coupon date is shorter than normal. |
| 2           | Larger than normal initial cash flow amount because the first coupon period is longer than normal.                                                                              |
| 3           | Nominal coupon cash flow amount.                                                                                                                                                |
| 4           | Normal maturity cash flow amount (face value plus the nominal coupon amount).                                                                                                   |
| 5           | End "stub" coupon amount (last coupon period is abnormally short and actual maturity cash flow is smaller than normal).                                                         |
| 6           | Larger than normal maturity cash flow because the last coupon period longer than normal.                                                                                        |
| 7           | Maturity cash flow on a coupon bond when the bond has less than one coupon period to maturity.                                                                                  |

| Flag | Cash Flow Type                                                                                                                                                                                        |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8    | Smaller than normal maturity cash flow when the bond has less than one coupon period to maturity.                                                                                                     |
| 9    | Larger than normal maturity cash flow when the bond has less than one coupon period to maturity.                                                                                                      |
| 10   | Maturity cash flow on a zero coupon bond.                                                                                                                                                             |
| 11   | Sinking principal and initial cash flow amount smaller than normal due to a "stub" coupon period. A stub period is created when the time from issue date to first coupon date is shorter than normal. |
| 12   | Sinking principal and larger than normal initial cash flow amount because the first coupon period is longer than normal.                                                                              |
| 13   | Sinking principal and nominal coupon cash flow amount.                                                                                                                                                |

### CFPrincipal – Principal cash flows

matrix

Principal cash flows, returned as a NBONDS-by-NCFS matrix.

If `PrincipalType` is 'sinking', `CFPrincipal` output indicates when the principal is returned.

If `PrincipalType` is 'bullet', `CFPrincipal` is all zeros and, at `Maturity`, the appropriate `Face` value.

## More About

### Time Factors

Time factors help determine the present value of a stream of cash flows.

The term time factors refer to the exponent  $TF$  in the discounting equation

$$PV = \sum_{i=1}^n \left( \frac{CF}{\left(1 + \frac{z}{f}\right)^{TF}} \right),$$

where:

|        |                                                                                                                                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $PV =$ | Present value of a cash flow.                                                                                                                                                                                                               |
| $CF =$ | Cash flow amount.                                                                                                                                                                                                                           |
| $z =$  | Risk-adjusted annualized rate or yield corresponding to a given cash flow. The yield is quoted on a semiannual basis.                                                                                                                       |
| $f =$  | Frequency of quotes for the yield. Default is 2 for <code>Basis</code> values 0 to 7 and 13 and 1 for <code>Basis</code> values 8 to 12. The default can be overridden by specifying the <code>CompoundingFrequency</code> name-value pair. |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>TF</i> = | <p>Time factor for a given cash flow. The time factor is computed using the compounding frequency and the discount basis. If these values are not specified, then the defaults are as follows: <code>CompoundingFrequency</code> default is 2 for <code>Basis</code> values 0 to 7 and 13 and 1 for <code>Basis</code> values 8 to 12.</p> <p><code>DiscountBasis</code> is 0 for <code>Basis</code> values 0 to 7 and 13 and the value of the input <code>Basis</code> for <code>Basis</code> values 8 to 12.</p> |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

---

**Note** The `Basis` is always used to compute accrued interest.

## cfconv

Cash flow convexity

### Syntax

```
CFlowConvexity = cfconv(CashFlow,Yield)
```

### Description

CFlowConvexity = cfconv(CashFlow,Yield) returns the convexity of a cash flow in periods.

### Examples

#### Compute the Convexity of a Cash Flow

This example shows how to return the convexity of a cash flow, given a cash flow of nine payments of \$2.50 and a final payment \$102.50, with a periodic yield of 2.5%.

```
CashFlow = [2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 102.5];
```

```
Convex = cfconv(CashFlow, 0.025)
```

```
Convex = 90.4493
```

### Input Arguments

#### CashFlow — Cash flow

vector of real numbers

Cash flow, specified as a vector of real numbers.

Data Types: double

#### Yield — Periodic yield

scalar decimal

Periodic yield, specified as a scalar decimal.

Data Types: double

### Output Arguments

#### CFlowConvexity — Convexity

scalar

Convexity returned as a scalar.

## cfdates

Cash flow dates for fixed-income security

### Syntax

CFlowDates = cfdates(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCou...

### Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Settle       | Settlement date. A vector of serial date numbers, date character vectors, or datetime arrays. <b>Settle</b> must be earlier than <b>Maturity</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Maturity     | Maturity date. A vector of serial date numbers, date character vectors, or datetime arrays.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Period       | (Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Basis        | (Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (PSA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-18.</p> |
| EndMonthRule | (Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.                                                                                                                                                                                                                                               |
| IssueDate    | (Optional) Date, specified as a serial date number, date character vector, or datetime array, when a bond was issued.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FirstCouponDate | (Optional) Date, specified as a serial date number, date character vector, or datetime array, when a bond makes its first coupon payment. FirstCouponDate is used when a bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.                                                                                                                                           |
| LastCouponDate  | (Optional) Last coupon date of a bond before the maturity date, specified as a serial date number, date character vector, or datetime array. LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs. |
| StartDate       | (Optional) Date, specified as a serial date number, date character vector, or datetime array, when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date. If you do not specify StartDate, the effective start date is the Settle date.                                                                                                                                                                                                                                                                      |

Required arguments must be number of bonds (NUMBONDS)-by-1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if Maturity contains N dates, then Settle must contain N dates or a single date.

## Description

CFlowDates =  
 cfdates(Settle,Maturity,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate,StartDate) returns a matrix of cash flow dates for a bond or set of bonds. cfdates determines all cash flow dates for a bond whether or not the coupon payment structure is normal or the first and/or last coupon period is long or short.

CFlowDates is an N-row matrix of serial date numbers, padded with NaNs as necessary to ensure that all rows have the same number of elements. Use the function datestr to convert serial date numbers to formatted date character vectors.

If all of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, LastCouponDate, and StartDate are either serial date numbers or date character vectors, then CFlowDates is returned as a serial date number.

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, LastCouponDate, or StartDate are datetime arrays, then CFlowDates is returned as a datetime array.

---

**Note** The cash flow flags for a portfolio of bonds were formerly available as the `cfdates` second output argument, `CFlowFlags`. You can now use `cfamounts` to get these flags. If you specify a `CFlowFlags` argument, `cfdates` displays a message directing you to use `cfamounts`.

---

## Examples

```
CFlowDates = cfdates('14 Mar 1997', '30 Nov 1998', 2, 0, 1)
CFlowDates =
    729541    729724    729906    730089
datestr(CFlowDates)
```

```
ans =
31-May-1997
30-Nov-1997
31-May-1998
30-Nov-1998
```

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, or `StartDate` are datetime arrays, then `CFlowDates` is returned as a datetime array. For example:

```
CFlowDates = cfdates('14-Mar-1997', datetime('30-Nov-1998','Locale','en_US'), 2, 0, 1)
```

```
CFlowDates =
    31-May-1997    30-Nov-1997    31-May-1998    30-Nov-1998
```

Given three securities with different maturity dates and the same default arguments

```
Maturity = ['30-Sep-1997'; '31-Oct-1998'; '30-Nov-1998'];
CFlowDates = cfdates('14-Mar-1997', Maturity)
```

```
CFlowDates =
    729480    729663         NaN         NaN
    729510    729694    729875    730059
    729541    729724    729906    730089
```

Look at the cash-flow dates for the last security.

```
datestr(CFlowDates(3,:))
```

```
ans =
31-May-1997
30-Nov-1997
31-May-1998
30-Nov-1998
```

## cfdatesq

Quasi-coupon dates for fixed-income security

### Syntax

QuasiCouponDates = cfdatesq(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, ...)

### Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Settle       | Settlement date. A vector of serial date numbers, date character vectors, or datetime arrays. <b>Settle</b> must be earlier than <b>Maturity</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Maturity     | Maturity date. A vector of serial date numbers, date character vectors, or datetime arrays.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Period       | (Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Basis        | <p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (PSA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-18.</p> |
| EndMonthRule | (Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.                                                                                                                                                                                                                                                      |
| IssueDate    | (Optional) Date, specified as a serial date number, date character vector, or datetime array, when a bond was issued.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FirstCouponDate</b>      | (Optional) Date, specified as a serial date number, date character vector, or datetime array, when a bond makes its first coupon payment. <b>FirstCouponDate</b> is used when a bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b> , the cash flow payment dates are determined from other inputs.                                                                                                                                             |
| <b>LastCouponDate</b>       | (Optional) Last coupon date of a bond before the maturity date, specified as a serial date number, date character vector, or datetime array. <b>LastCouponDate</b> is used when a bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b> , a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b> , regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b> , the cash flow payment dates are determined from other inputs. |
| <b>PeriodsBeforeSettle</b>  | (Optional) Number of quasi-coupon dates on or before settlement to include (non-negative integer); default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>PeriodsAfterMaturity</b> | (Optional) Number of quasi-coupon dates after maturity to include (non-negative integer); default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Required arguments must be number of bonds (NUMBONDS)-by-1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if **Maturity** contains N dates, then **Settle** must contain N dates or a single date.

## Description

**QuasiCouponDates** = `cfdatesq(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, PeriodsBeforeSettle, PeriodsAfterMaturity)` returns a matrix of quasi-coupon dates expressed in serial date format (default) or datetime format (if any inputs are in datetime format).

Successive quasi-coupon dates determine the length of the standard coupon period for the fixed-income security of interest, and do not necessarily coincide with actual coupon payment dates. Quasi-coupon dates are determined regardless of whether the first or last coupon periods are normal, long, or short.

**QuasiCouponDates** has NUMBONDS rows and the number of columns is determined by the maximum number of quasi-coupon dates required to hold the bond portfolio. NaNs are padded for bonds which have less than the maximum number quasi-coupon dates. By default, quasi-coupon dates after settlement and on or preceding maturity are returned. If settlement occurs on maturity, and maturity is a quasi-coupon date, then the maturity date is returned.

If the date inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `QuasiCouponDates` is returned as a serial date number.

If any of the date inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, or `LastCouponDate` are datetime arrays, then `QuasiCouponDates` is returned as a datetime array.

## Examples

```
QuasiCouponDates = cfdatesq('14-Mar-1997', '30-Nov-1998', 2, 0, 1)
```

```
QuasiCouponDates =
```

```
    729541    729724    729906    730089
```

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, or `LastCouponDate` are datetime arrays, then `CFlowDates` is returned as a datetime array. For example:

```
QuasiCouponDates = cfdatesq('14-Mar-1997', datetime('30-Nov-1998', 'Locale', 'en_US'), 2, 0, 1)
```

```
QuasiCouponDates =
```

```
    31-May-1997    30-Nov-1997    31-May-1998    30-Nov-1998
```

## cfdur

Cash-flow duration and modified duration

### Syntax

```
[Duration,ModDuration] = cfdur(CashFlow,Yield)
```

### Description

[Duration,ModDuration] = cfdur(CashFlow,Yield) calculates the duration and modified duration of a cash flow in periods.

### Examples

#### Compute the Duration and Modified Duration of a Cash Flow

This example shows how to calculate the duration and modified duration of a cash flow, given a cash flow of nine payments of \$2.50 and a final payment \$102.50, with a periodic yield of 2.5%.

```
CashFlow=[2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 102.5];
```

```
[Duration, ModDuration] = cfdur(CashFlow, 0.025)
```

```
Duration = 8.9709
```

```
ModDuration = 8.7521
```

### Input Arguments

#### CashFlow — Cash flow

vector of real numbers | matrix of real numbers

Cash flow, specified as a vector or matrix of real numbers. When using a matrix, each column of the matrix is a separate CashFlow.

Data Types: double

#### Yield — Periodic yield

scalar decimal | vector of decimals

Periodic yield, specified as a scalar decimal or a vector of decimals.

Data Types: double

### Output Arguments

#### Duration — Duration

vector

Duration returned as a scalar or vector.

**ModDuration – Modified duration**

vector

Modified duration, returned as a scalar or vector.

## cfplot

Visualize cash flows of financial instruments

### Syntax

```
cfplot(CFlowDates,CFlowAmounts)
cfplot( ____,Name,Value)

h = cfplot( ____,Name,Value)
[h,axes_handle] = cfplot( ____,Name,Value)
```

### Description

`cfplot(CFlowDates,CFlowAmounts)` plots a cash flow diagram for the specified cash flow amounts (`CFlowAmounts`) and dates (`CFlowDates`). The length and orientation of each arrow correspond to the cash flow amount.

`cfplot( ____,Name,Value)` plots a cash flow diagram for the specified cash flow amounts (`CFlowAmounts`), dates (`CFlowDates`), and optional name-value pair arguments.

`h = cfplot( ____,Name,Value)` returns the handle to the line objects used in the cash flow diagram.

`[h,axes_handle] = cfplot( ____,Name,Value)` returns the handles to the line objects and the axes using optional name-value pair arguments.

### Examples

#### Plot Cash Flows

Define `CFlowAmounts` and `CFlowDates` using the `cfamounts` function.

```
CouponRate = [0.06; 0.05; 0.03];
Settle = '03-Jun-1999';
Maturity = ['15-Aug-2000';'15-Dec-2000';'15-Jun-2000'];
Period = [1; 2; 2]; Basis = [1; 0; 0];
[CFlowAmounts, CFlowDates] = cfamounts(...
CouponRate, Settle, Maturity, Period, Basis)
```

```
CFlowAmounts = 3×5
```

```
-4.8000    6.0000   106.0000         NaN         NaN
-2.3352    2.5000    2.5000    2.5000   102.5000
-1.4011    1.5000    1.5000   101.5000         NaN
```

```
CFlowDates = 3×5
```

```
730274    730347    730713         NaN         NaN
730274    730286    730469    730652    730835
```

730274      730286      730469      730652      NaN

Plot all cash flows on the same axes, and label the first two.

```
cfplot(CFlowDates, CFlowAmounts, 'ShowAmnt', [1 2])
```

Group the second and third cash flows.

```
figure;
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[2 3]}, 'ShowAmnt', 1);
```

Format the date axis and place ticks on actual cash flow dates.

```
figure;  
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[2 3]}, 'ShowAmnt', 1, ...  
'DateFormat', 6, 'DateSpacing', 100);
```

Stack the cash flow arrows occurring on the same dates.

```
figure;  
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[2 3]}, 'ShowAmt', 1, ...  
'DateFormat', 6, 'DateSpacing', 100, 'Stacked', 1);
```

Form subplots of multiple groups and add titles using axes handles.

```
figure;
[h, axes_handle] = cfplot(CFlowDates, CFlowAmounts, ...
    'Groups', {[1] [2 3]}, 'ShowAmnt', 1, 'Stacked', 2, ...
    'DateSpacing', [1 60 2 100], 'DateFormat', [1 12 2 6]);
title(axes_handle(1), 'Group 1', 'FontWeight', 'bold');
title(axes_handle(2), 'Group 2', 'FontWeight', 'bold');
```

### Plot Cash Flows Using datetime Input for CFlowDates

Define CFlowDates using datetime input and plot the cash flow.

```
CouponRate = [0.06; 0.05; 0.03];
Settle = '03-Jun-1999';
Maturity = ['15-Aug-2000'; '15-Dec-2000'; '15-Jun-2000'];
Period = [1; 2; 2]; Basis = [1; 0; 0];
[CFlowAmounts, CFlowDates] = cfamounts(...
CouponRate, Settle, Maturity, Period, Basis);
cfplot(datetime(CFlowDates, 'ConvertFrom', 'datenum', 'Locale', 'en_US'), CFlowAmounts, 'ShowAmtt',
```

### Plot Cash Flows for Swap

Define the swap using the `swapbyzero` function.

```
Settle = datenum('08-Jun-2010');
RateSpec = intenvset('Rates', [.005 .0075 .01 .014 .02 .025 .03]', ...
    'StartDates', Settle, 'EndDates', {'08-Dec-2010', '08-Jun-2011', ...
    '08-Jun-2012', '08-Jun-2013', '08-Jun-2015', '08-Jun-2017', ...
    '08-Jun-2020'});
Maturity = datenum('15-Sep-2020');
LegRate = [.025 50];
LegType = [1 0]; % fixed/floating
LatestFloatingRate = .005;
[Price, SwapRate, AI, RecCF, RecCFDates, PayCF, PayCFDates] = ...
    swapbyzero(RateSpec, LegRate, Settle, Maturity, 'LegType', LegType, ...
    'LatestFloatingRate', LatestFloatingRate)
```

```
Price = -6.7258
```

```
SwapRate = NaN
```

```
AI = 1.4575
```

```
RecCF = 1x12
```

```

-1.8219    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000
RecCFDates = 1x12
    734297    734396    734761    735127    735492    735857    736222    736588
PayCF = 1x12
   -0.3644    0.5000    1.4048    1.9823    2.8436    3.2842    3.8218    4.1733    4.5164    4.4
PayCFDates = 1x12
    734297    734396    734761    735127    735492    735857    736222    736588

```

Define CFlowDates and CFlowAmounts for the swap and generate a cash flow plot using cfplot.

```

CFlowDates = [PayCFDates;RecCFDates];
CFlowAmounts = [-PayCF;RecCF];
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[1 2]});
xlabel('Numeric Cash Flow Dates');

```

## Input Arguments

### CFlowDates — Matrix of serial date numbers for cash flows

vector

Matrix of serial date numbers or datetime arrays for cash flows, specified as a NINST-by-(Number of cash flows) matrix of cash flow dates in date numbers, with empty entries padded with NaNs.

Each row of the CFlowDates matrix represents an instrument so that CFlowDates(k, :) is the vector of cash flow dates for the kth instrument. Rows are padded with trailing NaNs if the number of cash flows is not the same for all instruments.

cfamounts can be used to generate CFlowDates.

Data Types: double

### CFlowAmounts — Matrix of cash flow amounts

vector

Matrix of cash flow amounts, specified as a NINST-by-(Number of cash flows) matrix of cash flow amounts, with empty entries padded with NaNs. The CFlowAmounts matrix must be the same size as CFlowDates.

cfamounts can be used to generate CFlowAmounts.

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: cfplot(CFlowDates, CFlowAmounts, 'Groups', {[2 3]}, 'ShowAmnt', 1, 'DateFormat', 6, 'DateSpacing', 100)

### Groups — Group cash flows

'off' (default) | character vector with value 'off' or 'individual' | cell array of character vectors

Group cash flows, specified as the comma-separated pair consisting of 'Groups' and the following values:

- 'off' — Show all instruments in one set of axes, arranged from top to bottom.
- 'individual' — Generate subplots and plot each instrument in its own axis.
- GRP — Cell array of instrument groups, {Group1, Group2, ... }. This generates subplots and plots each group in each axis. When specifying {Group1, Group2, ... }, each Group must be mutually exclusive vectors of INSTIndex. Unspecified instruments are not shown in the grouped plot.

Data Types: char | cell

### Stacked — Stack arrows if cash flows are in same direction on same day

ignored when 'Groups' is 'off', otherwise 'off' (default) | character vector with values 'off', 'all', or 'GRPIndex'

Stack arrows if the cash flows are in the same direction on the same day, specified as the comma-separated pair consisting of `'Stacked'` and the following values:

- `'off'` — For all groups, all arrows originate from the horizontal line.
- `'all'` — For all groups, arrows are stacked if the cash flows are in the same direction on the same day.
- `'GRPIndex'` — For specified groups, arrows are stacked if the cash flows are in the same direction on the same day.

Data Types: char

### ShowAmnt — Show amount on arrows

`'off'` (default) | character vector with values `'off'` or `'individual'` | cell array of character vectors

Show amount on the arrows, specified as the comma-separated pair consisting of `'ShowAmnt'` and the following values:

- `'off'` — Hide cash flow amounts on arrows.
- `'all'` — Show cash flow amounts on arrows.
- `[INSTIndex or GRPIndex]` — Show cash flow amounts for the specified vector of instruments (when `'Groups'` is `'off'`) or groups.

Data Types: char | cell

### DateSpacing — Control for date axis tick spacing

`'off'` (default) | character vector with values `'off'` or `TickDateSpace` | numeric value for `TickDateSpace`

Control for data spacing, specified as the comma-separated pair consisting of `'DateSpacing'` and the following values:

- `'off'` — The date axis ticks are spaced regularly.
- `TickDateSpace` — The date axis ticks are placed on actual cash flow dates. The ticks skip some cash flows if they are less than `TickDateSpace` apart.

Data Types: char | double

### DateFormat — Date format

`'off'` (default) | character vector with values `'off'` or `DateFormNum` | numeric value for `DateFormNum`

Date format, specified as the comma-separated pair consisting of `'DateFormat'` and the following values:

- `'off'` — The date axis tick labels are in date numbers.
- `DateFormNum` — The date format number (2 = `'mm/dd/yy'`, 6 = `'mm/dd'`, and 10 = `'yyyy'`). Additional values for `DateFormNum` are as follows:

| DateFormNum | Example  |
|-------------|----------|
| 2           | 03/01/00 |
| 3           | Mar      |

| DateFormNum | Example    |
|-------------|------------|
| 5           | 03         |
| 6           | 03/01      |

| 28          | Mar2000    |
| 29          | 2000-03-01 |

Data Types: char | double

## Output Arguments

### **h** — Handles to line objects

vector

Handles to line objects, returned as a NINST-by-3 matrix of handles to line objects, containing [hLines, hUArrowHead, hDArrowHead] where:

- hLines — Horizontal and vertical lines used in the cash flow diagram
- hUArrowHead — "Up" arrowheads
- hDArrowHead — "Down" arrowheads

### **axes\_handle** — Handles to axes for plot or subplots

vector

Handles to axes for the plot or subplots, returned as a (Number of axes)-by-1 vector of handles to axes.

**Introduced in R2013a**

## cfport

Portfolio form of cash flow amounts

### Syntax

```
[CFBondDate,AllDates,AllTF,IndByBond] = cfport(CFlowAmounts,CFlowDates)
[CFBondDate,AllDates,AllTF,IndByBond] = cfport( ____,TFactors)
```

### Description

[CFBondDate,AllDates,AllTF,IndByBond] = cfport(CFlowAmounts,CFlowDates) computes a vector of all cash flow dates of a bond portfolio, and a matrix mapping the cash flows of each bond to those dates. Use the matrix for pricing the bonds against a curve of discount factors.

[CFBondDate,AllDates,AllTF,IndByBond] = cfport( \_\_\_\_,TFactors) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Price for a Cash Flow Given Yield to Maturity

Use `cfprice` to compute the price for a cash flow given yield to maturity.

Define data for the yield curve.

```
Settle = datenum('01-Jul-2003');
Yield = .05;
CFAmounts = [30;40;30];
CFDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});
```

Compute the Price.

```
Price = cfprice(CFAmounts, CFDates, Yield, Settle)
```

```
Price = 3×1
```

```
28.4999
36.1689
25.8195
```

#### Compute the Price for a Cash Flow Given Yield to Maturity Using datetime Inputs

Use `cfprice` to compute the price for a cash flow given yield to maturity using `datetime` inputs.

```
Settle = datenum('01-Jul-2003');
Yield = .05;
CFAmounts = [30;40;30];
```

```
CFDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});
CFDates = datetime(CFDates, 'ConvertFrom', 'datenum', 'Locale', 'en_US');
Settle = datetime(Settle, 'ConvertFrom', 'datenum', 'Locale', 'en_US');
Price = cfprice(CFAmounts, CFDates, Yield, Settle)

Price = 3×1

    28.4999
    36.1689
    25.8195
```

## Input Arguments

### CFAmounts — Cash flow amounts

matrix

Cash flow amounts, specified as number of bonds (NUMBONDS) by number of cash flows (NUMCFS) matrix with entries listing cash flow amounts corresponding to each date in CFflowDates.

Data Types: double

### CFflowDates — Cash flow dates

serial date numbers | date character vector | datetime array

Cash flow dates, specified as an NUMBONDS-by-NUMCFS matrix with rows listing cash flow dates using a serial date number, date character vector, or datetime array, for each bond and padded with NaNs. If CFflowDates is a serial date number or a date character vector, AllDates is returned as an array of serial date numbers. If CFflowDates is a datetime array, then AllDates is returned as a datetime array.

Data Types: double

### TFactors — Time between settlement and the cash flow date

matrix

(Optional) Time between settlement and the cash flow date, specified as an NUMBONDS-by-NUMCFS matrix with entries listing the time between settlement and the cash flow date measured in semiannual coupon periods.

Data Types: double

## Output Arguments

### CFBondDate — Cash flows indexed by bond and by date

matrix

Cash flows indexed by bond and by date, returned as an NUMBONDS by number of dates (NUMDATES) matrix. Each row contains a bond's cash flow values at the indices corresponding to entries in AllDates. Other indices in the row contain zeros.

### AllDates — List of all dates that have any cash flow from the bond portfolio

matrix

List of all dates that have any cash flow from the bond portfolio, returned as an NUMDATES-by-1 matrix. The AllDates matrix is expressed in serial date format (default) or datetime format (if CFflowDates is in datetime format).

### **AllTF — Time factors corresponding to the dates in AllDates**

matrix

Time factors corresponding to the dates in AllDates, returned as an NUMDATES-by-1 matrix. If TFactors is not entered, AllTF contains the number of days from the first date in AllDates.

### **IndByBond — Indices by bond**

matrix

Indices by bond, returned as an NUMBONDS-by-NUMCFS matrix. The *ith* row contains a list of indices into AllDates where the *ith* bond has cash flows. Since some bonds have more cash flows than others, the matrix is padded with NaNs.

## cfprice

Compute price for cash flow given yield to maturity

### Syntax

```
Price = cfprice(CFlowAmounts,CFlowDates,Yield,Settle)
Price = cfprice( ____,Name,Value)
```

### Description

Price = cfprice(CFlowAmounts,CFlowDates,Yield,Settle) computes a price given yield for a cash flow.

Price = cfprice( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Price for a Cash Flow Given Yield to Maturity

Use cfprice to compute the price for a cash flow given yield to maturity.

Define data for the yield curve.

```
Settle = datenum('01-Jul-2003');
Yield = .05;
CFAmounts = [30;40;30];
CFDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});
```

Compute the Price.

```
Price = cfprice(CFAmounts, CFDates, Yield, Settle)
```

```
Price = 3×1
```

```
28.4999
36.1689
25.8195
```

#### Compute the Price for a Cash Flow Given Yield to Maturity Using datetime Inputs

Use cfprice to compute the price for a cash flow given yield to maturity using datetime inputs.

```
Settle = datenum('01-Jul-2003');
Yield = .05;
CFAmounts = [30;40;30];
CFDates = datetime({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});
```

```
CFDates = datetime(CFDates, 'ConvertFrom', 'datenum', 'Locale', 'en_US');
Settle = datetime(Settle, 'ConvertFrom', 'datenum', 'Locale', 'en_US');
Price = cfprice(CFAmounts, CFDates, Yield, Settle)
```

```
Price = 3×1
```

```
28.4999
36.1689
25.8195
```

## Input Arguments

### CFlowAmounts — Cash flow amounts

vector

Cash flow amounts, specified as an NINST-by-MOSTCFS matrix. Each row is a list of cash flow values for one instrument. If an instrument has fewer than MOSTCFS cash flows, the end of the row is padded with NaNs.

Data Types: double

### CFlowDates — Cash flow dates

serial date number | date character vector | datetime array

Cash flow dates, specified as an NINST-by-MOSTCFS matrix. Each entry contains the date of the corresponding cash flow in CFlowAmounts.

Data Types: double | char | datetime

### Yield — Yields

vector

Yields specified as an NINST-by-1 vector.

Data Types: double

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. The Settle date is the date on which the cash flows are priced.

Data Types: double | char | cell

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

---

**Note** An optional input of size NINST-by-1 is also acceptable as a single value applicable to all contracts. Single values are internally expanded to an array of size NINST-by-1.

---

Example: `Price = cfprice(CFlowAmounts,CFlowDates,Yield,Settle,'Basis',4,'CompoundingFrequency',4)`

### **Basis — Day-count basis**

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a N-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

### **CompoundingFrequency — Compounding frequency**

2 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Compounding frequency, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a positive integer using a N-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

### **CompoundingFrequency — Compounding frequency**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

## **Output Arguments**

### **Price — Price of cash flows**

vector

Price of cash flows, returned as an NINST-by-1 vector.

## **See Also**

## cfspread

Compute spread over yield curve for cash flow

### Syntax

```
Spread = cfspread(RateSpec,Price,CFlowAmounts,CFlowDates,Settle)
Spread = cfspread( ____,Name,Value)
```

### Description

`Spread = cfspread(RateSpec,Price,CFlowAmounts,CFlowDates,Settle)` computes spread over a yield curve for a cash flow.

`Spread = cfspread( ____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute Spread Over a Yield Curve for a Cash Flow

Use `cfspread` to compute the spread over a yield curve for a cash flow.

Define data for the yield curve.

```
Settle = datenum('01-Jul-2003');
CurveDates = daysadd(Settle,360* [.25 .5 1 2 3 5 7 10 20],1);
ZeroRates = [.0089 .0096 .0107 .0130 .0166 .0248 .0306 .0356 .0454]';
```

Compute the `RateSpec`.

```
RateSpec = intenvset('StartDates', Settle, 'EndDates', CurveDates, ...
    'Rates', ZeroRates)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: [9x1 double]
    Rates: [9x1 double]
    EndTimes: [9x1 double]
    StartTimes: [9x1 double]
    EndDates: [9x1 double]
    StartDates: 731763
    ValuationDate: 731763
    Basis: 0
    EndMonthRule: 1
```

Compute the spread.

```
Price = 98;
CFAmounts = [30;40;30];
```

```
CFDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});
Spread = cfspread(RateSpec, Price, CFAmounts, CFDates, Settle)

Spread = 3×1
103 ×

    -8.7956
    -4.0774
    -3.7073
```

### Compute Spread Over a Yield Curve for a Cash Flow Using datetime Inputs

Use `cfspread` to compute the spread over a yield curve for a cash flow using `datetime` inputs.

```
Settle = datenum('01-Jul-2003');
CurveDates = daysadd(Settle,360* [.25 .5 1 2 3 5 7 10 20],1);
ZeroRates = [.0089 .0096 .0107 .0130 .0166 .0248 .0306 .0356 .0454]';
RateSpec = intenvset('StartDates', Settle, 'EndDates', CurveDates, ...
    'Rates', ZeroRates);
Price = 98;
CFAmounts = [30;40;30];
CFDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});

CFDates = datetime(CFDates,'ConvertFrom','datenum','Locale','en_US');
Settle = datetime(Settle,'ConvertFrom','datenum','Locale','en_US');
Spread = cfspread(RateSpec, Price, CFAmounts, CFDates, Settle)

Spread = 3×1
103 ×

    -8.7956
    -4.0774
    -3.7073
```

## Input Arguments

### RateSpec — Interest-rate specification for initial risk-free rate curve

structure

Interest-rate specification for initial risk-free rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### Price — Price of cash flows

vector

Price of cash flows, specified as an NINST-by-1 vector.

Data Types: `double`

**CFlowAmounts — Cash flow amounts**

vector

Cash flow amounts, specified as an NINST-by-MOSTCFS matrix . Each row is a list of cash flow values for one instrument. If an instrument has fewer than MOSTCFS cash flows, the end of the row is padded with NaNs.

Data Types: double

**CFlowDates — Cash flow dates**

serial date number | date character vector | datetime array

Cash flow dates, specified as an NINST-by-MOSTCFS matrix . Each entry contains the date of the corresponding cash flow in CFlowAmounts.

Data Types: double | char | datetime

**Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NINST-by-1 vector using serial date numbers or a cell array of date character vectors. The Settle date is the date on which the cash flows are priced.

Data Types: double | char | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

---

**Note** An optional input of size NINST-by-1 is also acceptable as a single value applicable to all contracts. Single values are internally expanded to an array of size NINST-by-1.

---

Example: Spread =  
`cfspread(RateSpec, Price, CFlowAmounts, CFlowDates, Settle, 'Basis', 4)`

**Basis — Day-count basis**

0 (actual/actual) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

## Output Arguments

### **Spread — Spread of cash flows over a zero curve**

vector

Spread of cash flows over a zero curve, returned as an NINST-by-1 vector. The Spread is expressed in basis points.

### **See Also**

cfbyzero | cfprice | cfyield | datetime

### **Topics**

“Analyzing and Computing Cash Flows” on page 2-14

### **Introduced in R2012a**

## cfyield

Compute yield to maturity for cash flow given price

### Syntax

```
Yield = cfyield(CFlowAmounts,CFlowDates,Price,Settle)
Yield = cfyield( ____,Name,Value)
```

### Description

Yield = cfyield(CFlowAmounts,CFlowDates,Price,Settle) computes yield to maturity for a cash flow given price.

Yield = cfyield( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Yield to Maturity for a Cash Flow When Given a Price

Use cfyield to compute yield to maturity for a cash flow when given a price.

Define data for the yield curve and price.

```
Settle = datenum('01-Jul-2003');
Price = 98;
CFlowAmounts = [30 40 30];
CFlowDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'})';
```

Compute the Yield.

```
Yield = cfyield(CFlowAmounts, CFlowDates, Price, Settle)

Yield = 0.0099
```

#### Compute the Yield to Maturity for a Cash Flow When Given a Price Using datetime Inputs

Use cfyield to compute yield to maturity for a cash flow, when given a price using datetime inputs.

```
Settle = datenum('01-Jul-2003');
Price = 98;
CFlowAmounts = [30 40 30];
CFlowDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'})';

CFlowDates = datetime(CFlowDates,'ConvertFrom','datenum','Locale','en_US');
Settle = datetime(Settle,'ConvertFrom','datenum','Locale','en_US');
Yield = cfyield(CFlowAmounts, CFlowDates, Price, Settle)
```

Yield = 0.0099

## Input Arguments

### CFlowAmounts — Cash flow amounts

vector

Cash flow amounts, specified as an NINST-by-MOSTCFS matrix. Each row is a list of cash flow values for one instrument. If an instrument has fewer than MOSTCFS cash flows, the end of the row is padded with NaNs.

Data Types: double

### CFlowDates — Cash flow dates

serial date number | date character vector | datetime array

Cash flow dates, specified as an NINST-by-MOSTCFS matrix. Each entry contains the date of the corresponding cash flow in CFlowAmounts.

Data Types: double | char | datetime

### Price — Prices

vector

Prices specified as an NINST-by-1 vector.

Data Types: double

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. The Settle date is the date on which the cash flows are priced.

Data Types: double | char | cell

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

---

**Note** An optional input of size NINST-by-1 is also acceptable as a single value applicable to all contracts. Single values are internally expanded to an array of size NINST-by-1.

---

Example: Yield =

```
cfyield(CFAmounts,CFDates,Yield,Settle,'Basis',4,'CompoundingFrequency',4)
```

### Basis — Day-count basis

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a N-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

### **CompoundingFrequency — Compounding frequency**

2 (actual/actual) (default) | positive integers of the set [1 . . . 13] | vector of positive integers of the set [1 . . . 13]

Compounding frequency, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a positive integer using a N-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

**CompoundingFrequency — Compounding frequency**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**Output Arguments****Yield — Yield for cash flows**

vector

Yield for cash flows, returned as an NINST-by-1 vector.

## cftimes

Time factors corresponding to bond cash flow dates

### Syntax

```
[TFactors] = cftimes(Settle,Maturity)
[TFactors] =
cftimes(Settle,Maturity,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate,StartDate)
[TFactors] = cftimes(Settle,Maturity,'ParameterName',ParameterValue, ...)
```

### Description

`[TFactors] = cftimes(Settle,Maturity)` determines the time factors corresponding to the cash flows of a bond or set of bonds.

`cftimes` computes the time factor of a cash flow, which is the difference between the settlement date and the cash flow date, in units of semiannual coupon periods. In computing time factors, use SIA actual/actual day count conventions for all time factor calculations.

`[TFactors] = cftimes(Settle,Maturity,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate,StartDate)` determines the time factors corresponding to the cash flows of a bond or set of bonds, including optional inputs.

`[TFactors] = cftimes(Settle,Maturity,'ParameterName',ParameterValue, ...)` accepts optional inputs as one or more comma-separated parameter/value pairs. *ParameterName* is the name of the parameter inside single quotes. *ParameterValue* is the value corresponding to *ParameterName*. Specify parameter/value pairs in any order. Names are case-insensitive.

### Input Arguments

#### Settle

Settlement date. A vector of serial date numbers, date character vectors, or datetime array. `Settle` must be earlier than `Maturity`.

#### Maturity

Maturity date. A vector of serial date numbers, date character vectors, or datetime array.

#### Ordered Input or Parameter-Value Pairs

Enter the following inputs using an ordered syntax or as parameter/value pairs. You cannot mix ordered syntax with parameter/value pairs.

#### Period

Coupons per year of the bond. A vector of integers. Values are 0, 1, 2, 3, 4, 6, and 12.

**Default:** 2

**Basis**

Day-count basis of the instrument. A vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

**Default:** 0

**EndMonthRule**

End-of-month rule. A vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month. 1 = set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

**Default:** 1

**IssueDate**

Issue date, specified as a serial date number, date character vector, or datetime array, for a bond.

**FirstCouponDate**

Date, specified as a serial date number, date character vector, or datetime array, when a bond makes its first coupon payment. `FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure.

**Default:** If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

**LastCouponDate**

Last coupon date of a bond before the maturity date, specified as a serial date number, date character vector, or datetime array. `LastCouponDate` is used when bond has an irregular last coupon period.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

**Default:** If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

### StartDate

Date when a bond actually starts (the date from which a bond cash flow is considered), specified as a serial date number, date character vector, or datetime array. To make an instrument forward-starting, specify this date as a future date. If you do not specify `StartDate`, the effective start date is the `Settle` date.

### Parameter-Value Pairs

Enter the following inputs only as parameter/value pairs.

### CompoundingFrequency

Compounding frequency for yield calculation. By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

### DiscountBasis

Basis used to compute the discount factors for computing the yield. The default behavior is for SIA bases to use the actual/actual day count to compute discount factors. If you use ICMA day counts and BUS/252, the specified bases are used.

## Output Arguments

### TFactors

`TFactors` has `NUMBONDS` rows and the number of columns is determined by the maximum number of cash flow payment dates required to hold the bond portfolio. `NaNs` are padded for bonds which have less than the maximum number of cash flow payment dates.

## Examples

### Compute the Time Factor of a Cash Flow

This example shows how to calculate a cash flow time factor.

```
Settle = '15-Mar-1997';
Maturity = '01-Sep-1999';
Period = 2;
TFactors = cftimes(Settle, Maturity, Period)
```

```
TFactors = 1x5
```

```
    0.9239    1.9239    2.9239    3.9239    4.9239
```

## chiakosc

Chaikin oscillator

---

**Note** `chaikosc` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
chosc = chaikocs(Data)
```

### Description

`chosc = chaikocs(Data)` calculates the Chaikin oscillator.

### Examples

#### Calculate the Chaikin Oscillator for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
oscillator = chaikosc(TMW);
plot(oscillator.Time, oscillator.ChaikinOscillator)
title('Chaikin Oscillator for TMW')
```

## Input Arguments

### Data — Data with high, low, open, close information

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-4 matrix of high, low, opening, and closing prices. Timetables and tables with M rows must contain variables named 'High', 'Low', 'Open', and 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### chosc — Chaikin oscillator

matrix | table | timetable

Chaikin oscillator, returned with the same number of rows (M) and type (matrix, table, or timetable) as the input Data.

# chaikvolat

Chaikin volatility

---

**Note** chaikvolat has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
volatility = chaikvolat(Data)
volatility = chaikvolat(___,Name,Value)
```

## Description

`volatility = chaikvolat(Data)` calculates the Chaikin volatility from a data series of high and low stock prices.

`volatility = chaikvolat(___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Chaikin Volatility for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
volatility = chaikvolat(TMW,'NumPeriods',14,'WindowSize',14);
plot(volatility.Time,volatility.ChaikinVolatility)
title('Chaikin Volatility for TMW')
```

## Input Arguments

### Data — Data with high, low, open, close information

matrix | table | timetable

Data with high, low, open, close information, specified as a vector, matrix, table, or timetable. For matrix input, `Data` is an M-by-2 matrix of high and low prices stored in the first and second columns. Timetables and tables with M rows must contain variables named 'High' and 'Low' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `volatility = chaikvolat(TMW, 'NumPeriods', 10, 'WindowSize', 10)`

### NumPeriods — Period difference

10 (default) | positive integer

Period difference, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

### **WindowSize — Length of the exponential moving average in periods**

10 (default) | positive integer

Length of the exponential moving average in periods, specified as the comma-separated pair consisting of 'WindowSize' and a scalar positive integer.

Data Types: double

## **Output Arguments**

### **volatility — Chaikin volatility**

matrix | table | timetable

Chaikin volatility, returned with the same number of rows (**M**) and the same type (matrix, table, or timetable) as the input **Data**.

## **More About**

### **Chaikin volatility**

Chaikin volatility calculates the Chaikin's volatility from the series of high and low stock prices.

By default, Chaikin's volatility values are based on a 10-period exponential moving average and 10-period difference.

## **References**

[1] Achelis, S. B. *Technical Analysis from A to Z*. Second Edition. McGraw-Hill, 1995, pp. 304–305.

## chartfts

Interactive display

---

**Note** `chartfts` will be removed in a future release and will no longer accept a `fints` object.

Use `fts2timetable` to convert a `fints` object to a `timetable` object. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
chartfts(tsobj)
```

### Description

`chartfts(tsobj)` produces a figure window that contains one or more plots. You can use the mouse to observe the data at a particular time point of the plot.

---

**Note** **Help** menu item is not available for `chartfts` in MATLAB Online.

---

### Examples

Create a financial time series object from the supplied data file `ibm9599.dat`:

```
ibmfts = ascii2fts('ibm9599.dat', 1, 3, 2);
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In ascii2fts (line 64)
```

Chart the financial time series object `ibmfts`:

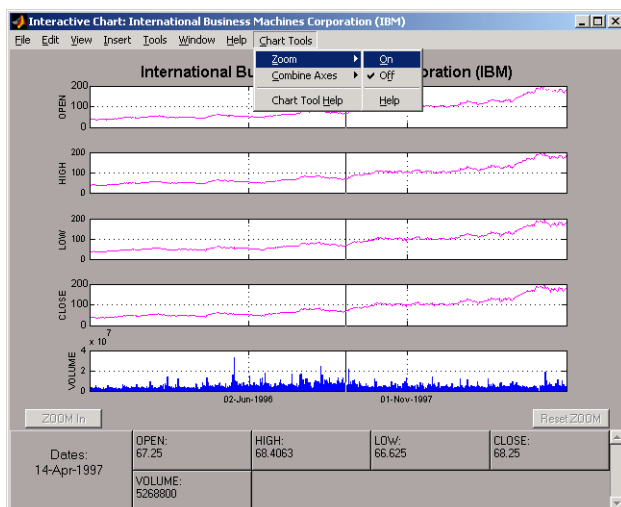

```
chartfts(ibmfts)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/chartfts (line 24)
```

With the **Zoom** feature set off, a mouse click on the indicator line displays object data in a pop-up box.

With the **Zoom** feature set on, mouse clicks indicate the area of the chart to zoom.

You can find a tutorial on using chartfts in “Visualizing Financial Time Series Objects” on page 11-24. See “Zoom Tool” on page 11-26 for details on performing the zoom. Also see “Combine Axes Tool” on page 11-29 for information about combining axes for specified plots.

## checkFeasibility

Check feasibility of input portfolios against portfolio object

### Syntax

```
status = checkFeasibility(obj,pwgt)
```

### Description

Use the `checkFeasibility` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to check the feasibility of input portfolios against a portfolio object.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`status = checkFeasibility(obj,pwgt)` checks the feasibility of input portfolios against a portfolio object.

### Examples

#### Determine if the Portfolio Is Feasible for a Portfolio Object

Given portfolio `p`, determine if `p` is feasible.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);

checkFeasibility(p, pwgt)

ans = 1x10 logical array

     1     1     1     1     1     1     1     1     1     1
```

#### Determine if the Portfolio Is Feasible for a PortfolioCVaR Object

Given portfolio `p`, determine if `p` is feasible.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
```

```

    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontier(p);

checkFeasibility(p, pwgt)

ans = 1x10 logical array

    1    1    1    1    1    1    1    1    1    1

```

### Determine if the Portfolio Is Feasible for a PortfolioMAD Object

Given portfolio p, determine if p is feasible.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontier(p);

checkFeasibility(p, pwgt)

ans = 1x10 logical array

    1    1    1    1    1    1    1    1    1    1

```

### Input Arguments

**obj** — Object for portfolio  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

### **pwgt — Portfolios to check**

matrix

Portfolios to check, specified as a NumAssets-by-NumPorts matrix.

Data Types: `double`

## **Output Arguments**

### **status — Indicator if portfolio is feasible**

row vector

Indicator if portfolio is feasible, returned as a row vector of NumPorts indicators that are `true` if portfolio is feasible and `false` otherwise.

---

**Note** By definition, any portfolio set must be nonempty and bounded. If the set is empty, no portfolios can be feasible. Use `estimateBounds` to test for nonempty and bounded sets.

---

Feasibility status is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## **Tips**

- You can also use dot notation to check the feasibility of input portfolios against a portfolio object.
 

```
status = obj.checkFeasibility(pwgt);
```
- The constraint tolerance to assess whether a constraint is satisfied is obtained from the hidden property `obj.defaultTolCon`.

## chfield

Change data series name

---

**Note** `chfield` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = chfield(oldfts,oldname,newname)
```

### Arguments

|                      |                                                                                                         |
|----------------------|---------------------------------------------------------------------------------------------------------|
| <code>oldfts</code>  | Name of an existing financial time series object.                                                       |
| <code>oldname</code> | Name of the existing component in <code>oldfts</code> . A MATLAB character vector or column cell array. |
| <code>newname</code> | New name for the component in <code>oldfts</code> . A MATLAB character vector or column cell array.     |

### Description

`newfts = chfield(oldfts,oldname,newname)` changes the name of the financial time series object component from `oldname` to `newname`.

Set `newfts = oldfts` to change the name of an existing component without changing the name of the financial time series object.

To change the names of several components at once, specify the series of old and new component names in corresponding column cell arrays.

You cannot change the names of the object components `desc`, `freq`, and `dates`.

# convert2sur

Convert multivariate normal regression model to seemingly unrelated regression (SUR) model

## Syntax

```
DesignSUR = convert2sur(Design,Group)
```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Design | <p>A matrix or a cell array that depends on the number of data series <code>NUMSERIES</code>.</p> <ul style="list-style-type: none"> <li>• If <code>NUMSERIES = 1</code>, <code>convert2sur</code> returns the <code>Design</code> matrix.</li> <li>• If <code>NUMSERIES &gt; 1</code>, <code>Design</code> is a cell array with <code>NUMSAMPLES</code> cells, where each cell contains a <code>NUMSERIES</code>-by-<code>NUMPARAMS</code> matrix of known values.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Group  | <p>Contains information about how data series are to be grouped, with separate parameters for each group. Specify groups either by series or by groups:</p> <ul style="list-style-type: none"> <li>• To identify groups by series, construct an index vector that has <code>NUMSERIES</code> elements. Element <math>i = 1, \dots, \text{NUMSERIES}</math> in the vector, and has the index <math>j = 1, \dots, \text{NUMGROUPS}</math> of the group in which series <math>i</math> is a member.</li> <li>• To identify groups by groups, construct a cell array with <code>NUMGROUPS</code> elements. Each cell contains a vector with the indexes of the series that populate a given group.</li> </ul> <p>In either case, the number of series is <code>NUMSERIES</code> and the number of groups is <code>NUMGROUPS</code>, with <math>1 \leq \text{NUMGROUPS} \leq \text{NUMSERIES}</math>.</p> |

## Description

`DesignSUR = convert2sur(Design,Group)` converts a multivariate normal regression model into a seemingly unrelated regression model with a specified grouping of the data series. `DesignSUR` is either a matrix or a cell array that depends on the value of `NUMSERIES`:

- If `NUMSERIES = 1`, `DesignSUR = Design`, which is a `NUMSAMPLES`-by-`NUMPARAMS` matrix.
- If `NUMSERIES > 1` and `NUMGROUPS` groups are to be formed, `Design` is a cell array with `NUMSAMPLES` cells, where each cell contains a `NUMSERIES`-by- $(\text{NUMGROUPS} * \text{NUMPARAMS})$  matrix of known values.

The original collection of parameters that are common to all series are replicated to form collections of parameters for each group.

## Examples

### Use `convert2sur` to Estimate Stock Alpha and Beta Values

This example shows a CAPM demonstration using 6 stocks and 60 months of simulated asset returns, where the model for each stock is  $\text{AssetReturn} = \text{Alpha} * 1 + \text{CashReturn} + \text{Beta} * (\text{MarketReturn} - \text{CashReturn}) + \text{Noise}$  and the parameters to estimate are Alpha and Beta.

Using simulated data, where the Alpha estimate(s) are displayed in the first row(s) and the Beta estimate(s) are display in the second row(s).

```
Market = (0.1 - 0.04) + 0.17*randn(60, 1);
Asset = (0.1 - 0.04) + 0.35*randn(60, 6);

Design = cell(60, 1);
for i = 1:60
    Design{i} = repmat([ 1, Market(i) ], 6, 1);
end
```

Obtain the aggregate estimates for all stocks.

```
[Param, Covar] = mvnrml(Asset, Design);

disp({'All 6 Assets Combined'});
    {'All 6 Assets Combined'}

disp(Param);
    0.0233
    0.1050
```

Estimate parameters for individual stocks using `convert2sur`

```
Group = 1:6;
DesignSUR = convert2sur(Design, Group);
[Param, Covar] = mvnrml(Asset, DesignSUR);
Param = reshape(Param, 2, 6);

disp({'A', 'B', 'C', 'D', 'E', 'F'});
    {'A'}    {'B'}    {'C'}    {'D'}    {'E'}    {'F'}

disp(Param);
    0.0144    0.0270    0.0046    0.0419    0.0376    0.0291
    0.3264   -0.1716    0.3248   -0.0630   -0.0001    0.0637
```

Estimate parameters for pairs of stocks by forming groups.

```
disp({'A & B', 'C & D', 'E & F'});
    {'A & B'}    {'C & D'}    {'E & F'}

Group = { [1,2 ], [3,4], [5,6]};
DesignSUR = convert2sur(Design, Group);
[Param, Covar] = mvnrml(Asset, DesignSUR);

Param = reshape(Param, 2, 3);

disp(Param);
```

## Introduced in R2006a

## convertto

Convert to specified frequency

---

**Note** `convertto` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to `Timetables`”.

---

### Syntax

```
newfts = convertto(oldfts,newfreq)
```

```
newfts = convertto(oldfts,newfreq,'param1','value1','param2','value2', ... )
```

### Arguments

|                      |                                                                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>oldfts</code>  | Name of an existing financial time series object.                                                                                                                                                                                   |
| <code>newfreq</code> | 1, DAILY, Daily, daily, D, d<br>2, WEEKLY, Weekly, weekly, W, w<br>3, MONTHLY, Monthly, monthly, M, m<br>4, QUARTERLY, Quarterly, quarterly, Q, q<br>5, SEMIANNUAL, Semiannual, semiannual, S, s<br>6, ANNUAL, Annual, annual, A, a |

### Description

`convertto` converts a financial time series of any frequency to one of a specified frequency.

`newfts = convertto(oldfts,newfreq)` converts the object `oldfts` to the new time series object `newfts` with the frequency `newfreq`.

Refer to the documentation for each frequency conversion function to determine the valid parameter/value pairs.

# corrcoef

Correlation coefficients

---

**Note** `corrcoef` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

`r = corrcoef(X)`

`r = corrcoef(X,Y)`

## Arguments

|   |                                                                        |
|---|------------------------------------------------------------------------|
| X | Matrix where each row is an observation and each column is a variable. |
| Y | Matrix where each row is an observation and each column is a variable. |

## Description

`corrcoef` is based on the MATLAB `corrcoef` function. See `corrcoef`.

`r=corrcoef(X)` calculates a matrix `r` of correlation coefficients for an array `X`, in which each row is an observation, and each column is a variable.

`r=corrcoef(X,Y)`, where `X` and `Y` are column vectors, is the same as `r=corrcoef([X Y])`. `corrcoef` converts `X` and `Y` to column vectors if they are not; that is, `r = corrcoef(X,Y)` is equivalent to `r=corrcoef([X(:) Y(:)])` in that case.

If `c` is the covariance matrix, `c= cov(X)`, then `corrcoef(X)` is the matrix whose  $(i, j)$  'th element is  $c_{i, j}/\sqrt{c_{i, i}*c_{j, j}}$ .

`[r,p]=corrcoef(...)` also returns `p`, a matrix of `p`-values for testing the hypothesis of no correlation. Each `p`-value is the probability of getting a correlation as large as the observed value by random chance, when the true correlation is zero. If `p(i, j)` is less than 0.05, then the correlation `r(i, j)` is significant.

`[r,p,rlo,rup]=corrcoef(...)` also returns matrices `rlo` and `rup`, of the same size as `r`, containing lower and upper bounds for a 95% confidence interval for each coefficient.

`[...]=corrcoef(..., 'PARAM1', VAL1, 'PARAM2', VAL2, ...)` specifies additional parameters and their values. Valid parameters are:

- `'alpha'` — A number from 0 through 1 to specify a confidence level of  $100*(1-ALPHA)\%$ . Default is 0.05 for 95% confidence intervals.
- `'rows'` — Either `'all'` (default) to use all rows, `'complete'` to use rows with no NaN values, or `'pairwise'` to compute `r(i, j)` using rows with no NaN values in column `i` or `j`.

The `p`-value is computed by transforming the correlation to create a `t`-statistic having `N - 2` degrees of freedom, where `N` is the number of rows of `X`. The confidence bounds are based on an asymptotic

normal distribution of  $0.5 \cdot \log((1 + r)/(1 - r))$ , with an approximate variance equal to  $1/(N - 3)$ . These bounds are accurate for large samples when  $X$  has a multivariate normal distribution. The 'pairwise' option can produce an  $r$  matrix that is not positive definite.

## Examples

### Compute Correlation Coefficients

This example shows how to generate random data having correlation between column 4 and the other columns.

```
x = randn(30,4);           % uncorrelated data
x(:,4) = sum(x,2);        % introduce correlation
f = fints('today:today+29', x); % create a fints object using x
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
[r,p] = corrcoef(x);      % compute sample correlation and p-values
[i,j] = find(p<0.05);    % find significant correlations
[i,j]
```

```
ans = 4x2
```

```
     4     1
     3     2
     2     3
     1     4
```

Class support for inputs X,Y: float: double and single.

## corr2cov

Convert standard deviation and correlation to covariance

### Syntax

```
ExpCovariance = corr2cov(ExpSigma)
ExpCovariance = corr2cov( ____, ExpCorrC)
```

### Description

`ExpCovariance = corr2cov(ExpSigma)` converts standard deviation and correlation to covariance.

`ExpCovariance = corr2cov( ____, ExpCorrC)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Convert Standard Deviation and Correlation to Covariance

This example shows how to convert standard deviation and correlation to covariance.

```
ExpSigma = [0.5  2.0];
ExpCorrC = [1.0 -0.5
            -0.5  1.0];

ExpCovariance = corr2cov(ExpSigma, ExpCorrC)

ExpCovariance = 2×2

    0.2500    -0.5000
   -0.5000    4.0000
```

### Input Arguments

#### ExpSigma — Standard deviations of each process

vector

Standard deviations of each process, specified as a vector of length *n* with the standard deviations of each process. *n* is the number of random processes.

Data Types: double

#### ExpCorrC — Correlation matrix

matrix

(Optional) Correlation matrix, specified as an n-by-n correlation coefficient matrix. A correlation coefficient is a statistic in which the covariance is scaled to a value between minus one (perfect negative correlation) and plus one (perfect positive correlation).

If `ExpCorrC` is not specified, the processes are assumed to be uncorrelated, and the identity matrix is used.

Data Types: double

## Output Arguments

### **ExpCovariance — Covariance matrix**

matrix

Covariance matrix, returned as an n-by-n covariance matrix, where n is the number of processes.

The  $(i,j)$  entry is the expectation of the  $i$ 'th fluctuation from the mean times the  $j$ 'th fluctuation from the mean.

$\text{ExpCov}(i,j) = \text{ExpCorrC}(i,j) * \text{ExpSigma}(i) * \text{ExpSigma}(j)$

## See Also

## COV

Covariance matrix for financial times series object

---

**Note** `cov` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

`cov(X)`

`cov(X,Y)`

### Arguments

|   |                                |
|---|--------------------------------|
| X | Financial times series object. |
| Y | Financial times series object. |

### Description

`cov` for financial time series objects is based on the MATLAB `cov` function. See `cov`.

If `X` is a financial time series object with one series, `cov(X)` returns the variance. For a financial time series object containing multiple series, where each row is an observation, and each series a variable, `cov(X)` is the covariance matrix.

`diag(cov(X))` is a vector of variances for each series and `sqrt(diag(cov(X)))` is a vector of standard deviations.

`cov(X, Y)`, where `X` and `Y` are financial time series objects with the same number of elements, is equivalent to `cov([X(:) Y(:)])`.

`cov(X)` or `cov(X, Y)` normalizes by  $(N - 1)$  if  $N > 1$ , where  $N$  is the number of observations. This makes `cov(X)` the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For  $N = 1$ , `cov` normalizes by  $N$ .

`cov(X, 1)` or `cov(X, Y, 1)` normalizes by  $N$  and produces the second moment matrix of the observations about their mean. `cov(X, Y, 0)` is the same as `cov(X, Y)` and `cov(X, 0)` is the same as `cov(X)`. The mean is removed from each column before calculating the result.

### Examples

#### Create a Covariance Matrix

This example shows how to create a covariance matrix for the following dates.

```
dates = {'01-Jan-2007'; '02-Jan-2007'; '03-Jan-2007'};  
A = [-1 1 2 ; -2 3 1 ; 4 0 3];  
f = fints(dates, A);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
c = cov(f)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
c = 3×3
```

```
10.3333    -4.1667     3.0000  
-4.1667     2.3333    -1.5000  
 3.0000    -1.5000     1.0000
```

## cov2corr

Convert covariance to standard deviation and correlation coefficient

### Syntax

```
[ExpSigma,ExpCorrC] = cov2corr(ExpCovariance)
```

### Description

[ExpSigma,ExpCorrC] = cov2corr(ExpCovariance) converts covariance to standard deviations and correlation coefficients.

### Examples

#### Convert Covariance to Standard Deviations and Correlation Coefficients

This example shows how to convert a covariance matrix to standard deviations and correlation coefficients.

```
ExpCovariance = [0.25 -0.5
                 -0.5  4.0];
```

```
[ExpSigma, ExpCorrC] = cov2corr(ExpCovariance)
```

```
ExpSigma = 1×2
```

```
    0.5000    2.0000
```

```
ExpCorrC = 2×2
```

```
    1.0000   -0.5000
   -0.5000    1.0000
```

### Input Arguments

#### ExpCovariance — Covariance matrix

matrix

Covariance matrix, specified as an n-by-n covariance matrix, where n is the number of random processes. For an example, see cov or ewstats.

Data Types: double

### Output Arguments

#### ExpSigma — Standard deviation of each process

vector

Standard deviation of each process, returned as an 1-by-n vector.

The entries of `ExpCorrC` range from 1 (completely correlated) to -1 (completely anti-correlated). A value of 0 in the  $(i,j)$  entry indicates that the  $i$ 'th and  $j$ 'th processes are uncorrelated.

```
ExpSigma(i) = sqrt( ExpCovariance(i,i) );  
ExpCorrC(i,j) = ExpCovariance(i,j)/( ExpSigma(i)*ExpSigma(j) );
```

Data Types: double

### **ExpCorrC – Correlation coefficients**

matrix

Correlation coefficients, returned as an n-by-n matrix.

# cpncount

Coupon payments remaining until maturity

## Syntax

```
NumCouponsRemaining = cpncount(Settle,Maturity)
NumCouponsRemaining = cpncount( ____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

## Description

`NumCouponsRemaining = cpncount(Settle,Maturity)` returns the whole number of coupon payments between the `Settle` and `Maturity` dates for a coupon bond or set of bonds. Coupons falling on or before `Settle` are not counted, except for the `Maturity` payment which is always counted.

Required input arguments must be number of bonds, `NUMBONDS-by-1` or `1-by-NUMBONDS`, conforming vectors or scalars.

`NumCouponsRemaining = cpncount( ____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the whole number of coupon payments between the `Settle` and `Maturity` dates for a coupon bond or set of bonds using optional input arguments.

Optional input arguments must be either `NUMBONDS-by-1` or `1-by-NUMBONDS` conforming vectors, scalars, or empty matrices.

## Examples

### Find Coupon Payments Remaining Until Maturity

This example shows how to find the coupon payments remaining until maturity.

```
NumCouponsRemaining = cpncount('14 Mar 1997', '30 Nov 2000',...
2, 0, 0)
```

```
NumCouponsRemaining = 8
```

### Find Coupon Payments Remaining Until Maturity for Different Maturity Dates

This example shows how to find the coupon payments remaining until maturity, given three coupon bonds with different maturity dates and the same default arguments.

```
Maturity = ['30 Sep 2000'; '31 Oct 2001'; '30 Nov 2002'];
NumCouponsRemaining = cpncount('14 Sep 1997', Maturity)
```

```
NumCouponsRemaining = 3×1
```

9  
11

## Input Arguments

### Settle — Settlement date

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. **Settle** must be earlier than **Maturity**.

Data Types: double | char | datetime

### Maturity — Maturity date

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Period — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: single | double

### Basis — Day-count basis of the bond

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the bond, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

### **EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [0, 1] or a using an N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

### **IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: `double` | `char` | `datetime`

### **FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

## Output Arguments

**NumCouponsRemaining** — Whole number of coupon payments between the settlement and maturity dates for a coupon bond or set of bonds

vector

Whole number of coupon payments between the settlement and maturity dates for a coupon bond or set of bonds, returned as an NBONDS-by-1 vector.

Coupons falling on or before settlement are not counted, except for the maturity payment which is always counted.

**Introduced before R2006a**

# cpndaten

Next coupon date for fixed-income security

## Syntax

```
NextCouponDate = cpndaten(Settle,Maturity)
NextCouponDate = cpndaten( ____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

## Description

`NextCouponDate = cpndaten(Settle,Maturity)` returns the next coupon date after the `Settle` date. This function finds the next coupon date whether or not the coupon structure is synchronized with the `Maturity` date.

Required input arguments must be number of bonds, `NUMBONDS-by-1` or `1-by-NUMBONDS`, conforming vectors or scalars.

`NextCouponDate = cpndaten( ____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the next coupon date after the `Settle` date using optional input arguments.

Optional input arguments must be either `NUMBONDS-by-1` or `1-by-NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NextCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NextCouponDate` is returned as a datetime array.

## Examples

### Calculate the Next Coupon Date After the Settlement Date

Determine the `NextCouponDate` when using character vectors for input arguments.

```
NextCouponDate = cpndaten('14-Mar-1997', '30-Nov-2000', 2, 0, 0);
datestr(NextCouponDate)
```

```
ans =
'30-May-1997'
```

Determine the `NextCouponDate` when using datetime arrays for input arguments.

```
NextCouponDate = cpndaten('14-Mar-1997', datetime('30-Nov-2000','Locale','en_US'),...
2, 0, 0)
```

```
NextCouponDate = datetime
    30-May-1997
```

Determine the `NextCouponDate` when using character vectors for input arguments and the optional argument for `EndMonthRule`.

```
NextCouponDate = cpndaten('14-Mar-1997', '30-Nov-2000', 2, 0, 1);
datestr(NextCouponDate)

ans =
'31-May-1997'
```

Determine the `NextCouponDate` when using an input vector for `Maturity`.

```
Maturity = ['30-Sep-2000'; '31-Oct-2000'; '30-Nov-2000'];
NextCouponDate = cpndaten('14-Mar-1997', Maturity);
datestr(NextCouponDate)

ans = 3x11 char array
    '31-Mar-1997'
    '30-Apr-1997'
    '31-May-1997'
```

## Input Arguments

### Settle — Settlement date

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. `Settle` must be earlier than `Maturity`.

Data Types: double | char | datetime

### Maturity — Maturity date

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Period — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: single | double

### Basis — Day-count basis of the bond

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the bond, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

### **EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [0, 1] or a using an N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

### **IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: `double` | `char` | `datetime`

### **FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## **Output Arguments**

### **NextCouponDate — Next coupon date after the settlement date**

vector

Next coupon date after the settlement date, returned as an NUMBONDS-by-1 vector of next actual coupon dates after settlement. If settlement is a coupon date, this function never returns the settlement date. Instead, the actual coupon date strictly after settlement is returned, but not exceeding the maturity date. Thus, this function will always return the lesser of the actual maturity date and the next coupon payment date.

If all the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are either serial date numbers or date character vectors, then NextCouponDate is returned as a serial date number. The function datestr converts a serial date number to a formatted date character vector.

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are datetime arrays, then NextCouponDate is returned as a datetime array.

## cpndatenq

Next quasi-coupon date for fixed-income security

### Syntax

```
NextQuasiCouponDate = cpndatenq(Settle,Maturity)
NextQuasiCouponDate = cpndatenq( ____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

### Description

`NextQuasiCouponDate = cpndatenq(Settle,Maturity)` determines the next quasi coupon date for a portfolio of `NUMBONDS` fixed income securities whether or not the first or last coupon is normal, short, or long. For zero coupon bonds, `cpndatenq` returns quasi coupon dates as if the bond had a semiannual coupon structure. Successive quasi coupon dates determine the length of the standard coupon period for the fixed income security of interest and do not necessarily coincide with actual coupon payment dates.

Required input arguments must be number of bonds, `NUMBONDS-by-1` or `1-by-NUMBONDS`, conforming vectors or scalars.

`NextQuasiCouponDate = cpndatenq( ____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` determines the next quasi coupon date for a portfolio of `NUMBONDS` fixed income securities whether or not the first or last coupon is normal, short, or long using optional input arguments.

Optional input arguments must be either `NUMBONDS-by-1` or `1-by-NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NextQuasiCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NextQuasiCouponDate` is returned as a datetime array.

### Examples

#### Determine the Next Quasi Coupon Date for a Portfolio of Fixed-Income Securities

Given a pair of bonds with the following characteristics:

```
Settle = char('30-May-1997','10-Dec-1997');
Maturity = char('30-Nov-2002','10-Jun-2004');
```

Compute `NextCouponDate` for this pair of bonds.

```
NextCouponDate = cpndaten(Settle, Maturity);
datestr(NextCouponDate)
```

```
ans = 2x11 char array
    '31-May-1997'
    '10-Jun-1998'
```

Compute the next quasi coupon dates for these two bonds.

```
NextQuasiCouponDate = cpndatenq(Settle, Maturity);
datestr(NextQuasiCouponDate)
```

```
ans = 2x11 char array
    '31-May-1997'
    '10-Jun-1998'
```

Because no `FirstCouponDate` has been specified, the results are identical.

Now supply an explicit `FirstCouponDate` for each bond.

```
FirstCouponDate = char('30-Nov-1997', '10-Dec-1998');
```

Compute the next coupon dates.

```
NextCouponDate = cpndaten(Settle, Maturity, 2, 0, 1, [], ...
    FirstCouponDate);
datestr(NextCouponDate)
```

```
ans = 2x11 char array
    '30-Nov-1997'
    '10-Dec-1998'
```

The next coupon dates are identical to the specified first coupon dates.

Now recompute the next quasi coupon dates.

```
NextQuasiCouponDate = cpndatenq(Settle, Maturity, 2, 0, 1, [], ...
    FirstCouponDate);
datestr(NextQuasiCouponDate)
```

```
ans = 2x11 char array
    '31-May-1997'
    '10-Jun-1998'
```

These results illustrate the distinction between actual coupon payment dates and quasi coupon dates. `FirstCouponDate` (and `LastCouponDate`, as well), when specified, is associated with an actual coupon payment and also serves as the synchronization date for determining all quasi coupon dates. Since each bond in this example pays semiannual coupons, and the first coupon date occurs more than six months after settlement, each will have an intermediate quasi coupon date before the actual first coupon payment occurs.

## Input Arguments

### **Settle** — Settlement date

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. **Settle** must be earlier than **Maturity**.

Data Types: `double` | `char` | `datetime`

### **Maturity — Maturity date**

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `char` | `datetime`

### **Period — Coupons per year of the bond**

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: `single` | `double`

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

### **EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: `logical`

### **IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: `double` | `char` | `datetime`

### **FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

## **Output Arguments**

### **NextQuasiCouponDate — Next quasi coupon date for portfolio of NUMBONDS fixed income securities**

vector

Next quasi coupon date for a portfolio of `NUMBONDS` fixed income securities, whether or not the first or last coupon is normal, short, or long, returned as a `NUMBONDS`-by-1 vector.

For zero coupon bonds, `cpndatenq` returns quasi coupon dates as if the bond had a semiannual coupon structure. Successive quasi coupon dates determine the length of the standard coupon period

for the fixed income security of interest and do not necessarily coincide with actual coupon payment dates.

If all of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NextQuasiCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NextQuasiCouponDate` is returned as a datetime array.

## cpndatepq

Previous quasi-coupon date for fixed-income security

### Syntax

```
PreviousQuasiCouponDate = cpndatepq(Settle,Maturity)
PreviousQuasiCouponDate = cpndatepq( ____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

### Description

`PreviousQuasiCouponDate = cpndatepq(Settle,Maturity)` determines the previous quasi-coupon date for a set of `NUMBONDS` fixed income securities. Prior quasi-coupon dates determine the length of the standard coupon period for the fixed income security of interest, and do not necessarily coincide with actual coupon payment dates. This function finds the previous quasi-coupon date for bonds with a coupon structure whose first or last period is either normal, short, or long.

Required input arguments must be number of bonds, `NUMBONDS-by-1` or `1-by-NUMBONDS`, conforming vectors or scalars.

`PreviousQuasiCouponDate = cpndatepq( ____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)`, using optional input arguments, determines the previous quasi-coupon date for a set of `NUMBONDS` fixed income securities.

Optional input arguments must be either `NUMBONDS-by-1` or `1-by-NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `PreviousQuasiCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `PreviousQuasiCouponDate` is returned as a datetime array.

### Examples

#### Determine the Previous Quasi Coupon Date for a Portfolio of Fixed-Income Securities

Given a pair of bonds with the following characteristics:

```
Settle = char('30-May-1997','10-Dec-1997');
Maturity = char('30-Nov-2002','10-Jun-2004');
```

With no `FirstCouponDate` explicitly supplied, compute the `PreviousCouponDate` for this pair of bonds.

```
PreviousCouponDate = cpndatepq(Settle, Maturity);
datestr(PreviousCouponDate)
```

```
ans = 2x11 char array
    '30-Nov-1996'
    '10-Dec-1997'
```

Note that since the settlement date for the second bond is also a coupon date, `cpndatepq` returns this date as the previous coupon date.

Now establish a `FirstCouponDate` and `IssueDate` for this pair of bonds.

```
FirstCouponDate = char('30-Nov-1997', '10-Dec-1998');
IssueDate = char('30-May-1996', '10-Dec-1996');
```

Recompute the `PreviousCouponDate` for this pair of bonds.

```
PreviousCouponDate = cpndatepq(Settle, Maturity, 2, 0, 1, ...
IssueDate, FirstCouponDate);
datestr(PreviousCouponDate)
```

```
ans = 2x11 char array
    '30-May-1996'
    '10-Dec-1996'
```

Since both of these bonds settled before the first coupon had been paid, `cpndatepq` returns the `IssueDate` as the `PreviousCouponDate`.

Using the same data, compute `PreviousQuasiCouponDate`.

```
PreviousQuasiCouponDate = cpndatepqq(Settle, Maturity, 2, 0, 1, ...
IssueDate, FirstCouponDate);
datestr(PreviousQuasiCouponDate)
```

```
ans = 2x11 char array
    '30-Nov-1996'
    '10-Dec-1997'
```

For the first bond the settlement date is not a normal coupon date. The `PreviousQuasiCouponDate` is the coupon date before or on the settlement date. Since the coupon structure is synchronized to `FirstCouponDate`, the previous quasi coupon date is 30-Nov-1996. `PreviousQuasiCouponDate` disregards `IssueDate` and `FirstCouponDate` in this case. For the second bond the settlement date (10-Dec-1997) occurs on a date when a coupon would normally be paid in the absence of an explicit `FirstCouponDate`. `cpndatepqq` returns this date as `PreviousQuasiCouponDate`.

## Input Arguments

### Settle — Settlement date

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. `Settle` must be earlier than `Maturity`.

Data Types: double | char | datetime

### Maturity — Maturity date

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `char` | `datetime`

### **Period — Coupons per year of the bond**

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: `single` | `double`

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

### **EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: logical

### **IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### **FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

### **LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## **Output Arguments**

### **PreviousQuasiCouponDate — Previous quasi coupon date for portfolio of NUMBONDS fixed income securities**

vector

Previous quasi coupon date for a portfolio of `NUMBONDS` fixed income securities, whether or not the first or last coupon is normal, short, or long, returned as a `NUMBONDS-by-1` vector of previous quasi-coupon dates before settlement. If settlement is a coupon date, this function returns the settlement date.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `PreviousQuasiCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `PreviousQuasiCouponDate` is returned as a datetime array.

# cpndatep

Previous coupon date for fixed-income security

## Syntax

```
PreviousCouponDate = cpndatep(Settle,Maturity)
PreviousCouponDate = cpndatep(____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

## Description

`PreviousCouponDate = cpndatep(Settle,Maturity)` returns the previous coupon date on or before settlement for a portfolio of bonds. This function finds the previous coupon date whether or not the coupon structure is synchronized with the maturity date. For zero coupon bonds the previous coupon date is the issue date, if available. However, if the issue date is not supplied, the previous coupon date for zero coupon bonds is the previous quasi coupon date calculated as if the frequency is semiannual.

Required input arguments must be number of bonds, `NUMBONDS-by-1` or `1-by-NUMBONDS`, conforming vectors or scalars.

`PreviousCouponDate = cpndatep(____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the previous coupon date on or before settlement for a portfolio of bonds.

Optional input arguments must be either `NUMBONDS-by-1` or `1-by-NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `PreviousCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `PreviousCouponDate` is returned as a datetime array.

## Examples

### Calculate the Previous Coupon Date on or Before Settlement

Determine the `PreviousCouponDate` when using character vectors for input arguments.

```
PreviousCouponDate = cpndatep('14-Mar-1997', '30-Jun-2000', ...
2, 0, 0);
datestr(PreviousCouponDate)
```

```
ans =
'30-Dec-1996'
```

Determine the `PreviousCouponDate` when using datetime arrays for input arguments.

```
PreviousCouponDate = cpndatep(datetime('14-Mar-1997','Locale','en_US'), '30-Jun-2000', ...
2, 0, 0)
```

```
PreviousCouponDate = datetime
    30-Dec-1996
```

Determine the `PreviousCouponDate` when using character vectors for input arguments and the optional argument for `EndMonthRule`.

```
PreviousCouponDate = cpndatep('14-Mar-1997', '30-Jun-2000', ...
2, 0, 1);
datestr(PreviousCouponDate)
```

```
ans =
    '31-Dec-1996'
```

Determine the `PreviousCouponDate` when using an input vector for `Maturity`.

```
Maturity = ['30-Apr-2000'; '31-May-2000'; '30-Jun-2000'];
PreviousCouponDate = cpndatep('14-Mar-1997', Maturity);
datestr(PreviousCouponDate)
```

```
ans = 3x11 char array
    '31-Oct-1996'
    '30-Nov-1996'
    '31-Dec-1996'
```

## Input Arguments

### Settle — Settlement date

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. `Settle` must be earlier than `Maturity`.

Data Types: double | char | datetime

### Maturity — Maturity date

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Period — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: single | double

**Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

**IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: `double` | `char` | `datetime`

**FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

## **Output Arguments**

### **PreviousCouponDate — Previous coupon date on or before settlement for portfolio of bonds**

vector

Previous coupon date on or before settlement for portfolio of bonds, returned as an `NUMBONDS`-by-1 vector. If settlement is a coupon date, this function returns the settlement date. The actual coupon date strictly on or before settlement is returned, but not exceeding the issue date, if available. Thus, this function always returns the lesser of the actual issue date and the previous coupon payment date with respect to the settlement date.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `PreviousCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `PreviousCouponDate` is returned as a datetime array.

# cpndaysn

Number of days to next coupon date

## Syntax

```
NumDaysNext = cpndaysn(Settle,Maturity)
NumDaysNext = cpndaysn(____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

## Description

`NumDaysNext = cpndaysn(Settle,Maturity)` returns the number of days from the settlement date to the next coupon date for a bond or set of bonds. For zero coupon bonds coupon dates are computed as if the bonds have a semiannual coupon structure. `NumDaysNext` returns a double for serial date number, date character vector, and datetime inputs.

Required input arguments must be number of bonds, `NUMBONDS-by-1` or `1-by-NUMBONDS`, conforming vectors or scalars.

`NumDaysNext = cpndaysn(____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the number of days from the settlement date to the next coupon date for a bond or set of bonds using optional input arguments.

Optional input arguments must be either `NUMBONDS-by-1` or `1-by-NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysNext` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NumDaysNext` is returned as a datetime array.

## Examples

### Calculate the Number of Days From Settlement Date to Next Coupon Date

Determine the `NumDaysNext` when using character vectors for input arguments.

```
NumDaysNext = cpndaysn('14-Sep-2000', '30-Jun-2001', 2, 0, 0)
```

```
NumDaysNext = 107
```

Determine the `NumDaysNext` when using datetime arrays for input arguments.

```
NumDaysNext = cpndaysn(datetime('14-Sep-2000','Locale','en_US'), '30-Jun-2001', 2, 0, 0)
```

```
NumDaysNext = 107
```

Determine the `NumDaysNext` when using character vectors for input arguments and the optional argument for `EndMonthRule`.

```
NumDaysNext = cpndaysn('14-Sep-2000', '30-Jun-2001', 2, 0, 1)
NumDaysNext = 108
```

Determine the NumDaysNext when using an input vector for Maturity.

```
Maturity = ['30-Apr-2001'; '31-May-2001'; '30-Jun-2001'];
NumDaysNext = cpndaysn('14-Sep-2000', Maturity)
```

```
NumDaysNext = 3×1
```

```
    47
    77
   108
```

## Input Arguments

### Settle — Settlement date

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. **Settle** must be earlier than **Maturity**.

Data Types: double | char | datetime

### Maturity — Maturity date

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Period — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: single | double

### Basis — Day-count basis of the instrument

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

### **EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

### **IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: `double` | `char` | `datetime`

### **FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

## Output Arguments

### **NumDaysNext** — Number of days from settlement date to next coupon date

vector

Number of days from settlement date to next coupon date, returned as an `NUMBONDS`-by-1 vector. For zero coupon bonds coupon dates are computed as if the bonds have a semiannual coupon structure. `NumDaysNext` returns a double for serial date number, date character vector, and `datetime` inputs.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysNext` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are `datetime` arrays, then `NumDaysNext` is returned as a `datetime` array.

# cpndaysp

Number of days since previous coupon date

## Syntax

```
NumDaysPrevious = cpndaysp(Settle,Maturity)
NumDaysPrevious = cpndaysp(____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

## Description

`NumDaysPrevious = cpndaysp(Settle,Maturity)` returns the number of days between the previous coupon date and the settlement date for a bond or set of bonds. When the coupon frequency is 0 (a zero coupon bond), the previous coupon date is calculated as if the frequency were semiannual. `NumDaysPrevious` returns a double for serial date number, date character vector, and datetime inputs.

Required input arguments must be number of bonds, `NUMBONDS-by-1` or `1-by-NUMBONDS`, conforming vectors or scalars.

`NumDaysPrevious = cpndaysp(____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the number of days between the previous coupon date and the settlement date for a bond or set of bonds using optional input arguments.

Optional input arguments must be either `NUMBONDS-by-1` or `1-by-NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysPrevious` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NumDaysPrevious` is returned as a datetime array.

## Examples

### Calculate the Number of Days Between Previous Coupon Date and Settlement Date

Determine the `NumDaysPrevious` when using character vectors for input arguments.

```
NumDaysPrevious = cpndaysp('14-Mar-2000', '30-Jun-2001', 2, 0, 0)
```

```
NumDaysPrevious = 75
```

Determine the `NumDaysPrevious` when using a datetime array for an input argument.

```
NumDaysPrevious = cpndaysp(datetime('14-Mar-2000','Locale','en_US'), '30-Jun-2001', 2, 0, 0)
```

```
NumDaysPrevious = 75
```

Determine the `NumDaysPrevious` when using character vectors for input arguments and the optional argument for `EndMonthRule`.

```
NumDaysPrevious = cpndaysp('14-Mar-2000', '30-Jun-2001', 2, 0, 1)
NumDaysPrevious = 74
```

Determine the `NumDaysPrevious` when using an input vector for `Maturity`.

```
Maturity = ['30-Apr-2001'; '31-May-2001'; '30-Jun-2001'];
NumDaysPrevious = cpndaysp('14-Mar-2000', Maturity)
```

```
NumDaysPrevious = 3×1
```

```
135
105
74
```

## Input Arguments

### Settle — Settlement date

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. `Settle` must be earlier than `Maturity`.

Data Types: double | char | datetime

### Maturity — Maturity date

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Period — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set [1,2,3,4,6,12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1,2,3,4,6,12].

Data Types: single | double

### Basis — Day-count basis of the instrument

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a with value 0 through 13 or an N-by-1 vector of integers with values 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

### **EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

### **IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: `double` | `char` | `datetime`

### **FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## Output Arguments

**NumDaysPrevious** — Number of days between previous coupon date and settlement date  
vector

Number of days between the previous coupon date and the settlement date, returned as an `NUMBONDS`-by-1 vector. If the settlement date is a coupon date, this function always returns the settlement date.

When the coupon frequency is 0 (a zero coupon bond), the previous coupon date is calculated as if the frequency were semiannual. `NumDaysPrevious` returns a double for serial date number, date character vector, and datetime inputs.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysPrevious` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NumDaysPrevious` is returned as a datetime array.

## cnpersz

Number of days in coupon period

### Syntax

```
NumDaysPeriod = cnpersz(Settle,Maturity)
NumDaysPeriod = cnpersz( ____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

### Description

`NumDaysPeriod = cnpersz(Settle,Maturity)` returns the number of days in the coupon period containing the settlement date. For zero coupon bonds, coupon dates are computed as if the bonds have a semiannual coupon structure. `NumDaysPeriod` returns a double for serial date number, date character vector, and datetime inputs.

Required input arguments must be number of bonds, `NUMBONDS-by-1` or `1-by-NUMBONDS`, conforming vectors or scalars.

`NumDaysPeriod = cnpersz( ____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the number of days in the coupon period containing the settlement date using optional input arguments.

Optional input arguments must be either `NUMBONDS-by-1` or `1-by-NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysPeriod` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NumDaysPeriod` is returned as a datetime array.

### Examples

#### Calculate the Number of Days in the Coupon Period Containing Settlement Date

Determine the `NumDaysPeriod` when using character vectors for input arguments.

```
NumDaysPeriod = cnpersz('14-Sep-2000', '30-Jun-2001', 2, 0, 0)
```

```
NumDaysPeriod = 183
```

Determine the `NumDaysPeriod` when using a datetime array for an input argument.

```
NumDaysPeriod = cnpersz(datetime('14-Sep-2000','Locale','en_US'), '30-Jun-2001', 2, 0, 0)
```

```
NumDaysPeriod = 183
```

Determine the NumDaysPeriod when using character vectors for input arguments and the optional argument for EndMonthRule.

```
NumDaysPeriod = cnpersz('14-Sep-2000', '30-Jun-2001', 2, 0, 1)
```

```
NumDaysPeriod = 184
```

Determine the NumDaysPeriod when using an input vector for Maturity.

```
Maturity = ['30-Apr-2001'; '31-May-2001'; '30-Jun-2001'];
NumDaysPeriod = cnpersz('14-Sep-2000', Maturity)
```

```
NumDaysPeriod = 3x1
```

```
184
183
184
```

## Input Arguments

### Settle — Settlement date

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. **Settle** must be earlier than **Maturity**.

Data Types: double | char | datetime

### Maturity — Maturity date

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Period — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set [1,2,3,4,6,12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1,2,3,4,6,12].

Data Types: single | double

### Basis — Day-count basis of the instrument

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

### **EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

### **IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: `double` | `char` | `datetime`

### **FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

### **LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## Output Arguments

### **NumDaysPeriod** — Number of days in coupon period containing settlement date

vector

Number of days in the coupon period containing the settlement date, returned as an NUMBONDS-by-1 vector. For zero coupon bonds, coupon dates are computed as if the bonds have a semiannual coupon structure.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysPeriod` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NumDaysPeriod` is returned as a datetime array.

# createholidays

Create trading calendars

## Syntax

```
createholidays(FileName,Codefile,InfoFile,TargetDir,IncludeWkds,Wprompt,  
NoGUI)
```

## Description

createholidays(FileName,Codefile,InfoFile,TargetDir,IncludeWkds,Wprompt, NoGUI) programmatically generates the market-specific holidays.m files (from FinancialCalendar.com financial center holiday data) without displaying the interface.

---

**Note** To use createholidays, you must obtain data, codes, and info files from <https://www.FinancialCalendar.com> trading calendars. The data files must be in the required MATLAB format.

---

## Examples

### Create holidays.m Files Using createholidays

Use createholidays to create holidays\*.m files from My\_datafile.csv in the folder c:\work. Weekends are included in the holidays list based on the input flag INCLUDEWDKS = 1

```
createholidays('FinancialCalendar\My_datafile.csv',...  
'FinancialCalendar\My_codesfile.csv',...  
'FinancialCalendar\My_infofile.csv','c:\work',1,1,1)
```

## Input Arguments

### FileName — Data file name

character vector

Data file name, specified using a character vector.

Data Types: char

### Codefile — Code file name

character vector

Code file name, specified using a character vector.

Data Types: char

### InfoFile — Info file name

character vector

Info file name, specified using a character vector.

Data Types: `char`

**TargetDir — Target folder where to write new holidays.m files**

character vector

Target folder where to write the new `holidays.m` files, specified using a character vector.

Data Types: `char`

**IncludeWkds — Option to include weekends in holiday list**

numeric with value 0 or 1

Option to include weekends in the holiday list, specified using a numeric with value 0 or 1. Values are:

- 0 - Do not include weekends in the holiday list.
- 1 - Include weekends in the holiday list.

Data Types: `logical`

**Wprompt — Option to prompt for file location for each holiday.m file that is created**

numeric with value 0 or 1

Option to prompt for the file location for each `holiday.m` file that is created, specified using a numeric with value 0 or 1. Values are:

- 0 - Do not prompt for the file location.
- 1 - Prompt for the file location.

Data Types: `logical`

**NoGUI — Run createholidays without displaying Trading Calendars user interface**

numeric with value 0 or 1

Run `createholidays` without displaying the Trading Calendars user interface, specified using a numeric with value 0 or 1. Values are:

- 0 - Display the GUI.
- 1 - Do not display the GUI.

Data Types: `logical`

**See Also**

`holidays`

# cumsum

Cumulative sum

---

**Note** `cumsum` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = cumsum(oldfts)
```

## Description

`newfts = cumsum(oldfts)` calculates the cumulative sum of each individual time series data series in the financial time series object `oldfts` and returns the result in another financial time series object `newfts`. `newfts` contains the same data series names as `oldfts`.

## Examples

### Compute the Cumulative Sum

This example shows how to compute the cumulative sum for Disney stock and plot the results.

```
load disney.mat
cs_dis = cumsum(fillts(dis));
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
```

```
plot(cs_dis)
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
```

```
title('Cumulative Sum for Disney')
```

# cur2frac

Decimal currency values to fractional values

## Syntax

```
Fraction = cur2frac(Decimal,Denominator)
```

## Description

`Fraction = cur2frac(Decimal,Denominator)` converts decimal currency values to fractional values. `Fraction` is returned as a character vector.

## Examples

### Convert Decimal Currency Values to Fractional Values

This example shows how to convert decimal currency values to fractional values.

```
Fraction = cur2frac(12.125, 8)
```

```
Fraction =  
'12.1'
```

## Input Arguments

### Decimal — Decimal currency value

numeric decimal

Decimal currency value, specified as a scalar or vector using numeric decimal values.

Data Types: double

### Denominator — Denominator of the fractions

numeric

Denominator of the fractions, specified as a scalar or vector using numeric values for the denominator.

Data Types: double

## Output Arguments

### Fraction — Fractional values

character vector | cell array of character vectors

Fractional values, returned as a character vector or cell array of character vectors.

**See Also**

cur2str | frac2cur

**Introduced before R2006a**

# cur2str

Bank-formatted text

## Syntax

```
BankText = cur2str(Value,Digits)
```

## Description

`BankText = cur2str(Value,Digits)` returns the given value in bank format.

The output format for `BankText` is a numerical format with dollar sign prefix, two decimal places, and negative numbers in parentheses; for example, (\$123.45) and \$6789.01. The standard MATLAB bank format uses two decimal places, no dollar sign, and a minus sign for negative numbers; for example, -123.45 and 6789.01.

## Examples

### Return Bank Formatted Text

Return bank formatted text for a negative numeric value.

```
BankText = cur2str(-826444.4456,3)
```

```
BankText =  
'($826444.446)'
```

```
% Negative numbers are displayed in parentheses.
```

## Input Arguments

### Value — Value to be formatted

numeric value

Value to be formatted, specified as a numeric value.

Data Types: double

### Digits — Number of significant digits

2 (default) | integer

Number of significant digits, specified as an integer. A negative `Digits` rounds the value to the left of the decimal point.

Data Types: double

## Output Arguments

### **BankText** — Bank-formatted text

character vector

Bank-formatted text (`BankText`) is returned as a character vector with a leading dollar sign (\$). Negative numbers are displayed in parentheses.

### **See Also**

`cur2frac` | `frac2cur`

**Introduced before R2006a**

# date2time

Time and frequency from dates

## Syntax

```
[TFactors,F] = date2time(Settle,Maturity)
[TFactors,F] = date2time( ____,Compounding,Basis,EndMonthRule)
```

## Description

[TFactors,F] = date2time(Settle,Maturity) computes time factors appropriate to compounded rate quotes between the Settle and Maturity dates. date2time is the inverse of time2date.

[TFactors,F] = date2time( \_\_\_\_,Compounding,Basis,EndMonthRule) computes time factors appropriate to compounded rate quotes between the Settle and Maturity dates using optional input arguments for Compounding, Basis, and EndMonthRule. date2time is the inverse of time2date.

## Examples

### Compute date2time Using an actual/actual Basis

To get the date2time period between '31-Jul-2015' and '30-Sep-2015' using an actual/actual basis:

```
date2time('31-Jul-2015', '30-Sep-2015', 2, 0, 1)
```

```
ans = 0.3333
```

When using date2time quasi coupon, two quasi coupon dates are computed for a bond with a maturity corresponding to the Dates input. In this case, that would be "30-Sep-2015". Assuming that the compounding frequency is 2, the other quasi coupon date is six months prior to this date. Assuming the end of month rule is in place, then the other quasi coupon date is "31-Mar-2015". You can use these two dates to compute the total number of actual days in a period (which is 183). Given this, the fraction of time between the start and end date for the actual/actual basis is computed as follows.

(Actual Days between Start Date and End Date)/(Actual Number of Days between Quasi Coupon Dates)

There are 61 days between 31-Jul-2015 and 30-Sep-2015 and 183 days between the quasi coupon dates ("31-Mar-2015" and "30-Sep-2015") which leads to a final result of 61/183 or exactly 1/3.

## Input Arguments

### Settle — Settlement date

serial date number | date character vector | datetime object

Settlement date, specified as a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### **Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as a scalar or N-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Compounding — Rate at which input zero rates are compounded when annualized**

2 (Semiannual compounding) (default) | scalar with numeric values of 0, 1, 2, 3, 4, 5, 6, 12, 365, -1

Rate at which input zero rates are compounded when annualized, specified as a scalar with numeric values of: 0, 1, 2, 3, 4, 5, 6, 12, 365, or -1. Allowed values are defined as:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

The optional Compounding argument determines the formula for the discount factors (Disc):

- Compounding = 0 for simple interest
  - $\text{Disc} = 1 / (1 + Z * T)$ , where T is time in years and simple interest assumes annual times  $F = 1$ .
- Compounding = 1, 2, 3, 4, 6, 12
  - $\text{Disc} = (1 + Z/F)^{-T}$ , where F is the compounding frequency, Z is the zero rate, and T is the time in periodic units, for example,  $T = F$  is one year.
- Compounding = 365
  - $\text{Disc} = (1 + Z/F)^{-T}$ , where F is the number of days in the basis year and T is a number of days elapsed computed by basis.
- Compounding = -1
  - $\text{Disc} = \exp(-T*Z)$ , where T is time in years.

### **Basis — Day-count basis**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis, specified as an integer with a value 0 through 13 or a N-by-1 vector of integers with values 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

### **EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [0, 1] or a using a N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

## **Output Arguments**

### **TFactors — Time factors**

vector

Time factors, appropriate to compounded rate quotes between `Settle` and `Maturity` dates, returned as a vector.

### **F — Compounding frequencies**

scalar

Compounding frequencies, returned as a scalar.

## More About

### Difference Between `yearfrac` and `date2time`

The difference between `yearfrac` and `date2time` is that `date2time` counts full periods as a whole integer, even if the number of actual days in the periods are different. `yearfrac` does not count full periods.

For example,

```
yearfrac('1/1/2000', '1/1/2001', 9)
```

```
ans =
```

```
1.0167
```

`yearfrac` for Basis 9 (ACT/360 ICMA) calculates  $366/360 = 1.0167$ . So, even if the dates have the same month and date, with a difference of 1 in the year, the returned value may not be exactly 1. On the other hand, `date2time` calculates one full year period:

```
date2time('1/1/2000', '1/1/2001', 1, 9)
```

```
ans =
```

```
1
```

## dateaxis

Convert serial-date axis labels to calendar-date axis labels

### Syntax

`dateaxis(Tickaxis,DateForm,StartDate)`

### Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tickaxis  | (Optional) Determines which axis tick labels— <i>x</i> , <i>y</i> , or <i>z</i> —to replace. Enter as a character vector. Default = 'x'.                                                                                                                                                                                                                                                                                                                                                         |
| DateForm  | (Optional) Specifies which date format to use. Enter as an integer from 0 to 17. If no DateForm argument is entered, this function determines the date format based on the span of the axis limits. For example, if the difference between the axis minimum and maximum is less than 15, the tick labels are converted to three-letter day-of-the-week abbreviations (DateForm = 8). See DateForm on page 19-575 format descriptions.                                                            |
| StartDate | (Optional) Assigns the date to the first axis tick value, specified as a serial date number, date character vector, or datetime array. The tick values are treated as serial date numbers. The default StartDate is the lower axis limit converted to the appropriate date number. For example, a tick value of 1 is converted to the date 01-Jan-0000. Entering StartDate as '06-apr-1999' assigns the date April 6, 1999 to the first tick value and the axis tick labels are set accordingly. |

### Description

`dateaxis(Tickaxis,DateForm,StartDate)` replaces axis tick labels with date labels on a graphic figure.

See the MATLAB `set` command for information on modifying the axis tick values and other axis parameters.

| DateForm | Format               | Description                       |
|----------|----------------------|-----------------------------------|
| 0        | 01-Mar-1999 15:45:17 | day-month-year hour:minute:second |
| 1        | 01-mar-1999          | day-month-year                    |
| 2        | 03/01/99             | month/day/year                    |
| 3        | Mar                  | month, three letters              |
| 4        | M                    | month, single letter              |
| 5        | 3                    | month                             |
| 6        | 03/01                | month/day                         |
| 7        | 1                    | day of month                      |
| 8        | Wed                  | day of week, three letters        |
| 9        | W                    | day of week, single letter        |

| DateForm | Format      | Description                 |
|----------|-------------|-----------------------------|
| 10       | 1999        | year, four digits           |
| 11       | 99          | year, two digits            |
| 12       | Mar99       | month year                  |
| 13       | 15:45:17    | hour:minute:second          |
| 14       | 03:45:17 PM | hour:minute:second AM or PM |
| 15       | 15:45       | hour:minute                 |
| 16       | 03:45 PM    | hour:minute AM or PM        |
| 17       | 95/03/01    | year month day              |

## Examples

```
dateaxis('x') or dateaxis
```

converts the x-axis labels to an automatically determined date format.

```
dateaxis('y', 6)
```

converts the y-axis labels to the month/day format.

```
dateaxis('x', 2, '03-Mar-1999')
```

or

```
dateaxis('x', 2, datetime('03-Mar-1999'))
```

converts the x-axis labels to the month/day/year format. The minimum x-tick value is treated as March 3, 1999.

# datedisp

Display date entries

## Syntax

```
datedisp(NumMat)
datedisp( ____,DateForm)
CharMat = datedisp(NumMat,DateForm)
```

## Description

`datedisp(NumMat)` displays a matrix with the serial dates formatted as date character vectors, using a matrix with mixed numeric entries and serial date number entries. Integers between `datenum('01-Jan-1900')` and `datenum('01-Jan-2200')` are assumed to be serial date numbers, while all other values are treated as numeric entries.

`datedisp( ____,DateForm)`, using the optional argument `DateForm`, displays a matrix with the serial dates formatted as date character vectors, using a matrix with mixed numeric entries and serial date number entries. Integers between `datenum('01-Jan-1900')` and `datenum('01-Jan-2200')` are assumed to be serial date numbers, while all other values are treated as numeric entries.

`CharMat = datedisp(NumMat,DateForm)` returns `CharMat`, character array representing `NumMat`. If no output variable is assigned, the function prints the array to the display.

## Examples

### Display a Matrix with the Serial Dates Formatted as Date Character Vectors

This example shows how to display a matrix with the serial dates formatted as date character vectors.

```
NumMat = [730730, 0.03, 1200 730100;
          730731, 0.05, 1000 NaN];
```

```
datedisp(NumMat)
```

```
01-Sep-2000    0.03    1200    11-Dec-1998
02-Sep-2000    0.05    1000         NaN
```

## Input Arguments

### **NumMat** — Numeric matrix to display

serial date numbers

Numeric matrix to display, specified as a serial date numbers.

Data Types: double

**DateForm — Date format**

scalar character vector to indicate format of text representing dates

Date format, specified as a scalar character vector to indicate the format of text representing dates. See `datestr` for available and default format flags.

Data Types: `char`

**Output Arguments****CharMat — Character array representing NumMat**

array of date character vectors

Character array representing `NumMat`, returned as an array of date character vectors. If no output variable is assigned, the function prints the array to the display.

# datefind

Indices of dates in matrix

## Syntax

```
Indices = datefind(Subset,Superset)
Indices = datefind( ___,Tolerance)
```

## Description

`Indices = datefind(Subset,Superset)` returns a vector of indices to the date numbers in `Superset` that are present in `Subset`. If no date numbers match, `Indices = []`.

`Indices = datefind( ___,Tolerance)` returns a vector of indices to the date numbers in `Superset` that are present in `Subset`, plus the optional argument for `Tolerance`. If no date numbers match, `Indices = []`.

## Examples

### Return a Vector of Indices to Date Numbers

This example shows how to return a vector of indices to date numbers.

```
Superset = datenum(1999, 7, 1:31);
Subset = [datenum(1999, 7, 10); datenum(1999, 7, 20)];
Indices = datefind(Subset, Superset, 1)
```

```
Indices = 6×1
```

```
    9
   10
   11
   19
   20
   21
```

## Input Arguments

### Subset — Subset of dates to find matching dates

matrix of nonnegative integers with values for serial date numbers or datetime arrays

Subset of dates to find matching dates in `Superset`, specified as a matrix of nonnegative integers with values for serial date numbers or datetime arrays.

`Subset` and `Superset` can be either serial date numbers or datetime arrays. These types do not have to match. `datefind` determines the underlying date to match dates of different data types.

---

**Note** The elements of `Subset` must be contained in `Superset`, without repetition. `datefind` works with non-repeating sequences of dates.

---

Example: `Subset = [datenum(1997,7,10); datenum(1997,7,20)];`

Data Types: `single` | `double`

### **Superset — Superset of dates**

matrix of nonnegative integers with values for serial date numbers or datetime arrays

Superset of dates, specified as a matrix of serial date numbers or datetime arrays, whose elements are sought.

`Subset` and `Superset` can be either serial date numbers or datetime arrays. These types do not have to match. `datefind` determines the underlying date to match dates of different data types.

---

**Note** The elements of `Subset` must be contained in `Superset`, without repetition. `datefind` works with non-repeating sequences of dates.

---

Example: `Superset = datenum(1997,7,1:31);`

Data Types: `single` | `double`

### **Tolerance — Tolerance for matching dates in Superset**

0 (default) | positive integer or duration object

Tolerance for matching dates (+/-) in `Superset`, specified as a positive integer or duration object.

Data Types: `single` | `double`

## **Output Arguments**

### **Indices — Indices of dates in Superset that are present in Subset**

vector

Indices of dates in `Superset` that are present in `Subset` (plus or minus the tolerance if defined using the optional argument `Tolerance`), returned as a vector of indices to the date numbers or datetimes.

## **See Also**

`datenum` | `datetime`

# datemnth

Date of day in future or past month

## Syntax

```
TargetDate = datemnth(StartDate,NumberMonths)
TargetDate = datemnth( ____,DayFlag,Basis,EndMonthRule)
```

## Description

`TargetDate = datemnth(StartDate,NumberMonths)` determines a date in a future or past month based on movement either forward or backward in time by a given number of months.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `NumberMonths` must be an  $N$ -by-1 vector of integers or a single integer. `TargetDate` is then an  $N$ -by-1 vector of date numbers.

If `StartDate` is a serial date number or date character vector, `TargetDate` is returned as a serial date number. Use `datestr` to convert serial date numbers to formatted date character vectors.

If `StartDate` is a datetime array, then `TargetDate` is returned as a datetime array.

`TargetDate = datemnth( ____,DayFlag,Basis,EndMonthRule)` determines a date in a future or past month based on movement either forward or backward in time by a given number of months, using optional input arguments for `DayFlag`, `Basis`, and `EndMonthRule`.

## Examples

### Determine the Dates of Days in a Future Month

Determine the `TargetDate` in a future month using a date character vector for `StartDate`.

```
StartDate = '03-Jun-1997';
NumberMonths = 6;
DayFlag = 0;
Basis = 0;
EndMonthRule = 1;

TargetDate = datemnth(StartDate, NumberMonths, DayFlag, ...
Basis, EndMonthRule)

TargetDate = 729727

datestr(TargetDate)

ans =
'03-Dec-1997'
```

Determine the `TargetDate` in a future month using a datetime array for `StartDate`.

```
Day = datemnth(datetime('3-jun-2001','Locale','en_US'), 6, 0, 0, 0)
```

```
Day = datetime
    03-Dec-2001
```

Determine the `TargetDate` in a future month using a vector for `NumberMonths`.

```
NumberMonths = [1; 3; 5; 7; 9];
TargetDate = datemnth('31-jan-2001', NumberMonths);
datestr(TargetDate)
```

```
ans = 5x11 char array
    '28-Feb-2001'
    '30-Apr-2001'
    '30-Jun-2001'
    '31-Aug-2001'
    '31-Oct-2001'
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### NumberMonths — Number of months in future (positive) or past (negative)

positive or negative integers

Number of months in future (positive) or past (negative), specified as an N-by-1 or 1-by-N vector containing positive or negative integers.

Data Types: double

### DayFlag — Flag for how actual day number for target date in future or past month is determined

0 (day number should be the day in the future or past month corresponding to the actual day number of the start date) (default) | numeric with values 0, 1, or 2

Flag for how the actual day number for the target date in future or past month is determined, specified as an N-by-1 or 1-by-N vector using a numeric with values 0, 1, or 2.

Possible values are:

- 0 (default) = day number should be the day in the future or past month corresponding to the actual day number of the start date.
- 1 = day number should be the first day of the future or past month.
- 2 = day number should be the last day of the future or past month.

This flag has no effect if `EndMonthRule` is set to 1.

Data Types: double

**Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis to be used when determining the past or future date, specified as a scalar value with an integer with value of 0 through 13, or an N-by-1 or 1-by-N vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: single | double

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

0 (not in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a scalar with a nonnegative integer 0 or 1, or as an N-by-1 or 1-by-N vector of values 0 or 1.

- 0 = Ignore rule, meaning that rule is not in effect.
- 1 = Set rule on, meaning that if you are beginning on the last day of a month, and the month has 30 or fewer days, you will end on the last actual day of the future or past month regardless of whether that month has 28, 29, 30 or 31 days.

Data Types: logical

**Output Arguments****TargetDate — Target date in the future or past month**

vector

Target date in the future or past month, returned as an N-by-1 or 1-by-N vector containing the serial date number (default) or datetime (if `StartDate` is a datetime array) of the target date.

# datewrkdy

Date of future or past workday

## Syntax

```
EndDate = datewrkdy(StartDate,NumberWorkDays,NumberHolidays)
```

## Description

`EndDate = datewrkdy(StartDate,NumberWorkDays,NumberHolidays)` returns the serial number of the date a given number of workdays before or after the start date.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all.

For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `NumberWorkDays` must be an  $N$ -by-1 vector of integers or a single integer. `EndDate` is then an  $N$ -by-1 vector of date numbers.

If `StartDate` is a serial date number or date character vector, `EndDate` is returned as a date number. Use `datestr` to convert serial date numbers to formatted date character vectors.

If `StartDate` is a datetime array, then `EndDate` is returned as a datetime array.

## Examples

### Determine the Date for a Future Workday

Determine the `EndDate` for a future workday using a date character vector for `StartDate`.

```
StartDate = '20-Dec-1994';
NumberWorkDays = 16;
NumberHolidays = 2;
```

```
EndDate = datewrkdy(StartDate, NumberWorkDays, NumberHolidays)
```

```
EndDate = 728671
```

```
datestr(EndDate)
```

```
ans =
'12-Jan-1995'
```

Determine the `EndDate` for a future workday using a datetime array for `StartDate`.

```
EndDate = datewrkdy(datetime('12-dec-2000','Locale','en_US'), 16, 2)
```

```
EndDate = datetime
04-Jan-2001
```

Determine the `EndDate` for future workdays using a vector for `NumberWorkDays`.

```

NumberWorkDays = [16; 20; 44];
EndDate = datewrkdy('12-dec-2000', NumberWorkDays, 2);
datestr(EndDate)

ans = 3x11 char array
    '04-Jan-2001'
    '10-Jan-2001'
    '13-Feb-2001'

```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### NumberWorkDays — Number of work or business days in future (positive) or past (negative)

positive or negative integers

Number of work or business days in future (positive) or past (negative) that includes the starting date, specified as an N-by-1 or 1-by-N vector containing positive or negative integers.

NumberHolidays and NumberWorkDays must have the same sign.

Data Types: double

### NumberHolidays — Number of holidays within NumberWorkDays

positive or negative integers

Number of holidays within NumberWorkDays, specified as positive or negative integers using an N-by-1 or 1-by-N containing values for the number of days movement in terms of holidays into the future (if positive) or past (if negative).

NumberHolidays and NumberWorkDays must have the same sign.

Data Types: double

## Output Arguments

### EndDate — Date of future or past workday

vector

Date of future or past workday, returned as an N-by-1 or 1-by-N vector containing the serial date number (default) or the datetime (if StartDate is a datetime array) of the future or past date.

## day

Day of month

### Syntax

```
DayMonth = day(Date)
DayMonth = day( ____, F)
```

### Description

`DayMonth = day(Date)` returns the day of the month given a serial date number or date character vector.

`DayMonth = day( ____, F)` returns the day of the month, given a serial date number, or character vector and an optional argument, `F`, defining the date format for `Date`.

### Examples

#### Determine the Day of the Month for Various Date Formats

Find the day of the month using a serial date number.

```
DayMonth = day(730544)
```

```
DayMonth = 28
```

Find the day of the month using a date character vector.

```
DayMonth = day('2/28/00')
```

```
DayMonth = 28
```

Find the day of the month using a date character vector with an optional argument `F` for a country-specific date format.

```
DayMonth = day('28/02/00', 'dd/mm/yyyy')
```

```
DayMonth = 28
```

### Input Arguments

#### Date — Date to determine day of month

serial date number | date character vector | cell array of date character vectors

Date to determine day of month, specified as a serial date number, date character vector, or cell array of date character vectors.

All the date character vectors in `Date` must have same date character vector format. For more information on supported date character vector formats, see `datestr`.

---

Example: `DayMonth = day({'2/28/00', '3/10/06'})`

Data Types: `single | double | char | cell`

### **F — Country-specific date format**

character vector designating date format

Country-specific date format, specified as a character vector to designate the date format for the input argument `Date`. For more information on supported date character vector format symbols, see `datestr`. Note, formats with 'Q' are not accepted.

Example: `DayMonth = day('28/02/00', 'dd/mm/yyyy')`

Data Types: `char`

## **Output Arguments**

### **DayMonth — Day of the month**

nonnegative integer

Day of the month, returned as a nonnegative integer, given a serial date number, or date character vector.

## days252bus

Number of business days between dates

### Syntax

```
NumberDays = days252bus(StartDate,EndDate)
```

```
NumberDays = days252bus(StartDate,EndDate,HolidayVector)
```

### Arguments

|               |                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| StartDate     | N-by-1 or 1-by-N vector or scalar value, in serial date number, date character vector, or datetime array form, representing the start date. |
| EndDate       | N-by-1 or 1-by-N vector or scalar value, in serial date number, date character vector, or datetime array form, representing the end date.   |
| HolidayVector | (Optional) N-by-1 or 1-by-N vector, in serial date number, date character vector, or datetime array form, representing holidays.            |

### Description

`NumberDays = days252bus(StartDate,EndDate,HolidayVector)` computes the number of business days (that is, non-holiday or non-weekend) between the two input dates. Note that a holiday vector may be optionally specified; if it is not, then the `holidays.m` file is used to determine the holidays.

`days252bus` returns `NumberDays`, a N-by-1 or 1-by-N vector or scalar value for the number of days between two dates. `NumberDays` returns as a double for serial date number, date character vector, and datetime inputs.

### Examples

#### Computes the Number of Business Days Between Two Input Dates

This example shows how to compute the number of business days (i.e. non-holiday or non-weekend) between two dates using the `days252bus` convention.

```
NumberDays = days252bus('1/1/2009', '8/1/2009')
```

```
NumberDays = 146
```

#### Computes the Number of Business Days Between Two Input Dates Using a datetime Array

This example shows how to compute the number of business days (i.e. non-holiday or non-weekend) between two dates, specified as a datetime array, using the `days252bus` convention.

```
NumberDays = days252bus(datetime('1-Jan-2009','Locale','en_US'), '8/1/2009')
```

NumberDays = 146

## days360

Days between dates based on 360-day year

### Syntax

```
NumDays = days360(StartDate,EndDate)
```

### Description

`NumDays = days360(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 360-day year (that is, all months contain 30 days). If `EndDate` is earlier than `StartDate`, `NumDays` is negative.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `EndDate` must be an  $N$ -by-1 vector of integers or a single integer. `NumDays` is then an  $N$ -by-1 vector of date numbers.

### Examples

#### Determine the Number of Days Between Two Dates Based on a 360-Day Year

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = days360('15-jan-2000', '15-mar-2000')
```

```
NumDays = 60
```

Determine the `NumDays` using a datetime array for `StartDate`.

```
NumDays = days360(datetime('15-jan-2000','Locale','en_US'), '15-mar-2000')
```

```
NumDays = 60
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
NumDays = days360('15-jan-2000', MoreDays)
```

```
NumDays = 3×1
```

```
60
90
150
```

### Input Arguments

#### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

#### **EndDate — End date**

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## **Output Arguments**

#### **NumDays — Number of days between two dates**

vector

Number of days between two dates, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for StartDate and EndDate.

## days360e

Days between dates based on 360-day year (European)

### Syntax

```
NumDays = days360e(StartDate,EndDate)
```

### Description

`NumDays = days360e(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 360-day year (that is, all months contain 30 days). If `EndDate` is earlier than `StartDate`, `NumDays` is negative. This day count convention is used primarily in Europe. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `EndDate` must be an  $N$ -by-1 vector of integers or a single integer. “Determine the Number of Days Between Two Dates Given a Basis of 30/360 Based on European Convention” on page 19-594 `NumDays` is then an  $N$ -by-1 vector of date numbers.

### Examples

#### Determine the Number of Days Between Two Dates Given a Basis of 30/360 Based on European Convention

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate` for the month of January.

```
StartDate = '1-Jan-2002';
EndDate = '1-Feb-2002';
NumDays = days360e(StartDate, EndDate)
```

```
NumDays = 30
```

Determine the `NumDays` in the month of January using a datetime array for `StartDate`.

```
NumDays = days360e(datetime('1-Jan-2002','Locale','en_US'), '1-Feb-2002')
```

```
NumDays = 30
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
NumDays = days360e('15-jan-2000', MoreDays)
```

```
NumDays = 3×1
```

```
60
90
150
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### EndDate — End date

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### NumDays — Number of days between two dates given a basis of 30/360 based on European convention

vector

Number of days between two dates given a basis of 30/360 based on European convention, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for StartDate and EndDate.

## days360isda

Days between dates based on 360-day year (International Swap Dealer Association (ISDA) compliant)

### Syntax

```
NumDays = days360isda(StartDate,EndDate)
```

### Description

`NumDays = days360isda(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 360-day year (that is, all months contain 30 days) and is International Swap Dealer Association (ISDA) compliant. If `EndDate` is earlier than `StartDate`, `NumDays` is negative. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `EndDate` must be an  $N$ -by-1 vector of integers or a single integer. `NumDays` is then an  $N$ -by-1 vector of date numbers.

### Examples

#### Determine the Number of Days Between Two Dates Given a Basis of 30/360 Based on ISDA Compliance

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate` for the month of January.

```
StartDate = '1-Jan-2002';
EndDate = '1-Feb-2002';
NumDays = days360isda(StartDate, EndDate)
```

```
NumDays = 30
```

Determine the `NumDays` in the month of January using a datetime array for `StartDate`.

```
NumDays = days360isda(datetime('1-Jan-2002', 'Locale', 'en_US'), '1-Feb-2002')
```

```
NumDays = 30
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
NumDays = days360isda('15-jan-2000', MoreDays)
```

```
NumDays = 3×1
```

```
    60
    90
   150
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### EndDate — End date

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### NumDays — Number of days between two dates given a basis of 30/360 based on European convention

vector

Number of days between two dates given a basis of 30/360 based on International Swap Dealer Association (ISDA) compliance, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for StartDate and EndDate.

## days360psa

Days between dates based on 360-day year (Public Securities Association (PSA) compliant)

### Syntax

```
NumDays = days360psa(StartDate,EndDate)
```

### Description

`NumDays = days360psa(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 360-day year (that is, all months contain 30 days) and is Public Securities Association (PSA) compliant. If `EndDate` is earlier than `StartDate`, `NumDays` is negative. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `EndDate` must be an  $N$ -by-1 vector of integers or a single integer. `NumDays` is then an  $N$ -by-1 vector of date numbers.

### Examples

#### Determine the Number of Days Between Two Dates Given a Basis of 30/360 Based on PSA Compliance

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate` for the month of January.

```
StartDate = '1-Jan-2002';
EndDate = '1-Feb-2002';
NumDays = days360psa(StartDate, EndDate)
```

```
NumDays = 30
```

Determine the `NumDays` in the month of January using a datetime array for `StartDate`.

```
NumDays = days360psa(datetime('1-Jan-2002', 'Locale', 'en_US'), '1-Feb-2002')
```

```
NumDays = 30
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
NumDays = days360psa('15-jan-2000', MoreDays)
```

```
NumDays = 3×1
```

```
60
90
150
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### EndDate — End date

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### NumDays — Number of days between two dates given a basis of 30/360 based on European convention

vector

Number of days between two dates given a basis of 30/360 based on Public Securities Association (PSA) compliance, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for StartDate and EndDate.

## days365

Days between dates based on 365-day year

### Syntax

```
NumDays = days365(StartDate,EndDate)
```

### Description

`NumDays = days365(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 365-day year. All months contain their actual number of days. February always contains 28 days.

If `EndDate` is earlier than `StartDate`, `NumDays` is negative. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `EndDate` must be an  $N$ -by-1 vector of integers or a single integer. `NumDays` is then an  $N$ -by-1 vector of date numbers.

### Examples

#### Determine the Number of Days Between Two Dates Based on a 365-Day Year

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = days365('15-jan-2000', '15-mar-2000')
```

```
NumDays = 59
```

Determine the `NumDays` using a datetime array for `StartDate`.

```
NumDays = days365(datetime('15-jan-2000','Locale','en_US'), '15-mar-2000')
```

```
NumDays = 59
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
```

```
NumDays = days365('15-jan-2000', MoreDays)
```

```
NumDays = 3×1
```

```
    59  
    90  
   151
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### EndDate — End date

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### NumDays — Number of days between two dates based on 365-day year

vector

Number of days between two dates based on a 365-day year, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for StartDate and EndDate.

## References

### Topics

“Handle and Convert Dates” on page 2-2

**Introduced before R2006a**

## daysact

Actual number of days between dates

### Syntax

```
NumDays = daysact(StartDate)
NumDays = daysact( ____,EndDate)
```

### Description

`NumDays = daysact(StartDate)` returns the actual number of days between the MATLAB base date and `StartDate`. In MATLAB, the base date 1 is 1-Jan-0000 A.D. See `datenum` for a similar function.

`NumDays = daysact( ____,EndDate)` returns the actual number of days between `StartDate` and the optional argument `EndDate`.

If `EndDate` is earlier than `StartDate`, `NumDays` is negative. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `EndDate` must be an  $N$ -by-1 vector of integers or a single integer. `NumDays` is then an  $N$ -by-1 vector of date numbers.

### Examples

#### Determine the Number of Days Between Two Dates Based the Actual Number of Days

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = daysact('7-sep-2002', '25-dec-2002')
NumDays = 109
```

Determine the `NumDays` using a datetime array for `StartDate`.

```
NumDays = daysact(datetime('7-sep-2002','Locale','en_US'), '25-dec-2002')
NumDays = 109
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['09/07/2002'; '10/22/2002'; '11/05/2002'];
NumDays = daysact(MoreDays, '12/25/2002')

NumDays = 3×1

    109
     64
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### EndDate — End date

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### NumDays — Number of days between two dates based actual number of days

vector

Number of days between two dates based on the actual number of days, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for StartDate and EndDate.

## daysadd

Date away from starting date for any day-count basis

### Syntax

```
NewDate = daysadd(StartDate, NumDays)
NewDate = daysadd( ____, Basis)
```

### Description

`NewDate = daysadd(StartDate, NumDays)` returns a date `NewDate` number of days away from `StartDate`.

If `StartDate` is a serial date number or date character vector, `NewDate` is returned as a date number.

If `StartDate` is a datetime array, then `NewDate` is returned as a datetime array.

`NewDate = daysadd( ____, Basis)` returns a date `NewDate` number of days away from `StartDate`, using the optional argument `Basis` for day-count.

If `StartDate` is a serial date number or date character vector, `NewDate` is returned as a date number.

If `StartDate` is a datetime array, then `NewDate` is returned as a datetime array.

### Examples

#### Determine the Date for Given Number of Days Away From StartDate

Determine the `NewDate` using a date character vector for `StartDate`.

```
NewDate = daysadd('01-Feb-2004', 31)
```

```
NewDate = 732009
```

```
datestr(NewDate)
```

```
ans =
'03-Mar-2004'
```

Determine the `NewDate` using a datetime array for `StartDate`.

```
NewDate = daysadd(datetime('01-Feb-2004', 'Locale', 'en_US'), 31)
```

```
NewDate = datetime
03-Mar-2004
```

Determine the `NewDate` using a vector for `StartDate`.

```
MoreDays = ['09/07/2002'; '10/22/2002'; '11/05/2002'];
NewDate = daysadd(MoreDays, 31, 2)
```

```
NewDate = 3×1
```

```
731497
731542
731556
```

```
datestr(NewDate)
```

```
ans = 3×11 char array
'08-Oct-2002'
'22-Nov-2002'
'06-Dec-2002'
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### NumDays — Number of days from StartDate

positive or negative integer

Number of days from StartDate, specified as an N-by-1 or 1-by-N vector using positive or negative integers. Enter a negative integer for dates before start date.

Data Types: double

### Basis — Day-count basis of the instrument

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or a N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** When using the 30/360 day-count basis, it is not always possible to find the exact date `NewDate` number of days away because of a known discontinuity in the method of counting days. A warning is displayed if this occurs.

---

Data Types: `single` | `double`

## Output Arguments

### **NewDate** — Date for given number of days away from `StartDate`

vector

Date for given number of days away from `StartDate`, returned as a scalar or an N-by-1 vector containing dates.

If `StartDate` is a serial date number or date character vector, `NewDate` is returned as a date number.

If `StartDate` is a datetime array, then `NewDate` is returned as a datetime array.

# daysdif

Days between dates for any for any day-count basis

## Syntax

```
NumDays = daysdif(StartDate,EndDate)
NumDays = daysdif( ____,Basis)
```

## Description

`NumDays = daysdif(StartDate,EndDate)` returns the number of days between dates `StartDate` and `EndDate`. The first date for `StartDate` is not included when determining the number of days between first and last date.

Any input argument can contain multiple values, but if so, the other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row array of character vector dates, then `EndDate` must be an  $n$ -row array of character vector dates or a single date. `NumDays` is then an  $N$ -by-1 vector of numbers.

`NumDays = daysdif( ____,Basis)` returns the number of days between dates `StartDate` and `EndDate` using the optional argument `Basis` for day-count. The first date for `StartDate` is not included when determining the number of days between first and last date.

Any input argument can contain multiple values, but if so, the other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row array of character vector dates, then `EndDate` must be an  $n$ -row array of character vector dates or a single date. `NumDays` is then an  $N$ -by-1 vector of numbers.

## Examples

### Determine the Number of Days Between StartDate and EndDate

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = daysdif('3/1/99', '3/1/00', 1)
```

```
NumDays = 360
```

Determine the `NumDays` using a datetime array for `StartDate`.

```
NumDays = daysdif(datetime('1-Mar-1999','Locale','en_US'), '3/1/00', 1)
```

```
NumDays = 360
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['3/1/2001'; '3/1/2002'; '3/1/2003'];
NumDays = daysdif('3/1/98', MoreDays)
```

```
NumDays = 3×1
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### EndDate — End date

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Basis — Day-count basis of the instrument

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or a N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: single | double

## Output Arguments

### **NumDays — Number of days between dates StartDate and EndDate**

integer

Number of days between the StartDate and EndDate. NumDays returns as a double for serial date number, date character vector, and datetime inputs.

The first date for StartDate is not included when determining the number of days between first and last date.

## dec2thirtytwo

Decimal to thirty-second quotation

### Syntax

```
[OutNumber, Fractions] = dec2thirtytwo(InNumber, Accuracy)
```

### Description

[OutNumber, Fractions] = dec2thirtytwo(InNumber, Accuracy) changes a decimal price quotation for a bond or bond future to a fraction with a denominator of 32.

### Examples

#### Convert Decimal to Thirty-Second Quotation

This example shows two bonds that are quoted with decimal prices of 101.78 and 102.96. These prices are converted to fractions with a denominator of 32.

```
InNumber = [101.78; 102.96];
[OutNumber, Fractions] = dec2thirtytwo(InNumber)
```

```
OutNumber = 2×1
```

```
101
102
```

```
Fractions = 2×1
```

```
25
31
```

### Input Arguments

#### InNumber — Input number

numeric decimal fraction

Input number, specified as an N-by-1 vector of numeric decimal fractions.

Data Types: double

#### Accuracy — Rounding

1 (round down to nearest thirty second) (default) | numeric with values 1, 2, 4 or 10

Rounding, specified as an N-by-1 vector of accuracy desired with numeric values of 1, 2, 4 or 10. The values are: 1, round down to nearest thirty second, 2 (nearest half), 4 (nearest quarter), or 10 (nearest decile).

Data Types: double

## Output Arguments

**OutNumber** — Output number which is InNumber rounded downward to closest integer  
numeric

Output number which is InNumber rounded downward to closest integer, returned as a numeric value.

**Fractions** — Fractional part in units of thirty-second  
numeric

Fractional part in units of thirty-second, returned as a numeric value. The Fractions output conforms to accuracy as prescribed by the input Accuracy.

## deprfixdb

Fixed declining-balance depreciation schedule

### Syntax

Depreciation = deprfixdb(Cost,Salvage,Life,Period,Month)

### Arguments

|         |                                                                                                 |
|---------|-------------------------------------------------------------------------------------------------|
| Cost    | Scalar for the initial value of the asset.                                                      |
| Salvage | Scalar for the salvage value of the asset.                                                      |
| Life    | Scalar value for the life of the asset in years.                                                |
| Period  | Scalar integer for the number of years to calculate.                                            |
| Month   | (Optional) Scalar value for the number of months in the first year of asset life. Default = 12. |

### Description

Depreciation = deprfixdb(Cost,Salvage,Life,Period,Month) calculates the fixed declining-balance depreciation for each period.

### Examples

#### Compute the Fixed Declining-Balance Depreciation

This example shows how to calculate the depreciation for the first five years for a car is purchased for \$11,000, with a salvage value of \$1500, and a lifetime of eight years.

```
Depreciation = deprfixdb(11000, 1500, 8, 5)
```

```
Depreciation = 1×5  
103 ×
```

```
2.4251    1.8904    1.4737    1.1488    0.8955
```

# depgendb

General declining-balance depreciation schedule

## Syntax

Depreciation = depgendb(Cost,Salvage,Life,Factor)

## Arguments

|         |                                                                           |
|---------|---------------------------------------------------------------------------|
| Cost    | Cost of the asset.                                                        |
| Salvage | Estimated salvage value of the asset.                                     |
| Life    | Number of periods over which the asset is depreciated.                    |
| Factor  | Depreciation factor. Factor = 2 uses the double-declining-balance method. |

## Description

Depreciation = depgendb(Cost,Salvage,Life,Factor) calculates the declining-balance depreciation for each period.

## Examples

### Calculate the Declining-Balance Depreciation

A car is purchased for \$10,000 and is to be depreciated over five years. The estimated salvage value is \$1000. Using the double-declining-balance method, the function calculates the depreciation for each year and returns the remaining depreciable value at the end of the life of the car.

Define the depreciation.

```
Life = 5;
Salvage = 0;
Cost = 10000;
Factor=2;
```

Use depgendb to calculate the depreciation.

```
Depreciation = depgendb(10000, 1000, 5, 2)
```

```
Depreciation = 1×5
103 ×
```

```
4.0000    2.4000    1.4400    0.8640    0.2960
```

The large value returned at the final year is the sum of the depreciation over the life time and is equal to the difference between the Cost and Salvage. The value of the asset in the final year is computed as (Cost - Salvage) = Sum\_Depreciation\_Upto\_Final\_Year.

## deprdv

Remaining depreciable value

### Syntax

Value = deprdv(Cost,Salvage,Accum)

### Arguments

|         |                                                          |
|---------|----------------------------------------------------------|
| Cost    | Cost of the asset.                                       |
| Salvage | Salvage value of the asset.                              |
| Accum   | Accumulated depreciation of the asset for prior periods. |

### Description

Value = deprdv(Cost,Salvage,Accum) returns the remaining depreciable value for an asset.

### Examples

#### Compute the Remaining Depreciable Value for an Asset

This example shows how to find the remaining depreciable value after six years for the cost of an asset for \$13,000 with a life of 10 years. The salvage value is \$1000.

```
Accum = depstln(13000, 1000, 10) * 6
```

```
Accum = 7200
```

```
Value = deprdv(13000, 1000, 7200)
```

```
Value = 4800
```

## depsyod

Sum of years' digits depreciation

### Syntax

Sum = depsyod(Cost,Salvage,Life)

### Arguments

|         |                                         |
|---------|-----------------------------------------|
| Cost    | Cost of the asset.                      |
| Salvage | Salvage value of the asset.             |
| Life    | Depreciable life of the asset in years. |

### Description

Sum = depsyod(Cost,Salvage,Life) calculates the depreciation for an asset using the sum of years' digits method. Sum is a 1-by-Life vector of depreciation values with each element corresponding to a year of the asset's life.

### Examples

#### Compute the Depreciation for an Asset Using the Sum of Years' Digits Method

This example shows how to calculate the depreciation for an asset using the sum of years' digits method where the asset is \$13,000 with a life of 10 years. The salvage value of the asset is \$1000.

```
Sum = depsyod(13000, 1000, 10)'
```

```
Sum = 10×1  
103 ×
```

```

## depstln

Straight-line depreciation schedule

### Syntax

Depreciation = depstln(Cost,Salvage,Life)

### Arguments

|         |                                         |
|---------|-----------------------------------------|
| Cost    | Cost of the asset.                      |
| Salvage | Salvage value of the asset.             |
| Life    | Depreciable life of the asset in years. |

### Description

Depreciation = depstln(Cost,Salvage,Life) calculates straight-line depreciation for an asset.

### Examples

#### Compute the Straight-Line Depreciation for an Asset

This example shows how to calculate the straight-line depreciation for an asset that costs \$13,000 with a life of 10 years. The salvage value of the asset is \$1000.

```
Depreciation = depstln(13000, 1000, 10)
```

```
Depreciation = 1200
```

**Introduced before R2006a**

# diff

Differencing

---

**Note** `diff` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = diff(oldfts)
```

## Description

`diff` computes the differences of the data series in a financial time series object. It returns another time series object containing the difference.

`newfts = diff(oldfts)` computes the difference of all the data in the data series of the object `oldfts` and returns the result in the object `newfts`. `newfts` is a financial time series object containing the same data series (names) as the input `oldfts`.

## See Also

`diff`

## Topics

“Data Transformation and Frequency Conversion” on page 13-11

**Introduced before R2006a**

## disc2zero

Zero curve given discount curve

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Compounding` and `Basis`.

---

### Syntax

```
[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, Settle)
[ZeroRates, CurveDates] = disc2zero( ___, Name, Value)
```

### Description

`[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, Settle)` returns a zero curve given a discount curve and its maturity dates. If either inputs for `CurveDates` or `Settle` are datetime arrays, the output `CurveDates` is returned as datetime arrays.

`[ZeroRates, CurveDates] = disc2zero( ___, Name, Value)` adds optional name-value pair arguments

### Examples

#### Determine the Zero Curve Given a Discount Curve and Maturity Dates

Given the following discount factors `DiscRates` over a set of maturity dates `CurveDates`, and a settlement date `Settle`:

```
DiscRates = [0.9996
             0.9947
             0.9896
             0.9866
             0.9826
             0.9786
             0.9745
             0.9665
             0.9552
             0.9466];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')
              datenum('25-Jun-2001')
              datenum('04-Sep-2001')
              datenum('12-Nov-2001')];
```

```
Settle = datenum('03-Nov-2000');
```

Set daily compounding for the output zero curve, on an actual/365 basis.

```
Compounding = 365;
Basis = 3;
```

Execute the function `disc2zero` which returns the zero curve `ZeroRates` at the maturity dates `CurveDates`.

```
[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, ...
Settle, Compounding, Basis)
```

```
ZeroRates = 10×1
```

```
0.0487
0.0510
0.0523
0.0524
0.0530
0.0526
0.0530
0.0532
0.0549
0.0536
```

```
CurveDates = 10×1
```

```

730914
730943
730971
731027
731098
731167
```

For readability, `DiscRates` and `ZeroRates` are shown here only to the basis point. However, MATLAB® software computed them at full precision. If you enter `DiscRates` as shown, `ZeroRates` may differ due to rounding.

### Determine the Zero Curve Given a Discount Curve and Maturity Dates Using `datetime` Inputs

Given the following discount factors, `DiscRates`, over a set of maturity dates, `CurveDates`, and a settlement date, `Settle`, use `datetime` inputs to return the zero curve, `ZeroRates`, at the maturity dates, `CurveDates`.

```
DiscRates = [0.9996
0.9947
```

```
0.9896
0.9866
0.9826
0.9786
0.9745
0.9665
0.9552
0.9466];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')
              datenum('25-Jun-2001')
              datenum('04-Sep-2001')
              datenum('12-Nov-2001')];

Settle = datenum('03-Nov-2000');
Compounding = 365;
Basis = 3;

CurveDates = datetime(CurveDates,'ConvertFrom','datenum','Locale','en_US');
Settle = datetime(Settle,'ConvertFrom','datenum','Locale','en_US');

[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates,...
Settle, Compounding, Basis)

ZeroRates = 10x1

```

## Input Arguments

### DiscRates — Discount factors

decimal fraction

Discount factors, specified as a column vector of decimal fractions. In aggregate, the factors in `DiscRates` constitute a discount curve for the investment horizon represented by `CurveDates`.

Data Types: double

### CurveDates — Maturity dates

serial date number | date character vector | datetime

Maturity dates that correspond to the discount factors in `DiscRates`, specified as a column vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

### Settle — Common settlement date for discount rates in DiscRates

serial date number | date character vector | datetime

Common settlement date for the discount rates in `DiscRates`, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, Settle, 'Compounding', 6, 'Basis', 9)`

### Compounding — Rate at which output zero rates are compounded when annualized

2 (default) | numeric values: 0, 1, 2, 3, 4, 6, 12, 365, -1

Rate at which the output zero rates are compounded when annualized, specified as a numeric value. Allowed values are:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

Data Types: double

**Basis — Day-count basis used for annualizing output zero rates**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis used for annualizing the output zero rates, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `double`

**Output Arguments****ZeroRates — Zero curve for investment horizon represented by CurveDates**

numeric

Zero curve for the investment horizon represented by `CurveDates`, returned as a column vector of decimal fractions. The zero rates are the yields to maturity on theoretical zero-coupon bonds.

**CurveDates — Maturity dates that correspond to ZeroRates**

serial date number | date character vector | datetime

Maturity dates that correspond to the `ZeroRates`, returned as a column vector. This vector is the same as the input vector `CurveDates`, but the output is sorted by ascending maturity. If either inputs for `CurveDates` or `Settle` are datetime arrays, the output `CurveDates` is returned as datetime arrays.

## discrate

Bank discount rate of security

### Syntax

```
DiscRate = discrate(Settle,Maturity,Face,Price)
DiscRate = discrate( ____,Basis)
```

### Description

`DiscRate = discrate(Settle,Maturity,Face,Price)` computes the bank discount rate of a security. The bank discount rate normalizes by the face value of the security (for example, U. S. Treasury Bills) and understates the true yield earned by investors.

`DiscRate = discrate( ____,Basis)` adds an optional argument for Basis.

### Examples

#### Compute the Bank Discount Rate of a Security

This example shows how to find the bank discount rate of a security.

```
DiscRate = discrate('12-jan-2000', '25-jun-2000', 100, 97.74, 0)
```

```
DiscRate = 0.0501
```

#### Compute the Bank Discount Rate of a Security Using datetime Inputs

This example shows how to use `datetime` inputs to find the bank discount rate of a security.

```
DiscRate = discrate(datetime('12-jan-2000','Locale','en_US'), datetime('25-jun-2000','Locale','en_US'), 100, 97.74, 0)
```

```
DiscRate = 0.0501
```

### Input Arguments

#### Settle — Settlement date

serial date number | date character vector | datetime

Settlement date, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

#### Maturity — Maturity date

serial date number | date character vector | datetime

Maturity date, specified as serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### **Face — Redemption (par, face) value**

numeric

Redemption (par, face) value, specified as a numeric value.

Data Types: double

### **Price — Security price**

numeric

Security price, specified as a numeric value.

Data Types: double

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | integer with value of 0 to 13

(Optional) Day-count basis of the instrument, specified as a vector of integers.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

## **Output Arguments**

### **DiscRate — Discount rate of security**

decimal

Discount rate of security, returned as a decimal.

# ecmlsrmlle

Least-squares regression with missing data

## Syntax

[Parameters,Covariance,Resid,Info] = ecmlsrmlle(Data,Design,MaxIterations,TolParam,TolObj,Param0,

## Arguments

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data          | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use mvnrmlle.)                                                                                                                                                                                                                                                                                                                                                                                                     |
| Design        | <p>A matrix or a cell array that handles two model structures:</p> <ul style="list-style-type: none"> <li>• If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>• If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> <p>If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.</p> |
| MaxIterations | (Optional) Maximum number of iterations for the estimation algorithm. Default value is 100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TolParam      | (Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates. Default value is sqrt(eps) which is about 1.0e-8 for double precision. The convergence test for changes in model parameters is                                                                                                                                                                                                                                                                                                                                                                                                                |
|               | $\ Param_k - Param_{k-1}\  < TolParam \times (1 + \ Param_k\ )$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|               | where Param represents the output Parameters, and iteration $k = 2, 3, \dots$ . Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.                                                                                                                                                                                                                                                                                                                                            |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TolObj      | <p>(Optional) Convergence tolerance for estimation algorithm based on changes in the objective function. Default value is <math>\text{eps} \wedge 3/4</math> which is about <math>1.0\text{e-}12</math> for double precision. The convergence test for changes in the objective function is</p> $ Obj_k - Obj_{k-1}  < TolObj \times (1 +  Obj_k )$ <p>for iteration <math>k = 2, 3, \dots</math>. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam <math>\leq 0</math> and TolObj <math>\leq 0</math>, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.</p> |
| Param0      | <p>(Optional) NUMPARAMS-by-1 column vector that contains a user-supplied initial estimate for the parameters of the regression model. Default is a zero vector.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Covar0      | <p>(Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied initial or known estimate for the covariance matrix of the regression residuals. Default is an identity matrix.</p> <p>For covariance-weighted least-squares calculations, this matrix corresponds with weights for each series in the regression. The matrix also serves as an initial guess for the residual covariance in the expectation conditional maximization (ECM) algorithm.</p>                                                                                                                                                                                               |
| CovarFormat | <p>(Optional) Character vector that specifies the format for the covariance matrix. The choices are:</p> <ul style="list-style-type: none"> <li>• 'full' — Default method. Compute the full covariance matrix.</li> <li>• 'diagonal' — Force the covariance matrix to be a diagonal matrix.</li> </ul>                                                                                                                                                                                                                                                                                                                                                             |

## Description

[Parameters, Covariance, Resid, Info] = ecmlsrml(Data, Design, MaxIterations, TolParam, TolObj, Param0, Covar0, CovarFormat) estimates a least-squares regression model with missing data. The model has the form

$$Data_k \sim N(\text{Design}_k \times \text{Parameters}, \text{Covariance})$$

for samples  $k = 1, \dots, \text{NUMSAMPLES}$ .

ecmlsrml estimates a NUMPARAMS-by-1 column vector of model parameters called Parameters, and a NUMSERIES-by-NUMSERIES matrix of covariance parameters called Covariance.

ecmlsrml(Data, Design) with no output arguments plots the log-likelihood function for each iteration of the algorithm.

To summarize the outputs of ecmlsrml:

- Parameters is a NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.
- Covariance is a NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression model's residuals. For least-squares models, this estimate may not be a maximum likelihood estimate except under special circumstances.

- `Resid` is a `NUMSAMPLES`-by-`NUMSERIES` matrix of residuals from the regression.

Another output, `Info`, is a structure that contains additional information from the regression. The structure has these fields:

- `Info.Obj` — A variable-extent column vector, with no more than `MaxIterations` elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, `Obj(end)`, is the terminal estimate of the objective function. If you do least-squares, the objective function is the least-squares objective function.
- `Info.PrevParameters` — `NUMPARAMS`-by-1 column vector of estimates for the model parameters from the iteration just prior to the terminal iteration.
- `Info.PrevCovariance` — `NUMSERIES`-by-`NUMSERIES` matrix of estimates for the covariance parameters from the iteration just prior to the terminal iteration.

## Notes

If doing covariance-weighted least-squares, `Covar0` should usually be a diagonal matrix. Series with greater influence should have smaller diagonal elements in `Covar0` and series with lesser influence should have larger diagonal elements. Note that if doing CWLS, `Covar0` do not need to be a diagonal matrix even if `CovarFormat = 'diagonal'`.

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a `NUMPARAMS` row vector.
- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix.

These points concern how `Design` handles missing data:

- Although `Design` should not have NaN values, ignored samples due to NaN values in `Data` are also ignored in the corresponding `Design` array.
- If `Design` is a 1-by-1 cell array, which has a single `Design` matrix for each sample, no NaN values are permitted in the array. A model with this structure must have `NUMSERIES ≥ NUMPARAMS` with `rank(Design{1}) = NUMPARAMS`.
- `ecmlsrmlle` is more strict than `mvnrmlle` about the presence of NaN values in the `Design` array.

Use the estimates in the optional output structure `Info` for diagnostic purposes.

# ecmlsrobj

Log-likelihood function for least-squares regression with missing data

## Syntax

Objective = ecmlsrobj(Data,Design,Parameters,Covariance)

## Arguments

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data       | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use <code>mvnrml</code> .)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Design     | <p>A matrix or a cell array that handles two model structures:</p> <ul style="list-style-type: none"> <li>• If <code>NUMSERIES = 1</code>, <code>Design</code> is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>• If <code>NUMSERIES ≥ 1</code>, <code>Design</code> is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> <p>If <code>Design</code> has a single cell, it is assumed to have the same <code>Design</code> matrix for each sample. If <code>Design</code> has more than one cell, each cell contains a <code>Design</code> matrix for each sample.</p> |
| Parameters | NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Covariance | (Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied estimate for the covariance matrix of the residuals of the regression. Default is an identity matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Description

`Objective = ecmlsrobj(Data,Design,Parameters,Covariance)` computes a least-squares objective function based on current parameter estimates with missing data. `Objective` is a scalar that contains the least-squares objective function.

## Notes

`ecmlsrobj` requires that `Covariance` be positive-definite.

Note that

```
ecmlsrobj(Data, Design, Parameters) = ecmmvrobj(Data, ...
Design, Parameters, IdentityMatrix)
```

where `IdentityMatrix` is a NUMSERIES-by-NUMSERIES identity matrix.

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a `NUMPARAMS` row vector.
- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix.

## ecmmvnrfish

Fisher information matrix for multivariate normal regression model

### Syntax

Fisher = ecmmvnrfish(Data,Design,Covariance,Method,MatrixFormat,CovarFormat)

### Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data         | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use mvnrfish.)                                                                                                                                                                                                                                                                                                                                                                                                     |
| Design       | <p>A matrix or a cell array that handles two model structures:</p> <ul style="list-style-type: none"> <li>• If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>• If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> <p>If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.</p> |
| Covariance   | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the residuals of the regression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Method       | <p>(Optional) Character vector that identifies method of calculation for the information matrix:</p> <ul style="list-style-type: none"> <li>• <code>hessian</code> — Default method. Use the expected Hessian matrix of the observed log-likelihood function. This method is recommended since the resultant standard errors incorporate the increased uncertainties due to missing data.</li> <li>• <code>fisher</code> — Use the Fisher information matrix.</li> </ul>                                                                                                                                                                               |
| MatrixFormat | <p>(Optional) Character vector that identifies parameters to be included in the Fisher information matrix:</p> <ul style="list-style-type: none"> <li>• <code>full</code> — Default format. Compute the full Fisher information matrix for both model and covariance parameter estimates.</li> <li>• <code>paramonly</code> — Compute only components of the Fisher information matrix associated with the model parameter estimates.</li> </ul>                                                                                                                                                                                                       |

|             |                                                                                                                                                                                                                                                                                            |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CovarFormat | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"> <li>• 'full' — Default method. The covariance matrix is a full matrix.</li> <li>• 'diagonal' — The covariance matrix is a diagonal matrix.</li> </ul> |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Description

`Fisher = ecmmvnrfish(Data, Design, Covariance, Method, MatrixFormat, CovarFormat)` computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates that account for missing data.

`Fisher` is a `NUMPARAMS`-by-`NUMPARAMS` Fisher information matrix or Hessian matrix. The size of `NUMPARAMS` depends on `MatrixFormat` and on current parameter estimates. If `MatrixFormat = 'full'`,

$$\text{NUMPARAMS} = \text{NUMSERIES} * (\text{NUMSERIES} + 3)/2$$

If `MatrixFormat = 'paramonly'`,

$$\text{NUMPARAMS} = \text{NUMSERIES}$$

---

**Note** `ecmmvnrfish` operates slowly if you calculate the full Fisher information matrix.

| Design        | <p>A matrix or a cell array that handles two model structures:</p> <ul style="list-style-type: none"> <li>• If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>• If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> <p>If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.</p> |
| MaxIterations | (Optional) Maximum number of iterations for the estimation algorithm. Default value is 100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TolParam      | <p>(Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates. Default value is sqrt(eps) which is about 1.0e-8 for double precision. The convergence test for changes in model parameters is</p> $\ Param_k - Param_{k-1}\  < TolParam \times (1 + \ Param_k\ )$ <p>where Param represents the output Parameters, and iteration <math>k = 2, 3, \dots</math>. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.</p>            |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TolObj      | (Optional) Convergence tolerance for estimation algorithm based on changes in the objective function. Default value is $\text{eps} \wedge 3/4$ which is about $1.0\text{e-}12$ for double precision. The convergence test for changes in the objective function is<br>$ Obj_k - Obj_{k-1}  < TolObj \times (1 +  Obj_k )$ for iteration $k = 2, 3, \dots$ . Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both $TolParam \leq 0$ and $TolObj \leq 0$ , do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests. |
| Param0      | (Optional) Numparms-by-1 column vector that contains a user-supplied initial estimate for the parameters of the regression model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Covar0      | (Optional) Numseries-by-numseries matrix that contains a user-supplied initial or known estimate for the covariance matrix of the regression residuals.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| CovarFormat | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"> <li>'full' — Default method. Compute the full covariance matrix.</li> <li>'diagonal' — Force the covariance matrix to be a diagonal matrix.</li> </ul>                                                                                                                                                                                                                                                                                                        |

## Description

`[Parameters, Covariance, Resid, Info] = ecmmvnrml(Data, Design, MaxIterations, TolParam, TolObj, Param0, Covar0, CovarFormat)` estimates a multivariate normal regression model with missing data. The model has the form

$$Data_k \sim N(\text{Design}_k \times \text{Parameters}, \text{Covariance})$$

for samples  $k = 1, \dots, \text{NUMSAMPLES}$ .

`ecmmvnrml` estimates a Numparms-by-1 column vector of model parameters called `Parameters`, and a Numseries-by-numseries matrix of covariance parameters called `Covariance`.

`ecmmvnrml(Data, Design)` with no output arguments plots the log-likelihood function for each iteration of the algorithm.

To summarize the outputs of `ecmmvnrml`:

- `Parameters` is a Numparms-by-1 column vector of estimates for the parameters of the regression model.
- `Covariance` is a Numseries-by-numseries matrix of estimates for the covariance of the regression model's residuals.
- `Resid` is a Numsamples-by-numseries matrix of residuals from the regression. For any missing values in `Data`, the corresponding residual is the difference between the conditionally imputed value for `Data` and the model, that is, the imputed residual.

---

**Note** The covariance estimate `Covariance` cannot be derived from the residuals.

---

Another output, `Info`, is a structure that contains additional information from the regression. The structure has these fields:

- `Info.Obj` — A variable-extent column vector, with no more than `MaxIterations` elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, `Obj(end)`, is the terminal estimate of the objective function. If you do maximum likelihood estimation, the objective function is the log-likelihood function.
- `Info.PrevParameters` — `NUMPARAMS`-by-1 column vector of estimates for the model parameters from the iteration just prior to the terminal iteration. `Info.PrevCovariance` - `NUMSERIES`-by-`NUMSERIES` matrix of estimates for the covariance parameters from the iteration just prior to the terminal iteration.

## Notes

`ecmmvnrmlc` does not accept an initial parameter vector, since the parameters are estimated directly from the first iteration onward.

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a `NUMPARAMS` row vector.
- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix.

These points concern how `Design` handles missing data:

- Although `Design` should not have NaN values, ignored samples due to NaN values in `Data` are also ignored in the corresponding `Design` array.
- If `Design` is a 1-by-1 cell array, which has a single `Design` matrix for each sample, no NaN values are permitted in the array. A model with this structure must have `NUMSERIES ≥ NUMPARAMS` with `rank(Design{1}) = NUMPARAMS`.
- `ecmmvnrmlc` is more strict than `mvnrmlc` about the presence of NaN values in the `Design` array.

Use the estimates in the optional output structure `Info` for diagnostic purposes.

# ecmmvnrobj

Log-likelihood function for multivariate normal regression with missing data

## Syntax

Objective = ecmmvnrobj(Data,Design,Parameters,Covariance,CovarFormat)

## Arguments

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data        | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use <code>mvnrml</code> .)                                                                                                                                                                                                                                                                                                                                                                                  |
| Design      | A matrix or a cell array that handles two model structures: <ul style="list-style-type: none"> <li>• If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. ## Description

Objective = ecmmvnrobj(Data,Design,Parameters,Covariance,CovarFormat) computes a log-likelihood function based on current maximum likelihood parameter estimates with missing data. Objective is a scalar that contains the least-squares objective function.

## Notes

You can configure Design as a matrix if NUMSERIES = 1 or as a cell array if NUMSERIES ≥ 1.

- If Design is a cell array and NUMSERIES = 1, each cell contains a NUMPARAMS row vector.

- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix.

|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data        | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use <code>mvnrstd</code> .)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Design      | A matrix or a cell array that handles two model structures: <ul style="list-style-type: none"> <li>• If <code>NUMSERIES = 1</code>, <code>Design</code> is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>• If <code>NUMSERIES ≥ 1</code>, <code>Design</code> is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> <p>If <code>Design</code> has a single cell, it is assumed to have the same <code>Design</code> matrix for each sample. If <code>Design</code> has more than one cell, each cell contains a <code>Design</code> matrix for each sample.</p> |
| Covariance  | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression residuals.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Method      | (Optional) Character vector that identifies method of calculation for the information matrix: <ul style="list-style-type: none"> <li>• <code>hessian</code> — Default method. Use the expected Hessian matrix of the observed log-likelihood function. This method is recommended since the resultant standard errors incorporate the increased uncertainties due to missing data.</li> <li>• <code>fisher</code> — Use the Fisher information matrix.</li> </ul>                                                                                                                                                                                                                                                                                       |
| CovarFormat | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"> <li>• <code>'full'</code> — Default method. The covariance matrix is a full matrix.</li> <li>• <code>'diagonal'</code> — The covariance matrix is a diagonal matrix.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### Description

`[StdParameters, StdCovariance] = ecmmvnrstd(Data,Design,Covariance,Method,CovarFormat)` evaluates standard errors for a multivariate normal regression model with missing data. The model has the form

$$Data_k \sim N(\text{Design}_k \times \text{Parameters}, \text{Covariance})$$

for samples  $k = 1, \dots, \text{NUMSAMPLES}$ .

`ecmmvnrstd` computes two outputs:

- `StdParameters` is a `NUMPARAMS`-by-1 column vector of standard errors for each element of `Parameters`, the vector of estimated model parameters.
- `StdCovariance` is a `NUMSERIES`-by-`NUMSERIES` matrix of standard errors for each element of `Covariance`, the matrix of estimated covariance parameters.

---

**Note** `ecmmvnrstd` operates slowly when you calculate the standard errors associated with the covariance matrix `Covariance`.

---

## Notes

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a `NUMPARAMS` row vector.
- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix.

| MatrixFormat  | (Optional) Character vector that identifies parameters included in the Fisher information matrix. If <code>MatrixFormat = []</code> or <code>''</code> , the default method <code>full</code> is used. The parameter choices are <ul style="list-style-type: none"> <li><code>full</code> — (Default) Compute full Fisher information matrix.</li> <li><code>meanonly</code> — Compute only components of the Fisher information matrix associated with the mean.</li> </ul> |

## Description

`Fisher = ecmnfish(Data,Covariance,InvCovariance,MatrixFormat)` computes a NUMPARAMS-by-NUMPARAMS Fisher information matrix based on current parameter estimates, where

$\text{NUMPARAMS} = \text{NUMSERIES} * (\text{NUMSERIES} + 3) / 2$

if `MatrixFormat = 'full'` and

$\text{NUMPARAMS} = \text{NUMSERIES}$

if `MatrixFormat = 'meanonly'`.

The data matrix has NaNs for missing observations. The multivariate normal model has

$\text{NUMPARAMS} = \text{NUMSERIES} + \text{NUMSERIES} * (\text{NUMSERIES} + 1) / 2$

distinct parameters. Therefore, the full Fisher information matrix is of size NUMPARAMS-by-NUMPARAMS. The first NUMSERIES parameters are estimates for the mean of the data in `Mean` and the remaining  $\text{NUMSERIES} * (\text{NUMSERIES} + 1) / 2$  parameters are estimates for the lower-triangular portion of the covariance of the data in `Covariance`, in row-major order.

If `MatrixFormat = 'meanonly'`, the number of parameters is reduced to  $\text{NUMPARAMS} = \text{NUMSERIES}$ , where the Fisher information matrix is computed for the mean parameters only. In this format, the routine executes fastest.

This routine expects the inverse of the covariance matrix as an input. If you do not pass in the inverse, the routine computes it. You can obtain an approximation for the lower-bound standard errors of estimation of the parameters from

```
Stderr = (1.0/sqrt(NumSamples)) .* sqrt(diag(inv(Fisher)));
```

Because of missing information, these standard errors can be smaller than the estimated standard errors derived from the expected Hessian matrix. To see the difference, compare to standard errors calculated with `ecmhess`.

### Description

`Hessian = ecmnhess(Data,Covariance,InvCovariance,MatrixFormat)` computes a `NUMPARAMS`-by-`NUMPARAMS` Hessian matrix of the observed negative log-likelihood function based on current parameter estimates, where

$$\text{NUMPARAMS} = \text{NUMSERIES} * (\text{NUMSERIES} + 3) / 2$$

if `MatrixFormat = 'full'` and

$$\text{NUMPARAMS} = \text{NUMSERIES}$$

if `MatrixFormat = 'meanonly'`.

This routine is slow for `NUMSERIES > 10` or `NUMSAMPLES > 1000`.

The data matrix has NaNs for missing observations. The multivariate normal model has

$$\text{NUMPARAMS} = \text{NUMSERIES} + \text{NUMSERIES} * (\text{NUMSERIES} + 1) / 2$$

distinct parameters. Therefore, the full Hessian is a `NUMPARAMS`-by-`NUMPARAMS` matrix.

The first `NUMSERIES` parameters are estimates for the mean of the data in `Mean` and the remaining `NUMSERIES * (NUMSERIES + 1) / 2` parameters are estimates for the lower-triangular portion of the covariance of the data in `Covariance`, in row-major order.

If `MatrixFormat = 'meanonly'`, the number of parameters is reduced to `NUMPARAMS = NUMSERIES`, where the Hessian is computed for the mean parameters only. In this format, the routine executes fastest.

This routine expects the inverse of the covariance matrix as an input. If you do not pass in the inverse, the routine computes it.

The equation

```
Stderr = (1.0/sqrt(NumSamples)) .* sqrt(diag(inv(Hessian)));
```

provides an approximation for the observed standard errors of estimation of the parameters.

Because of the additional uncertainties introduced by missing information, these standard errors can be larger than the estimated standard errors derived from the Fisher information matrix. To see the difference, compare to standard errors calculated from `ecmnfish`.

## Description

[Mean,Covariance] = ecmninit(Data,InitMethod) creates initial mean and covariance estimates for the function ecmnmlc. Mean is a NUMSERIES-by-1 column vector estimate for the mean of Data. Covariance is a NUMSERIES-by-NUMSERIES matrix estimate for the covariance of Data.

## Algorithms

### Model

The general model is

$$Z \sim N(\text{Mean}, \text{Covariance}),$$

where each row of Data is an observation of Z.

Each observation of Z is assumed to be iid (independent, identically distributed) multivariate normal, and missing values are assumed to be missing at random (MAR).

### Initialization Methods

This routine has three initialization methods that cover most cases, each with its advantages and disadvantages.

#### nanskip

The nanskip method works well with small problems (fewer than 10 series or with monotone missing data patterns). It skips over any records with NaNs and estimates initial values from

complete-data records only. This initialization method tends to yield fastest convergence of the ECM algorithm. This routine switches to the `twostage` method if it determines that significant numbers of records contain NaN.

**twostage**

The `twostage` method is the best choice for large problems (more than 10 series). It estimates the mean for each series using all available data for each series. It then estimates the covariance matrix with missing values treated as equal to the mean rather than as NaNs. This initialization method is robust but tends to result in slower convergence of the ECM algorithm.

**diagonal**

The `diagonal` method is a worst-case approach that deals with problematic data, such as disjoint series and excessive missing data (more than 33% missing data). Of the three initialization methods, this method causes the slowest convergence of the ECM algorithm.

|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data          | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are indicated by NaNs. A sample is also called an <i>observation</i> or a <i>record</i> .                                                                                                                                                                                                                                                                                                                                                                            |
| InitMethod    | (Optional) Character vector that identifies one of three defined initialization methods to compute initial estimates for the mean and covariance of the data. If InitMethod = [] or '', the default method nanskip is used. The initialization methods are: <ul style="list-style-type: none"> <li>• nanskip — (Default) Skip all records with NaNs.</li> <li>• twostage — Estimate mean. Fill NaNs with mean. Then estimate covariance.</li> <li>• diagonal — Form a diagonal covariance.</li> </ul> <p><b>Note</b> If you supply Mean0 and Covar0, InitMethod is not executed.</p> |
| MaxIterations | (Optional) Maximum number of iterations for the expectation conditional maximization (ECM) algorithm. Default = 50.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Tolerance     | (Optional) Convergence tolerance for the ECM algorithm (Default = 1.0e-8.) If Tolerance ≤ 0, perform maximum iterations specified by MaxIterations and do not evaluate the objective function at each step unless in display mode, as described below.                                                                                                                                                                                                                                                                                                                               |
| Mean0         | (Optional) Initial NUMSERIES-by-1 column vector estimate for the mean. If you leave Mean0 unspecified ([ ]), the method specified by InitMethod is used. If you specify Mean0, you must also specify Covar0.                                                                                                                                                                                                                                                                                                                                                                         |
| Covar0        | (Optional) Initial NUMSERIES-by-NUMSERIES matrix estimate for the covariance, where the input matrix must be positive-definite. If you leave Covar0 unspecified ([ ]), the method specified by InitMethod is used. If you specify Covar0, you must also specify Mean0.                                                                                                                                                                                                                                                                                                               |

## Description

[Mean,Covariance] = ecmmle(Data,InitMethod,MaxIterations,Tolerance,Mean0,Covar0) estimates the mean and covariance of a data set. If the data set has missing values, this routine implements the ECM algorithm of Meng and Rubin [2] with enhancements by Sexton and Swensen [3]. ECM stands for

*expectation conditional maximization*, a conditional maximization form of the EM algorithm of Dempster, Laird, and Rubin [4].

This routine has two operational modes.

### Display Mode

With no output arguments, this mode displays the convergence of the ECM algorithm. It estimates and plots objective function values for each iteration of the ECM algorithm until termination, as shown in the following plot.

Display mode can determine `MaxIter` and `Tolerance` values or serve as a diagnostic tool. The objective function is the negative log-likelihood function of the observed data and convergence to a maximum likelihood estimate corresponds with minimization of the objective.

### Estimation Mode

With output arguments, this mode estimates the mean and covariance via the ECM algorithm.

### Examples

To see an example of how to use `ecmmle`, run the program `ecmguidemo`.

### Algorithms

#### Model

The general model is

$$Z \sim N(\text{Mean}, \text{Covariance}),$$

where each row of `Data` is an observation of `Z`.

Each observation of  $Z$  is assumed to be iid (independent, identically distributed) multivariate normal, and missing values are assumed to be missing at random (MAR). See Little and Rubin [1] for a precise definition of MAR.

This routine estimates the mean and covariance from given data. If data values are missing, the routine implements the ECM algorithm of Meng and Rubin [2] with enhancements by Sexton and Swensen [3].

If a record is empty (every value in a sample is NaN), this routine ignores the record because it contributes no information. If such records exist in the data, the number of nonempty samples used in the estimation is  $\leq \text{NumSamples}$ .

The estimate for the covariance is a biased maximum likelihood estimate (MLE). To convert to an unbiased estimate, multiply the covariance by  $\text{Count}/(\text{Count} - 1)$ , where  $\text{Count}$  is the number of nonempty samples used in the estimation.

### Requirements

This routine requires consistent values for `NUMSAMPLES` and `NUMSERIES` with `NUMSAMPLES > NUMSERIES`. It must have enough nonmissing values to converge. Finally, it must have a positive-definite covariance matrix. Although the references provide some necessary and sufficient conditions, general conditions for existence and uniqueness of solutions in the missing-data case, do not exist. The main failure mode is an ill-conditioned covariance matrix estimate. Nonetheless, this routine works for most cases that have less than 15% missing data (a typical upper bound for financial data).

### Initialization Methods

This routine has three initialization methods that cover most cases, each with its advantages and disadvantages. The ECM algorithm always converges to a minimum of the observed negative log-likelihood function. If you override the initialization methods, you must ensure that the initial estimate for the covariance matrix is positive-definite.

The following is a guide to the supported initialization methods.

#### **nanskip**

The `nanskip` method works well with small problems (fewer than 10 series or with monotone missing data patterns). It skips over any records with NaNs and estimates initial values from complete-data records only. This initialization method tends to yield fastest convergence of the ECM algorithm. This routine switches to the `twostage` method if it determines that significant numbers of records contain NaN.

#### **twostage**

The `twostage` method is the best choice for large problems (more than 10 series). It estimates the mean for each series using all available data for each series. It then estimates the covariance matrix with missing values treated as equal to the mean rather than as NaNs. This initialization method is robust but tends to result in slower convergence of the ECM algorithm.

#### **diagonal**

The `diagonal` method is a worst-case approach that deals with problematic data, such as disjoint series and excessive missing data (more than 33% of data missing). Of the three initialization methods, this method causes the slowest convergence of the ECM algorithm. If problems occur with

this method, use display mode to examine convergence and modify either `MaxIterations` or `Tolerance`, or try alternative initial estimates with `Mean0` and `Covar0`. If all else fails, try

```
Mean0 = zeros(NumSeries);  
Covar0 = eye(NumSeries,NumSeries);
```

Given estimates for mean and covariance from this routine, you can estimate standard errors with the companion routine `ecmnstd`.

### Convergence

The ECM algorithm does not work for all patterns of missing values. Although it works in most cases, it can fail to converge if the covariance becomes singular. If this occurs, plots of the log-likelihood function tend to have a constant upward slope over many iterations as the log of the negative determinant of the covariance goes to zero. In some cases, the objective fails to converge due to machine precision errors. No general theory of missing data patterns exists to determine these cases. An example of a known failure occurs when two time series are proportional wherever both series contain nonmissing values.

| Covariance     | NUMSERIES-by-NUMSERIES matrix with covariance estimate of Data              |
| CholCovariance | (Optional) Cholesky decomposition of covariance matrix:<br>chol(Covariance) |

## Description

Objective = ecmnojb(Data,Mean,Covariance,CholCovariance) computes the value of the observed negative log-likelihood function over the data given current estimates for the mean and covariance of the data.

The data matrix has NaNs for missing observations. The inputs Mean and Covariance are current estimates for model parameters.

This routine expects the Cholesky decomposition of the covariance matrix as an input. The routine computes the Cholesky decomposition if you do not explicitly specify it.

### Description

`[StdMean, StdCovariance] = ecmnstd(Data, Mean, Covariance, Method)` computes standard errors for mean and covariance of incomplete data.

`StdMean` is a NUMSERIES-by-1 column vector of standard errors of estimates for each element of the mean vector `Mean`.

`StdCovariance` is a NUMSERIES-by-NUMSERIES matrix of standard errors of estimates for each element of the covariance matrix `Covariance`.

Use this routine after estimating the mean and covariance of `Data` with `ecmnmle`. If the mean and distinct covariance elements are treated as the parameter  $\theta$  in a complete-data maximum-likelihood estimation, then as the number of samples increases,  $\theta$  attains asymptotic normality such that

$$\theta - E[\theta] \sim N(0, I^{-1}(\theta)),$$

where  $E[\theta]$  is the mean and  $I(\theta)$  is the Fisher information matrix.

With missing data, the Hessian  $H(\theta)$  is a good approximation for the Fisher information (which can only be approximated when data is missing).

It is usually advisable to use the default `Method` since the resultant standard errors incorporate the increased uncertainty due to missing data. In particular, standard errors calculated with the Hessian are generally larger than standard errors calculated with the Fisher information matrix.

---

**Note** This routine is slow for `NUMSERIES > 10` or `NUMSAMPLES > 1000`.

## effrr

Effective rate of return

### Syntax

```
Return = effrr(Rate, NumPeriods)
```

### Description

`Return = effrr(Rate, NumPeriods)` calculates the annual effective rate of return. Compounding continuously returns `Return` equivalent to  $(e^{\text{Rate}} - 1)$ .

### Examples

#### Compute the Annual Effective Rate of Return

This example shows how to find the effective annual rate of return based on an annual percentage rate of 9% compounded monthly.

```
Return = effrr(0.09, 12)
```

```
Return = 0.0938
```

### Input Arguments

#### Rate — Annual percentage rate

scalar numeric decimal

Annual percentage rate, specified as a scalar numeric decimal.

Data Types: double

#### NumPeriods — Number of compounding periods per year

scalar integer

Number of compounding periods per year, specified as a scalar integer.

Data Types: double

### Output Arguments

#### Return — Annual effective rate of return

scalar numeric decimal

Annual effective rate of return, returned as a scalar numeric decimal.

## elpm

Compute expected lower partial moments for normal asset returns

### Syntax

```
elpm(Mean, Sigma)
```

```
elpm(Mean, Sigma, MAR)
```

```
elpm(Mean, Sigma, MAR, Order)
```

```
Moment = elpm(Mean, Sigma, MAR, Order)
```

### Arguments

|       |                                                                                                                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mean  | NUMSERIES vector with mean returns for a collection of NUMSERIES assets.                                                                                                                                                            |
| Sigma | NUMSERIES vector with standard deviation of returns for a collection of NUMSERIES assets.                                                                                                                                           |
| MAR   | (Optional) Scalar minimum acceptable return (default MAR = 0). This is a cutoff level of return such that all returns above MAR contribute nothing to the lower partial moment.                                                     |
| Order | (Optional) Either a scalar or a NUMORDERS vector of nonnegative integer moment orders. If no order specified, default Order = 0, which is the shortfall probability. This function will not work for negative or noninteger orders. |

### Description

Given NUMSERIES asset returns with a vector of mean returns in a NUMSERIES vector `Mean`, a vector of standard deviations of returns in a NUMSERIES vector `Sigma`, a scalar minimum acceptable return `MAR`, and one or more nonnegative integer moment orders in a NUMORDERS vector `Order`, compute expected lower partial moments (`elpm`) relative to `MAR` for each asset in a NUMORDERS-by-NUMSERIES matrix `Moment`.

The output, `Moment`, is a NUMORDERS-by-NUMSERIES matrix of expected lower partial moments with NUMORDERS `Orders` and NUMSERIES series, that is, each row contains expected lower partial moments for a given order. The output `Moment` for the lower partial moment represents the moments of asset returns that fall below a minimum acceptable level of return.

---

**Note** To compute upper partial moments, reverse the signs of both the input `Mean` and `MAR` (do not reverse the signs of either `Sigma` or the output). This function computes expected lower partial moments with the mean and standard deviation of normally distributed asset returns. To compute sample lower partial moments from asset returns which have no distributional assumptions, use `lpm`.

---

### Examples

See “Expected Lower Partial Moments” on page 7-13.

## emaxdrawdown

Compute expected maximum drawdown for Brownian motion

### Syntax

EDD = emaxdrawdown(Mu, Sigma, T)

### Arguments

|       |                                                         |
|-------|---------------------------------------------------------|
| Mu    | Scalar. Drift term of a Brownian motion with drift.     |
| Sigma | Scalar. Diffusion term of a Brownian motion with drift. |
| T     | A time period of interest or a vector of times.         |

### Description

EDD = emaxdrawdown(Mu, Sigma, T) computes the expected maximum drawdown for a Brownian motion for each time period in T using the following equation:

$$dX(t) = \mu dt + \sigma dW(t).$$

If the Brownian motion is geometric with the stochastic differential equation

$$dS(t) = \mu_0 S(t) dt + \sigma_0 S(t) dW(t)$$

then use Ito's lemma with  $X(t) = \log(S(t))$  such that

$$\begin{aligned}\mu &= \mu_0 - 0.5\sigma_0^2, \\ \sigma &= \sigma_0\end{aligned}$$

converts it to the form used here.

The output argument ExpDrawdown is computed using an interpolation method. Values are accurate to a fraction of a basis point. Maximum drawdown is nonnegative since it is the change from a peak to a trough.

---

**Note** To compare the actual results from maxdrawdown with the expected results of emaxdrawdown, set the Format input argument of maxdrawdown to either of the nondefault values ('arithmetic' or 'geometric'). These are the only two formats emaxdrawdown supports.

---

### Examples

See "Expected Maximum Drawdown" on page 7-16.

## end

Last date entry

---

**Note** `end` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

`end`

## Description

`end` returns the index to the last date entry in a financial time series object.

## Examples

Consider a financial time series object called `MyFts`:

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
                     times]);
myFts = fints(dates_times, (1:6)', {'Data1'}, 1, 'My first FINTS')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints` (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints/display` (line 66)

`myFts =`

```
desc: My first FINTS
freq: Daily (1)
```

```
   'dates: (6)'   'times: (6)'   'Data1: (6)'
   '01-Jan-2001' '11:00'       [         1]
   '   "         ' '12:00'       [         2]
   '02-Jan-2001' '11:00'       [         3]
   '   "         ' '12:00'       [         4]
   '03-Jan-2001' '11:00'       [         5]
   '   "         ' '12:00'       [         6]
```

Use `end` to return the last date entry in the financial time series object `myFts`.

`myFts(end)`

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints/end` (line 57)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints/subsref` (line 106)

---

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/display (line 66)

ans =

```
desc: My first FINTS  
freq: Daily (1)
```

```
'dates: (1)'    'times: (1)'    'Data1: (1)'  
'03-Jan-2001'  '12:00'        [          6]
```

## eomdate

Last date of month

### Syntax

```
DayMonth = eomdate(Date)
DayMonth = eomdate(Year,Month,outputType)
```

### Description

`DayMonth = eomdate(Date)` returns the serial date number of the last date of the month for the given `Date`.

`DayMonth = eomdate(Year,Month,outputType)` returns the serial date number of the last date of the month for the given year and month. However, if `outputType` is 'datetime', then `DayMonth` is a datetime array. By default, `outputType` is 'datenum'.

### Examples

#### Determine the Last Day of the Month for Various Dates

Find the last day of the month using `Year` and `Month`.

```
DayMonth = eomdate(2001, 2)
```

```
DayMonth = 730910
```

```
datestr(DayMonth)
```

```
ans =
'28-Feb-2001'
```

Find the last day of the month using multiples values for `Year` and a single `Month`.

```
Year = [2002 2003 2004 2005];
```

```
DayMonth = eomdate(Year, 2);
```

```
datestr(DayMonth)
```

```
ans = 4x11 char array
'28-Feb-2002'
'28-Feb-2003'
'29-Feb-2004'
'28-Feb-2005'
```

Find the last day of the month using a datetime array for `Date`.

```
DayMonth = eomdate(datetime('1-Jan-2015','Locale','en_US'))
```

```
DayMonth = datetime
31-Jan-2015
```

Find the last day of the month using an `outputType` for 'datetime'.

```
DayMonth = eomdate(2001, 2, 'datetime')
```

```
DayMonth = datetime
          28-Feb-2001
```

## Input Arguments

### Date — Date to determine last day of month

serial date number | date character vector | datetime array

Date to determine last day of month, specified as a serial date number, date character vector, or datetime array.

If `Date` is a serial date number or a date character vector, `DayMonth` is returned as a serial date number. If `Date` is a datetime array, then `DayMonth` is returned as a datetime array.

Use the function `datestr` to convert serial date numbers to formatted date character vectors or `datenum` to convert date and time to a serial date number.

Data Types: `single` | `double` | `char` | `datetime`

### Year — Year to determine last date of month

four-digit nonnegative integer | vector of four-digit nonnegative integers

Year to determine last date of month, specified as a four-digit nonnegative integer.

Either input argument for `Year` or `Month` can contain multiple values, but if so, the other input must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by-*n* vector of integers, then `Month` must be a 1-by-*n* vector of integers or a single integer. `DayMonth` output is then a 1-by-*n* vector of date numbers.

Data Types: `single` | `double`

### Month — Month to determine last date of month

integer from 1 through 12 | vector of integers from 1 through 12

Month to determine last date of month, specified as an integer from 1 through 12.

Either input argument for `Year` or `Month` can contain multiple values, but if so, the other input must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by-*n* vector of integers, then `Month` must be a 1-by-*n* vector of integers or a single integer. `DayMonth` output is then a 1-by-*n* vector of date numbers.

Data Types: `single` | `double`

### outputType — Output date format

'datenum' (default) | character vector with values 'datenum' or 'datetime'

Output date format, specified as a character vector with values 'datenum' or 'datetime'. If `outputType` is 'datenum', then `DayMonth` is a serial date number. However, if `outputType` is 'datetime', then `DayMonth` is a datetime array.

Data Types: `char`

## **Output Arguments**

### **DayMonth — Last day of month**

serial date number | datetime array

Last day of the month, returned as a serial date number or datetime array.

## **See Also**

datetime | day | eomday | lbusdate | month | year

## eq (fts)

Multiple financial times series object equality

---

**Note** `eq (fts)` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
tsubj_1 == tsubj_2
iseq = eq(tsubj_1,tsubj_2)
```

### Arguments

|                      |                               |
|----------------------|-------------------------------|
| <code>tsubj_1</code> | Financial time series object. |
| <code>tsubj_2</code> | Financial time series object. |

### Description

`tsubj_1 == tsubj_2` returns True (1) if both financial time series objects have the same dates, frequencies, data series names, and data values. Otherwise, `eq` returns False (0).

---

**Note** The data series names are case-sensitive, but do not have to be in the same order within each object.

---

### Examples

#### Determine Multiple Financial Times Series Object Equality

This example shows how to determine if multiple financial times series objects are equal.

```
load disney
dis == dis

ans = logical
     1
```

# estimateAssetMoments

Estimate mean and covariance of asset returns from data

---

**Note** estimateAssetMoments has been partially removed and will no longer accept a `fints` object for the `AssetReturns` argument. Use `timetable` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
obj = estimateAssetMoments(obj,AssetReturns)
obj = estimateAssetMoments( ___,Name,Value)
```

## Description

`obj = estimateAssetMoments(obj,AssetReturns)` estimates mean and covariance of asset returns from data for a `Portfolio` object. For details on the workflow, see “Portfolio Object Workflow” on page 4-16.

`obj = estimateAssetMoments( ___,Name,Value)` estimates mean and covariance of asset returns from data for a `Portfolio` object with additional options for one or more `Name, Value` pair arguments.

## Examples

### Estimate Mean and Covariance of Asset Returns from Data for a Portfolio Object

To illustrate using the `estimateAssetMoments` function, generate random samples of 120 observations of asset returns for four assets from the mean and covariance of asset returns in the variables `m` and `C` with the `portsim` function. The default behavior `portsim` creates simulated data with estimated mean and covariance identical to the input moments `m` and `C`. In addition to a return series created by the `portsim` function in the variable `X`, a price series is created in the variable `Y`:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
X = portsim(m', C, 120);
Y = ret2tick(X);
```

Given asset returns and prices in the variables `X` and `Y` from above, the following examples demonstrate equivalent ways to estimate asset moments for the `Portfolio` object. A `Portfolio` object is created in `p` with the moments of asset returns set directly in the `Portfolio` object and a second `Portfolio` object is created in `q` to obtain the mean and covariance of asset returns from asset return data in `X` using the `estimateAssetMoments` function.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

X = portsim(m', C, 120);
p = Portfolio('mean',m,'covar',C);
q = Portfolio;
q = estimateAssetMoments(q, X);

[passetmean, passetcovar] = getAssetMoments(p)

passetmean = 4x1

    0.0042
    0.0083
    0.0100
    0.0150

passetcovar = 4x4

    0.0005    0.0003    0.0002         0
    0.0003    0.0024    0.0017    0.0010
    0.0002    0.0017    0.0048    0.0028
         0     0.0010    0.0028    0.0102

[qassetmean, qassetcovar] = getAssetMoments(q)

qassetmean = 4x1

    0.0042
    0.0083
    0.0100
    0.0150

qassetcovar = 4x4

    0.0005    0.0003    0.0002   -0.0000
    0.0003    0.0024    0.0017    0.0010
    0.0002    0.0017    0.0048    0.0028
   -0.0000    0.0010    0.0028    0.0102

```

Notice how either approach yields the same moments. The default behavior of the `estimateAssetMoments` function is to work with asset returns. If, instead, you have asset prices, such as in the variable `Y`, the `estimateAssetMoments` function accepts a parameter name `'DataFormat'` with a corresponding value set to `'prices'` to indicate that the input to the method is in the form of asset prices and not returns (the default parameter value for `'DataFormat'` is `'returns'`). The following example compares direct assignment of moments in the Portfolio object `p` with estimated moments from asset price data in `Y` in the Portfolio object `q`:

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;

```

```

    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

X = portsim(m', C, 120);
Y = ret2tick(X);

p = Portfolio('mean',m,'covar',C);

q = Portfolio;
q = estimateAssetMoments(q, Y, 'dataformat', 'prices');

[passetmean, passetcovar] = getAssetMoments(p)

passetmean = 4x1

    0.0042
    0.0083
    0.0100
    0.0150

passetcovar = 4x4

    0.0005    0.0003    0.0002         0
    0.0003    0.0024    0.0017    0.0010
    0.0002    0.0017    0.0048    0.0028
         0     0.0010    0.0028    0.0102

[qassetmean, qassetcovar] = getAssetMoments(q)

qassetmean = 4x1

    0.0042
    0.0083
    0.0100
    0.0150

qassetcovar = 4x4

    0.0005    0.0003    0.0002   -0.0000
    0.0003    0.0024    0.0017    0.0010
    0.0002    0.0017    0.0048    0.0028
   -0.0000    0.0010    0.0028    0.0102

```

### Estimate Mean and Covariance of Asset Returns from Timetable Data for a Portfolio Object

To illustrate using the `estimateAssetMoments` function with `AssetReturns` data continued in a `timetable` object, use the `CAPMuniverse.mat` which contains a `timetable` object (`AssetTimeTable`) for returns data.

```
load CAPMuniverse
AssetsTimeTable.Properties;
head(AssetsTimeTable,5)
```

```
ans=5x14 timetable
```

| Time        | AAPL      | AMZN      | CSCO      | DELL      | EBAY      | GOOG | HP   |

Notice that GOOG has missing data (NaN), because it was not listed before Aug 2004. The `estimateAssetMoments` function has a name-value pair argument `'MissingData'` that indicates with a Boolean value whether to use the missing data capabilities of Financial Toolbox™ software. The default value for `'MissingData'` is false which removes all samples with NaN values. If, however, `'MissingData'` is set to true, `estimateAssetMoments` uses the ECM algorithm to estimate asset moments.

```
r = Portfolio;
r = estimateAssetMoments(r,AssetsTimeTable,'dataformat','returns','missingdata',true);
```

In addition, the `estimateAssetMoments` function also extracts asset names or identifiers from a timetable object when the name-value argument `'GetAssetList'` set to true (its default value is false). If the `'GetAssetList'` value is true, the timetable column identifiers are used to set the `AssetList` property of the Portfolio object. To show this, the formation of the Portfolio object `r` is repeated with the `'GetAssetList'` flag set to true.

```
r = estimateAssetMoments(r,AssetsTimeTable,'GetAssetList',true);
disp(r.AssetList')
```

```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using a Portfolio object. For more information on creating a portfolio object, see

- Portfolio

Data Types: object

### **AssetReturns — Matrix, table, or timetable that contains asset price data that can be converted to asset returns**

matrix | table | table

Matrix, table, or timetable that contains asset price data that can be converted to asset returns, specified by a NumSamples-by-NumAssets matrix.

AssetReturns data can be:

- NumSamples-by-NumAssets matrix.
- Table of NumSamples prices or returns at a given periodicity for a collection of NumAssets assets
- Timetable object with NumSamples observations and NumAssets time series

Use the optional DataFormat argument to convert AssetReturns input data that is asset prices into asset returns. Be careful when using asset price data because portfolio optimization usually requires total returns and not simply price returns.

Data Types: double | table | timetable

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `p = estimateAssetMoments(p,Y,'dataformat','prices')`

### **DataFormat — Flag to convert input data as prices into returns**

'Returns' (default) | character vector with values 'Returns' or 'Prices'

Flag to convert input data as prices into returns, specified as the comma-separated pair consisting of 'DataFormat' and a character vector with the values:

- 'Returns' — Data in AssetReturns contains asset total returns.
- 'Prices' — Data in AssetReturns contains asset total return prices.

Data Types: char

### **MissingData — Flag indicating whether to use ECM algorithm or exclude samples with NaN values**

false (default) | logical with value true or false

Flag indicating whether to use ECM algorithm or excludes samples with NaN values, specified as the comma-separated pair consisting of 'MissingData' and a logical with a value of true or false.

To handle time series with missing data (indicated with NaN values), the MissingData flag either uses the ECM algorithm to obtain maximum likelihood estimates in the presences of NaN values or excludes samples with NaN values. Since the default is false, it is necessary to specify MissingData as true to use the ECM algorithm.

Acceptable values for MissingData are:

- `false` — Do not use ECM algorithm to handle NaN values (exclude NaN values).
- `true` — Use ECM algorithm to handle NaN values.

For more information on the ECM algorithm, see `ecmmle` and “Multivariate Normal Regression” on page 9-2.

Data Types: `logical`

### **GetAssetList** — Flag indicating which asset names to use for asset list

`false` (default) | `logical` with value `true` or `false`

Flag indicating which asset names to use for the asset list, specified as the comma-separated pair consisting of 'GetAssetList' and a `logical` with a value of `true` or `false`. Acceptable values for `GetAssetList` are:

- `false` — Do not extract or create asset names.
- `true` — Extract or create asset names from a table or timetable object.

If a table or timetable is passed into this function using the `AssetReturns` argument and the `GetAssetList` flag is `true`, the column names from the table or timetable object are used as asset names in `obj.AssetList`.

If a matrix is passed and the `GetAssetList` flag is `true`, default asset names are created based on the `AbstractPortfolio` property `defaultforAssetList`, which is 'Asset'.

If the `GetAssetList` flag is `false`, no action occurs, which is the default behavior.

Data Types: `logical`

## **Output Arguments**

### **obj** — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio` object. For more information on creating a portfolio object, see

- `Portfolio`

## **Tips**

You can also use dot notation to estimate the mean and covariance of asset returns from data.

```
obj = obj.estimateAssetMoments(AssetReturns);
```

## estimateBounds

Estimate global lower and upper bounds for set of portfolios

### Syntax

```
[glb,gub,isbounded] = estimateBounds(obj)
[glb,gub,isbounded] = estimateBounds(obj,obtainExactBounds)
```

### Description

[glb,gub,isbounded] = estimateBounds(obj) estimates global lower and upper bounds for set of portfolios for Portfolio, PortfolioCVaR, or PortfolioMAD objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

---

**Note** The estimateBounds function does not consider cardinality or semicontinuous constraints. For more information, see “Working with 'Conditional' BoundType, MinNumAssets, and MaxNumAssets Constraints Using Portfolio Objects” on page 4-74.

---

[glb,gub,isbounded] = estimateBounds(obj,obtainExactBounds) estimates global lower and upper bounds for set of portfolios with an additional option specified for obtainExactBounds.

### Examples

#### Create an Unbounded Portfolio for a Portfolio Object

Create an unbounded portfolio set.

```
p = Portfolio('AInequality', [1 -1; 1 1 ], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)
```

```
lb = 2×1
```

```
-Inf
-Inf
```

```
ub = 2×1
```

```
0
Inf
```

```
isbounded = logical
0
```

The `estimateBounds` function returns (possibly infinite) bounds and sets the `isbounded` flag to `false`. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

### Create an Unbounded Portfolio for a PortfolioCVaR Object

Create an unbounded portfolio set.

```
p = PortfolioCVaR('AInequality', [1 -1; 1 1 ], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)
```

```
lb = 2×1
```

```
-Inf
-Inf
```

```
ub = 2×1
```

```
0
Inf
```

```
isbounded = logical
0
```

The `estimateBounds` function returns (possibly infinite) bounds and sets the `isbounded` flag to `false`. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

### Create an Unbounded Portfolio for a PortfolioMAD Object

Create an unbounded portfolio set.

```
p = PortfolioMAD('AInequality', [1 -1; 1 1 ], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)
```

```
lb = 2×1
```

```
-Inf
-Inf
```

```
ub = 2×1
```

```
0
Inf
```

```
isbounded = logical
0
```

The `estimateBounds` function returns (possibly infinite) bounds and sets the `isbounded` flag to `false`. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

### **obtainExactBounds** — Flag to specify whether to solve for all bounds or to accept specified bounds whenever available

`true` (default) | logical

Flag to specify whether to solve for all bounds or to accept specified bounds whenever available, specified as a logical with values of `true` or `false`. If bounds are known, set `obtainExactBounds` to `false` to accept known bounds. The default for `obtainExactBounds` is `true`.

Data Types: `logical`

## Output Arguments

### **glb** — Global lower bounds for portfolio set

vector

Global lower bounds for portfolio set, returned as vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **gub** — Global upper bounds for portfolio set

vector

Global upper bounds for portfolio set, returned as vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **isbounded** — Indicator for whether portfolio set is empty, bounded, or unbounded

logical

Indicator for whether portfolio set is empty (`[]`), bounded (`true`), or unbounded (`false`), returned as a logical.

---

**Note** By definition, any portfolio set must be nonempty and bounded:

- If the set is empty, `isbounded = []`.

- If the set is nonempty and unbounded, `isbounded = false`.
  - If the set is nonempty and bounded, `isbounded = true`.
  - If the set is empty, `glb` and `gub` are set to NaN vectors.
- 

An `isbounded` value is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

- You can also use dot notation to estimate the global lower and upper bounds for a given set of portfolios.

```
[glb, gub, isbounded] = obj.estimateBounds;
```

- Estimated bounds are accurate in most cases to within  $1.0e-8$ . If you intend to use these bounds directly in a portfolio object, ensure that if you impose such bound constraints, a lower bound of 0 is probably preferable to a lower bound of, for example,  $1.0e-10$  for portfolio weights.

## estimateFrontier

Estimate specified number of optimal portfolios on the efficient frontier

### Syntax

```
[pwgt,pbuy,psell] = estimateFrontier(obj)  
[pwgt,pbuy,psell] = estimateFrontier(obj,NumPorts)
```

### Description

[pwgt,pbuy,psell] = estimateFrontier(obj) estimates the specified number of optimal portfolios on the efficient frontier for Portfolio, PortfolioCVaR, or PortfolioMAD objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

[pwgt,pbuy,psell] = estimateFrontier(obj,NumPorts) estimates the specified number of optimal portfolios on the efficient frontier with an additional option specified for NumPorts.

### Examples

#### Create a Portfolio Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse  
  
p = Portfolio('AssetList',Assets(1:12));  
p = estimateAssetMoments(p, Data(:,1:12), 'missingdata', true);  
p = setDefaultConstraints(p);  
plotFrontier(p);
```

```

pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([pwgt],pnames,'obsnames',p.AssetList);

disp(Blotter);

```

### Create a Portfolio Object with BoundType and MaxNumAssets Constraints and Determine Efficient Portfolios

Create a Portfolio object for 12 stocks based on CAPMuniverse.mat.

```
load CAPMuniverse
p0 = Portfolio('AssetList',Assets(1:12));
p0 = estimateAssetMoments(p0, Data(:,1:12), 'missingdata', true);
p0 = setDefaultConstraints(p0);
```

Use setMinMaxNumAssets to define a maximum number of 3 assets.

```
p1 = setMinMaxNumAssets(p0, [], 3);
```

Use setBounds to define a lower and upper bound and a BoundType of 'Conditional'.

```
p1 = setBounds(p1, 0.1, 0.5, 'BoundType', 'Conditional');
pwgt = estimateFrontier(p1, 5);
```

The following table shows that the optimized allocations only have maximum 3 assets invested, and small positions less than 0.1 are avoided.

```
result = table(p0.AssetList', pwgt)
```

```
result=12x2 table
      Var1                pwgt
      _____
```

|          |         |         |         |         |     |
|----------|---------|---------|---------|---------|-----|
| {'AAPL'} | 0       | 0       | 0       | 0.14301 | 0   |
| {'AMZN'} | 0       | 0       | 0       | 0       | 0   |
| {'CSCO'} | 0       | 0       | 0       | 0       | 0   |
| {'DELL'} | 0       | 0       | 0       | 0       | 0   |
| {'EBAY'} | 0       | 0       | 0       | 0       | 0.5 |
| {'GOOG'} | 0.16981 | 0.29588 | 0.42214 | 0.49999 | 0.5 |
| {'HPQ' } | 0       | 0       | 0       | 0       | 0   |
| {'IBM' } | 0.49592 | 0.43629 | 0.37308 | 0.35699 | 0   |
| {'INTC'} | 0       | 0       | 0       | 0       | 0   |
| {'MSFT'} | 0.33426 | 0.26783 | 0.20478 | 0       | 0   |
| {'ORCL'} | 0       | 0       | 0       | 0       | 0   |
| {'YHOO'} | 0       | 0       | 0       | 0       | 0   |

The estimateFrontier function uses the MINLP solver to solve this problem. Use the setSolverMINLP function to configure the SolverType and options.

```
p1.solverTypeMINLP
```

```
ans =
'OuterApproximation'
```

```
p1.solverOptionsMINLP
```

```
ans = struct with fields:
      MaxIterations: 1000
      AbsoluteGapTolerance: 1.0000e-07
      RelativeGapTolerance: 1.0000e-05
      NonlinearScalingFactor: 1000
      ObjectiveScalingFactor: 1000
      Display: 'off'
```

```

CutGeneration: 'basic'
MaxIterationsInactiveCut: 30
ActiveCutTolerance: 1.0000e-07
IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
NumIterationsEarlyIntegerConvergence: 30

```

### Construct a PortfolioCVaR Object and Determine Efficient Portfolios

Create efficient portfolios:

```

load CAPMuniverse

p = PortfolioCVaR('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 , 'missingdata', true);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

plotFrontier(p);

```

```

pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5

```

```

    pnames{i} = sprintf('Port%d',i);
end
Blotter = dataset([{pwgt},pnames], 'obsnames', p.AssetList);
disp(Blotter);

```

|      | Port1    | Port2     | Port3    | Port4   | Port5 |
|------|----------|-----------|----------|---------|-------|
| AAPL | 0.010562 | 0.07364   | 0.11931  | 0.13073 | 0     |

### Create a PortfolioMAD Object and Determine Efficient Portfolios

Create efficient portfolios:

```

load CAPMuniverse
p = PortfolioMAD('AssetList', Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000, 'missingdata', true);
p = setDefaultConstraints(p);

plotFrontier(p);

```

```

pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([pwgt],pnames,'obsnames',p.AssetList);

disp(Blotter);

```

|      | Port1     | Port2    | Port3    | Port4   | Port5 |
|------|-----------|----------|----------|---------|-------|

| YHOO | 0         | 0        | 0        | 0       | 0     |

### Obtain the Default Number of Efficient Portfolios for a Portfolio Object

Obtain the default number of efficient portfolios over the entire range of the efficient frontier.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);
disp(pwgt);
```

Columns 1 through 7

```
0.8891    0.7215    0.5540    0.3865    0.2190    0.0515         0
0.0369    0.1289    0.2209    0.3129    0.4049    0.4969    0.4049
0.0404    0.0567    0.0730    0.0893    0.1056    0.1219    0.1320
0.0336    0.0929    0.1521    0.2113    0.2705    0.3297    0.4630
```

Columns 8 through 10

```
0         0         0
0.2314    0.0579         0
0.1394    0.1468         0
0.6292    0.7953    1.0000
```

### Obtain Purchases and Sales for Portfolios on the Efficient Frontier for a Portfolio Object

Starting from the initial portfolio, the `estimateFrontier` function returns purchases and sales to get from your initial portfolio to each efficient portfolio on the efficient frontier. Given an initial portfolio in `pwgt0`, you can obtain purchases and sales.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **NumPorts — Number of points to obtain on efficient frontier**

value from hidden property `defaultNumPorts` (default value is 10) (default) | scalar integer

Number of points to obtain on the efficient frontier, specified as a scalar integer.

---

**Note** If no value is specified for `NumPorts`, the default value is obtained from the hidden property `defaultNumPorts` (default value is 10). If `NumPorts = 1`, this function returns the portfolio specified by the hidden property `defaultFrontierLimit` (current default value is 'min').

---

Data Types: double

## Output Arguments

### **pwgt — Optimal portfolios on efficient frontier with specified number of portfolios spaced equally from minimum to maximum portfolio return**

matrix

Optimal portfolios on the efficient frontier with specified number of portfolios spaced equally from minimum to maximum portfolio return, returned as a `NumAssets`-by-`NumPorts` matrix. `pwgt` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **pbuy — Purchases relative to initial portfolio for optimal portfolios on efficient frontier**

matrix

Purchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as `NumAssets`-by-`NumPorts` matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that  $pbuy = \max(0, pwgt)$  and  $psell = \max(0, -pwgt)$ .

---

`pbuy` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **psell — Sales relative to initial portfolio for optimal portfolios on efficient frontier**

matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

---

`psell` is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

- You can also use dot notation to estimate the specified number of optimal portfolios over the entire efficient frontier.

```
[pwgt, pbuy, psell] = obj.estimateFrontier(NumPorts);
```

- When introducing transaction costs and turnover constraints to the `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object, the portfolio optimization objective contains a term with an absolute value. For more information on how Financial Toolbox handles such cases algorithmically, see “References” on page 19-694.

## Introduced in R2011a

# estimateFrontierByReturn

Estimate optimal portfolios with targeted portfolio returns

## Syntax

```
[pwgt,pbuy,psell] = estimateFrontierByReturn(obj,TargetReturn)
```

## Description

[pwgt,pbuy,psell] = estimateFrontierByReturn(obj,TargetReturn) estimates optimal portfolios with targeted portfolio returns for Portfolio, PortfolioCVaR, or PortfolioMAD objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

## Examples

### Obtain the Portfolio for Targeted Portfolio Returns for a Portfolio Object

To obtain efficient portfolios that have targeted portfolio returns, the estimateFrontierByReturn function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 6%, 9%, and 12%.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByReturn(p, [0.06, 0.09, 0.12]);
```

```
display(pwgt);
```

```
pwgt = 4×3
```

```
    0.8772    0.5032    0.1293
    0.0434    0.2488    0.4541
    0.0416    0.0780    0.1143
    0.0378    0.1700    0.3022
```

### Obtain Portfolios with Targeted Portfolio Returns for a Portfolio Object with BoundType, MinNumAsset, and MaxNumAsset Constraints

When any one, or any combination of the constraints from 'Conditional' BoundType, MinNumAssets, and MaxNumAssets are active, the portfolio problem is formulated as mixed integer programming problem and the MINLP solver is used.

Create a Portfolio object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use setBounds with semicontinuous constraints to set  $x_i = 0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i = 1, \dots, \text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.7, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a Portfolio object, the setMinMaxNumAssets function enables you to set up the limits on the number of assets invested (as known as cardinality) constraints. This sets the total number of allocated assets satisfying the Bound constraints that are between MinNumAssets and MaxNumAssets. By setting MinNumAssets = MaxNumAssets = 2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use estimateFrontierByReturn to estimate optimal portfolios with targeted portfolio returns.

```
[pwgt, pbuy, psell] = estimateFrontierByReturn(p, [ 0.0072321, 0.0119084 ])
```

```
pwgt = 3×2
```

```
    0    0.5000
0.6922    0
0.3078    0.5000
```

```
pbuy = 3×2
```

```
    0    0.5000
0.6922    0
0.3078    0.5000
```

```
psell = 3×2
```

```
    0    0
    0    0
    0    0
```

The estimateFrontierByReturn function uses the MINLP solver to solve this problem. Use the setSolverMINLP function to configure the SolverType and options.

```
p.solverTypeMINLP
```

```

ans =
'OuterApproximation'

p.solverOptionsMINLP

ans = struct with fields:

### Obtain the Portfolio for Targeted Portfolio Returns for a PortfolioCVaR Object

To obtain efficient portfolios that have targeted portfolio returns, the `estimateFrontierByReturn` function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 7%, 10%, and 13%.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioCVaR;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierByReturn(p, [0.07 0.10, 0.13]);

display(pwgt);

pwgt = 4x3

    0.7370    0.3067         0
    0.1502    0.3937    0.4396
    0.0290    0.0997    0.1360
    0.0838    0.1999    0.4244

```

The function `rng(seed)` is used to reset the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Obtain the Portfolio for Targeted Portfolio Returns for a PortfolioMAD Object

To obtain efficient portfolios that have targeted portfolio returns, the `estimateFrontierByReturn` function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 7%, 10%, and 13%.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioMAD;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);

pwgt = estimateFrontierByReturn(p, [0.07 0.10, 0.13]);

display(pwgt);

pwgt = 4x3

    0.7437    0.3146         0
    0.1357    0.3837    0.4425
    0.0326    0.0939    0.1319
    0.0881    0.2079    0.4255
```

The function `rng(seed)` is used to reset the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### TargetReturn — Target values for portfolio return

vector

Target values for portfolio return, specified as a `NumPorts` vector.

---

**Note** `TargetReturn` specifies target returns for portfolios on the efficient frontier. If any `TargetReturn` values are outside the range of returns for efficient portfolios, the `TargetReturn` is

replaced with the minimum or maximum efficient portfolio return, depending upon whether the target return is below or above the range of efficient portfolio returns.

---

Data Types: double

## Output Arguments

### **pwgt — Optimal portfolios on efficient frontier with specified target returns**

matrix

Optimal portfolios on the efficient frontier with specified target returns from TargetReturn, returned as a NumAssets-by-NumPorts matrix. pwgt is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

### **pbuy — Purchases relative to initial portfolio for optimal portfolios on efficient frontier**

matrix

Purchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as NumAssets-by-NumPorts matrix.

---

**Note** If no initial portfolio is specified in obj . InitPort, that value is assumed to be 0 such that  $pbuy = \max(0, pwgt)$  and  $psell = \max(0, -pwgt)$ .

---

pbuy is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

### **psell — Sales relative to initial portfolio for optimal portfolios on efficient frontier**

matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

---

**Note** If no initial portfolio is specified in obj . InitPort, that value is assumed to be 0 such that  $pbuy = \max(0, pwgt)$  and  $psell = \max(0, -pwgt)$ .

---

psell is returned for Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## Tips

You can also use dot notation to estimate optimal portfolios with targeted portfolio returns.

```
[pwgt, pbuy, psell] = obj.estimateFrontierByReturn(TargetReturn);
```

# estimateFrontierByRisk

Estimate optimal portfolios with targeted portfolio risks

## Syntax

```
[pwgt,pbuy,psell] = estimateFrontierByRisk(obj,TargetRisk)
```

```
[pwgt,pbuy,psell] = estimateFrontierByRisk( ___,Name,Value)
```

## Description

[pwgt,pbuy,psell] = estimateFrontierByRisk(obj,TargetRisk) estimates optimal portfolios with targeted portfolio risks for Portfolio, PortfolioCVaR, or PortfolioMAD objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

[pwgt,pbuy,psell] = estimateFrontierByRisk( \_\_\_,Name,Value) adds name-optional name-value pair arguments for Portfolio or PortfolioMAD objects.

## Examples

### Obtain Portfolios with Targeted Portfolio Risks for a Portfolio Object

To obtain efficient portfolios that have targeted portfolio risks, the estimateFrontierByRisk function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 14%, and 16%. This example uses the default 'direct' method to estimate the optimal portfolios with targeted portfolio risks.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);

display(pwgt);

pwgt = 4×3

    0.3984    0.2659    0.1416
    0.3064    0.3791    0.4474
    0.0882    0.1010    0.1131
    0.2071    0.2540    0.2979
```

### Obtain Portfolios with Targeted Portfolio Risks for a Portfolio Object with BoundType, MinNumAsset, and MaxNumAsset Constraints

When any one, or any combination of the constraints from 'Conditional' BoundType, MinNumAssets, and MaxNumAssets are active, the portfolio problem is formulated as mixed integer programming problem and the MINLP solver is used.

Create a Portfolio object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use setBounds with semicontinuous constraints to set  $x_i = 0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i = 1, \dots, \text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.7, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a Portfolio object, the setMinMaxNumAssets function enables you to set up the limits on the number of assets invested (as known as cardinality) constraints. This sets the total number of allocated assets satisfying the Bound constraints that are between MinNumAssets and MaxNumAssets. By setting MinNumAssets = MaxNumAssets = 2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use estimateFrontierByRisk to estimate optimal portfolios with targeted portfolio risks.

```
[pwgt, pbuy, psell] = estimateFrontierByRisk(p, [0.0324241, 0.0694534 ])
```

```
pwgt = 3×2
```

```
    0.0000    0.5000
    0.6907         0
    0.3093    0.5000
```

```
pbuy = 3×2
```

```
    0.0000    0.5000
    0.6907         0
    0.3093    0.5000
```

```
psell = 3×2
```

```
         0         0
         0         0
         0         0
```

The estimateFrontierByRisk function uses the MINLP solver to solve this problem. Use the setSolverMINLP function to configure the SolverType and options.

```

p.solverTypeMINLP

ans =
'OuterApproximation'

p.solverOptionsMINLP

ans = struct with fields:
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    Display: 'off'
    CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30

```

### Obtain Portfolios with Targeted Portfolio Risks for a Portfolio Object Using the Direct Method and Solver Options

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 14%, and 16%. This example uses the default `'direct'` method to estimate the optimal portfolios with targeted portfolio risks. The `'direct'` method uses `fmincon` to solve the optimization problem that maximizes portfolio return, subject to the target risk as the quadratic nonlinear constraint. `setSolver` specifies the `solverType` and `SolverOptions` for `fmincon`.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);

p = setSolver(p, 'fmincon', 'Display', 'off', 'Algorithm', 'sqp', ...
    'SpecifyObjectiveGradient', true, 'SpecifyConstraintGradient', true, ...
    'ConstraintTolerance', 1.0e-8, 'OptimalityTolerance', 1.0e-8, 'StepTolerance', 1.0e-8);

pwgt = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);

display(pwgt);

pwgt = 4x3

    0.3984    0.2659    0.1416
    0.3064    0.3791    0.4474

```

```

0.0882    0.1010    0.1131
0.2071    0.2540    0.2979

```

### Obtain Portfolios with Targeted Portfolio Risks for a PortfolioCVaR Object

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 20%, and 30%.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioCVaR;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierByRisk(p, [0.12, 0.20, 0.30]);

display(pwgt);

pwgt = 4x3

    0.5363    0.1387         0
    0.2655    0.4991    0.3830
    0.0570    0.1239    0.1461
    0.1412    0.2382    0.4709

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Obtain Portfolios with Targeted Portfolio Risks for a PortfolioMAD Object

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 20%, and 25%. This example uses the default 'direct' method to estimate the optimal portfolios with targeted portfolio risks.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

```

```

rng(11);

p = PortfolioMAD;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);

pwgt = estimateFrontierByRisk(p, [0.12, 0.20, 0.25]);

display(pwgt);

pwgt = 4×3

    0.1610         0         0
    0.4784    0.2137    0.0047
    0.1116    0.1384    0.1200
    0.2490    0.6480    0.8753

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Obtain Portfolios with Targeted Portfolio Risks for a PortfolioMAD Object Using the Direct Method and Solver Options

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 20%, and 25%. This example uses the default 'direct' method to estimate the optimal portfolios with targeted portfolio risks. The 'direct' method uses `fmincon` to solve the optimization problem that maximizes portfolio return, subject to the target risk as the quadratic nonlinear constraint. `setSolver` specifies the `solverType` and `SolverOptions` for `fmincon`.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioMAD;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);

p = setSolver(p, 'fmincon', 'Display', 'off', 'Algorithm', 'sqp', ...
              'SpecifyObjectiveGradient', true, 'SpecifyConstraintGradient', true, ...
              'ConstraintTolerance', 1.0e-8, 'OptimalityTolerance', 1.0e-8, 'StepTolerance', 1.0e-8);
plotFrontier(p);

```

```
pwgt = estimateFrontierByRisk(p, [0.12 0.20, 0.25]);
```

```
display(pwgt);
```

```
pwgt = 4×3
```

```

0.1613    0.0000         0
0.4777    0.2139    0.0037

0.2492    0.6480    0.8749

```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

---

**Note** If no initial portfolio is specified in `obj.InitPort`, it is assumed to be 0 so that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`. For more information on setting an initial portfolio, see `setInitPort`.

---

Data Types: object

### TargetRisk — Target values for portfolio risk

vector

Target values for portfolio risk, specified as a `NumPorts` vector.

---

**Note** If any `TargetRisk` values are outside the range of risks for efficient portfolios, the target risk is replaced with the minimum or maximum efficient portfolio risk, depending on whether the target risk is below or above the range of efficient portfolio risks.

---

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[pwgt, pbuy, psell] = estimateFrontierByRisk(p, 'method', 'direct')`

### Method — Method to estimate frontier by risk for Portfolio or PortfolioMAD objects

'direct' (default) | character vector with value 'direct' or 'iterative'

Method to estimate frontier by risk for `Portfolio` or `PortfolioMAD` objects, specified as the comma-separated pair consisting of 'Method' and a character vector with one of the following values:

- 'direct' — Construct one optimization problem to maximize the portfolio return with target risk as the nonlinear constraint, and solve it directly using `fmincon`, instead of iteratively exploring the efficient frontier. For an example of using the 'direct' option, see “Obtain Portfolios with Targeted Portfolio Risks for a Portfolio Object Using the Direct Method and Solver Options” on page 19-703 and “Obtain Portfolios with Targeted Portfolio Risks for a PortfolioMAD Object Using the Direct Method and Solver Options” on page 19-705.
- 'iterative' — One-dimensional optimization using `fminbnd` to find the portfolio return between min and max return on the frontier that minimizes the difference between the actual risk and target risk. Then the portfolio weights are obtained by solving a frontier by return problem. Consequently, the 'iterative' method is slower than the 'direct'.

Data Types: char

## Output Arguments

### pwgt — Optimal portfolios on efficient frontier with specified target risks

matrix

Optimal portfolios on the efficient frontier with specified target returns from `TargetRisk`, returned as a `NumAssets-by-NumPorts` matrix. `pwgt` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**pbuy** — Purchases relative to initial portfolio for optimal portfolios on efficient frontier matrix

Purchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as `NumAssets-by-NumPorts` matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

---

`pbuy` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**psell** — Sales relative to initial portfolio for optimal portfolios on efficient frontier matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a `NumAssets-by-NumPorts` matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

---

`psell` is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

You can also use dot notation to estimate optimal portfolios with targeted portfolio risks.

```
[pwgt,pbuy,psell] = obj.estimateFrontierByRisk(TargetRisk);
```

or

```
[pwgt,pbuy,psell] = obj.estimateFrontierByRisk(TargetRisk,Name,Value);
```

## estimateFrontierLimits

Estimate optimal portfolios at endpoints of efficient frontier

### Syntax

```
[pwgt,pbuy,psell] = estimateFrontierLimits(obj)
[pwgt,pbuy,psell] = estimateFrontierLimits(obj,Choice)
```

### Description

[pwgt,pbuy,psell] = estimateFrontierLimits(obj) estimates optimal portfolios at endpoints of efficient frontier for Portfolio, PortfolioCVaR, or PortfolioMAD objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

[pwgt,pbuy,psell] = estimateFrontierLimits(obj,Choice) estimates optimal portfolios at endpoints of efficient frontier with an additional option specified for the Choice argument.

### Examples

#### Obtain Endpoint Portfolios for a Portfolio Object

Given portfolio p, the estimateFrontierLimits function obtains the endpoint portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
```

```
disp(pwgt);
```

```
0.8891      0
0.0369      0
0.0404      0
0.0336      1.0000
```

### Obtain Endpoint Portfolios for a Portfolio Object with BoundType, MinNumAsset, and MaxNumAsset Constraints

When any one, or any combination of the constraints from 'Conditional' BoundType, MinNumAssets, and MaxNumAssets are active, the portfolio problem is formulated as mixed integer programming problem and the MINLP solver is used.

Create a Portfolio object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use setBounds with semicontinuous constraints to set  $x_i = 0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i = 1, \dots, \text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.7, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a Portfolio object, the setMinMaxNumAssets function enables you to set up the limits on the number of assets invested (as known as cardinality) constraints. This sets the total number of allocated assets satisfying the Bound constraints that are between MinNumAssets and MaxNumAssets. By setting MinNumAssets = MaxNumAssets = 2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use estimateFrontierLimits to estimate the optimal portfolios at endpoints of the efficient frontier.

```
[pwgt, pbuy, psell] = estimateFrontierLimits(p, 'Both')
```

```
pwgt = 3x2
```

```
    0.3000    0.3000
    0.7000         0
         0    0.7000
```

```
pbuy = 3x2
```

```
    0.3000    0.3000
    0.7000         0
         0    0.7000
```

```
psell = 3x2
```

```
         0         0
         0         0
         0         0
```

The estimateFrontierLimits function uses the MINLP solver to solve this problem. Use the setSolverMINLP function to configure the SolverType and options.

```

p.solverTypeMINLP

ans =
'OuterApproximation'

p.solverOptionsMINLP

ans = struct with fields:
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    Display: 'off'
    CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30

```

### Obtain Endpoint Portfolios for a PortfolioCVaR Object

Given portfolio `p`, the `estimateFrontierLimits` function obtains the endpoint portfolios.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);

disp(pwgt);

```

|        |        |
|--------|--------|
| 0.8451 | 0      |
| 0.0613 | 0      |
| 0.0451 | 0      |
| 0.0485 | 1.0000 |

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Obtain Endpoint Portfolios for a PortfolioMAD Object

Given portfolio `p`, the `estimateFrontierLimits` function obtains the endpoint portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontierLimits(p);

disp(pwgt);

    0.8817         0
    0.0431         0
    0.0387         0
    0.0366    1.0000
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **Choice** — Indicator for which portfolios to obtain at extreme ends of efficient frontier

[ ] (default) | character vector with values 'Both', 'Min', 'Max' | string with values "Both", "Min", "Max"

(Optional) Indicator which portfolios to obtain at the extreme ends of the efficient frontier, specified as a character vector with values 'Both' or "Both", 'Min' or "Min", or 'Max' or "Max". The options for a `Choice` action are:

- `[]` — Compute both minimum-risk and maximum-return portfolios.
- `'Both'` or `"Both"` — Compute both minimum-risk and maximum-return portfolios.
- `'Min'` or `"Min"` — Compute minimum-risk portfolio only.
- `'Max'` or `"Max"` — Compute maximum-return portfolio only.

Data Types: `char` | `string`

## Output Arguments

### **pwgt — Optimal portfolios at endpoints of efficient frontier**

matrix

Optimal portfolios at the endpoints of the efficient frontier `TargetReturn`, returned as a `NumAssets-by-NumPorts` matrix. `pwgt` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **pbuy — Purchases relative to an initial portfolio for optimal portfolios at endpoints of efficient frontier**

matrix

Purchases relative to an initial portfolio for optimal portfolios at the endpoints of the efficient frontier, returned as `NumAssets-by-NumPorts` matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

---

`pbuy` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **psell — Sales relative to an initial portfolio for optimal portfolios at endpoints of efficient frontier**

matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a `NumAssets-by-NumPorts` matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

---

`psell` is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

You can also use dot notation to estimate the optimal portfolios at the endpoints of the efficient frontier.

```
[pwgt, pbuy, psell] = obj.estimateFrontierLimits(Choice);
```

## estimateMaxSharpeRatio

Estimate efficient portfolio to maximize Sharpe ratio for Portfolio object

### Syntax

```
[pwgt,pbuy,psell] = estimateMaxSharpeRatio(obj)
[pwgt,pbuy,psell] = estimateMaxSharpeRatio( ___,Name,Value)
```

### Description

[pwgt,pbuy,psell] = estimateMaxSharpeRatio(obj) estimates efficient portfolio to maximize Sharpe ratio for Portfolio object. For details on the workflow, see “Portfolio Object Workflow” on page 4-16.

[pwgt,pbuy,psell] = estimateMaxSharpeRatio( \_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object

Estimate the efficient portfolio that maximizes the Sharpe ratio. The estimateMaxSharpeRatio function maximizes the Sharpe ratio among portfolios on the efficient frontier. This example uses the default 'direct' method to estimate the maximum Sharpe ratio. For more information on the 'direct' method, see “Algorithms” on page 19-723.

```
p = Portfolio('AssetMean',[0.3, 0.1, 0.5], 'AssetCovar',...
[0.01, -0.010, 0.004; -0.010, 0.040, -0.002; 0.004, -0.002, 0.023]);
p = setDefaultConstraints(p);
plotFrontier(p, 20);
weights = estimateMaxSharpeRatio(p);
[risk, ret] = estimatePortMoments(p, weights);
hold on
plot(risk,ret,'*r');
```

### Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object Using Solver Options with the Direct Method

Estimate the efficient portfolio that maximizes the Sharpe ratio. The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier. This example uses the 'direct' method for a `Portfolio` object (`p`) that does not specify a tracking error and only uses linear constraints. The `setSolver` function is used to control the `SolverType` and `SolverOptions`. In this case, the `SolverType` is `quadprog`. For more information on the 'direct' method, see "Algorithms" on page 19-723.

```
p = Portfolio('AssetMean',[0.3, 0.1, 0.5], 'AssetCovar',...
[0.01, -0.010, 0.004; -0.010, 0.040, -0.002; 0.004, -0.002, 0.023]);
p = setDefaultConstraints(p);
plotFrontier(p, 20);
p = setSolver(p,'quadprog','Display','off','ConstraintTolerance',1.0e-8,'OptimalityTolerance',1.0e-8);
weights = estimateMaxSharpeRatio(p);
[risk, ret] = estimatePortMoments(p, weights);
hold on
plot(risk,ret,'*r');
```

### Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object With Tracking Error Using the Direct Method and Solver Options

Estimate the efficient portfolio that maximizes the Sharpe ratio. The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier. This example uses the 'direct' method for a `Portfolio` object (`p`) that specifies a tracking error uses nonlinear constraints. The `setSolver` function is used to control the `SolverType` and `SolverOptions`. In this case `fmincon` is the `SolverType`.

```
p = Portfolio('AssetMean',[0.3, 0.1, 0.5], 'AssetCovar',...
[0.01, -0.010, 0.004; -0.010, 0.040, -0.002; 0.004, -0.002, 0.023], 'lb', 0, 'budget', 1);
plotFrontier(p, 20);

p = setSolver(p, 'fmincon', 'Display', 'off', 'Algorithm', 'sqp', ...
'SpecifyObjectiveGradient', true, 'SpecifyConstraintGradient', true, ...
'ConstraintTolerance', 1.0e-8, 'OptimalityTolerance', 1.0e-8, 'StepTolerance', 1.0e-8);

weights = estimateMaxSharpeRatio(p);

te = 0.08;
p = setTrackingError(p, te, weights);

[risk, ret] = estimatePortMoments(p, weights);
```

```
hold on
plot(risk,ret,'*r');
```

### Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object With a Risk-Free Asset Using the Direct and Iterative Method

The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier. In the case of Portfolio with a risk-free asset, there are multiple efficient portfolios that maximize the Sharpe ratio on the capital asset line. Because of the nature of 'direct' and 'iterative' methods, the portfolio weights (`pwgts`) output from each of these methods might be different, but the Sharpe ratio is the same. This example demonstrates the scenario where the `pwgts` are different and the Sharpe ratio is the same.

```
load BlueChipStockMoments

mret = MarketMean;
mrsk = sqrt(MarketVar);
cret = CashMean;
crsk = sqrt(CashVar);

p = Portfolio('AssetList', AssetList, 'RiskFreeRate', CashMean);
p = setAssetMoments(p, AssetMean, AssetCovar);

p = setInitPort(p, 1/p.NumAssets);
```

```
[ersk, eret] = estimatePortMoments(p, p.InitPort);
```

```
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p, 20);
[prsk, pret] = estimatePortMoments(p, pwgt);
pwgtshpr_fully = estimateMaxSharpeRatio(p, 'Method', 'direct');
[riskshpr_fully, retshpr_fully] = estimatePortMoments(p, pwgtshpr_fully);
```

```
q = setBudget(p, 0, 1);
qwgt = estimateFrontier(q, 20);
[qrsk, qret] = estimatePortMoments(q, qwgt);
```

Plot the efficient frontier with a tangent line (0 to 1 cash).

```
pwgtshpr_direct = estimateMaxSharpeRatio(q, 'Method', 'direct');
pwgtshpr_iter = estimateMaxSharpeRatio(q, 'Method', 'iterative');
[riskshpr_diret, retshpr_diret] = estimatePortMoments(q, pwgtshpr_direct);
[riskshpr_iter, retshpr_iter] = estimatePortMoments(q, pwgtshpr_iter);
```

```
clf;
```

```
portfolioexamples_plot('Efficient Frontier with Capital Allocation Line', ...
    {'line', prsk, pret, {'EF'}, '-r', 2}, ...
    {'line', qrsk, qret, {'EF with riskfree'}, '-b', 1}, ...
    {'scatter', [mrsk, crsk, ersk, riskshpr_fully, riskshpr_diret, riskshpr_iter], .
    [mret, cret, eret, retshpr_fully, retshpr_diret, retshpr_iter], {'Market', 'Cash', 'Equal',
    {'scatter', sqrt(diag(p.AssetCovar)), p.AssetMean, p.AssetList, '.r'}});
```

When a risk-free asset is not available to the portfolio, or in other words, the portfolio is fully invested, the efficient frontier is curved, corresponding to the red line in the above figure. Therefore, there is a unique (risk, return) point that maximizes the Sharpe ratio, which the 'iterative' and 'direct' methods will both find. If the portfolio is allowed to invest in a risk-free asset, part of the red efficient frontier line is replaced by the capital allocation line, resulting in the efficient frontier of a portfolio with a risk-free investment (blue line). All the (risk, return) points on the straight blue line share the same Sharpe ratio. Also, it is likely that the 'iterative' and 'direct' methods end up with different points, therefore there are different portfolio allocations.

### Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object with Semicontinuous and Cardinality Constraints

Create a Portfolio object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semicontinuous constraints to set  $x_i = 0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i = 1, \dots, \text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.5, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a Portfolio object, the `setMinNumAssets` function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the Portfolio object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets = MaxNumAssets = 2`, only two of the three assets are invested in the portfolio.

```
p = setMinNumAssets(p, 2, 2);
```

Use `estimateMaxSharpeRatio` to estimate efficient portfolio to maximize Sharpe ratio.

```
weights = estimateMaxSharpeRatio(p, 'Method', 'iterative')
```

```
weights = 3×1
```

```
0.0000
0.5000
0.5000
```

The `estimateMaxSharpeRatio` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverOptionsMINLP
```

```
ans = struct with fields:
```

```
    MaxIterations: 1000
  AbsoluteGapTolerance: 1.0000e-07
  RelativeGapTolerance: 1.0000e-05
  NonlinearScalingFactor: 1000
```

```

ObjectiveScalingFactor: 1000
    Display: 'off'
    CutGeneration: 'basic'
MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
NumIterationsEarlyIntegerConvergence: 30

```

## Input Arguments

### obj — Object for portfolio

object

Object for portfolio, specified using a `Portfolio` object.

---

**Note** The risk-free rate is obtained from the property `RiskFreeRate` in the `Portfolio` object. If you leave the `RiskFreeRate` unset, it is assumed to be 0. If the max return of portfolio is less than the `RiskFreeRate`, the solution is set as `pwgt` at max return and the resulting Sharpe ratio will be negative.

---

For more information on creating a portfolio object, see

- `Portfolio`

Data Types: object

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[pwgt,pbuy,psell] = estimateMaxSharpeRatio(p,'Method','iterative')`

### Method — Method to estimate Sharpe ratio

'direct' (default) | character vector with value 'direct' or 'iterative'

Method to estimate Sharpe ratio, specified as the comma-separated pair consisting of 'Method' and a character vector with one of the following values:

- 'direct' — Transform the Sharpe ratio function into a quadratic one and solve one optimization problem directly, instead of iteratively exploring the efficient frontier. The 'direct' option either uses the solver `quadprog` (for a problem with linear constraints) or `fmincon` (for a problem with nonlinear constraints). For an example of using the 'direct' option, see “Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object Using Solver Options with the Direct Method” on page 19-717 and “Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object With Tracking Error Using the Direct Method and Solver Options” on page 19-718.
- 'iterative' — One-dimensional optimization using `fminbnd` to find the portfolio that maximizes the Sharpe ratio by iteratively exploring the efficient frontier.

---

**Note** If you are using `estimateMaxSharpeRatio` with a `Portfolio` object with semicontinuous and cardinality constraints specified by `setBounds` and `setMinMaxNumAssets`, you can only use the `'iterative'` method.

---

Data Types: `char`

## Output Arguments

### **pwgt — Portfolio on efficient frontier with maximum Sharpe ratio**

vector

Portfolio on the efficient frontier with a maximum Sharpe ratio, returned as a `NumAssets` vector.

### **pbuy — Purchases relative to initial portfolio for portfolio on efficient frontier with maximum Sharpe ratio**

vector

Purchases relative to an initial portfolio for a portfolio on the efficient frontier with a maximum Sharpe ratio, returned as a `NumAssets` vector.

`pbuy` is returned for a `Portfolio` input object (`obj`).

### **psell — Sales relative to initial portfolio for portfolio on efficient frontier with maximum Sharpe ratio**

vector

Sales relative to an initial portfolio for a portfolio on the efficient frontier with maximum Sharpe ratio, returned as a `NumAssets` vector.

`psell` is returned for a `Portfolio` input object (`obj`).

## More About

### Sharpe Ratio

The Sharpe ratio is the ratio of the difference between the mean of portfolio returns and the risk-free rate divided by the standard deviation of portfolio returns.

The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier.

## Tips

You can also use dot notation to estimate an efficient portfolio that maximizes the Sharpe ratio.

```
[pwgt,pbuy,psell] = obj.estimateMaxSharpeRatio;
```

## Algorithms

The maximization of the Sharpe ratio is accomplished by either using the `'direct'` or `'iterative'` method. For the `'direct'` method, consider the following scenario. To maximize the Sharpe ratio is to:

$$\text{Maximize } \frac{\mu^T x - r_f}{\sqrt{x^T C x}}, \text{ s.t. } \sum x_i = 1, \quad 0 \leq x_i \leq 1,$$

where  $\mu$  and  $C$  are the mean and covariance matrix, and  $r_f$  is the risk-free rate.

If  $\mu^T x - r_f \leq 0$  for all  $x$  the portfolio that maximizes the Sharpe ratio is the one with maximum return.

$$\text{If } \mu^T x - r_f > 0, \text{ let } t = \frac{1}{\mu^T x - r_f}$$

and  $y = tx$  (Cornuejols [1] section 8.2). Then after some substitutions, we can transform the original problem into the following form,

$$\text{Minimize } y^T C y, \text{ s.t. } \sum y_i = t, \quad t > 0, \quad 0 \leq y_i \leq t, \quad \mu^T y - r_f t = 1.$$

Only one optimization needs to be solved, hence the name “direct”. The portfolio weights can be recovered by  $x^* = y^* / t^*$ .

For the 'iterative' method, the idea is to iteratively explore the portfolios at different return levels on the efficient frontier and locate the one with maximum Sharpe ratio. Therefore, multiple optimization problems are solved during the process, instead of only one in the 'direct' method. Consequently, the 'iterative' method is slow compared to 'direct' method.

## Introduced in R2011b

# estimatePortSharpeRatio

Estimate Sharpe ratio of given portfolio weights for Portfolio object

## Syntax

```
psharpe = estimatePortSharpeRatio(obj,pwgt)
```

## Description

`psharpe = estimatePortSharpeRatio(obj,pwgt)` estimates the Sharpe ratio of given portfolio weights for a `Portfolio` object. For details on the workflow, see “Portfolio Object Workflow” on page 4-16.

## Examples

### Estimate Sharpe Ratios of the Given Portfolio Weights

This example shows how to find efficient portfolios that satisfy the target returns and then find the Sharpe ratios corresponding to each of the portfolios.

To obtain efficient portfolios that have targeted portfolio returns, the `estimateFrontierByReturn` function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 6%, 9%, and 12%. Use `estimatePortSharpeRatio` to obtain the Sharpe ratio for the collection of portfolios (`pwgt`).

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByReturn(p, [0.06, 0.09, 0.12]);

display(pwgt);

pwgt = 4×3

    0.8772    0.5032    0.1293
    0.0434    0.2488    0.4541
    0.0416    0.0780    0.1143
    0.0378    0.1700    0.3022
```

`pwgt` is a `NumAssets-by-NumPorts` matrix where `NumAssets` is the number of asset in the universe and `NumPorts` is the number of portfolios in the collection of portfolios.

```
psharpe = estimatePortSharpeRatio(p,pwgt)
```

```
psharpe = 3×1  
  0.7796  
  0.8519  
  0.7406
```

`psharpe` is a NumPorts-by-1 vector, where NumPorts is the number of portfolios in the collection of portfolios.

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using a Portfolio object.

---

**Note** The risk-free rate is obtained from the property `RiskFreeRate` in the Portfolio object. If you leave the `RiskFreeRate` unset, it is assumed to be 0. For more information on creating a portfolio object, see `Portfolio`.

---

Data Types: object

### **pwgt** — Collection of portfolios

matrix

Collection of portfolios, specified as a NumAssets-by- NumPorts matrix where NumAssets is the number of assets in the universe and NumPorts is the number of portfolios in the collection of portfolios.

Data Types: double

## Output Arguments

### **psharpe** — Sharpe ratios of the given portfolios

vector

Sharpe ratios of the given portfolios, returned as a NumPorts-by-1 vector.

## More About

### Sharpe Ratio

The Sharpe ratio is the ratio of the difference between the mean of portfolio returns and the risk-free rate divided by the standard deviation of portfolio returns for each portfolio in `pwgt`.

`estimatePortSharpeRatio` computes the Sharpe ratio with mean and standard deviation (which is the square-root of variance) of portfolio returns.

## Tips

You can also use dot notation to estimate the Sharpe ratio of given portfolio weights.

```
psharpe = obj.estimatePortSharpeRatio(pwgt);
```

## Introduced in R2018a

## estimatePortMoments

Estimate moments of portfolio returns for Portfolio object

### Syntax

```
[prsk,pret] = estimatePortMoments(obj,pwgt)
```

### Description

`[prsk,pret] = estimatePortMoments(obj,pwgt)` estimate moments of portfolio returns for a Portfolio object. For details on the workflow, see “Portfolio Object Workflow” on page 4-16.

The estimate of port moments is specific to mean-variance portfolio optimization and computes the mean and standard deviation (which is the square-root of variance) of portfolio returns.

### Examples

#### Identify the Range of Risks and Returns for Efficient Portfolios for a Portfolio Object

Given portfolio `p`, use the `estimatePortMoments` function to show the range of risks and returns for efficient portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);

[prsk, pret] = estimatePortMoments(p, pwgt);
disp([prsk, pret]);

    0.0769    0.0590
    0.3500    0.1800
```

### Input Arguments

#### **obj** — Object for portfolio

object

Object for portfolio, specified using a Portfolio object. For more information on creating a portfolio object, see

- Portfolio

Data Types: object

### **pwgt — Collection of portfolios**

matrix

Collection of portfolios, specified as a NumAssets-by-NumPorts matrix where NumAssets is the number of assets in the universe and NumPorts is the number of portfolios in the collection of portfolios.

Data Types: double

## **Output Arguments**

### **prsk — Estimates for standard deviations of portfolio returns for each portfolio in pwgt**

vector

Estimates for standard deviations of portfolio returns for each portfolio in pwgt, returned as a NumPorts vector.

prsk is returned for a Portfolio input object (obj).

### **pret — Estimates for means of portfolio returns for each portfolio in pwgt**

vector

Estimates for means of portfolio returns for each portfolio in pwgt, returned as a NumPorts vector.

pret is returned for a Portfolio input object (obj).

## **Tips**

You can also use dot notation to estimate the moments of portfolio returns.

```
[prsk, pret] = obj.estimatePortMoments(pwgt);
```

## **See Also**

estimatePortReturn | estimatePortRisk

## **Topics**

## estimatePortReturn

Estimate mean of portfolio returns

### Syntax

```
pret = estimatePortReturn(obj,pwgt)
```

### Description

`pret = estimatePortReturn(obj,pwgt)` estimates the mean of portfolio returns (as the proxy for portfolio return) for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

### Examples

#### Estimate the Mean of Portfolio Returns for a Portfolio Object

Given portfolio `p`, use the `estimatePortReturn` function to estimate the mean of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)

    0.0590
    0.1800
```

#### Estimate the Mean of Portfolio Returns for a PortfolioCVaR Object

Given portfolio `p`, use the `estimatePortReturn` function to estimate the mean of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
```

```

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)

    0.0050
    0.0154

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Estimate the Mean of Portfolio Returns for a PortfolioMAD Object

Given portfolio `p`, use the `estimatePortReturn` function to estimate the mean of portfolio returns.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)

    0.0048
    0.0154

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

### **pwgt** — Collection of portfolios

`matrix`

Collection of portfolios, specified as a `NumAssets`-by-`NumPorts` matrix, where `NumAssets` is the number of assets in the universe and `NumPorts` is the number of portfolios in the collection of portfolios.

Data Types: `double`

## Output Arguments

### **pret** — Estimates for means of portfolio returns for each portfolio in `pwgt`

`vector`

Estimates for means of portfolio returns for each portfolio in `pwgt`, returned as a `NumPorts` vector.

`pret` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** Depending on whether costs have been set, the portfolio return is either gross or net portfolio returns. For information on setting costs, see `setCosts`.

---

## Tips

You can also use dot notation to estimate the mean of portfolio returns (as the proxy for portfolio return).

```
pret = obj.estimatePortReturn(pwgt);
```

## estimatePortRisk

Estimate portfolio risk according to risk proxy associated with corresponding object

### Syntax

```
prsk = estimatePortRisk(obj,pwgt)
```

### Description

`prsk = estimatePortRisk(obj,pwgt)` estimates portfolio risk according to the risk proxy associated with the corresponding object (`obj`) for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

### Examples

#### Standard Deviation of Portfolio Returns as the Proxy for Portfolio Risk for a Portfolio Object

Given portfolio `p`, use the `estimatePortRisk` function to show the standard deviation of portfolio returns for each portfolio in `pwgt`.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
disp(prsk)
```

```
0.0769
0.3500
```

#### Conditional Value-at-Risk of Portfolio Returns as the Proxy for Portfolio Risk for a PortfolioCVaR Object

Given a portfolio `pwgt`, use the `estimatePortRisk` function to show the conditional value-at-risk (CVaR) of portfolio returns for each portfolio.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
```

```

    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
disp(prsk)

    0.0407
    0.1911

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Mean-Absolute Deviation Returns as the Proxy for Portfolio Risk for a PortfolioMAD Object

Given a portfolio `pwgt`, use the `estimatePortRisk` function to show the mean-absolute deviation of portfolio returns for each portfolio.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
disp(prsk)

    0.0177
    0.0809

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **pwgt — Collection of portfolios**

matrix

Collection of portfolios, specified as a `NumAssets`-by-`NumPorts` matrix, where `NumAssets` is the number of assets in the universe and `NumPorts` is the number of portfolios in the collection of portfolios.

Data Types: double

## Output Arguments

### **prsk — Estimates for portfolio risk according to the risk proxy associated with the corresponding object (obj) for each portfolio in pwgt**

vector

Estimates for portfolio risk according to the risk proxy associated with the corresponding object (`obj`) for each portfolio in `pwgt`, returned as a `NumPorts` vector.

`prsk` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

You can also use dot notation to estimate portfolio risk according to the risk proxy associated with the corresponding object (`obj`).

```
prsk = obj.estimatePortRisk(pwgt);
```

## estimatePortStd

Estimate standard deviation of portfolio returns

### Syntax

```
pstd = estimatePortStd(obj,pwgt)
```

### Description

`pstd = estimatePortStd(obj,pwgt)` estimate standard deviation of portfolio returns for `PortfolioCVaR` or `PortfolioMAD` objects. For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-14 and “PortfolioMAD Object Workflow” on page 6-14.

### Examples

#### Estimate Standard Deviations for Portfolio Returns for a PortfolioCVaR Object

Given a portfolio `pwgt`, use the `estimatePortStd` function to show the standard deviation of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);

pstd = estimatePortStd(p, pwgt);
disp(pstd)

    0.0223
    0.1010
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Estimate Standard Deviations for Portfolio Returns for a PortfolioMAD Object

Given a portfolio `pwgt`, use the `estimatePortStd` function to show the standard deviation of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontierLimits(p);

pstd = estimatePortStd(p, pwgt);
disp(pstd)

    0.0222
    0.1010
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using a `PortfolioCVaR` or `PortfolioMAD` object.

For more information on creating a `PortfolioCVaR` or `PortfolioMAD` object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **pwgt** — Collection of portfolios

matrix

Collection of portfolios, specified as a `NumAssets`-by-`NumPorts` matrix, where `NumAssets` is the number of assets in the universe and `NumPorts` is the number of portfolios in the collection of portfolios.

Data Types: double

## Output Arguments

**pstd** — Estimates for standard deviations of portfolio returns for each portfolio in `pwgt` vector

Estimates for standard deviations of portfolio returns for each portfolio in `pwgt`, returned as a `NumPorts` vector.

## Tips

You can also use dot notation to estimate the standard deviation of portfolio returns.

```
pstd = obj.estimatePortStd(pwgt);
```

# estimatePortVaR

Estimate value-at-risk for PortfolioCVaR object

## Syntax

```
pvar = estimatePortVaR(obj,pwgt)
```

## Description

`pvar = estimatePortVaR(obj,pwgt)` estimates value-at-risk for a `PortfolioCVaR` object where the probability level used is from the `PortfolioCVaR` property `ProbabilityLevel`. For details on the workflow, see “PortfolioCVaR Object Workflow” on page 5-14.

## Examples

### Estimate Value-at-Risk for a PortfolioCVaR Object

Given a portfolio `pwgt`, use the `estimatePortVaR` function to estimate the value-at-risk of portfolio.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);

pvar = estimatePortVaR(p, pwgt);
disp(pvar)

    0.0314
    0.1483
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using a PortfolioCVaR object.

For more information on creating a PortfolioCVaR object, see

- PortfolioCVaR

Data Types: object

### **pwgt** — Collection of portfolios

matrix

Collection of portfolios, specified as a NumAssets-by-NumPorts matrix, where NumAssets is the number of assets in the universe and NumPorts is the number of portfolios in the collection of portfolios.

Data Types: double

## Output Arguments

### **pvar** — Estimates for value-at-risk of portfolio returns for each portfolio in pwgt

vector

Estimates for value-at-risk of portfolio returns for each portfolio in pwgt, returned as a NumPorts vector.

## Tips

You can also use dot notation to estimate the value-at-risk of PortfolioCVaR object.

```
pvar = obj.estimatePortVaR(pwgt);
```

## See Also

# estimateScenarioMoments

Estimate mean and covariance of asset return scenarios

## Syntax

```
[ScenarioMean, ScenarioCovar] = estimateScenarioMoments(obj)
```

## Description

[ScenarioMean, ScenarioCovar] = estimateScenarioMoments(obj) estimates mean and covariance of asset return scenarios for PortfolioCVaR or PortfolioMAD objects. For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

## Examples

### Estimate Mean and Covariance of Asset Return Scenarios for a PortfolioCVaR Object

Given PortfolioCVaR object p, use the estimatePortRisk function to estimate mean and covariance of asset return scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

[ScenarioMean, ScenarioCovar] = estimateScenarioMoments(p)

ScenarioMean = 4x1

    0.0039
    0.0082
    0.0102
    0.0154

ScenarioCovar = 4x4

    0.0005    0.0003    0.0001   -0.0001
```

```

0.0003    0.0024    0.0017    0.0010
0.0001    0.0017    0.0048    0.0028
-0.0001   0.0010    0.0028    0.0102

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Estimate Mean and Covariance of Asset Return Scenarios for a PortfolioMAD Object

Given PortfolioMAD object `p`, use the `estimatePortRisk` function to estimate mean and covariance of asset return scenarios.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

[ScenarioMean, ScenarioCovar] = estimateScenarioMoments(p)

ScenarioMean = 4x1

    0.0039
    0.0082
    0.0102
    0.0154

```

```

ScenarioCovar = 4x4

    0.0005    0.0003    0.0001   -0.0001
    0.0003    0.0024    0.0017    0.0010
    0.0001    0.0017    0.0048    0.0028
   -0.0001    0.0010    0.0028    0.0102

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

**obj** — Object for portfolio  
object

Object for portfolio, specified using a `PortfolioCVaR` or `PortfolioMAD` object.

For more information on creating a `PortfolioCVaR` or `PortfolioMAD` object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

## Output Arguments

### ScenarioMean — Estimate for mean of scenarios

`[]` (default) | vector

Estimate for mean of scenarios, returned as a `NumPorts` vector or `[]`.

---

**Note** If no scenarios are associated with the specified object, both `ScenarioMean` and `ScenarioCovar` are set to empty `[]`.

---

### ScenarioCovar — Estimate for covariance of scenarios

`[]` (default) | matrix

Estimate for covariance of scenarios, returned as a `NumAssets-by-NumAssets` matrix or `[]`.

---

**Note** If no scenarios are associated with the specified object, both `ScenarioMean` and `ScenarioCovar` are set to empty `[]`.

---

## Tips

You can also use dot notation to estimate the mean and covariance of asset return scenarios for a portfolio.

```
[ScenarioMean, ScenarioCovar] = obj.estimateScenarioMoments
```

## ewstats

Expected return and covariance from return time series

### Syntax

```
[ExpReturn,ExpCovariance,NumEffObs] = ewstats(RetSeries)
[ExpReturn,ExpCovariance,NumEffObs] = ewstats( ____,DecayFactor,WindowLength)
```

### Description

[ExpReturn,ExpCovariance,NumEffObs] = ewstats(RetSeries) computes estimated expected returns (ExpReturn), estimated covariance matrix (ExpCovariance), and the number of effective observations (NumEffObs). These outputs are maximum likelihood estimates which are biased.

[ExpReturn,ExpCovariance,NumEffObs] = ewstats( \_\_\_\_,DecayFactor,WindowLength) adds optional input arguments for DecayFactor and WindowLength.

### Examples

#### Compute Estimated Expected Returns and Estimated Covariance Matrix

This example shows how to compute the estimated expected returns and the estimated covariance matrix.

```
RetSeries = [ 0.24 0.08
              0.15 0.13
              0.27 0.06
              0.14 0.13 ];
```

```
DecayFactor = 0.98;
```

```
[ExpReturn, ExpCovariance] = ewstats(RetSeries, DecayFactor)
```

```
ExpReturn = 1×2
```

```
    0.1995    0.1002
```

```
ExpCovariance = 2×2
```

```
    0.0032   -0.0017
   -0.0017    0.0010
```

### Input Arguments

**RetSeries** — Return series  
matrix

Return series, specified the number of observations (NUMOBS) by number of assets (NASSETS) matrix of equally spaced incremental return observations. The first row is the oldest observation, and the last row is the most recent.

Data Types: double

**DecayFactor — Controls how much less each observation is weighted than its successor**

1 (default) | numeric

(Optional) Controls how much less each observation is weighted than its successor, specified as a numeric value. The  $k$ th observation back in time has weight  $\text{DecayFactor}^k$ . DecayFactor must lie in the range:  $0 < \text{DecayFactor} \leq 1$ .

The default value of 1 is the equally weighted linear moving average model (BIS).

Data Types: double

**WindowLength — Number of recent observations in computation**

NUMOBS (default) | numeric

(Optional) Number of recent observations in the computation, specified as a numeric value.

Data Types: double

## Output Arguments

**ExpReturn — Estimated expected returns**

vector

Estimated expected returns, returned as a 1-by-NASSETS vector.

**ExpCovariance — Estimated covariance matrix**

matrix

Estimated covariance matrix, returned as a NASSETS-by-NASSETS matrix.

The standard deviations of the asset return processes are defined as

$$\text{STDVec} = \text{sqrt}(\text{diag}(\text{ExpCovariance}))$$

The correlation matrix is

$$\text{CorrMat} = \text{ExpCovariance} ./ (\text{STDVec} * \text{STDVec}' )$$

**NumEffObs — Number of effective observations**

numeric

NumEffObs is the number of effective observations where

$$\text{NumEffObs} = \frac{1 - \text{DecayFactor}^{\text{WindowLength}}}{1 - \text{DecayFactor}}$$

A smaller DecayFactor or WindowLength emphasizes recent data more strongly but uses less of the available data set.

## Algorithms

For a return series  $r(1), \dots, r(n)$ , where  $(n)$  is the most recent observation, and  $w$  is the decay factor, the expected returns (ExpReturn) are calculated by

$$E(r) = \frac{(r(n) + wr(n-1) + w^2r(n-2) + \dots + w^{n-1}r(1))}{NumEffObs}$$

where the number of effective observations NumEffObs is defined as

$$NumEffObs = 1 + w + w^2 + \dots + w^{n-1} = \frac{1 - w^n}{1 - w}$$

$E(r)$  is the weighed average of  $r(n), \dots, r(1)$ . The unnormalized weights are  $w, w^2, \dots, w^{(n-1)}$ . The unnormalized weights do not sum up to 1, so NumEffObs rescales the unnormalized weights. After rescaling, the normalized weights (which sum up to 1) are used for averaging. When  $w = 1$ , then NumEffObs =  $n$ , which is the number of observations. When  $w < 1$ , NumEffObs is still interpreted as the sample size, but it is less than  $n$  due to the down-weight on the observations of the remote past.

---

**Note** There is no relationship between `ewstats` function and the RiskMetrics® approach for determining the expected return and covariance from a return time series.

# exp

Exponential values

---

**Note** `exp` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = exp(tsobj)
```

## Description

`newfts = exp(tsobj)` calculates the natural exponential (base  $e$ ) of all the data in the data series of the financial time series object `tsobj` and returns the result in the object `newfts`.

## extfield

Data series extraction

---

**Note** `extfield` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
ftse = extfield(tsoj,fieldnames)
```

### Arguments

|                         |                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsoj</code>       | Financial time series object                                                                                                                                                     |
| <code>fieldnames</code> | Data series to be extracted. A cell array of character vectors if a list of data series names ( <code>fieldnames</code> ) is supplied. A character vector if only one is wanted. |

### Description

`ftse = extfield(tsoj,fieldnames)` extracts from `tsoj` the dates and data series specified by `fieldnames` into a new financial time series object `ftse`. `ftse` has all the dates in `tsoj` but contains a smaller number of data series.

### Examples

`extfield` is identical to referencing a field in the object. For example,

```
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
        '02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1),...
times]);
myFts = fints(dates_times,(1:6)', {'Data1'},1, 'My first FINTS');
ftse = extfield(myFts, 'Data1')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

## fanplot

Plot combined historical and forecast data to visualize possible outcomes

### Syntax

```
fanplot(historical, forecast)
fanplot( ____, Name, Value)
```

```
fanplot(ax, historical, forecast)
fanplot( ____, Name, Value)
```

```
h = fanplot(ax, historical, forecast)
h = fanplot( ____, Name, Value)
```

### Description

`fanplot(historical, forecast)` generates a fan chart. In time series analysis, a fan chart is a chart that joins a simple line chart for observed past data with ranges for possible values of future data. The historical data and possible future data are joined with a line showing a central estimate or most likely value for the future outcomes.

`fanplot` supports three plotting scenarios:

- Matching — This scenario occurs when the time period perfectly matches for historical and forecast data.
- Backtest — This scenario occurs when there are overlaps between historical and forecast data.
- Gap — This scenario occurs when there are NaN values in the historical or forecast data.

`fanplot( ____, Name, Value)` generates a fan chart using optional name-value pair arguments.

`fanplot(ax, historical, forecast)` generates a fan chart using an optional `ax` argument.

`fanplot( ____, Name, Value)` generates a fan chart using optional name-value pair arguments.

`h = fanplot(ax, historical, forecast)` generates a fan chart and returns the figure handle `h`. In time series analysis, a fan chart is a chart that joins a simple line chart for observed past data with ranges for possible values of future data. The historical data and possible future data are joined with a line showing a central estimate or most likely value for the future outcomes.

`fanplot` supports three plotting scenarios:

- Matching — This scenario occurs when the time period perfectly matches for historical and forecast data.
- Backtest — This scenario occurs when there are overlaps between historical and forecast data.
- Gap — This scenario occurs when there are NaN values in the historical or forecast data.

`h = fanplot( ____, Name, Value)` generates a fan chart and returns the figure handle `h` using optional name-value pair arguments.

## Examples

### Create a Fan Plot Using Cell Array Data

Define the data inputs for `historical` as a 5-by-2 cell array and `forecast` as a 5-by-21 cell array with 20 observations.

```
historical = {[2006]    [-0.0110]
              [2007]    [ 0.0120]
              [2008]    [ 0.0090]
              [2009]    [ 0.0120]
              [2010]    [ 0.0150]};

forecast = {[2011] [0.0203]    [-0.0155]    [0.0311]    [-0.0026]    [0.0035]    [0.0049]
            [2011] [0.0533]    [0.0139]    [0.0037]    [-0.0727]    [-0.0291]    [-0.0051]
            [2012] [0.0430]    [-0.0094]    [0.0587]    [ 0.0095]    [0.0185]    [0.0205]
            [2012] [0.0141]    [0.0337]    [0.0187]    [0.0132]    [-0.0292]    [0.0048]
            [2013] [0.0518]    [-0.0116]    [0.0708]    [0.0112]    [0.0221]    [0.0246]
            [2013] [0.0168]    [0.0405]    [0.0224]    [0.0157]    [-0.0356]    [0.0056]
            [2014] [0.0546]    [-0.0171]    [0.0762]    [0.0088]    [0.0210]    [0.0239]
            [2014] [0.0151]    [0.0419]    [0.0214]    [0.0139]    [-0.0442]    [0.0024]
            [2015] [0.0565]    [-0.0207]    [0.0797]    [0.0072]    [0.0203]    [0.0234]
            [2015] [0.0139]    [0.0428]    [0.0207]    [0.0126]    [-0.0499]    [0.0026]
```

Generate the fan plot.

```
fanplot (historical, forecast);
```

The dotted points are the historical lines and the filled lines indicate the mean for the forecasts. This fanplot represents a matching scenario where the time period perfectly matches for the historical and forecast data.

### Create a Fan Plot Using Matrix Data

Define the data inputs for `historical` as a 5-by-2 matrix and `forecast` as a 5-by-21 matrix with 20 observations.

```
historical = [ 1.0000    2.8046 ;
              2.0000    4.1040 ;
              3.0000    6.7292 ;
              4.0000    8.6486 ;
              5.0000   10.4747 ];
```

```
forecast = [ 3.0000    28.9874    18.3958    19.6376    29.5627    8.3462    7.1502    25.3845    2
            20.8557    27.0691    23.0803    20.7885    18.0205    17.2294    10.0197    29
            4.0000    4.8933    27.2659    7.2206    24.4703    10.5895    15.0212    29.1137    6
            8.0007    18.7114    19.1691    24.5963    4.2835    4.0676    3.2612    29
            5.0000    20.9732    19.7069    11.6862    25.7018    31.8940    7.2664    19.2113    10
            31.7996    3.6419    3.2695    27.1422    10.5487    32.6529    18.8370    6
            6.0000    11.0069    29.1965    4.5551    20.2627    10.9209    15.2675    28.5359    11
            23.9532    18.4804    25.5484    4.8747    8.0036    11.5329    11.6807    21
            7.0000    5.9699    11.1486    26.0449    13.4619    21.1196    28.8068    26.2525    10
            21.2390    29.2396    18.4828    28.3945    21.9342    14.4642    17.2613    15
```

Generate the fan plot and return the figure handle.

```
h = fanplot(historical, forecast)
```

```
h =
Figure (1) with properties:

    Number: 1
    Name: ''
    Color: [0.9400 0.9400 0.9400]
    Position: [360 502 560 420]
    Units: 'pixels'
```

Show all properties

The dotted points are the historical lines and the filled lines indicate the mean for the forecasts. This fanplot represents a backtest scenario where there is an overlap between the historical and forecast data.

### Create a Fan Plot Using Cell Array Data and Customize the Plot With Name-Value Pair Arguments

Define the data inputs for `historical` as a 5-by-2 cell array and `forecast` as a 5-by-21 cell array with 20 observations.

```
historical = {[2006]    [-0.0110]
              [2007]    [ 0.0120]}
```

```

[2008] [ 0.0090]
[2009] [ 0.0120]
[2010] [ 0.0150]};

forecast = {[2011] [0.0203] [-0.0155] [0.0311] [-0.0026] [0.0035] [0.0049]
            [0.0533] [0.0139] [0.0037] [-0.0727] [-0.0291] [-0.0055]
            [2012] [0.0430] [-0.0094] [0.0587] [ 0.0095] [0.0185] [0.0205]
            [0.0141] [0.0337] [0.0187] [0.0132] [-0.0292] [0.0048]
            [2013] [0.0518] [-0.0116] [0.0708] [0.0112] [0.0221] [0.0246]
            [0.0168] [0.0405] [0.0224] [0.0157] [-0.0356] [0.0056]
            [2014] [0.0546] [-0.0171] [0.0762] [0.0088] [0.0210] [0.0239]
            [0.0151] [0.0419] [0.0214] [0.0139] [-0.0442] [0.0024]
            [2015] [0.0565] [-0.0207] [0.0797] [0.0072] [0.0203] [0.0234]
            [0.0139] [0.0428] [0.0207] [0.0126] [-0.0499] [0.0026]

```

Generate the fan plot using name-value pair arguments to customize the presentation.

```
fanplot(historical,forecast,'FanFaceColor',[1 1 1;1 0 0],'FanLineStyle','--','ForecastMarker','p'
```

### Create a Fan Plot Using Table Data

Create table of historical dates and data.

```

historicalDates = datetime(2006:2010,1,1)';
historicalData = [-0.0110;0.0120;0.0090;0.0120;0.0150];
historical = table(historicalDates,historicalData,'VariableNames',{'Dates','Data'});

```

Create table of forecast dates and data.

```
forecastDates = datetime(2011:2015,1,1)';
forecastData = [0.0203    -0.0155    0.0311    -0.0026    0.0035    0.0049    0.0026
                0.0533    0.0139    0.0037    -0.0727    -0.0291   -0.0058    0.0183
                0.0430   -0.0094    0.0587    0.0095    0.0185    0.0205    0.0172
                0.0141    0.0337    0.0187    0.0132   -0.0292    0.0048    0.0400
                0.0518   -0.0116    0.0708    0.0112    0.0221    0.0246    0.0205
                0.0168    0.0405    0.0224    0.0157   -0.0356    0.0056    0.0482
                0.0546   -0.0171    0.0762    0.0088    0.0210    0.0239    0.0193
                0.0151    0.0419    0.0214    0.0139   -0.0442    0.0024    0.0506
                0.0565   -0.0207    0.0797    0.0072    0.0203    0.0234    0.0185
                0.0139    0.0428    0.0207    0.0126   -0.0499    0.0026    0.0522];
forecast = [table(forecastDates, 'VariableName', {'Dates'}), array2table(forecastData)];
```

Plot the data using fanplot.

```
fanplot(historical, forecast);
```

## Input Arguments

### **historical** – Historical dates and data

matrix | cell array | table | timetable

Historical dates and data, specified as an N-by-2 matrix, cell array, table, or timetable where the first column is the date, and the second column is the data associated for that date. N indicates the

number of dates. By using the cell array format for the input, you can make the first column datetime and produce the same plot as would serial date numbers or date character vectors. For example:

```
historical(:,1) = num2cell(datetime(2006:2010,1,1));
forecast(:,1) = num2cell(datetime(2011:2015,1,1));
fanplot (historical, forecast);
```

Data Types: cell | double | table | timetable

### forecast — Forecast dates and data

matrix | cell array of character vectors | table | timetable

Forecast dates and data, specified as an N-by-M matrix, cell array, table, or timetable where the first column is the date, and the second to the last columns are the data observations. N indicates the number of the dates and (M - 1) is the number for data observations. By using the cell array format for the input, you can make the first column datetime and produce the same plot as would serial date numbers or date character vectors. For example:

```
historical(:,1) = num2cell(datetime(2006:2010,1,1));
forecast(:,1) = num2cell(datetime(2011:2015,1,1));
fanplot (historical, forecast);
```

Data Types: cell | double | table | timetable

### ax — Valid axis object

object

(Optional) Valid axis object, specified as an `ax` object that is created using `axes`. The plot will be created in the axes specified by the optional `ax` argument instead of in the current axes (`gca`). The optional argument `ax` can precede any of the input argument combinations.

Data Types: object

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
fanplot(historical, forecast, 'NumQuantiles', 14, 'FanLineColor', 'blue', 'HistoricalLineWidth', 1.8, 'ForecastLineColor', 'red')
```

### NumQuantiles — Number of quantiles to display

20 (default) | positive integer

Number of quantiles to display in fan chart, specified as a positive integer.

Data Types: double

### FanLineStyle — Style of the lines separating fans

'none' (default) | character vector

Style of the lines separating fans, specified as a character vector. For more information on supported character vectors for line styles, see `Primitive Line`.

Data Types: char

**FanLineColor — Color of lines separating fans**`'black'` (default) | character vector for color or RGB triplet

Color of lines separating fans, specified as a character vector for color or an RGB triplet. For more information on supported color character vectors, see Primitive Line.

Data Types: `double` | `char`**FanFaceColor — Color of each fan**`[1 1 0;1 0 0]` (yellow to red) (default) | matrix

Color of each fan, specified as an N-by-3 matrix controlling the color of each fan, where each row is an RGB triplet. There are three possible values of N:

- When  $N = \text{NumQuantiles}$ , the color of each fan is specified by the corresponding row in the matrix.
- When  $N = \text{ceil}(\text{NumQuantiles}/2)$ , the specified colors represent the bottom half of the fans. The colors of the top half are determined by reversing the order of these colors. For more information, see `ceil`.
- When  $N = 2$ , the colors in the bottom half of the fan are a linear interpolation between the two specified colors. The pattern is reversed for the top half.

Data Types: `double`**HistoricalMarker — Marker symbol of historical line**`'o'` (default) | character vector

Marker symbol of historical line, specified as a character vector. For more information on supported character vectors for markers, see Primitive Line.

Data Types: `char`**HistoricalMarkerSize — Marker size of historical line**

5 (default) | positive value in point units

Marker size of historical line, specified as a positive value in point units.

Data Types: `double` | `char`**HistoricalMarkerFaceColor — Marker fill color of historical line**`'blue'` (default) | character vector with a value of `'none'`, `'auto'`, color identifier, or RGB triplet

Marker fill color of historical line, specified as a character vector with a value of `'none'`, `'auto'`, a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: `double` | `char`**HistoricalMarkerEdgeColor — Marker outline color of historical line**`'blue'` (default) | character vector with a value of `'none'`, `'auto'`, color identifier, or RGB triplet

Marker outline color of historical line, specified as a character vector with a value of `'none'`, `'auto'`, a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: `double` | `char`

**HistoricalLineColor — Color of historical line**

'black' (default) | character vector with a value of 'none', color identifier, or RGB triplet

Color of historical line, specified as a character vector with a value of 'none', a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: double | char

**HistoricalLineStyle — Style of historical line**

'--' (default) | character vector

Style of historical line, specified as a character vector. For more information on supported character vectors for line styles, see Primitive Line.

Data Types: char

**HistoricalLineWidth — Width of historical line**

1.5 (default) | positive value in point units

Width of historical line, specified as a positive value in point units.

Data Types: double

**ForecastMarker — Marker symbol of forecast line**

'none' (default) | character vector

Marker symbol of forecast line, specified as a character vector. For more information on supported character vectors for marker symbols, see Primitive Line.

Data Types: char

**ForecastMarkerSize — Marker size of forecast line**

5 (default) | positive value in point units

Marker size of forecast line, specified as a positive value in point units.

Data Types: double

**ForecastMarkerFaceColor — Marker fill color of forecast line**

'none' (default) | character vector with a value of 'none', 'auto', color identifier, or RGB triplet

Marker fill color of forecast line, specified as a character vector with a value of 'none', 'auto', a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: double | char

**ForecastMarkerEdgeColor — Marker outline color of forecast line**

'auto' (default) | character vector with a value of 'none', 'auto', color identifier, or RGB triplet

Marker outline color of forecast line, specified as a character vector with a value of 'none', 'auto', character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: double | char

**ForecastLineColor — Color of forecast line**

'black' (default) | character vector with a value of 'none', color identifier, or RGB triplet

Color of forecast line, specified as a character vector with a value of 'none', a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: double | char

### **ForecastLineStyle — Style of forecast line**

'-' (default) | character vector

Style of forecast line, specified as a character vector. For more information on supported character vectors for line styles, see Primitive Line.

Data Types: char

### **ForecastLineWidth — Width of forecast line**

2 (default) | positive value in point units

Width of forecast line, specified as a positive value in point units.

Data Types: double

## **Output Arguments**

### **h — Figure handle for fanplot**

handle object

Figure handle for the fanplot, returned as handle object.

| renko | timetable | volarea

### **Introduced in R2014b**

## fbusdate

First business date of month

### Syntax

```
Date = fbusdate(Year,Month)
Date = fbusdate( ____,Holiday,Weekend,outputType)
```

### Description

`Date = fbusdate(Year,Month)` returns the serial date number for the first business date of the given year and month.

`Year` and `Month` can contain multiple values. If one contains multiple values, the other must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by-N vector of integers, then `Month` must be a 1-by-N vector of integers or a single integer. `Date` is then a 1-by-N vector of date numbers.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

`Date = fbusdate( ____,Holiday,Weekend,outputType)` returns the serial date number for the first business date of the given year and month using optional input arguments. The optional argument `Holiday` specifies nontrading days.

If neither `Holiday` nor `outputType` are specified, `Date` is returned as a serial date number. If `Holiday` is specified, but not `outputType`, then the type of the holiday variable controls the type of date. If `Holiday` is a serial date number or date character vector, then `Date` is returned as a serial date number.

### Examples

#### Return a Serial Date Number for the First Business Date

This example shows how to return serial date numbers for the first business date, given year and month.

```
Date = fbusdate(2001, 11)
```

```
Date = 731156
```

```
datestr(Date)
```

```
ans =
'01-Nov-2001'
```

```
Year = [2002 2003 2004];
Date = fbusdate(Year, 11)
```

```
Date = 1×3
```

```
731521    731888    732252
```

```
datestr(Date)
```

```
ans = 3x11 char array
'01-Nov-2002'
'03-Nov-2003'
'01-Nov-2004'
```

### Return a Serial Date Number for the First Business Date Using the Weekend Argument

This example shows how to return serial date numbers for the first business date, given year and month, and also indicate that Saturday is a business day by setting the `Weekend` argument. March 1, 2003, is a Saturday. Use `fbusdate` to check that this Saturday is actually the first business day of the month.

```
Weekend = [1 0 0 0 0 0 0];
Date = datestr(fbusdate(2003, 3, [], Weekend))
```

```
Date =
'01-Mar-2003'
```

### Return a datetime array for Date for the First Business Date Using the outputType Argument

This example shows how to return a datetime array for `Date` using an `outputType` of `'datetime'`.

```
Date = fbusdate(2001, 11, [], [], 'datetime')
```

```
Date = datetime
01-Nov-2001
```

## Input Arguments

### Year — Year to determine occurrence of weekday

4-digit integer | vector of 4-digit integers

Year to determine occurrence of weekday, specified as a 4-digit integer or vector of 4-digit integers.

Data Types: `single` | `double`

### Month — Month to determine occurrence of weekday

integer with value 1 through 12 | vector of integers with values 1 through 12

Month to determine occurrence of weekday, specified as an integer or vector of integers with values 1 through 12.

Data Types: `single` | `double`

**Holiday — Holidays and nontrading-day dates**

non-trading day vector is determined by the routine `holidays` (default) | serial date number | date character vector | datetime array

Holidays and nontrading-day dates, specified as vector.

All dates in `Holiday` must be the same format: either serial date numbers, or date character vectors, or datetime arrays. (Using serial date numbers improves performance.) The `holidays` function supplies the default vector.

If `Holiday` is a datetime array, then `Date` is returned as a datetime array. If `outputType` is specified, then its value determines the output type of `Date`. This overrides any influence of `Holiday`.

Data Types: double | char | datetime

**Weekend — Weekend days**

[1 0 0 0 0 0 1] (Saturday and Sunday form the weekend) (default) | vector of length 7, containing 0 and 1, where 1 indicates weekend days

Weekend days, specified as a vector of length 7, containing 0 and 1, where 1 indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: double

**outputType — Year to determine days**

'datenum' (default) | character vector with values 'datenum' or 'datetime'

A character vector specified as either 'datenum' or 'datetime'. The output `Date` is in serial date format if 'datenum' is specified, or datetime format if 'datetime' is specified. By default the output `Date` is in serial date format, or match the format of `Holiday`, if specified.

Data Types: char

## Output Arguments

**Date — Date for the first business date of given year and month**

serial date number | date character vector | datetime array

Date for the first business date of a given year and month, returned as a serial date number, date character vector, or datetime array.

If neither `Holiday` nor `outputType` are specified, `Date` is returned as a serial date number. If `Holiday` is specified, but not `outputType`, then the type of the holiday variable controls the type of date:

- If `Holiday` is a serial date number or date character vector, then `Date` is returned as a serial date number
- If `Holiday` is a datetime array, then `Date` is returned as a datetime array.

## fetch

Data from financial time series object

---

**Note** `fetch` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = fetch(oldfts,StartDate,StartTime,EndDate,EndTime,delta,dmy_specifier,time_ref)
```

### Arguments

|                            |                                                                                                                                                                                                                                       |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>oldfts</code>        | Existing financial time series object.                                                                                                                                                                                                |
| <code>StartDate</code>     | First date in the range from which data is to be extracted.                                                                                                                                                                           |
| <code>StartTime</code>     | Beginning time on each day. If you do not require specific times or <code>oldfts</code> does not contain time information, use <code>[]</code> . If you specify <code>StartTime</code> , you must also specify <code>EndTime</code> . |
| <code>EndDate</code>       | Last date in the range from which data is to be extracted.                                                                                                                                                                            |
| <code>EndTime</code>       | Ending time on each day. If you do not require specific times or <code>oldfts</code> does not contain time information, use <code>[]</code> . If you specify <code>EndTime</code> , you must also specify <code>StartTime</code> .    |
| <code>delta</code>         | Skip interval. Can be any positive integer. Units for the skip interval specified by <code>dmy_specifier</code> .                                                                                                                     |
| <code>dmy_specifier</code> | Specifies the units for <code>delta</code> . Can be <ul style="list-style-type: none"> <li>• D, d (Days)</li> <li>• M, m (Months)</li> <li>• Y, y (Years)</li> </ul>                                                                  |
| <code>time_ref</code>      | Time reference intervals or specific times. Valid time reference intervals are 1, 5, 15, or 60 minutes. Enter specific times as <code>'hh:mm'</code> .                                                                                |

### Description

`newfts = fetch(oldfts,StartDate,StartTime,EndDate,EndTime,delta,dmy_specifier,time_ref)` requests data from a financial time series object beginning from the start date and/or start time to the end date and/or end time, skipping a specified number of days, months, or years.

---

**Note** If time information is present in `oldfts`, using `[]` for start or end times results in `fetch` returning all instances of a specific date.

---

## Examples

**Example 1.** Create a financial time series object containing both dates and times:

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
times]);
myFts = fints(dates_times, (1:6), {'Data1'}, 1, 'My first FINTS')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/display (line 66)

myFts =

```
desc: My first FINTS
freq: Daily (1)
```

| 'dates: (6)'  | 'times: (6)' | 'Data1: (6)' |
|---------------|--------------|--------------|
| '01-Jan-2001' | '11:00'      | [ 1]         |
| '    "    '   | '12:00'      | [ 2]         |
| '02-Jan-2001' | '11:00'      | [ 3]         |
| '    "    '   | '12:00'      | [ 4]         |
| '03-Jan-2001' | '11:00'      | [ 5]         |
| '    "    '   | '12:00'      | [ 6]         |

To fetch all dates and times from this financial time series, enter

```
fetch(myFts, '01-Jan-2001', [], '03-Jan-2001', [], 1, 'd')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/fetch (line 126)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/display (line 66)

ans =

```
desc: My first FINTS

```
ans =
```

```
desc: My first FINTS
freq: Daily (1)

'dates: (6)'      'times: (6)'      'Data1: (6)'
'01-Jan-2001'    '11:00'           [          1]
'      "      '    '12:00'           [          2]
'02-Jan-2001'    '11:00'           [          3]
'      "      '    '12:00'           [          4]
'03-Jan-2001'    '11:00'           [          5]
'      "      '    '12:00'           [          6]
```

These commands reproduce the entire time series shown above.

To fetch every other day's data, enter

```
fetch(myFts, '01-Jan-2001', [], '03-Jan-2001', [], 2, 'd')
```

This returns:

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/fetch (line 126)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```
desc: My first FINTS
freq: Daily (1)

'dates: (4)'      'times: (4)'      'Data1: (4)'
'01-Jan-2001'    '11:00'           [          1]
'      "      '    '12:00'           [          2]
'03-Jan-2001'    '11:00'           [          5]
'      "      '    '12:00'           [          6]
```

**Example 2.** Create a financial time series object with time intervals of less than 1 hour:

```
dates2 = ['01-Jan-2001'; '01-Jan-2001'; '01-Jan-2001'; ...
'02-Jan-2001'; '02-Jan-2001'; '02-Jan-2001'];
times2 = ['11:00'; '11:05'; '11:06'; '12:00'; '12:05'; '12:06'];
dates_times2 = cellstr([dates2, repmat(' ', size(dates2,1),1), ...
times2]);
myFts2 = fints(dates_times2, (1:6)', {'Data1'}, 1, 'My second FINTS')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
myFts2 =
```

```
desc: My second FINTS
freq: Daily (1)

'dates: (6)'      'times: (6)'      'Data1: (6)'
'01-Jan-2001'    '11:00'           [          1]
'      "      '    '11:05'           [          2]
'      "      '    '11:06'           [          3]
```

```
'02-Jan-2001'    '12:00'    [      4]
'    "    '    '12:05'    [      5]
'    "    '    '12:06'    [      6]
```

Use `fetch` to extract data from this time series object at 5-minute intervals for each day starting at 11:00 o'clock on January 1, 2001.

```
fetch(myFts2, '01-Jan-2001', [], '02-Jan-2001', [], 1, 'd', 5)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/fetch (line 126)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/display (line 66)
```

```
ans =
```

```
desc: My second FINTS
freq: Daily (1)
```

```
'dates: (4)'    'times: (4)'    'Data1: (4)'
'01-Jan-2001'    '11:00'    [      1]
'    "    '    '11:05'    [      2]
'02-Jan-2001'    '12:00'    [      4]
'    "    '    '12:05'    [      5]
```

You can use this version of `fetch` to extract data at specific times. For example, to fetch data only at 11:06 and 12:06 from `myFts2`, enter

```
fetch(myFts2, '01-Jan-2001', [], '02-Jan-2001', [], 1, 'd', ...
{'11:06'; '12:06'})
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/fetch (line 126)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/display (line 66)
```

```
ans =
```

```
desc: My second FINTS
freq: Daily (1)
```

```
'dates: (2)'    'times: (2)'    'Data1: (2)'
'01-Jan-2001'    '11:06'    [      3]
'02-Jan-2001'    '12:06'    [      6]
```

## Introduced before R2006a

## fieldnames

Get names of fields

---

**Note** `fieldnames` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
fnames = fieldnames(tsoobj)
```

```
fnames = fieldnames(tsoobj,srsnameonly)
```

### Arguments

|                          |                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------|
| <code>tsoobj</code>      | Financial time series object                                                           |
| <code>srsnameonly</code> | Field names returned:<br>0 = All field names (default).<br>1 = Data series names only. |

### Description

`fieldnames` gets field names in a financial time series object.

`fnames = fieldnames(tsoobj)` returns the field names associated with the financial time series object `tsoobj` as a cell array of character vectors, including the common fields: `desc`, `freq`, `dates` (and `times` if present).

`fnames = fieldnames(tsoobj,srsnameonly)` returns field names depending upon the setting of `srsnameonly`. If `srsnameonly` is 0, the function returns all field names, including the common fields: `desc`, `freq`, `dates`, and `times`. If `srsnameonly` is set to 1, `fieldnames` returns only the data series in `fnames`.

## fillts

Fill missing values in time series

---

**Note** `fillts` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = fillts(oldfts,fill_method)
```

```
newfts = fillts(oldfts,fill_method,newdates)
```

```
newfts = fillts(oldfts,fill_method,newdates,{'T1','T2',...})
```

```
newfts = fillts(oldfts,fill_method,newdates,'SPAN',{'TS','TE'},delta)
```

```
newfts = fillts(... sortmode)
```

### Arguments

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>newdates</code>       | (Optional) Column vector of serial dates, a date character vector, or a column cell array of character vector dates. If <code>oldfts</code> contains time of day information, <code>newdates</code> must be accompanied by a time vector ( <code>newtimes</code> ). Otherwise, <code>newdates</code> is assumed to have times of '00:00'. |
| <code>T1, T2, TS, TE</code> | First time, second time, start time, end time                                                                                                                                                                                                                                                                                             |
| <code>delta</code>          | Time interval in minutes to span between the start time and end time                                                                                                                                                                                                                                                                      |
| <code>sortmode</code>       | (Optional) Default = 0 (unsorted). 1 = sorted.                                                                                                                                                                                                                                                                                            |

## Description

`newfts = fillfts(oldfts, fill_method)` replaces missing values (represented by NaN) in the financial time series object `oldfts` with real values, using either a constant or the interpolation process indicated by `fill_method`.

`newfts = fillfts(oldfts, fill_method, newdates)` replaces all the missing values on the specified dates `newdates` added to the financial time series `oldfts` with new values. The values can be a single constant or values obtained through the interpolation process designated by `fill_method`. If any of the dates in `newdates` exists in `oldfts`, the existing one has precedence.

`newfts = fillfts(oldfts, fill_method, newdates, {'T1', 'T2', ...})` additionally allows the designation of specific times of day for addition or replacement of data.

`newfts = fillfts(oldfts, fill_method, newdates, 'SPAN', {'TS', 'TE'}, delta)` is similar to the previous format except that you designate only a start time and an end time. You follow these times with a spanning time interval, `delta`.

If you specify only one date for `newdates`, specifying a start and end time generates only times for that specific date.

`newfts = fillfts(..., sortmode)` additionally denotes whether you want the order of the dates in the output object to stay the same as in the input object or to be sorted chronologically.

`sortmode = 0` (unsorted) appends any new dates to the end. The interpolation and zero-order processes that calculate the values for the new dates work on a sorted object. Upon completion, the existing dates are reordered as they were originally, and the new dates are appended to the end.

`sortmode = 1` sorts the output. After interpolation, no reordering of the date sequence occurs.

## Examples

**Example 1.** Create a financial time series object with missing data in the fourth and fifth rows.

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
                      times]);
OpenFts = fints(dates_times, [(1:3)'; nan; nan; 6], {'Data1'}, 1, ...
               'Open Financial Time Series')
```

`OpenFts` looks like this:

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
 > In fints/display (line 66)

OpenFts =

```

## filter

Linear filtering

---

**Note** `filter` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = filter(B,A,oldfts)
```

### Description

`filter` filters an entire financial time series object with certain filter specifications. The filter is specified in a transfer function expression.

`newfts = filter(B,A,oldfts)` filters the data in the financial time series object `oldfts` with the filter described by vectors `A` and `B` to create the new financial time series object `newfts`. The filter is a “Direct Form II Transposed” implementation of the standard difference equation. `newfts` is a financial time series object containing the same data series (names) as the input `oldfts`.

## fints

Construct financial time series object

---

**Note** `fints` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
tsobj = fints(dates_and_data)
tsobj = fints(dates,data)
tsobj = fints(dates,data,datanames)
tsobj = fints(dates,data,datanames,freq)
tsobj = fints(dates,data,datanames,freq,desc)
```

### Arguments

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><code>dates_and_data</code></p> | <p>Column-oriented matrix containing one column of dates and a single column for each series of data. In this format, dates must be entered in serial date number format. If the input serial date numbers encode time-of-day information, the output object contains a column labeled 'dates' containing the date information and another labeled 'times' containing the time information.</p> <p>You can use the MATLAB function <code>today</code> to enter date information or the MATLAB function <code>now</code> to enter date with time information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <p><code>dates</code></p>          | <p>Column vector of dates. Dates can be date character vectors or serial date numbers and can include time of day information. When entering time-of-day information as serial date numbers, the entry must be a column-oriented matrix when multiple entries are present. If the time-of-day information is in character vector format, the entry must be a column-oriented cell array of character vector dates and times when multiple entries are present.</p> <p>Valid date and time character vector formats are:</p> <ul style="list-style-type: none"> <li>• 'ddmmyy hh:mm' or 'ddmmyyyy hh:mm'</li> <li>• 'mm/dd/yy hh:mm' or 'mm/dd/yyyy hh:mm'</li> <li>• 'dd-mmm-yy hh:mm' or 'dd-mmm-yyyy hh:mm'</li> <li>• 'mmm.dd,yy hh:mm' or 'mmm.dd,yyyy hh:mm'</li> </ul> <p>Dates and times can initially be separate column-oriented vectors, but they must be concatenated into a single column-oriented matrix before being passed to <code>fints</code>. You can use the MATLAB functions <code>today</code> and <code>now</code> to help with entering date and time information.</p> |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | Column-oriented matrix containing a column for each series of data. The number of values in each data series must match the number of dates. If a mismatch occurs, MATLAB does not generate the financial time series object, and you receive an error message.                                                                                                                                                                                                                                                           |
| <code>datanames</code> | Cell array of data series names. Overrides the default data series names. Default data series names are <code>series1</code> , <code>series2</code> , and so on.<br><br><b>Note</b> Not all character vectors are accepted as <code>datanames</code> parameters. Supported data series names cannot start with a number and must contain only these characters: <ul style="list-style-type: none"> <li>• Lowercase Latin alphabet, a to z</li> <li>• Uppercase Latin alphabet, A to Z</li> <li>• Underscore, _</li> </ul> |
| <code>freq</code>      | Frequency indicator. Allowed values are:<br><br>UNKNOWN, Unknown, unknown, U, u, 0<br><br>DAILY, Daily, daily, D, d, 1<br><br>WEEKLY, Weekly, weekly, W, w, 2<br><br>MONTHLY, Monthly, monthly, M, m, 3<br><br>QUARTERLY, Quarterly, quarterly, Q, q, 4<br><br>SEMIANNUAL, Semiannual, semiannual, S, s, 5<br><br>ANNUAL, Annual, annual, A, a, 6<br><br>Default = Unknown.                                                                                                                                               |
| <code>desc</code>      | Character vector providing descriptive name for financial time series object. Default = ''.                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Description

`fints` constructs a financial time series object. A financial time series object is a MATLAB object that contains a series of dates and one or more series of data. Before you perform an operation on the data, you must set the frequency indicator (`freq`). You can optionally provide a description (`desc`) for the time series.

`tobj = fints(dates_and_data)` creates a financial time series object containing the dates and data from the matrix `dates_and_data`. If the dates contain time-of-day information, the object contains an additional series of times. The date series and each data series must each be a column in the input matrix. The names of the data series default to `series1`, ..., `seriesn`. The `desc` and `freq` fields are set to their defaults.

`tobj = fints(dates,data)` generates a financial time series object containing dates from the `dates` column vector of dates and data from the matrix `data`. If the dates contain time-of-day information, the object contains an additional series of times. The data matrix must be column-

oriented, that is, each column in the matrix is a data series. The names of the series default to series1, ..., series $n$ , where  $n$  is the total number of columns in data. The desc and freq fields are set to their defaults.

`tsobj = fints(dates,data,datanames)` also allows you to rename the data series. The names are specified in the datanames cell array. The number of character vectors in datanames must correspond to the number of columns in data. The desc and freq fields are set to their defaults.

`tsobj = fints(dates,data,datanames,freq)` also sets the frequency when you create the object. The desc field is set to its default ' '.

`tsobj = fints(dates,data,datanames,freq,desc)` provides a description (desc) specified as a character vector for the financial time series object.

---

**Note** fints only supports hourly and minute time series. Seconds are not supported and will be disregarded when the fints object is created (that is, 01-jan-2001 12:00:01 will be considered as 01-jan-2001 12:00). If there are duplicate dates and times, the fints constructor sorts the dates and times and chooses the first instance of the duplicate dates and times. The other duplicate dates and times are removed from the object along with their corresponding data.

---

## Examples

### Create a Financial Time Series Object Containing Days and Data

Define the data:

```
data = [1:6]'
```

```
data = 6×1
```

```
1
2
3
4
5
6
```

Define the dates:

```
dates = [today:today+5]'
```

```
dates = 6×1
```

```
737850
737851
737852
737853
737854
737855
```

Create the financial times series object:

```
tsobjkt = fints(dates, data)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
tsobjkt =
```

```
desc: (none)
freq: Unknown (0)

{'dates: (6)'} {'series1: (6)'}
{'29-Feb-2020'} {[ 1]}
{'01-Mar-2020'} {[ 2]}
{'02-Mar-2020'} {[ 3]}
{'03-Mar-2020'} {[ 4]}
{'04-Mar-2020'} {[ 5]}
{'05-Mar-2020'} {[ 6]}
```

### Create a Financial Time Series Object Containing Days, Time of Day, and Data

Define the data:

```
data = [1:6]'
```

```
data = 6×1
```

```
1
2
3
4
5
6
```

Define the dates:

```
dates = [now:now+5]'
```

```
dates = 6×1
105 ×
```

```
7.3785
7.3785
7.3785
7.3785
7.3785
7.3786
```

Create the financial times series object:

```
tsobjkt = fints(dates, data)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
tsobjkt =
```

```

desc: (none)
freq: Unknown (0)

{'dates: (6)'} {'times: (6)'} {'series1: (6)'}
{'29-Feb-2020'} {'01:58'} {'[' 1]}
{'01-Mar-2020'} {'01:58'} {'[' 2]}
{'02-Mar-2020'} {'01:58'} {'[' 3]}
{'03-Mar-2020'} {'01:58'} {'[' 4]}
{'04-Mar-2020'} {'01:58'} {'[' 5]}
{'05-Mar-2020'} {'01:58'} {'[' 6]}

```

### Create a Financial Time Series Object From a Single Input for Dates and Times

Define the dates and times:

```
dates_and_times = (now:now+5)'
```

```
dates_and_times = 6×1
105 ×
```

```

7.3785
7.3785
7.3785
7.3785
7.3785
7.3786

```

Create the financial times series object:

```
f = fints(dates_and_times, randn(6,1))
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
f =
```

```

desc: (none)
freq: Unknown (0)

{'dates: (6)'} {'times: (6)'} {'series1: (6)'}
{'29-Feb-2020'} {'02:03'} {'[' 0.5377]}
{'01-Mar-2020'} {'02:03'} {'[' 1.8339]}
{'02-Mar-2020'} {'02:03'} {'[' -2.2588]}
{'03-Mar-2020'} {'02:03'} {'[' 0.8622]}
{'04-Mar-2020'} {'02:03'} {'[' 0.3188]}
{'05-Mar-2020'} {'02:03'} {'[' -1.3077]}

```

This generates a financial time series object, `f`, and obtains the dates and data from the matrix `dates_and_times`. The dates and times in the input matrix must be oriented column-wise (i.e. the date series and each time series are columns in the input matrix). In addition, the dates entered must be in the serial date format (i.e. 01-Jan-2001 is 730852). You can also use the function `now` to enter in date information. The names of the series will default to `'series1'`, ..., `'seriesN'` where `N` is the total number of columns in `dates_and_times` less 1 (that is the number of data columns). The default contents of the `desc` and `freq` fields are `''` and `'Unknown' (0)`, respectively.

# floatdiscmargin

Discount margin for floating-rate bond

## Syntax

```
Margin = floatdiscmargin(Price, SpreadSettle, Maturity, RateInfo,
LatestFloatingRate)
Margin = floatdiscmargin( ____, Name, Value)
```

## Description

Margin = floatdiscmargin(Price, SpreadSettle, Maturity, RateInfo, LatestFloatingRate) calculates the discount margin or zero discount margin for a floating-rate bond.

The input RateInfo determines whether the discount margin or the zero discount margin is calculated. Principal schedules are supported using Principal.

Margin = floatdiscmargin( \_\_\_\_, Name, Value) adds optional name-value pair arguments.

## Examples

### Compute the Zero Discount Margin Using a Yield Curve

Use floatdiscmargin to compute the discount margin and zero discount margin for a floating-rate note.

Define data for the floating-rate note.

```
Price = 99.99;
Spread = 50;
Settle = '20-Jan-2011';
Maturity = '15-Jan-2012';
LatestFloatingRate = 0.05;
StubRate = 0.049;
SpotRate = 0.05;
Reset = 4;
Basis = 2;
```

Compute the discount margin.

```
dMargin = floatdiscmargin(Price, Spread, Settle, Maturity, ...
[StubRate, SpotRate], LatestFloatingRate, 'Reset', Reset, 'Basis', Basis, ...
'AdjustCashFlowsBasis', true)
```

```
dMargin = 48.4810
```

Usually you want to set AdjustCashFlowsBasis to true, so cash flows are calculated with adjustments on accrual amounts.

Create an annualized zero-rate term structure to calculate the zero discount margin.

```

Rates = [0.0500;
         0.0505;
         0.0510;
         0.0520];
StartDates = ['20-Jan-2011';
              '15-Apr-2011';
              '15-Jul-2011';
              '15-Oct-2011'];
EndDates = ['15-Apr-2011';
            '15-Jul-2011';
            '15-Oct-2011';
            '15-Jan-2012'];
ValuationDate = '20-Jan-2011';
RateSpec = intenvset('Compounding', Reset, 'Rates', Rates, ...
                    'StartDates', StartDates, 'EndDates', EndDates, ...
                    'ValuationDate', ValuationDate, 'Basis', Basis);

```

Calculate the zero discount margin using the previous yield curve.

```

dMargin = floatdiscmargin(Price, Spread, Settle, Maturity, ...
                          RateSpec, LatestFloatingRate, 'Reset', Reset, 'Basis', Basis, ...
                          'AdjustCashFlowsBasis', true)

```

```
dMargin = 46.0688
```

### Compute the Zero Discount Margin Using a Yield Curve With datetime Inputs

Use `floatdiscmargin` to compute the discount margin and zero discount margin for a floating-rate note using datetime inputs.

```

Price = 99.99;
Spread = 50;
Settle = '20-Jan-2011';
Maturity = '15-Jan-2012';
LatestFloatingRate = 0.05;
StubRate = 0.049;
SpotRate = 0.05;
Reset = 4;
Basis = 2;

Settle = datetime(Settle, 'Locale', 'en_US');
Maturity = datetime(Maturity, 'Locale', 'en_US');
dMargin = floatdiscmargin(Price, Spread, Settle, Maturity, ...
                          [StubRate, SpotRate], LatestFloatingRate, 'Reset', Reset, 'Basis', Basis, ...
                          'AdjustCashFlowsBasis', true)

```

```
dMargin = 48.4810
```

## Input Arguments

### Price — Bond prices where discount margin is to be computed

matrix

Bond prices where discount margin is to be computed, specified as a NINST-by-1 matrix.

---

**Note** The spread is calculated against the clean price (the function internally does not add the accrued interest to the price specified by the `Price` input). If the spread is required against the dirty price, the price of a bond that includes the accrued interest, you must supply the dirty price for the `Price` input.

---

Data Types: double

**Spread — Number of basis points over the reference rate**

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 matrix.

Data Types: double

**Settle — Settlement date of the floating-rate bonds**

serial date number | date character vector | datetime

Settlement date of the floating-rate bonds, specified as serial date number, date character vector, or datetime array. If supplied as a NINST-by-1 vector of dates, all settlement dates must be the same (only a single settlement date is supported)

Data Types: double | char | datetime

**Maturity — Maturity date of the floating-rate bond**

serial date number | date character vector | datetime

Maturity date of the floating-rate bond, specified as serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

**RateInfo — Interest-rate information**

numeric

interest-rate information, specified as NINST-by-2 vector where the:

- First column is the stub rate between the settlement date and the first coupon rate.
- Second column is the reference rate for the term of the floating coupons (for example, the 3-month LIBOR from settlement date for a bond with a `Reset` of 4).

---

**Note** If the `RateInfo` argument is an annualized zero-rate term structure created by `intenvset`, the zero discount margin is calculated.

---

Data Types: double

**LatestFloatingRate — Rate for next floating payment set at last reset date**

numeric

Rate for the next floating payment set at the last reset date, specified as NINST-by-1 vector.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Margin = floatdiscmargin(Price, Spread, Settle, Maturity, RateInfo, LatestFloatingRate, 'Reset', 2, 'Basis', 5)`

**Reset — Frequency of payments per year**

1 (default) | numeric

Frequency of payments per year, specified as NINST-by-1 vector.

Data Types: double

**Basis — Day-count basis used for time factor calculations**

0 (actual/actual) (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Day-count basis used for time factor calculations, specified as a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

**Principal — Notional principal amounts**

100 (default) | numeric

Notional principal amounts, specified as a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NUMDATES-by-2 cell array where the first column is dates and the second column is the associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: double | cell

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

### **AdjustCashFlowsBasis — Adjust cash flows according to accrual amount**

0 (not in effect) (default) | nonnegative integer 0 or 1

Adjusts cash flows according to the accrual amount, specified as a NINST-by-1 vector of logicals.

---

**Note** Usually you want to set AdjustCashFlowsBasis to 1, so cash flows are calculated with adjustments on accrual amounts. The default is set to 0 to be consistent with floatbyzero.

---

Data Types: logical

### **Holidays — Dates for holidays**

holidays.m used (default)

Dates for holidays, specified as NHOLIDAYS-by-1 vector of MATLAB dates using serial date numbers, date character vectors, or datetime arrays. Holidays are used in computing business days.

Data Types: double | char | datetime

### **BusinessDayConvention — Business day conventions**

'actual' (default) | character vector with values 'actual', 'follow', 'modifiedfollow', 'previous' or 'modifiedprevious'

Business day conventions, specified as a NINST-by-1 cell array of character vectors of business day conventions to be used in computing payment dates. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

## Output Arguments

### Margin — Discount margin

numeric

Discount margin, returned as a NINST-by-1 vector of the discount margin if `RateInfo` is specified as a NINST-by-2 vector of stub and spot rates.

If `RateInfo` is specified as an annualized zero rate term structure created by `intenvset`, `Margin` is returned as a NINST-by-NCURVES matrix of the zero discount margin.

# floatmargin

Margin measures for floating-rate bond

## Syntax

```
[Margin,AdjPrice] = floatmargin(Price,SpreadSettle,Maturity)
[Margin,AdjPrice] = floatmargin( ____,Name,Value)
```

## Description

[Margin,AdjPrice] = floatmargin(Price,SpreadSettle,Maturity) calculates margin measures for a floating-rate bond.

Use floatmargin to calculate the following types of margin measures for a floating-rate bond:

- Spread for life
- Adjusted simple margin
- Adjusted total margin

To calculate the discount margin or zero discount margin, see floatdiscmargin.

[Margin,AdjPrice] = floatmargin( \_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Compute Margin Measures for a Floating-Rate Bond

Use floatmargin to compute margin measures for spreadforlife, adjustedsimple, and adjustedtotal for a floating-rate note.

Define data for the floating-rate note.

```
Price = 99.99;
Spread = 50;
Settle = '20-Jan-2011';
Maturity = '15-Jan-2012';
LatestFloatingRate = 0.05;
StubRate = 0.049;
SpotRate = 0.05;
Reset = 4;
Basis = 2;
```

Calculate spreadforlife.

```
Margin = floatmargin(Price, Spread, Settle, Maturity, 'Reset', ...
Reset, 'Basis', Basis)
```

```
Margin = 51.0051
```

Calculate `adjustedsimple` margin.

```
[Margin, AdjPrice] = floatmargin(Price, Spread, Settle, Maturity, ...
'SpreadType', 'adjustedsimple', 'RateInfo', [StubRate, SpotRate], ...
'LatestFloatingRate', LatestFloatingRate, 'Reset', Reset, 'Basis', Basis)
```

```
Margin = 53.2830
```

```
AdjPrice = 99.9673
```

Calculate `adjustedtotal` margin.

```
[Margin, AdjPrice] = floatmargin(Price, Spread, Settle, Maturity, ...
'SpreadType', 'adjustedtotal', 'RateInfo', [StubRate, SpotRate], ...
'LatestFloatingRate', LatestFloatingRate, 'Reset', Reset, 'Basis', Basis)
```

```
Margin = 53.4463
```

```
AdjPrice = 99.9673
```

### Compute Margin Measures for a Floating-Rate Bond Using `datetime` Inputs

Use `floatmargin` to calculate margin measures for `spreadforlife`, `adjustedsimple`, and `adjustedtotal` for a floating-rate note using `datetime` inputs.

```
Price = 99.99;
Spread = 50;
Settle = '20-Jan-2011';
Maturity = '15-Jan-2012';
LatestFloatingRate = 0.05;
StubRate = 0.049;
SpotRate = 0.05;
Reset = 4;
Basis = 2;
```

```
Settle = datetime(Settle, 'Locale', 'en_US');
Maturity = datetime(Maturity, 'Locale', 'en_US');
[Margin, AdjPrice] = floatmargin(Price, Spread, Settle, Maturity, ...
'SpreadType', 'adjustedsimple', 'RateInfo', [StubRate, SpotRate], ...
'LatestFloatingRate', LatestFloatingRate, 'Reset', Reset, 'Basis', Basis)
```

```
Margin = 53.2830
```

```
AdjPrice = 99.9673
```

## Input Arguments

### Price — Bond prices where spreads are to be computed

matrix

Bond prices where spreads are to be computed, specified as a NINST-by-1 matrix.

Data Types: double

**Spread — Number of basis points over the reference rate**

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 matrix.

Data Types: double

**Settle — Settlement date of the floating-rate bonds**

serial date number | date character vector | datetime

Settlement date of the floating-rate bonds, specified as serial date number, date character vector, or datetime array. If supplied as a NINST-by-1 vector of dates, all settlement dates must be the same (only a single settlement date is supported)

Data Types: double | char | datetime

**Maturity — Maturity date of the floating-rate bond**

serial date number | date character vector | datetime

Maturity date of the floating-rate bond, specified as serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Margin, AdjPrice] = floatmargin(Price, Spread, Settle, Maturity, 'SpreadType', 'adjustedtotal', 'RateInfo', [StubRate, SpotRate], 'LatestFloatingRate', .0445, 'Reset', 2, 'Basis', 5)`

**SpreadType — Type of spread to calculate**

spreadforlife (default) | adjustedsimple | adjustedtotal

Type of spread to calculate, specified by type, specified as `spreadforlife`, `adjustedsimple`, or `adjustedtotal`.

---

**Note** If the `SpreadType` is `spreadforlife` (default), then the name-value arguments `LatestFloatingRate` and `RateInfo` are not used. If the `SpreadType` is `adjustedsimple` or `adjustedtotal`, then the name-value arguments `LatestFloatingRate` and `RateInfo` must be specified.

---

Data Types: double

**LatestFloatingRate — Rate for next floating payment set at last reset date**

numeric

Rate for the next floating payment set at the last reset date, specified as NINST-by-1 vector.

---

**Note** This rate must be specified for a `SpreadType` of `adjustedsimple` and `adjustedtotal`.

---

Data Types: double

### RateInfo — Interest-rate information

numeric

interest-rate information, specified as NINST-by-2 vector where the:

- First column is the stub rate between the settlement date and the first coupon rate.
- Second column is the reference rate for the term of the floating coupons (for example, the 3-month LIBOR from settlement date for a bond with a Reset of 4).

---

**Note** The RateInfo must be specified for SpreadType of `adjustedsimple` and `adjustedtotal`.

---

Data Types: double

### Reset — Frequency of payments per year

1 (default) | numeric

Frequency of payments per year, specified as NINST-by-1 vector.

Data Types: double

### Basis — Day-count basis used for time factor calculations

0 (actual/actual) (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Day-count basis used for time factor calculations, specified as a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

### Principal — Notional principal amounts

100 (default) | numeric

Notional principal amounts, specified as NINST-by-1 vector.

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as a NINST-by-1 vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

### **Holidays — Dates for holidays**

`holidays.m` used (default)

Dates for holidays, specified as NHOLIDAYS-by-1 vector of MATLAB dates using serial date numbers, date character vectors, or datetime arrays. Holidays are used in computing business days.

Data Types: double | char | datetime

### **BusinessDayConvention — Business day conventions**

'actual' (default) | character vector with values 'actual', 'follow', 'modifiedfollow', 'previous' or 'modifiedprevious'

Business day conventions, specified as a NINST-by-1 cell array of character vectors of business day conventions to be used in computing payment dates. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

## **Output Arguments**

### **Margin — Spreads for floating-rate bond**

numeric

Spreads for the floating-rate bond, returned as a NINST-by-1 vector.

**AdjPrice — Adjusted price used to calculate spreads for SpreadType of adjustedsimple and adjustedtotal**

numeric

Adjusted price used to calculate spreads for SpreadType of adjustedsimple and adjustedtotal, returned as a NINST-by-1 vector.

## Arguments

|                 |                                                                                                                                                                                                              |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| highp           | High price (vector).                                                                                                                                                                                         |
| lowp            | Low price (vector).                                                                                                                                                                                          |
| closep          | Closing price (vector).                                                                                                                                                                                      |
| kperiods        | (Optional) %K periods. Default = 10.                                                                                                                                                                         |
| dperiods        | (Optional) %D periods. Default = 3.                                                                                                                                                                          |
| damethod        | (Optional) %D moving average method. Default = 'e' (exponential).                                                                                                                                            |
| tsoj            | Financial time series object.                                                                                                                                                                                |
| 'ParameterName' | Valid parameter names are: <ul style="list-style-type: none"> <li>• HighName: high prices series name</li> <li>• LowName: low prices series name</li> <li>• CloseName: closing prices series name</li> </ul> |
| ParameterValue  | Parameter values are the character vectors that represent the valid parameter names.                                                                                                                         |

## Description

fpctkd calculates the stochastic oscillator.

`[pctk,pctd] = fpctkd(highp,lowp,closep)` calculates the fast stochastics F%K and F%D from the stock price data `highp` (high prices), `lowp` (low prices), and `closep` (closing prices).

`[pctk,pctd] = fpctkd([highp lowp closep])` accepts a three-column matrix of high (`highp`), low (`lowp`), and closing prices (`closep`), in that order.

`[pctk,pctd] = fpctkd(highp,lowp,closep,kperiods,dperiods,dmmethod)` calculates the fast stochastics F%K and F%D from the stock price data `highp` (high prices), `lowp` (low prices), and `closep` (closing prices). `kperiods` sets the %K period. `dperiods` sets the %D period.

`dmmethod` specifies the %D moving average method. Valid moving average methods for %D are Exponential ('e') and Triangular ('t'). See `tsmovavg` for explanations of these methods.

`[pctk,pctd]= fpctkd([highp lowp closep],kperiods,dperiods,dmmethod)` accepts a three-column matrix of high (`highp`), low (`lowp`), and closing prices (`closep`), in that order.

`pkdts = fpctkd(tsobj,kperiods,dperiods,dmmethod)` calculates the fast stochastics F%K and F%D from the stock price data in the financial time series object `tsobj`. `tsobj` must minimally contain the series High (high prices), Low (low prices), and Close (closing prices). `pkdts` is a financial time series object with similar dates to `tsobj` and two data series named `PercentK` and `PercentD`.

`pkdts = fpctkd(tsobj,kperiods,dperiods,dmmethod,'ParameterName',ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Parameter values are the character vectors that represent the valid parameter names.

## Examples

### Compute the Stochastic Oscillator

This example shows how to compute the stochastic oscillator for Disney stock and plot the results.

```
load disney.mat
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
```

```
dis_FastStoc = fpctkd(dis);
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
```

```
plot(dis_FastStoc)
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
```

```
title('Stochastic Oscillator for Disney')
```

## frac2cur

Fractional currency value to decimal value

### Syntax

```
Decimal = frac2cur(Fraction,Denominator)
```

### Description

`Decimal = frac2cur(Fraction,Denominator)` converts a fractional currency value to a decimal value. `Fraction` is the fractional currency value input as a character vector, and `Denominator` is the denominator of the fraction.

### Examples

#### Convert a Fractional Currency Value to a Decimal Value

This example shows how to convert a fractional currency value to a decimal value.

```
Decimal = frac2cur('12.1', 8)
```

```
Decimal = 12.1250
```

### Input Arguments

#### Fraction — Fractional currency values

character vector | cell array of character vectors

Fractional currency values, specified as a character vector or cell array of character vectors.

Data Types: `char` | `cell`

#### Denominator — Denominator of the fractions

numeric

Denominator of the fractions, specified as a scalar or vector using numeric values for the denominator.

Data Types: `double`

### Output Arguments

#### Decimal — Decimal currency value

numeric decimal

Decimal currency value, returned as a scalar or vector with numeric decimal values.

Data Types: `double`

**See Also**

cur2frac | cur2str

**Introduced before R2006a**

## freqnum

Convert character vector frequency indicator to numeric frequency indicator

---

**Note** `freqnum` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
nfreq = freqnum(sfreq)
```

### Arguments

|       |                                                                                                                                                                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sfreq | UNKNOWN, Unknown, unknown, U, u<br>DAILY, Daily, daily, D, d<br>WEEKLY, Weekly, weekly, W, w<br>MONTHLY, Monthly, monthly, M, m<br>QUARTERLY, Quarterly, quarterly, Q, q<br>SEMIANNUAL, Semiannual, semiannual, S, s<br>ANNUAL, Annual, annual, A, a |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Description

`nfreq = freqnum(sfreq)` converts a character vector frequency indicator into a numeric value.

| Character Vector Frequency Indicator     | Numeric Representation |
|------------------------------------------|------------------------|
| UNKNOWN, Unknown, unknown, U, u          | 0                      |
| DAILY, Daily, daily, D, d                | 1                      |
| WEEKLY, Weekly, weekly, W, w             | 2                      |
| MONTHLY, Monthly, monthly, M, m          | 3                      |
| QUARTERLY, ly, quarterly, Q, q           | 4                      |
| SEMIANNUAL, Semiannual, semiannual, S, s | 5                      |
| ANNUAL, Annual, annual, A, a             | 6                      |

## freqstr

Convert numeric frequency indicator to character vector representation

---

**Note** `freqstr` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
sfreq = freqstr(nfreq)
```

### Arguments

|       |   |
|-------|---|
| nfreq | 0 |
|       | 1 |
|       | 2 |
|       | 3 |
|       | 4 |
|       | 5 |
|       | 6 |

### Description

`sfreq = freqstr(nfreq)` converts a numeric frequency indicator into a character vector representation.

| Numeric Frequency Indicator | Character Vector Representation |
|-----------------------------|---------------------------------|
| 0                           | Unknown                         |
| 1                           | Daily                           |
| 2                           | Weekly                          |
| 3                           | Monthly                         |
| 4                           | Quarterly                       |
| 5                           | Semiannual                      |
| 6                           | Annual                          |

## frontier

Rolling efficient frontier

### Syntax

```
[PortWts,AllMean,AllCovariance] = frontier(Universe,Window,Offset,NumPorts)
[PortWts,AllMean,AllCovariance] = frontier( ____,ActiveMap,Conset,NumNonNan)
```

### Description

[PortWts,AllMean,AllCovariance] = frontier(Universe,Window,Offset,NumPorts) generates a surface of efficient frontiers showing how asset allocation influences risk and return over time.

[PortWts,AllMean,AllCovariance] = frontier( \_\_\_\_,ActiveMap,Conset,NumNonNan) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Input Arguments

#### Universe — Total return data for a group of securities

array

Total return data for a group of securities, specified as a number of observations (NUMOBS) by number of assets plus one (NASSETS + 1) time series array. Each row represents an observation. Column 1 contains MATLAB serial date numbers. The remaining columns contain the total return data for each security.

Data Types: double

#### Window — Number of data periods used to calculate each frontier

positive integer

Number of data periods used to calculate each frontier, specified as a positive integer value.

Data Types: double

#### Offset — Increment in number of periods between each frontier

numeric

Increment in number of periods between each frontier, specified as a numeric value.

Data Types: double

#### NumPorts — Number of portfolios to calculate on each frontier

positive integer

Number of portfolios to calculate on each frontier, specified as a positive integer.

Data Types: double

**ActiveMap — Indicates if an asset is part of the Universe on the corresponding date**

NUMOBS-by-NASSETS matrix of 1's (all assets active on all dates) (default) | matrix

(Optional) Indicates if an asset is part of the Universe on the corresponding date, specified as a number of observations (NUMOBS) by number of assets (NASSETS) matrix with Boolean elements corresponding to the Universe.

Data Types: double

**Conset — Constraint matrix for a portfolio of asset investments**

matrix

Constraint matrix for a portfolio of asset investments, specified using portcons with the 'Default' constraint type. This single constraint matrix is applied to each frontier.

Data Types: double

**NumNonNan — Minimum number of non-NaN points for each active asset in each window of data**

Window - NASSETS (default) | numeric value

Minimum number of non-NaN points for each active asset in each window of data needed to perform the optimization, specified as a numeric value.

Data Types: double

**Output Arguments****PortWts — Weights allocated to each asset**

matrix

Weights allocated to each asset., returned as a number of curves (NCURVES)-by-1 cell array, where each element is a NPORTS-by-NASSETS matrix of weights.

**AllMean — Expected asset returns used to generate each curve on the surface**

vector

Expected asset returns used to generate each curve on the surface, returned as an NCURVES-by-1 cell array, where each element is a 1-by-NASSETS vector of the expected asset returns.

**AllCovariance — Covariance matrix used to generate each curve on the surface**

vector

Covariance matrix used to generate each curve on the surface, returned as an NCURVES-by-1 cell array, where each element is a NASSETS-by-NASSETS vector.

## fts2ascii

Write elements of time series data into ASCII file

---

**Note** `fts2ascii` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
stat = fts2ascii(filename,tsobj,exttext)
```

```
stat = fts2ascii(filename,dates,data,colheads,desc,exttext)
```

### Arguments

|                       |                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>filename</code> | Name of an ASCII file                                                                                                                                                       |
| <code>tsobj</code>    | Financial time series object                                                                                                                                                |
| <code>exttext</code>  | (Optional) Extra text written after the description line (line 2 in the file).                                                                                              |
| <code>dates</code>    | Column vector containing dates. Dates must be in serial date number format and can specify time of day.                                                                     |
| <code>data</code>     | Column-oriented matrix. Each column is a series.                                                                                                                            |
| <code>colheads</code> | (Optional) Cell array of column headers (names); first cell must always be the one for the dates column. <code>colheads</code> is written to the file just before the data. |
| <code>desc</code>     | (Optional) Description text, which is the first line in the file.                                                                                                           |

### Description

`stat = fts2ascii(filename,tsobj,exttext)` writes the financial time series object `tsobj` into an ASCII file `filename`. The data in the file is tab delimited.

`stat = fts2ascii(filename,dates,data,colheads,desc,exttext)` writes into an ASCII file `filename` the dates, times, and data contained in the column vector `dates` and the column-oriented matrix `data`. The first column in `filename` contains the dates, followed by `times` (if specified). Subsequent columns contain the `data`. The data in the file is tab delimited.

`stat` indicates whether file creation is successful (1) or not (0).

### Examples

#### Use `fts2ascii` to Write a Time Series to an ASCII File

Create a data file with time information.

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
```

```
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
serial_dates_times = [datenum(dates), datenum(times)];
data = round(10*rand(6,2));
```

Use `fts2ascii` to write the time series to an ascii file.

```
stat = fts2ascii('myfts_file2.txt',serial_dates_times,data, ...
{'dates';'times';'Data1';'Data2'},'My FTS with Time')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
stat = 1
```

Read the data file back and create a financial time series object using `ascii2fts`.

```
MyFts = ascii2fts('myfts_file2.txt','t',1,2,1)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
MyFts =
```

```
desc: My FTS with Time
freq: Unknown (0)
```

```
{'dates: (6)'} {'times: (6)'} {'Data1: (6)'} {'Data2: (6)'}
{'01-Jan-2001'} {'11:00' } {'[ 8]'} {'[ 3]'}
{' ' ' '} {'12:00' } {'[ 9]'} {'[ 5]'}
{'02-Jan-2001'} {'11:00' } {'[ 1]'} {'[ 10]'}
{' ' ' '} {'12:00' } {'[ 9]'} {'[ 10]'}
{'03-Jan-2001'} {'11:00' } {'[ 6]'} {'[ 2]'}
{' ' ' '} {'12:00' } {'[ 1]'} {'[ 10]'}

```

## fts2timetable

Convert financial time series objects (`fints`) to timetable object

### Syntax

```
TT = fts2timetable(FTS)
```

### Description

`TT = fts2timetable(FTS)` converts a M-by-N `fints` object to a M-by-N MATLAB timetable object (TT). The date and time information in the `fints` object becomes the TT time vector, while the remaining variables in the `fints` object become variables in TT. The `fints` description property (DESC) is mapped to `TT.Properties.Description`. The `fints` frequency indicator property (FREQ) is unused and removed from the output TT. For more information, see “Convert Financial Time Series Objects `fints` to Timetables” on page 12-2.

### Examples

#### Convert `fints` Object to a timetable Object and Plot the Financial Data

Load the financial data.

```
load SimulatedStockValues
```

Convert a `fints` object to a timetable object.

```
TMW = fts2timetable(TMW_fts);
TMW.Properties
```

```
ans =
```

```
    TimetableProperties with properties:
        Description: 'Simulated stock OHLCV data.'
        UserData: []
    DimensionNames: {'Time' 'Variables'}
    VariableNames: {'Open' 'High' 'Low' 'Close' 'Volume'}
    VariableDescriptions: {}
    VariableUnits: {}
    VariableContinuity: []
        RowTimes: [1000x1 datetime]
        StartTime: 31-Aug-2012
        SampleRate: NaN
        TimeStep: NaN
    CustomProperties: No custom properties are set.
    Use addprop and rmprop to modify CustomProperties.
```

Visualize the financial data.

```
ma1 = movavg(TMW, 'exponential', 14);
ma2 = movavg(TMW, 'exponential', 26);
```

```

selctRange = 70:120;
figure;
plot(ma1.Time(selctRange), ma1.Close(selctRange), ...
     ma2.Time(selctRange), ma2.Close(selctRange));
ax = gca;
hold on

% Plot on a target axis
candle(ax, TMW(selctRange,:));
legend(ax, '14-day MA', '26-day MA', 'Price')
ylabel(ax, 'Price')
xlabel(ax, 'Date')
title(ax, 'TMW Simulated Stock Prices')
hold off

```

## Input Arguments

### FTS — Financial time series object

object

Financial time series object, specified by using a M-by-N `fints` object.

Data Types: object

## **Output Arguments**

### **TT — Timetable**

object

Timetable, returned as a M-by-N object.

### **See Also**

timetable

### **Topics**

“Convert Financial Time Series Objects fints to Timetables” on page 12-2

### **Introduced in R2018a**

## fts2mat

Convert to matrix

---

**Note** `fts2mat` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
tsmat = fts2mat(tsoobj)
```

```
tsmat = fts2mat(tsoobj,datesflag)
```

```
tsmat = fts2mat(tsoobj,seriesnames)
```

```
tsmat = fts2mat(tsoobj,datesflag,seriesnames)
```

### Arguments

|                          |                                                                                                                                                                      |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsoobj</code>      | Financial time series object                                                                                                                                         |
| <code>datesflag</code>   | (Optional) Specifies inclusion of dates vector:<br><br><code>datesflag = 0</code> (default) excludes dates.<br><br><code>datesflag = 1</code> includes dates vector. |
| <code>seriesnames</code> | (Optional) Specifies the data series to be included in the matrix. Can be a cell array of character vectors.                                                         |

### Description

`tsmat = fts2mat(tsoobj)` takes the data series in the financial time series object `tsoobj` and puts them into the matrix `tsmat` as columns. The order of the columns is the same as the order of the data series in the object `tsoobj`.

`tsmat = fts2mat(tsoobj,datesflag)` specifies whether you want the dates vector included. The dates vector is the first column. The dates are represented as serial date numbers. Dates can include time-of-day information.

`tsmat = fts2mat(tsoobj,seriesnames)` extracts the data series named in `seriesnames` and puts its values into `tsmat`. The `seriesnames` argument can be a cell array of character vectors.

`tsmat = fts2mat(tsoobj,datesflag,seriesnames)` puts into `tsmat` the specific data series named in `seriesnames`. The `datesflag` argument must be specified. If `datesflag` is set to 1, the dates vector is included. If you specify an empty matrix (`[]`) for `datesflag`, the default behavior is adopted.

## ftsbound

Start and end dates

---

**Note** `ftsbound` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
datesbound = ftsbound(tsoobj)
```

```
datesbound = ftsbound(tsoobj,dateform)
```

### Arguments

|                       |                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsoobj</code>   | Financial time series object                                                                                                                         |
| <code>dateform</code> | <code>dateform</code> is an integer representing the format of a date character vector. See <code>datestr</code> for a description of these formats. |

### Description

`ftsbound` returns the start and end dates of a financial time series object. If the object contains time-of-day data, `ftsbound` also returns the starting time on the first date and the ending time on the last date.

`datesbound = ftsbound(tsoobj)` returns the start and end dates contained in `tsoobj` as serial dates in the column matrix `datesbound`. The first row in `datesbound` corresponds to the start date, and the second corresponds to the end date.

`datesbound = ftsbound(tsoobj,dateform)` returns the starting and ending dates contained in the object, `tsoobj`, as date character vectors in the column matrix, `datesbound`. The first row in `datesbound` corresponds to the start date, and the second corresponds to the end date. The `dateform` argument controls the format of the output dates.

# ftsgui

Financial time series GUI

---

**Note** ftsgui will be removed in a future release and will no longer accept a `fints` object.

Use `fts2timetable` to convert a `fints` object to a `timetable` object. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

`ftsgui`

## Description

`ftsgui` displays the financial time series graphical user interface (GUI) main window.

The use of the financial time series GUI is described in “Using the Financial Time Series GUI” on page 15-6.

---

**Note** **Help** menu item is not available for `ftsgui` in MATLAB Online.

---

## Examples

`ftsgui`

## ftsinfo

Financial time series object information

---

**Note** `ftsinfo` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
ftsinfo(tsoj)
```

```
infofts = ftsinfo(tsoj)
```

### Arguments

|                   |                               |
|-------------------|-------------------------------|
| <code>tsoj</code> | Financial time series object. |
|-------------------|-------------------------------|

### Description

`ftsinfo(tsoj)` displays information about the financial time series object `tsoj`.

`infofts = ftsinfo(tsoj)` stores information about the financial time series object `tsoj` in the structure `infofts`.

`infofts` has these fields.

| Field                    | Contents                                                                                                                                                               |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>version</code>     | Financial time series object version.                                                                                                                                  |
| <code>desc</code>        | Description of the time series object ( <code>tsoj.desc</code> ).                                                                                                      |
| <code>freq</code>        | Numeric representation of the time series data frequency ( <code>tsoj.freq</code> ). See <code>freqstr</code> for list of numeric frequencies and what they represent. |
| <code>startdate</code>   | Earliest date in the time series.                                                                                                                                      |
| <code>enddate</code>     | Latest date in the time series.                                                                                                                                        |
| <code>seriesnames</code> | Cell array containing the time series data column names.                                                                                                               |
| <code>ndata</code>       | Number of data points in the time series.                                                                                                                              |
| <code>nseries</code>     | Number of columns of time series data.                                                                                                                                 |

### Examples

Convert the supplied file `disney.dat` into a financial time series object named `dis`:

```
dis = ascii2fts('disney.dat', 1, 3);
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In ascii2fts (line 64)
```

Now use `ftsinfo` to obtain information about `dis`:

```
ftsinfo(dis)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/ftsinfo (line 64)
```

```
FINTS version: 2.0 or higher
Description: Walt Disney Company (DIS)
Frequency: Unknown
Start date: 29-Mar-1996
End date: 29-Mar-1999
Series names: OPEN
              HIGH
              LOW
              CLOSE
              VOLUME
# of data: 782
# of series: 5
```

Then, executing

```
infodis = ftsinfo(dis)
```

creates the structure `infodis` containing the values

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/ftsinfo (line 64)
```

```
infodis =
```

```
struct with fields:
```

```
    ver: '2.0 or higher'
    desc: 'Walt Disney Company (DIS)'
    freq: 0
    startdate: '29-Mar-1996'
    enddate: '29-Mar-1999'
    seriesnames: {5x1 cell}
    ndata: 782
    nseries: 5
```

**Introduced before R2006a**

## ftstool

Financial Time Series app

---

**Note** `ftstool` will be removed in a future release and will no longer accept a `fints` object.

Use `fts2timetable` to convert a `fints` object to a `timetable` object. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

`ftstool`

### Description

`ftstool` creates and manages Financial Time Series objects. `ftstool` allows the creation and management of Financial Time Series objects via the Financial Time Series app. `ftstool` can interface with `ftsgui`, meaning Line Plots generated with `ftstool` can be analyzed with `ftsgui`. However, `ftsgui` must be running prior to the generation of any Line Plots.

The use of the Financial Time Series app is described in “Getting Started with the Financial Time Series App” on page 14-4.

---

**Note** **Help** menu item is not available for `ftstool` in MATLAB Online.

---

### Examples

`ftstool`

Alternatively, on the MATLAB desktop toolstrip, click the **Apps** tab and in the apps gallery, under **Computational Finance**, click **Financial Time Series**. The Financial Time Series app opens. For an overview of the Financial Time Series app, see “What Is the Financial Time Series App?” on page 14-2.

## ftsuniq

Determine uniqueness

---

**Note** `ftsuniq` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
uniq = ftsuniq(dates_and_times)
```

```
[uniq,dup] = ftsuniq(dates_and_times)
```

### Arguments

|                              |                                                                                                             |
|------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>dates_and_times</code> | A single column vector of serial date numbers. The serial date numbers can include time-of-day information. |
|------------------------------|-------------------------------------------------------------------------------------------------------------|

### Description

`uniq = ftsuniq(dates_and_times)` returns 1 if the dates and times within the financial time series object are unique and 0 if duplicates exist.

`[uniq,dup] = ftsuniq(dates_and_times)` additionally returns a structure `dup`. In the structure

- `dup.DT` contains the character vectors of the duplicate dates and times and their locations in the object.
- `dup.intIdx` contains the integer indices of duplicate dates and times in the object.

## fvdisc

Future value of discounted security

### Syntax

`FutureVal = fvdisc(Settle,Maturity,Price,Discount,Basis)`

### Arguments

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Settle   | Settlement date. Enter as serial date number, date character vector, or datetime array. <b>Settle</b> must be earlier than <b>Maturity</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Maturity | Maturity date. Enter as serial date number, date character vector, or datetime array.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Price    | Price (present value) of the security.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Discount | Bank discount rate of the security. Enter as decimal fraction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Basis    | <p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (PSA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-18.</p> |

### Description

`FutureVal = fvdisc(Settle,Maturity,Price,Discount,Basis)` finds the amount received at maturity for a fully vested security.

### Examples

### Find the Amount Received at Maturity for a Fully-Vested Security

This example shows how to find the amount received at maturity for a fully-vested security, using the following data.

```
Settle = '02/15/2001';  
Maturity = '05/15/2001';  
Price = 100;  
Discount = 0.0575;  
Basis = 2;
```

```
FutureVal = fvdisc(Settle, Maturity, Price, Discount, Basis)
```

```
FutureVal = 101.4420
```

### Find the Amount Received at Maturity for a Fully-Vested Security Using datetime Inputs

This example shows how to use `datetime` inputs to find the amount received at maturity for a fully-vested security, using the following data.

```
Settle = datetime('02/15/2001','Locale','en_US');  
Maturity = datetime('05/15/2001','Locale','en_US');  
Price = 100;  
Discount = 0.0575;  
Basis = 2;
```

```
FutureVal = fvdisc(Settle, Maturity, Price, Discount, Basis)
```

```
FutureVal = 101.4420
```

# fvfix

Future value with fixed periodic payments

## Syntax

`FutureVal = fvfix(Rate,NumPeriods,Payment,PresentVal,Due)`

## Arguments

|            |                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------|
| Rate       | Periodic interest rate, as a decimal fraction.                                                     |
| NumPeriods | Number of periods.                                                                                 |
| Payment    | Periodic payment.                                                                                  |
| PresentVal | (Optional) Initial value. Default = 0.                                                             |
| Due        | (Optional) When payments are due or made: 0 = end of period (default), or 1 = beginning of period. |

## Description

`FutureVal = fvfix(Rate,NumPeriods,Payment,PresentVal,Due)` returns the future value of a series of equal payments.

## Examples

### Return the Future Value of a Series of Equal Payments

This example shows how to compute the future value of a series of equal payments using a savings account that has a starting balance of \$1500. \$200 is added at the end of each month for 10 years and the account pays 9% interest compounded monthly.

```
FutureVal = fvfix(0.09/12, 12*10, 200, 1500, 0)
```

```
FutureVal = 4.2380e+04
```

## fvvar

Future value of varying cash flow

### Syntax

`FutureVal = fvvar(CashFlow,Rate,CFDates)`

### Arguments

|          |                                                                                                                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CashFlow | A vector of varying cash flows. Include the initial investment as the initial cash flow value (a negative number).                                                                                                                                   |
| Rate     | Periodic interest rate. Enter as a decimal fraction.                                                                                                                                                                                                 |
| CFDates  | (Optional) For irregular (nonperiodic) cash flows, a vector of dates on which the cash flows occur. Enter dates as serial date numbers, date character vectors, or datetime arrays. Default assumes CashFlow contains regular (periodic) cash flows. |

### Description

`FutureVal = fvvar(CashFlow,Rate,CFDates)` returns the future value of a varying cash flow.

### Examples

This cash flow represents the yearly income from an initial investment of \$10,000. The annual interest rate is 8%.

|        |        |
|--------|--------|
| Year 1 | \$2000 |
| Year 2 | \$1500 |
| Year 3 | \$3000 |
| Year 4 | \$3800 |
| Year 5 | \$5000 |

For the future value of this regular (periodic) cash flow

`FutureVal = fvvar([-10000 2000 1500 3000 3800 5000], 0.08)`

returns

`FutureVal =`

2520.47

An investment of \$10,000 returns this irregular cash flow. The original investment and its date are included. The periodic interest rate is 9%.

| Cash Flow | Dates             |
|-----------|-------------------|
| (\$10000) | January 12, 2000  |
| \$2500    | February 14, 2001 |
| \$2000    | March 3, 2001     |
| \$3000    | June 14, 2001     |
| \$4000    | December 1, 2001  |

To calculate the future value of this irregular (nonperiodic) cash flow

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
```

```
CFDates = ['01/12/2000'
           '02/14/2001'

## fwd2zero

Zero curve given forward curve

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: `InputCompounding`, `InputBasis`, `OutputCompounding`, and `OutputBasis`.

---

### Syntax

```
[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle)
[ZeroRates, CurveDates] = fwd2zero( ___, Name, Value)
```

### Description

`[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle)` returns a zero curve given an implied forward rate curve and its maturity dates. If both inputs for `CurveDates` and `Settle` are serial date numbers or date character vectors, `CurveDates` is returned as serial date numbers. However, if either of the inputs for `CurveDates` and `Settle` are a datetime array, `CurveDates` is returned as a datetime array.

`[ZeroRates, CurveDates] = fwd2zero( ___, Name, Value)` adds optional name-value pair arguments

### Examples

#### Compute the Zero Curve Given the Forward Curve

This example shows how to compute the zero curve, given an implied forward rate curve over a set of maturity dates, a settlement date, and a compounding rate.

```
ForwardRates = [0.0469
                0.0519
                0.0549
                0.0535
                0.0558
                0.0508
                0.0560
                0.0545
                0.0615
                0.0486];
```

```
CurveDates = [datetime('06-Nov-2000')
              datetime('11-Dec-2000')
              datetime('15-Jan-2001')
              datetime('05-Feb-2001')
              datetime('04-Mar-2001')
              datetime('02-Apr-2001')]
```

```

    datenum('30-Apr-2001')
    datenum('25-Jun-2001')
    datenum('04-Sep-2001')
    datenum('12-Nov-2001')];

```

```
Settle = datenum('03-Nov-2000');
```

```

InputCompounding = 1;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;

```

Execute the function fwd2zero to return the zero-rate curve ZeroRates at the maturity dates CurveDates.

```
[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, ...
Settle, 'InputCompounding', 1, 'InputBasis', 2, 'OutputCompounding', 1, 'OutputBasis', 2)
```

```
ZeroRates = 10×1
```

### Compute the Zero Curve Given the Forward Curve Using datetime Inputs

This example shows how to use datetime inputs compute the zero curve, given an implied forward rate curve over a set of maturity dates, a settlement date, and a compounding rate.

```

ForwardRates = [0.0469
0.0519
0.0549
0.0535
0.0558

```

```
0.0508
0.0560
0.0545
0.0615
0.0486];

CurveDates = [datenum('06-Nov-2000')
datenum('11-Dec-2000')
datenum('15-Jan-2001')
datenum('05-Feb-2001')
datenum('04-Mar-2001')
datenum('02-Apr-2001')
datenum('30-Apr-2001')
datenum('25-Jun-2001')
datenum('04-Sep-2001')
datenum('12-Nov-2001')];

Settle = datenum('03-Nov-2000');

InputCompounding = 1;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2; CurveDates = datetime(CurveDates, 'ConvertFrom', 'datenum', 'Locale', 'en_US');
Settle = datetime(Settle, 'ConvertFrom', 'datenum', 'Locale', 'en_US');
[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, ...
Settle, 'InputCompounding', 1, 'InputBasis', 2, 'OutputCompounding', 1, 'OutputBasis', 2)

ZeroRates = 10x1

## Input Arguments

### ForwardRates — Annualized implied forward rates

decimal fraction

Annualized implied forward rates, specified as a (NUMBONDS)-by-1 vector using decimal fractions. In aggregate, the rates in `ForwardRates` constitute an implied forward curve for the investment horizon represented by `CurveDates`. The first element pertains to forward rates from the settlement date to the first curve date.

Data Types: double

### CurveDates — Maturity dates

serial date number | date character vector | datetime

Maturity dates, specified as a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays, that correspond to the `ForwardRates`.

Data Types: double | datetime | char

### Settle — Common settlement date for ForwardRates

serial date number | date character vector | datetime

Common settlement date for `ForwardRates`, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle, 'InputCompounding', 3, 'InputBasis', 5, 'OutputCompounding', 4, 'OutputBasis', 5)`

### InputCompounding — Compounding frequency of input forward rates

2 (default) | numeric values: 0, 1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of input forward rates, specified with allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

---

**Note** If `InputCompounding` is not specified, then `InputCompounding` is assigned the value specified for `OutputCompounding`. If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2

---

Data Types: double

**InputBasis — Day-count basis of input forward rates**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of input forward rates, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If `InputBasis` is not specified, then `InputBasis` is assigned the value specified for `OutputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

**OutputCompounding — Compounding frequency of output zero rates**

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of output zero rates, specified with the allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding

- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

---

**Note** If `OutputCompounding` is not specified, then `OutputCompounding` is assigned the value specified for `InputCompounding`. If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2 (semiannual) for both.

---

Data Types: double

### **OutputBasis — Day-count basis of output zero rates**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of output zero rates, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If `OutputBasis` is not specified, then `OutputBasis` is assigned the value specified for `InputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

## **Output Arguments**

### **ZeroRates — Zero curve for investment horizon represented by CurveDates**

numeric

Zero curve for the investment horizon represented by `CurveDates`, returned as a `NUMBONDS`-by-1 vector of decimal fractions. In aggregate, the rates in `ZeroRates` constitute a zero curve for the investment horizon represented by `CurveDates`.

**CurveDates — Maturity dates that correspond to ZeroRates**

serial date number | date character vector | datetime

Maturity dates that correspond to the `ZeroRates`, returned as a `NUMBONDS`-by-1 vector of maturity dates that correspond to the zero rates in `ZeroRates`. This vector is the same as the input vector `CurveDates`, but is sorted by ascending maturity.

If both inputs for `CurveDates` and `Settle` are serial date numbers or date character vectors, `CurveDates` is returned as serial date numbers. However, if either of the inputs for `CurveDates` and `Settle` are a datetime array, `CurveDates` is returned as a datetime array.

# geom2arith

Geometric to arithmetic moments of asset returns

## Syntax

`[ma,Ca] = geom2arith(mg,Cg)`

`[ma,Ca] = geom2arith(mg,Cg,t)`

## Arguments

|    |                                                                                                                                                                                                                                                                           |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mg | Continuously compounded or “geometric” mean of asset returns (positive n-vector).                                                                                                                                                                                         |
| Cg | Continuously compounded or “geometric” covariance of asset returns, a n-by-n symmetric, positive semidefinite matrix. If Cg is not a symmetric positive semidefinite matrix, use <code>nearcorr</code> to create a positive semidefinite matrix for a correlation matrix. |
| t  | (Optional) Target period of arithmetic moments in terms of periodicity of geometric moments with default value 1 (positive scalar).                                                                                                                                       |

## Description

`geom2arith` transforms moments associated with a continuously compounded geometric Brownian motion into equivalent moments associated with a simple Brownian motion with a possible change in periodicity.

`[ma,Ca] = geom2arith(mg,Cg,t)` returns `ma`, arithmetic mean of asset returns over the target period (n-vector), and `Ca`, which is an arithmetic covariance of asset returns over the target period (n-by-n matrix).

Geometric returns over period  $t_G$  are modeled as multivariate lognormal random variables with moments

$$E[Y] = 1 + m_G$$

and

$$\text{cov}(Y) = C_G$$

Arithmetic returns over period  $t_A$  are modeled as multivariate normal random variables with moments

$$E[X] = m_A$$

$$\text{cov}(X) = C_A$$

Given  $t = t_A / t_G$ , the transformation from geometric to arithmetic moments is

$$C_{A_{ij}} = t \log \left( 1 + \frac{C_{G_{ij}}}{(1 + m_{G_i})(1 + m_{G_j})} \right)$$

$$m_{A_i} = t \log(1 + m_{G_i}) - \frac{1}{2} C_{A_{ii}}$$

For  $i, j = 1, \dots, n$ .

---

**Note** If  $t = 1$ , then  $\mathbf{X} = \log(\mathbf{Y})$ .

---

This function requires that the input mean must satisfy  $1 + m_g > 0$  and that the input covariance  $C_g$  must be a symmetric, positive, semidefinite matrix.

The functions `geom2arith` and `arith2geom` are complementary so that, given  $m$ ,  $C$ , and  $t$ , the sequence

```
[ma, Ca] = geom2arith(m, C, t);
[mg, Cg] = arith2geom(ma, Ca, 1/t);
```

yields  $m_g = m$  and  $C_g = C$ .

## Examples

**Example 1.** Given geometric mean  $m$  and covariance  $C$  of monthly total returns, obtain annual arithmetic mean  $ma$  and covariance  $Ca$ . In this case, the output period (1 year) is 12 times the input period (1 month) so that  $t = 12$  with

```
[ma, Ca] = geom2arith(m, C, 12);
```

**Example 2.** Given annual geometric mean  $m$  and covariance  $C$  of asset returns, obtain monthly arithmetic mean  $ma$  and covariance  $Ca$ . In this case, the output period (1 month) is 1/12 times the input period (1 year) so that  $t = 1/12$  with

```
[ma, Ca] = geom2arith(m, C, 1/12);
```

**Example 3.** Given geometric means  $m$  and standard deviations  $s$  of daily total returns (derived from 260 business days per year), obtain annualized arithmetic mean  $ma$  and standard deviations  $sa$  with

```
[ma, Ca] = geom2arith(m, diag(s.^2), 260);
sa = sqrt(diag(Ca));
```

**Example 4.** Given geometric mean  $m$  and covariance  $C$  of monthly total returns, obtain quarterly arithmetic return moments. In this case, the output is 3 of the input periods so that  $t = 3$  with

```
[ma, Ca] = geom2arith(m, C, 3);
```

**Example 5.** Given geometric mean  $m$  and covariance  $C$  of 1254 observations of daily total returns over a 5-year period, obtain annualized arithmetic return moments. Since the periodicity of the geometric data is based on 1254 observations for a 5-year period, a 1-year period for arithmetic returns implies a target period of  $t = 1254/5$  so that

```
[ma, Ca] = geom2arith(m, C, 1254/5);
```

## getAssetMoments

Obtain mean and covariance of asset returns from Portfolio object

### Syntax

```
[AssetMean,AssetCovar] = getAssetMoments(obj)
```

### Description

Use the `getAssetMoments` function with a `Portfolio` object to obtain mean and covariance of asset returns.

For details on the workflow, see “Portfolio Object Workflow” on page 4-16.

`[AssetMean,AssetCovar] = getAssetMoments(obj)` obtains mean and covariance of asset returns for a `Portfolio` object.

### Examples

#### Obtain Asset Moment Properties for a Portfolio Object

Given the mean and covariance of asset returns in the variables `m` and `C`, the asset moment properties can be set and then obtained using the `getAssetMoments` function:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

p = Portfolio;
p = setAssetMoments(p, m, C);
[assetmean, assetcovar] = getAssetMoments(p)
```

```
assetmean = 4×1
```

```
0.0042
0.0083
0.0100
0.0150
```

```
assetcovar = 4×4
```

```
0.0005    0.0003    0.0002         0
0.0003    0.0024    0.0017    0.0010
0.0002    0.0017    0.0048    0.0028
         0    0.0010    0.0028    0.0102
```

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using a `Portfolio` object. For more information on creating a portfolio object, see

- `Portfolio`

Data Types: `object`

## Output Arguments

### **AssetMean — Mean of asset returns**

vector

Mean of asset returns, returned as a vector.

### **AssetCovar — Covariance of asset returns**

matrix

Covariance of asset returns, returned as a matrix.

## Tips

You can also use dot notation to obtain the mean and covariance of asset returns from a `Portfolio` object:

```
[AssetMean, AssetCovar] = obj.getAssetMoments;
```

## See Also

`setAssetMoments`

## getBounds

Obtain bounds for portfolio weights from portfolio object

### Syntax

```
[LowerBound,UpperBound] = getBounds(obj)
```

### Description

Use the `getBounds` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain bounds for portfolio weights from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`[LowerBound,UpperBound] = getBounds(obj)` obtains bounds for portfolio weights from portfolio objects.

### Examples

#### Obtain Values for Lower and Upper Bounds for a Portfolio Object

Given portfolio `p` with the default constraints set, obtain the values for `LowerBound` and `UpperBound`.

```
p = Portfolio;
p = setDefaultConstraints(p, 5);
[LowerBound, UpperBound] = getBounds(p)
```

```
LowerBound = 5×1
```

```
0

```

### Obtain Values for Lower and Upper Bounds for a PortfolioMAD Object

Given a PortfolioMAD object `p` with the default constraints set, obtain the values for `LowerBound` and `UpperBound`.

```
p = PortfolioMAD;
p = setDefaultConstraints(p, 5);
[LowerBound, UpperBound] = getBounds(p)
```

```
LowerBound = 5×1
```

```
0
0
0
0
0
```

```
UpperBound =
```

```
[]
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

### LowerBound — Lower-bound weight for each asset

vector

Lower-bound weight for each asset, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`). For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

### UpperBound — Upper-bound weight for each asset

vector

Upper-bound weight for each asset, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`). For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## Tips

You can also use dot notation to obtain bounds for portfolio weights from portfolio objects.

```
[LowerBound, UpperBound] = obj.getBounds;
```

## See Also

`setBounds`

### Introduced in R2011a

# getBudget

Obtain budget constraint bounds from portfolio object

## Syntax

```
[LowerBudget,UpperBudget] = getBudget(obj)
```

## Description

Use the `getBudget` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain budget constraint bounds from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`[LowerBudget,UpperBudget] = getBudget(obj)` obtains budget constraint bounds from portfolio objects.

## Examples

### Obtain Values for Lower and Upper Budgets for a Portfolio Object

Given portfolio `p` with the default constraints set, obtain the values for `LowerBudget` and `UpperBudget`.

```
p = Portfolio;
p = setDefaultConstraints(p, 5);
[LowerBudget, UpperBudget] = getBudget(p)
```

```
LowerBudget = 1
```

```
UpperBudget = 1
```

### Obtain Values for Lower and Upper Budgets for a PortfolioCVaR Object

Given a `PortfolioCVaR` object `p` with the default constraints set, obtain the values for `LowerBudget` and `UpperBudget`.

```
p = PortfolioCVaR;
p = setDefaultConstraints(p, 5);
[LowerBudget, UpperBudget] = getBudget(p)
```

```
LowerBudget = 1
```

```
UpperBudget = 1
```

### Obtain Values for Lower and Upper Budgets for a PortfolioMAD Object

Given a PortfolioMAD object `p` with the default constraints set, obtain the values for `LowerBudget` and `UpperBudget`.

```
p = PortfolioMAD;  
p = setDefaultConstraints(p, 5);  
[LowerBudget, UpperBudget] = getBudget(p)
```

```
LowerBudget = 1
```

```
UpperBudget = 1
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

### **LowerBudget** — Lower-bound weight for each asset

scalar

Lower bound for budget constraint, returned as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **UpperBudget** — Upper bound for budget constraint

scalar

Upper bound for budget constraint, returned as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

You can also use dot notation to obtain the budget constraint bounds from portfolio objects.

```
[LowerBudget, UpperBudget] = obj.getBudget;
```

## See Also

`setBudget`

## getCosts

Obtain buy and sell transaction costs from portfolio object

### Syntax

```
[BuyCost,SellCost] = getCosts(obj)
```

### Description

Use the `getCosts` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain buy and sell transaction costs from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`[BuyCost,SellCost] = getCosts(obj)` obtains buy and sell transaction costs from portfolio objects.

### Examples

#### Obtain Buy and Sell Costs for a Portfolio Object

Given portfolio `p` with the costs set, obtain the values for `BuyCost` and `SellCost`.

```
p = Portfolio;  
p = setCosts(p, 0.001, 0.001, 5);  
[BuyCost, SellCost] = getCosts(p)
```

```
BuyCost = 1.0000e-03
```

```
SellCost = 1.0000e-03
```

#### Obtain Buy and Sell Costs for a PortfolioCVaR Object

Given a `PortfolioCVaR` object `p` with the costs set, obtain the values for `BuyCost` and `SellCost`.

```
p = PortfolioCVaR;  
p = setCosts(p, 0.001, 0.001, 5);  
[BuyCost, SellCost] = getCosts(p)
```

```
BuyCost = 1.0000e-03
```

```
SellCost = 1.0000e-03
```

## Obtain Buy and Sell Costs for a PortfolioMAD Object

Given a PortfolioMAD object `p` with the costs set, obtain the values for `BuyCost` and `SellCost`.

```
p = PortfolioMAD;
p = setCosts(p, 0.001, 0.001, 5);
[BuyCost, SellCost] = getCosts(p)
```

```
BuyCost = 1.0000e-03
```

```
SellCost = 1.0000e-03
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

### **BuyCost** — Proportional transaction cost to purchase each asset

vector

Proportional transaction cost to purchase each asset, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **SellCost** — Proportional transaction cost to sell each asset

vector

Proportional transaction cost to sell each asset, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

You can also use dot notation to obtain the buy and sell transaction costs from portfolio objects.

```
[BuyCost, SellCost] = obj.getCosts;
```

## See Also

`setCosts`

## getEquality

Obtain equality constraint arrays from portfolio object

### Syntax

```
[AEquality,bEquality] = getEquality(obj)
```

### Description

Use the `getEquality` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain equality constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`[AEquality,bEquality] = getEquality(obj)` obtains equality constraint arrays from portfolio objects.

### Examples

#### Obtain Equality Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are exactly 50% of your portfolio. Given a `Portfolio` object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)
```

```
AEquality = 1×5
```

```
    1    1    1    0    0
```

```
bEquality = 0.5000
```

#### Obtain Equality Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are 50% of your portfolio. Given a `PortfolioCVaR` object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```
A = [ 1 1 1 0 0 ];
b = 0.5;
```

```
p = PortfolioCVaR;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)
```

```
AEquality = 1×5
```

```
    1    1    1    0    0
```

```
bEquality = 0.5000
```

### Obtain Equality Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are 50% of your portfolio. Given a PortfolioMAD object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)
```

```
AEquality = 1×5
```

```
    1    1    1    0    0
```

```
bEquality = 0.5000
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

### **AEquality** — Matrix to form linear equality constraints

matrix

Matrix to form linear equality constraints, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**bEquality – Vector to form linear equality constraints**

vector

Vector to form linear equality constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**Tips**

You can also use dot notation to obtain the equality constraint arrays from portfolio objects.

```
[AEquality, bEquality] = obj.getEquality;
```

## getGroupRatio

Obtain group ratio constraint arrays from portfolio object

### Syntax

```
[GroupA,GroupB,LowerRatio,UpperRatio] = getGroupRatio(obj)
```

### Description

Use the `getGroupRatio` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain group ratio constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`[GroupA,GroupB,LowerRatio,UpperRatio] = getGroupRatio(obj)` obtains equality constraint arrays from portfolio objects.

### Examples

#### Obtain Group Ratio Constraints for a Portfolio Object

Suppose you want to make sure that the ratio of financial to nonfinancial companies in your portfolios never goes above 50%. Assume you have 6 assets with 3 financial companies (assets 1-3) and 3 nonfinancial companies (assets 4-6). After setting group ratio constraints, obtain the values for `GroupA`, `GroupB`, `LowerRatio`, and `UpperRatio`.

```
GA = [ true true true false false false ];    % financial companies
GB = [ false false false true true true ];    % nonfinancial companies
p = Portfolio;
p = setGroupRatio(p, GA, GB, [], 0.5);
[GroupA, GroupB, LowerRatio, UpperRatio] = getGroupRatio(p)
```

```
GroupA = 1×6
```

```
    1    1    1    0    0    0
```

```
GroupB = 1×6
```

```
    0    0    0    1    1    1
```

```
LowerRatio =
```

```
    []
```

```
UpperRatio = 0.5000
```

### Obtain Group Ratio Constraints for a PortfolioCVaR Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolios never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). After setting group ratio constraints, obtain the values for GroupA, GroupB, LowerRatio, and UpperRatio.

```
GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = PortfolioCVaR;
p = setGroupRatio(p, GA, GB, [], 0.5);
[GroupA, GroupB, LowerRatio, UpperRatio] = getGroupRatio(p)
```

```
GroupA = 1×6
```

```
    1    1    1    0    0    0
```

```
GroupB = 1×6
```

```
    0    0    0    1    1    1
```

```
LowerRatio =
```

```
    []
```

```
UpperRatio = 0.5000
```

### Obtain Group Ratio Constraints for a PortfolioMAD Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolios never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). After setting group ratio constraints, obtain the values for GroupA, GroupB, LowerRatio, and UpperRatio.

```
GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = PortfolioMAD;
p = setGroupRatio(p, GA, GB, [], 0.5);
[GroupA, GroupB, LowerRatio, UpperRatio] = getGroupRatio(p)
```

```
GroupA = 1×6
```

```
    1    1    1    0    0    0
```

```
GroupB = 1×6
```

```
    0    0    0    1    1    1
```

```
LowerRatio =
```

```
    []
```

```
UpperRatio = 0.5000
```

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

### **GroupA — Matrix that forms base groups for comparison**

matrix

Matrix that forms base groups for comparison, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (obj).

### **GroupB — Matrix that forms comparison groups**

matrix

Matrix that forms comparison groups, returned as a matrix `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (obj).

### **LowerRatio — Lower bound for ratio of GroupB groups to GroupA groups**

vector

Lower bound for ratio of GroupB groups to GroupA groups, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (obj).

### **UpperRatio — Upper bound for ratio of GroupB groups to GroupA groups**

vector

Upper bound for ratio of GroupB groups to GroupA groups, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (obj).

## Tips

You can also use dot notation to obtain group ratio constraint arrays from portfolio objects.

```
[GroupA, GroupB, LowerRatio, UpperRatio] = obj.getGroupRatio;
```

## See Also

## getGroups

Obtain group constraint arrays from portfolio object

### Syntax

```
[GroupMatrix, LowerGroup, UpperGroup] = getGroups(obj)
```

### Description

Use the `getGroups` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain group constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`[GroupMatrix, LowerGroup, UpperGroup] = getGroups(obj)` obtains group constraint arrays from portfolio objects.

### Examples

#### Obtain Group Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute no more than 30% of your portfolio. Given a `Portfolio` object `p` with the group constraints set, obtain the values for `GroupMatrix`, `LowerGroup`, and `UpperGroup`.

```
G = [ true true true false false ];
p = Portfolio;
p = setGroups(p, G, [], 0.3);
[GroupMatrix, LowerGroup, UpperGroup] = getGroups(p)
```

```
GroupMatrix = 1x5
```

```
    1    1    1    0    0
```

```
LowerGroup =
```

```
    []
```

```
UpperGroup = 0.3000
```

#### Obtain Group Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given a `PortfolioCVaR` object `p` with the group constraints set, obtain the values for `GroupMatrix`, `LowerGroup`, and `UpperGroup`.

```
G = [ true true true false false ];
p = PortfolioCVaR;
p = setGroups(p, G, [], 0.3);
[GroupMatrix, LowerGroup, UpperGroup] = getGroups(p)
```

```
GroupMatrix = 1x5
```

```
    1    1    1    0    0
```

```
LowerGroup =
```

```
    []
```

```
UpperGroup = 0.3000
```

### Obtain Group Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given a PortfolioMAD object `p` with the group constraints set, obtain the values for `GroupMatrix`, `LowerGroup`, and `UpperGroup`.

```
G = [ true true true false false ];
p = PortfolioMAD;
p = setGroups(p, G, [], 0.3);
[GroupMatrix, LowerGroup, UpperGroup] = getGroups(p)
```

```
GroupMatrix = 1x5
```

```
    1    1    1    0    0
```

```
LowerGroup =
```

```
    []
```

```
UpperGroup = 0.3000
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

### **GroupMatrix** — Group constraint matrix

matrix

Group constraint matrix, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **LowerGroup** — Lower bound for group constraints

vector

Lower bound for group constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **UpperGroup** — Upper bound for group constraints

vector

Upper bound for group constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

You can also use dot notation to obtain the group constraint arrays from portfolio objects.

```
[GroupMatrix, LowerGroup, UpperGroup] = obj.getGroups;
```

## See Also

`setGroups`

### Introduced in R2011a

## getScenarios

Obtain scenarios from portfolio object

### Syntax

```
Y = getScenarios(obj)
```

### Description

Use the `getScenarios` function with a `PortfolioCVaR` or `PortfolioMAD` objects to obtain scenarios.

For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`Y = getScenarios(obj)` obtains scenarios for `PortfolioCVaR` or `PortfolioMAD` objects.

### Examples

#### Obtain Scenarios for a CVaR Portfolio Object

For a given `PortfolioCVaR` object `p`, display the defined scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 10);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

Y = getScenarios(p)

Y = 10x4

    -0.0056    0.0440    0.1186    0.0488
    -0.0368   -0.0753    0.0087    0.1124
     0.0025    0.0856    0.0484    0.1404
     0.0318    0.0826    0.0377    0.0404
     0.0013   -0.0561   -0.1466   -0.0621
     0.0035    0.0310   -0.0183    0.1225
```

```

-0.0519   -0.1634   -0.0526    0.1528
 0.0029   -0.1163   -0.0627   -0.0760
 0.0192   -0.0182   -0.1243   -0.1346
 0.0440    0.0189    0.0098    0.0821

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Obtain Scenarios for a MAD Portfolio Object

For a given PortfolioMAD object `p`, display the defined scenarios.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 10);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

Y = getScenarios(p)

Y = 10x4

-0.0056    0.0440    0.1186    0.0488
-0.0368   -0.0753    0.0087    0.1124
 0.0025    0.0856    0.0484    0.1404
 0.0318    0.0826    0.0377    0.0404
 0.0013   -0.0561   -0.1466   -0.0621
 0.0035    0.0310   -0.0183    0.1225
-0.0519   -0.1634   -0.0526    0.1528
 0.0029   -0.1163   -0.0627   -0.0760
 0.0192   -0.0182   -0.1243   -0.1346
 0.0440    0.0189    0.0098    0.0821

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using a PortfolioCVaR or PortfolioMAD object.

For more information on creating a `PortfolioCVaR` or `PortfolioMAD` object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

## Output Arguments

### **Y — Scenarios matrix**

matrix

Scenarios matrix, returned as a `NumScenarios`-by-`NumAssets` matrix for a `PortfolioCVaR` or `PortfolioMAD` object.

## Tips

You can also use dot notation to obtain scenarios from a `PortfolioCVaR` or `PortfolioMAD` object.

```
Y = obj.getScenarios;
```

## See Also

## getfield

Content of specific field

---

**Note** `getfield` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
fieldval = getfield(tsoobj,field)
```

```
fieldval = getfield(tsoobj,field,{dates})
```

### Arguments

|                     |                                                                       |
|---------------------|-----------------------------------------------------------------------|
| <code>tsoobj</code> | Financial time series object.                                         |
| <code>field</code>  | Field name within <code>tsoobj</code> .                               |
| <code>dates</code>  | Date range. Dates can be expanded to include time-of-day information. |

### Description

`getfield` treats the contents of a financial times series object `tsoobj` as fields in a structure.

`fieldval = getfield(tsoobj,field)` returns the contents of the specified field. This is equivalent to the syntax `fieldval = tsoobj.field`.

`fieldval = getfield(tsoobj,field,{dates})` returns the contents of the specified field for the specified dates. `dates` can be individual cells of date character vectors or a cell of a date character vector range using the `::` operator, such as `'03/01/99::03/31/99'`.

### Examples

Create a financial time series object containing both date and time-of-day information:

```
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1),...
times]);
AnFts = fints(dates_times,[1:4]; nan; 6),{'Data1'},1,...
        'Yet Another Financial Time Series')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)

## getInequality

Obtain inequality constraint arrays from portfolio object

### Syntax

```
[AInequality,bInequality] = getInequality(obj)
```

### Description

Use the `getInequality` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain inequality constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`[AInequality,bInequality] = getInequality(obj)` obtains equality constraint arrays from portfolio objects.

### Examples

#### Obtain Inequality Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than 50% of your portfolio. Given a `Portfolio` object `p`, set the linear inequality constraints and then obtain values for `AInequality` and `bInequality`.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setInequality(p, A, b);
[AInequality, bInequality] = getInequality(p)
```

```
AInequality = 1x5
    1    1    1    0    0
```

```
bInequality = 0.5000
```

#### Obtain Inequality Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 50% of your portfolio. Given a `PortfolioCVaR` object `p`, set the linear inequality constraints and then obtain values for `AInequality` and `bInequality`.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
```

```
p = PortfolioCVaR;
p = setInequality(p, A, b);
[AInequality, bInequality] = getInequality(p)
```

```
AInequality = 1x5
```

```
    1    1    1    0    0
```

```
bInequality = 0.5000
```

### Obtain Inequality Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 50% of your portfolio. Given a PortfolioMAD object `p`, set the linear inequality constraints and then obtain values for `AInequality` and `bInequality`.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD;
p = setInequality(p, A, b);
[AInequality, bInequality] = getInequality(p)
```

```
AInequality = 1x5
```

```
    1    1    1    0    0
```

```
bInequality = 0.5000
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

### **AInequality** — Matrix to form linear inequality constraints

matrix

Matrix to form linear inequality constraints, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**bInequality – Vector to form linear inequality constraints**

vector

Vector to form linear inequality constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**Tips**

You can also use dot notation to obtain the inequality constraint arrays from portfolio objects.

```
[AInequality, bInequality] = obj.getInequality;
```

**See Also**`setInequality`**Topics**

# getOneWayTurnover

Obtain one-way turnover constraints from portfolio object

## Syntax

```
[BuyTurnover,SellTurnover] = getOneWayTurnover(obj)
```

## Description

Use the `getOneWayTurnover` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain one-way turnover constraints from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`[BuyTurnover,SellTurnover] = getOneWayTurnover(obj)` obtain one-way turnover constraints from portfolio objects.

## Examples

### Obtain One-Way Turnover Costs for a Portfolio Object

Set one-way turnover costs.

```
p = Portfolio('AssetMean',[0.1, 0.2, 0.15], 'AssetCovar',...
[ 0.005, -0.010, 0.004; -0.010, 0.040, -0.002; 0.004, -0.002, 0.023]);
p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0);    %130-30 portfolio
plotFrontier(p);
```

Obtain one-way turnover costs.

```
[BuyTurnover, SellTurnover] = getOneWayTurnover(p)
```

```
BuyTurnover = 1.3000
```

```
SellTurnover = 0.3000
```

### Obtain One-Way Turnover Costs for a PortfolioCVaR Object

Set one-way turnover costs and obtain the buy and sell turnover values.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
```

```

p = setProbabilityLevel(p, 0.95);

p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0); %130-30 portfolio

[BuyTurnover,SellTurnover] = getOneWayTurnover(p)

BuyTurnover = 1.3000

SellTurnover = 0.3000

```

### Obtain One-Way Turnover Costs for a PortfolioMAD Object

Set one-way turnover costs and obtain the buy and sell turnover values.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0); %130-30 portfolio

[BuyTurnover,SellTurnover] = getOneWayTurnover(p)

BuyTurnover = 1.3000

SellTurnover = 0.3000

```

## Input Arguments

### obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

### BuyTurnover — Turnover constraint on purchases

scalar

Turnover constraint on purchases, returned as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### SellTurnover — Turnover constraint on sales

scalar

Turnover constraint on sales, returned as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## More About

### One-way Turnover Constraint

One-way turnover constraints ensure that estimated optimal portfolios differ from an initial portfolio by no more than specified amounts according to whether the differences are purchases or sales.

The constraints take the form

$$1^T \max\{0, x - x_0\} \leq \tau_B$$

$$1^T \max\{0, x_0 - x\} \leq \tau_S$$

with

- $x$  — The portfolio (*NumAssets* vector)
- $x_0$  — Initial portfolio (*NumAssets* vector)
- $\tau_B$  — Upper-bound for turnover constraint on purchases (scalar)
- $\tau_S$  — Upper-bound for turnover constraint on sales (scalar)

Specify one-way turnover constraints using the following properties in a supported portfolio object: `BuyTurnover` for  $\tau_B$ , `SellTurnover` for  $\tau_S$ , and `InitPort` for  $x_0$ .

---

**Note** The average turnover constraint (which is set using `setTurnover`) is not just the combination of the one-way turnover constraints with the same value for the constraint.

---

## Tips

You can also use dot notation to get the one-way turnover constraint for portfolio objects.

```
[BuyTurnover, SellTurnover] = obj.getOneWayTurnover
```

## getnameidx

Find name in list

---

**Note** `getnameidx` is not recommended. Use `contains` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
nameidx = getnameidx(list,name)
```

### Arguments

|                   |                                                           |
|-------------------|-----------------------------------------------------------|
| <code>list</code> | Cell array of name character vectors.                     |
| <code>name</code> | Character vector or cell array of name character vectors. |

### Description

`nameidx = getnameidx(list,name)` finds the occurrence of a name or set of names in a list. It returns an index (order number) indicating where the specified names are located within the list. If `name` is not found, `nameidx` returns 0.

If `name` is a cell array of names, `getnameidx` returns a vector containing the indices (order number) of the name character vectors within `list`. If none of the names in the `name` cell array is in `list`, it returns zero. If some of the names in `name` are not found, the indices for these names are zeros.

`getnameidx` finds only the first occurrence of the name in the list of names. This function is meant to be used on a list of unique names (character vectors) only. It does not find multiple occurrences of a name or a list of names within `list`.

### Examples

Given

```
poultry = {'duck', 'chicken'}
animals = {'duck', 'cow', 'sheep', 'horse', 'chicken'}
nameidx = getnameidx(animals, poultry)
```

```
ans =
     1     5
```

Given

```
poultry = {'duck', 'goose', 'chicken'}
animals = {'duck', 'cow', 'sheep', 'horse', 'chicken'}
nameidx = getnameidx(animals, poultry)
```

```
ans =
     1     0     5
```

**Introduced before R2006a**

## hhigh

Highest high

---

**Note** `hhigh` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
values = hhigh(Data)
values = hhigh(___,Name,Value)
```

### Description

`values = hhigh(Data)` generates a vector of highest high values from the series of high prices for the past  $n$  periods.

`values = hhigh(___,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Calculate the Highest High for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
values = hhigh(TMW);
plot(values.Time,values.HighestHigh)
title('Highest High for TMW')
```

## Input Arguments

### Data — Data for high prices

matrix | table | timetable

Data for high prices, specified as a matrix, table, or timetable. Timetables and tables with *M* rows must contain a variable named 'High' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside quotes. You can specify several name and value pair arguments in any order as *Name1*, *Value1*, ..., *NameN*, *ValueN*.

Example: `values = hhigh(TMW_HIGH, 'NumPeriods', 10)`

### NumPeriods — Moving window for the highest high calculation

14 (default) | positive integer

Moving window for the highest high calculation, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

## Output Arguments

### values — Highest high series

matrix | table | timetable

Highest high series, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## highlow (fts)

Time series High-Low plot

---

**Note** `highlow (fts)` is not recommended. Use `highlow` instead.

---

### Syntax

```
highlow(tsobj)
```

```
highlow(tsobj,color)
```

```
highlow(tsobj,color,dateform)
```

```
highlow(tsobj,color,dateform,'ParameterName',ParameterValue, ...)
```

```
hll = highlow(tsobj,color,dateform,'ParameterName',ParameterValue, ...)
```

### Arguments

|                             |                                                                                                                                                                                                                                                                                                            |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsobj</code>          | Financial time series object.                                                                                                                                                                                                                                                                              |
| <code>color</code>          | (Optional) A three-element row vector representing RGB or a color identifier. (See <code>plot</code> .)                                                                                                                                                                                                    |
| <code>dateform</code>       | (Optional) Date format used as the x-axis tick labels. (See <code>datetick</code> .) You can specify a <code>dateform</code> only when <code>tsobj</code> does not contain time-of-day data. If <code>tsobj</code> contains time-of-day data, <code>dateform</code> is restricted to 'dd-mmm-yyyy HH:MM'.  |
| 'ParameterName'             | 'ParameterName' can be: <ul style="list-style-type: none"> <li>• <code>HighName</code>: high prices series name</li> <li>• <code>LowName</code>: low prices series name</li> <li>• <code>OpenName</code>: open prices series name</li> <li>• <code>CloseName</code>: closing prices series name</li> </ul> |
| <code>ParameterValue</code> | The parameter value is a character vector that represents the valid parameter name.                                                                                                                                                                                                                        |

### Description

`highlow(tsobj)` generates a High-Low plot of the data in the financial time series object `tsobj`. `tsobj` must contain at least four data series representing the high, low, open, and closing prices. These series must have the names `High`, `Low`, `Open`, and `Close` (case-insensitive).

`highlow(tsobj,color)` additionally specifies the color of the plot.

`highlow(tsobj,color,dateform)` additionally specifies the date format used as the x-axis tick labels. See `datestr` for a list of date formats.

`highlow(tsoobj,color,dateform,'ParameterName',ParameterValue, ...)` indicates the actual names of the required data series if the data series do not have the default names.

You can specify open prices as optional by providing the parameter name `'OpenName'` and the parameter value `''`.

```
highlow(tsoobj, color, dateform, 'OpenName', '')
```

`hhll = highlow(tsoobj,color,dateform,'ParameterName',ParameterValue, ...)` returns the handle to the line object that makes up the High-Low plot.

## Examples

### Generate a High-Low Plot

This example shows how to generate a High-Low plot for Disney stock for the dates May 28 to June 18, 1998.

```
load disney.mat
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
highlow(dis('28-May-1998::18-Jun-1998'))
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
title('High-Low Plot for Disney')
```

**See Also**

candle

**Introduced before R2006a**

## highlow

High, low, open, close chart

---

**Note** highlow is updated to accept data input as a matrix, timetable, or table.

---

### Syntax

```
highlow(Data)
highlow(Data,Color)
h = highlow(ax, ___)
```

### Description

highlow(Data) displays a highlow chart from a series of opening, high, low, and closing prices of a security. The plots are vertical lines whose top is the high, bottom is the low, open is a left tick, and close is a right tick.

highlow(Data,Color) adds an optional argument for Color.

h = highlow(ax, \_\_\_) adds an optional argument for ax.

### Examples

#### Generate a Highlow Chart for a Data Series for a Stock

Load the file SimulatedStock.mat, which provides a timetable (TMW) for financial data for TMW stock. The highlow chart plots the price data using blue lines.

```
load SimulatedStock.mat
range = 1:25;
highlow(TMW(range,:), 'b');
title('High, Low, Open, Close Chart for TMW')
```

## Input Arguments

### Data — Data for opening, high, low, and closing prices

matrix | table | timetable

Data for opening, high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-4 matrix of opening, high, low, and closing prices stored in the corresponding columns. Timetables and tables with M rows must contain variables named 'Open', 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

### Color — Three element color vector

background color of figure window (default) | color vector [R G B] | string

(Optional) Three element color vector, specified as a [R G B] color vector or a string specifying the color name. The default color differs depending on the background color of the figure window. For more information, see `colspec`.

Data Types: double | string

### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The highlow plot is created in the axes specified by `ax` instead of in the current axes (`ax = gca`). The option `ax` can precede any of the input argument combinations.

Data Types: `object`

## Output Arguments

### **h** — Graphic handle of the figure

`handle object`

Graphic handle of the figure, returned as a handle object.

# hist

Histogram for financial times series object

---

**Note** `hist` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
hist(tsobj, numbins)
```

```
ftshist = hist(tsobj,numbins)
```

```
[ftshist,binpos] = hist(tsobj,numbins)
```

## Arguments

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>tsobj</code>   | Financial time series object.                      |
| <code>numbins</code> | (Optional) Number of histogram bins. Default = 10. |

## Description

`hist(tsobj,numbins)` calculates and displays the histogram of the data series contained in the financial time series object `tsobj`.

`ftshist = hist(tsobj,numbins)` calculates, but does not display, the histogram of the data series contained in the financial time series object `tsobj`. The output `ftshist` is a structure with field names similar to the data series names of `tsobj`.

`[ftshist,binpos] = hist(tsobj,numbins)` additionally returns the bin positions `binpos`. The positions are the centers of each bin. `binpos` is a column vector.

## Examples

### Create a Histogram

This example shows how to generate a histogram of Disney open, high, low, and close prices.

```
load disney.mat
dis = rmfield(dis, 'VOLUME'); % Remove VOLUME field
hist(dis)
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see [Convert Financial Time Series Objects `fints` to Timetables](#).

```
title('Disney Histogram')
```

# holdings2weights

Portfolio holdings into weights

## Syntax

`Weights = holdings2weights(Holdings,Prices,Budget)`

## Arguments

|          |                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------|
| Holdings | Number of portfolios (NPORTS) by number of assets (NASSETS) matrix with the holdings of NPORTS portfolios containing NASSETS assets. |
| Prices   | NASSETS vector of asset prices.                                                                                                      |
| Budget   | (Optional) Scalar or NPORTS vector of nonzero budget constraints. Default = 1.                                                       |

## Description

`Weights = holdings2weights(Holdings,Prices,Budget)` converts portfolio holdings into portfolio weights. The weights must satisfy a budget constraint such that the weights sum to `Budget` for each portfolio.

`Weights` is a NPORTS by NASSETS matrix containing the normalized weights of NPORTS portfolios containing NASSETS assets.

---

## Notes

- `Holdings` may be negative to indicate a short position, but the overall portfolio weights must satisfy a nonzero budget constraint.
  - The weights in each portfolio sum to the `Budget` value (which is 1 if `Budget` is unspecified.)
-

## holidays

Holidays and nontrading days

### Syntax

```
H = holidays
H = holidays(StartDate,EndDate)
H = holidays(___,AltHolidays)
```

### Description

H = holidays returns a vector of serial date numbers corresponding to all holidays and nontrading days.

H = holidays(StartDate,EndDate) returns a vector of serial date numbers corresponding to the holidays and nontrading days between StartDate and EndDate, inclusive.

H = holidays(\_\_\_,AltHolidays) returns a vector of serial date numbers corresponding to the alternate list of holidays and nontrading days.

### Examples

#### Determine Holidays for a Given StartDate and EndDate

Create a vector of serial date numbers corresponding to all holidays and nontrading dates between a specified StartDate and EndDate:

```
H = holidays('jan 1 2001', 'jun 23 2001')
```

```
H = 5×1
```

```
730852
730866
730901
730954
730999
```

```
datestr(H)
```

```
ans = 5×11 char array
'01-Jan-2001'
'15-Jan-2001'
'19-Feb-2001'
'13-Apr-2001'
'28-May-2001'
```

Alternatively, using a datetime array for StartDate and EndDate returns a datetime array for H.

```
H = holidays(datetime('1-Jan-2001', 'Locale', 'en_US'), ...
datetime('23-Jun-2001', 'Locale', 'en_US'))
```

```
H = 5x1 datetime
    01-Jan-2001
    15-Jan-2001
    19-Feb-2001
    13-Apr-2001
    28-May-2001
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified using a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### EndDate — End date

serial date number | date character vector | datetime object

End date, specified using a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### AltHolidays — Alternate list of holidays and nontrading days

serial date number | date character vector | datetime object

Alternate list of holidays and nontrading days, specified using a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

## Output Arguments

### H — Dates corresponding to all holidays and nontrading days

vector | datetime

Dates corresponding to all holidays and nontrading days, returned as a vector or a datetime array of dates.

If `StartDate`, `EndDate`, and `AltHolidays` are all either serial date numbers or date character vectors, `H` is returned as serial date numbers. If either `StartDate`, `EndDate`, or `AltHolidays` are datetime arrays, `H` is returned as a datetime array.

## More About

### holidays

The `holidays` function is based on a modern five-day workweek.

This function contains all holidays and special nontrading days for the New York Stock Exchange from January 1, 1885 to December 31, 2070.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 2070 include Saturday trading days. To capture these dates, use the function `nyseclosures`. The results from `holidays` and `nyseclosures` are identical if the `WorkWeekFormat` in `nyseclosures` is 'Modern'.

# horzcat

Concatenate financial time series objects horizontally

---

**Note** horzcat is not recommended. Use timetable instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
horzcat
```

## Description

horzcat implements horizontal concatenation of financial time series objects. horzcat essentially merges the data columns of the financial time series objects. The time series objects must contain the exact same dates and times.

When multiple instances of a data series name occur, concatenation adds a suffix to the current names of the data series. The suffix has the format `_objectname<n>`, where `n` is a number indicating the position of the time series, from left to right, in the concatenation command. The `n` part of the suffix appears only when there is more than one instance of a particular data series name.

The description fields are concatenated as well. They are separated by two forward slashes (`//`).

## Examples

Construct three financial time series, each containing a data series named `DataSeries`:

```
firstfts = fints((today:today+4)', (1:5)', 'DataSeries', 'd')
secondfts = fints((today:today+4)', (11:15)', 'DataSeries', 'd')
thirdfts = fints((today:today+4)', (21:25)', 'DataSeries', 'd')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints (line 165)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/display (line 66)
```

```
firstfts =
```

```
  desc: (none)
  freq: Daily (1)

  'dates: (5)'      'DataSeries: (5)'
  '02-Oct-2017'    [          1]
  '03-Oct-2017'    [          2]
  '04-Oct-2017'    [          3]
  '05-Oct-2017'    [          4]
  '06-Oct-2017'    [          5]
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints (line 165)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/display (line 66)
```

```
secondfts =
```

```
desc: (none)
freq: Daily (1)

'dates: (5)'   'DataSeries: (5)'
'02-Oct-2017' [          11]
'03-Oct-2017' [          12]
'04-Oct-2017' [          13]
'05-Oct-2017' [          14]
'06-Oct-2017' [          15]
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints (line 165)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/display (line 66)
```

```
thirdfts =
```

```
desc: (none)
freq: Daily (1)

'dates: (5)'   'DataSeries: (5)'
'02-Oct-2017' [          21]
'03-Oct-2017' [          22]
'04-Oct-2017' [          23]
'05-Oct-2017' [          24]
'06-Oct-2017' [          25]
```

Concatenate the time series horizontally into a new financial time series `newfts`:

```
newfts = [firstfts secondfts thirdfts secondfts]
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/horzcat (line 56)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/display (line 66)
```

```
newfts =
```

```
desc: // // //
freq: Daily (1)

'dates: (5)'   'DataSeries_firstfts'   'DataSeries_secondft'   'DataSeries_third
'           ': (5)'           's2: (5)'           ': (5)'
'02-Oct-2017' [          1] [          11] [
'03-Oct-2017' [          2] [          12] [
'04-Oct-2017' [          3] [          13] [
'05-Oct-2017' [          4] [          14] [
'06-Oct-2017' [          5] [          15] [
```

The resulting object `newfts` has data series names `DataSeries_firstfts`, `DataSeries_secondfts2`, `DataSeries_thirdfts`, and `DataSeries_secondfts4`.

Verify this with the command

```
fieldnames(newfts)
```

---

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/fieldnames (line 21)

ans =

```
'desc'  
'freq'  
'dates'  
'DataSeries_firstfts'  
'DataSeries_secondfts2'  
'DataSeries_thirdfts'  
'DataSeries_secondfts4'  
'times'
```

Use `chfield` to change the data series names.

---

**Note** If all input objects have the same frequency, the new object has that frequency as well. However, if one of the objects concatenated has a different frequency from the others, the frequency indicator of the resulting object is set to `Unknown (0)`.

---

## hour

Hour of date or time

### Syntax

```
Hour = hour(Date)
Hour = hour( ___, F)
```

### Description

`Hour = hour(Date)` returns the hour of the day given a serial date number or a character vector representing a date and time.

`Hour = hour( ___, F)` returns the hour of one or more character vectors representing a date and time using a format defined by the optional input `F`. `Date` can be an array of character vectors, where each row corresponds to one character vector, or a one-dimensional cell array of character vectors. All the character vectors in `Date` must have the same format `F`. `F` must designate a supported date format symbol. For more information on supported date formats, see `datestr`.

### Examples

#### Determine the Hour of the Day for Various Dates

Find the hour of the day for `Date` using a serial date number.

```
Hour = hour(730473.5584278936)
```

```
Hour = 13
```

Find the hour of the day for `Date` using a character vector representing a date and time.

```
Hour = hour('19-dec-1999, 13:24:08.17')
```

```
Hour = 13
```

### Input Arguments

#### Date — Date to determine hour

serial date number | character vector | cell array of character vectors

Date to determine hour, specified as a serial date number or a character vector representing a date and time.

`Date` can be an array of character vectors representing a date and time, where each row corresponds to one character vector, or a one-dimensional cell array of character vectors. All of the character vectors in `Date` must have the same format `F`. `F` must designate a supported date format symbol. For more information on supported date formats, see `datestr`.

Data Types: `single` | `double` | `char` | `cell`

**F — Date format symbol**

character vector designating date format

Date format symbol, specified as a character vector to designate the date format symbol for input argument `Date`. For more information on supported character vector formats, see `datestr`. Note, formats with 'Q' are not accepted.

Data Types: char

**Output Arguments****Hour — Hour of day**

nonnegative number

Hour of the day, returned as a nonnegative number.

**See Also**

`datevec` | `minute` | `second`

## inforatio

Calculate information ratio for one or more assets

### Syntax

```
inforatio(Asset,Benchmark)
```

```
Ratio = inforatio(Asset,Benchmark)
```

```
[Ratio,TE] = inforatio(Asset,Benchmark)
```

### Arguments

|           |                                                                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Asset     | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES observations of asset returns for NUMSERIES asset return series.                                                                                  |
| Benchmark | NUMSAMPLES vector of returns for a benchmark asset. The periodicity must be the same as the periodicity of Asset. For example, if Asset is monthly data, then Benchmark must be monthly returns. |

### Description

Given NUMSERIES assets with NUMSAMPLES returns for each asset in a NUMSAMPLES  $\times$  NUMSERIES matrix Asset and given a NUMSAMPLES vector of benchmark returns in Benchmark, inforatio computes the information ratio and tracking error for each asset relative to the Benchmark.

To summarize the outputs of inforatio:

- Ratio is a 1  $\times$  NUMSERIES row vector of information ratios for each series in Asset. Any series in Asset with a tracking error of 0 has a NaN value for its information ratio.
- TE is a 1  $\times$  NUMSERIES row vector of tracking errors, that is, the standard deviation of Asset relative to Benchmark returns, for each series.

---

**Note** NaN values in the data are ignored. If the Asset and Benchmark series are identical, the information ratio is NaN since the tracking error is 0. The information ratio and the Sharpe ratio of an Asset versus a riskless Benchmark (a Benchmark with standard deviation of returns equal to 0) are equivalent. This equivalence is not necessarily true if the Benchmark is risky.

---

### Examples

See “Information Ratio” on page 7-7.

## irr

Internal rate of return

### Syntax

```
Return = irr(CashFlow)
[Return,AllRates] = irr( ___ )
```

### Description

`Return = irr(CashFlow)` calculates the internal rate of return for a series of periodic cash flows.

`irr` uses the following conventions:

- If one or more internal rates of returns (warning if multiple) are strictly positive rates, `Return` sets to the minimum.
- If there is no strictly positive rate of returns, but one or multiple (warning if multiple) returns are nonpositive rates, `Return` sets to the maximum.
- If no real-valued rates exist, `Return` sets to NaN (no warnings).

`[Return,AllRates] = irr( ___ )` calculates the internal rate of return and a vector of all internal rates for a series of periodic cash flows.

### Examples

#### Find a Single Internal Rate of Return

Find the internal rate of return for a simple investment with a unique positive rate of return. The initial investment is \$100,000 and the following cash flows represent the yearly income from the investment.

- Year 1 — \$10,000
- Year 2 — \$20,000
- Year 3 — \$30,000
- Year 4 — \$40,000
- Year 5 — \$50,000

Calculate the internal rate of return on the investment:

```
Return = irr([-100000 10000 20000 30000 40000 50000])
```

This returns:

```
Return =  
    0.1201
```

If the cash flow payments were monthly, then the resulting rate of return is multiplied by 12 for the annual rate of return.

## Find Multiple Internal Rates of Return

Find the internal rate of return for multiple rates of return. The project has the following cash flows and a market rate of 10%.

```
CashFlow = [-1000 6000 -10900 5800]
```

Use `irr` with a single output argument:

```
Return = irr(CashFlow)
```

A warning appears and `irr` returns a 100% rate of return. The 100% rate on the project looks attractive:

```
Warning: Multiple rates of return
```

```
> In irr at 166
```

```
Return =
```

```
1.0000
```

Use `irr` with two output arguments:

```
[Return, AllRates] = irr(CashFlow)
```

This returns:

```
>> [Return, AllRates] = irr(CashFlow)
```

```
Return =
```

```
1.0000
```

```
AllRates =
```

```
-0.0488
```

```
1.0000
```

```
2.0488
```

The rates of return in `AllRates` are -4.88%, 100%, and 204.88%. Though some rates are lower and some higher than the market rate, based on the work of Hazen, any rate gives a consistent recommendation on the project. However, you can use a present value analysis in these kinds of situations. To check the present value of the project, use `pvvar`:

```
PV = pvvar(CashFlow,0.10)
```

This returns:

```
PV =
```

```
-196.0932
```

The second argument is the 10% market rate. The present value is -196.0932, negative, so the project is undesirable.

## Input Arguments

### CashFlow — Stream of periodic cash flows

vector | matrix

Stream of periodic cash flows, specified as a vector or matrix. The first entry in CashFlow is the initial investment. If CashFlow is a matrix, `irr` handles each column of CashFlow as a separate cash-flow stream.

Data Types: `double`

## Output Arguments

### Return — Internal rate of return

vector

Internal rate of return associated to CashFlow, returned as a vector whose entry `j` is an internal rate of return for column `j` in CashFlow

### AllRates — All the internal rates of return

serial date number | matrix

All the internal rates of return associated with CashFlow, returned as a matrix with the same number of columns as CashFlow and one less row. Also, column `j` in AllRates contains all the rates of return associated to column `j` in CashFlow (including complex-valued rates).

# isbusday

True for dates that are business days

## Syntax

```
Busday = isbusday(Date)
Busday = isbusday( ___,Holiday,Weekend)
```

## Description

`Busday = isbusday(Date)` returns logical true (1) if `Date` is a business day and logical false (0) otherwise.

`Busday = isbusday( ___,Holiday,Weekend)`, using optional input arguments, returns logical true (1) if `Date` is a business day, and logical false (0) otherwise.

## Examples

### Determine If a Given Date Is a Business Day

Determine if `Date` is a business day.

```
Busday = isbusday('16 jun 2001')
```

```
Busday = logical
    0
```

Determine if a `Date` vector are business days.

```
Date = ['15 feb 2001'; '16 feb 2001'; '17 feb 2001'];
Busday = isbusday(Date)
```

```
Busday = 3x1 logical array
```

```
    1
    1
    0
```

Determine if a `Date` vector are business days using a datetime array.

```
Date = ['15-feb-2001'; '16-feb-2001'; '17-feb-2001'];
Busday = isbusday(datetime(Date,'Locale','en_US'))
```

```
Busday = 3x1 logical array
```

```
    1
    1
    0
```

Set June 21, 2003 (a Saturday) as a business day.

```
Weekend = [1 0 0 0 0 0 0];
isbusday('June 21, 2003', [], Weekend)
```

```
ans = logical
      1
```

If the second argument, `Holiday`, is empty (`[]`), the default `Holidays` vector (generated with `holidays` and then associated to the NYSE calendar) is used.

## Input Arguments

### Date — Date being checked

serial date number | date character vector | datetime array

Date being checked, specified as a serial date number, date character vector, or datetime array. `Date` can contain multiple dates, but they must all be in the same format. Dates are assumed to be whole date numbers or date stamps with no fractional or time values.

Data Types: double | char | datetime

### Holiday — Holidays and nontrading-day dates

non-trading day vector is determined by the routine `holidays` (default) | serial date number | date character vector | datetime array

Holidays and nontrading-day dates, specified as vector.

All dates in `Holiday` must be the same format: either serial date numbers, or date character vectors, or datetime arrays. (Using serial date numbers improves performance.) The `holidays` function supplies the default vector.

Data Types: double | char | datetime

### Weekend — Weekend days

[1 0 0 0 0 0 1] (Saturday and Sunday form the weekend) (default) | vector of length 7, containing 0 and 1, where 1 indicates weekend days

Weekend days, specified as a vector of length 7, containing 0 and 1, where 1 indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: double

## Output Arguments

### Busday — Logical true if a business day

logical 0 or 1

Logical true if a business day, returned as a logical true (1) if `Date` is a business day and logical false (0) otherwise.

## See Also

## iscompatible

Structural equality

---

**Note** `iscompatible` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
iscomp = iscompatible(tsojb_1,tsojb_2)
```

### Arguments

|                               |                                          |
|-------------------------------|------------------------------------------|
| <code>tsojb_1, tsojb_2</code> | A pair of financial time series objects. |
|-------------------------------|------------------------------------------|

### Description

`iscomp = iscompatible(tsojb_1,tsojb_2)` returns 1 if both financial time series objects `tsojb_1` and `tsojb_2` have the same dates and data series names. It returns 0 if any component is different.

`iscomp = 1` indicates that the two objects contain the same number of data points and equal number of data series. However, the values contained in the data series can be different.

---

**Note** Data series names are case-sensitive.

---

Multiple object equality

---

**Note** `isequal` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
iseq = isequal(tsoobj_1,tsoobj_2, ...)
```

## Arguments

|                           |                                          |
|---------------------------|------------------------------------------|
| <code>tsoobj_1 ...</code> | A list of financial time series objects. |
|---------------------------|------------------------------------------|

## Description

`iseq = isequal(tsoobj_1,tsoobj_2, ...)` returns 1 if all listed financial time series objects have the same dates, data series names, and values contained in the data series. It returns 0 if any of those components is different.

---

**Note** Data series names are case-sensitive.

---

`iseq = 1` implies that each object contains the same number of dates and the same data. Only the descriptions can differ.

## See Also

`eq` | `iscompatible`

## Topics

**Introduced before R2006a**

## isempty

True for empty financial time series objects

---

**Note** `isempty` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
tf = isempty(fts)
```

### Arguments

|                  |                               |
|------------------|-------------------------------|
| <code>fts</code> | Financial time series object. |
|------------------|-------------------------------|

### Description

`isempty` for financial times series objects is based on the MATLAB `isempty` function. See `isempty`.

`tf = isempty(fts)` returns true (1) if `fts` is an empty financial time series object and false (0) otherwise. An empty financial times series object has no elements, that is, `length(fts) = 0`.

### See Also

# isfield

Check whether character vector is field name

---

**Note** `isfield` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
F = isfield(tsoobj,name)
```

## Description

`F = isfield(tsoobj,name)` returns true (1) if `name` is the name of a data series in `tsoobj`. Otherwise, `isfield` returns false (0).

## See Also

`fieldnames` | `getfield` | `setfield`

## Topics

“What Is the Financial Time Series App?” on page 14-2

## issorted

Check whether dates and times are monotonically increasing

---

**Note** `issorted` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
monod = issorted(tsoobj)
```

### Arguments

|                     |                              |
|---------------------|------------------------------|
| <code>tsoobj</code> | Financial time series object |
|---------------------|------------------------------|

### Description

`monod = issorted(tsoobj)` returns 1 if the dates and times in `tsoobj` are monotonically increasing or 0 if they are not.

### See Also

`sortfts`

# kagi

Kagi chart

---

**Note** `kagi` is updated to accept data input as a matrix, `timetable`, or `table`.

The syntax for `kagi` has changed. Previously, when using table input, the first column of dates could be serial date numbers, date character vectors, or datetime arrays, and you were required to have specific number of columns.

When using table input, the new syntax for `kagi` supports:

- No need for time information. If you want to pass in date information, use `timetable` input.
  - No requirement of specific number of columns. However, you must provide valid column names. `kagi` must contain a column named `'price'` (case insensitive).
- 

## Syntax

```
kagi(Data)
h = kagi(ax,Data)
```

## Description

`kagi(Data)` plots a Kagi chart from a series of prices.

`h = kagi(ax,Data)` adds an optional argument for `ax`.

## Examples

### Generate a Kagi Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock. This Kagi chart is for closing prices of the stock TMW for the most recent 21 days. Note that the variable name of asset price is be renamed to `'Price'` (case insensitive).

```
load SimulatedStock.mat
TMW.Properties.VariableNames{'Close'} = 'Price';
kagi(TMW(end-20:end,:))
title('Kagi Chart for TMW')
```

## Input Arguments

### Data — Data for a series of prices

matrix | table | timetable

Data for a series of prices, specified as a matrix, table, or timetable. Timetables and tables with M rows must contain a variable named 'Price' (case insensitive).

Data Types: double | table | timetable

### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The kagi plot is created in the axes specified by ax instead of in the current axes (ax = gca). The option ax can precede any of the input argument combinations.

Data Types: object

## Output Arguments

### h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

**See Also**

candle | highlow | linebreak | movavg | pointfig | priceandvol | renko | table | timetable

## lagts

Lag time series object

---

**Note** `lagts` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = lagts(oldfts)
```

```
newfts = lagts(oldfts, lagperiod)
```

```
newfts = lagts(oldfts, lagperiod, padmode)
```

### Arguments

|                        |                                                                            |
|------------------------|----------------------------------------------------------------------------|
| <code>oldfts</code>    | Financial time series object                                               |
| <code>lagperiod</code> | Number of lag periods expressed in the frequency of the time series object |
| <code>padmode</code>   | Data padding value                                                         |

### Description

`lagts` delays a financial time series object by a specified time step.

`newfts = lagts(oldfts)` delays the data series in `oldfts` by one time series date entry and returns the result in the object `newfts`. The end is padded with zeros, by default.

`newfts = lagts(oldfts, lagperiod)` shifts time series values to the right on an increasing time scale. `lagts` delays the data series to happen later. `lagperiod` is the number of lag periods expressed in the frequency of the time series object `oldfts`. For example, if `oldfts` is a daily time series, `lagperiod` is specified in days. `lagts` pads the data with zeros (default).

`newfts = lagts(oldfts, lagperiod, padmode)` lets you pad the data with an arbitrary value, NaN, or Inf rather than zeros by setting `padmode` to the desired value.

# lbusdate

Last business date of month

## Syntax

```
Date = lbusdate(Year,Month)
Date = lbusdate( ____,Holiday,Weekend,outputType)
```

## Description

`Date = lbusdate(Year,Month)` returns the serial date number for the last business date of the given year and month.

`Year` and `Month` can contain multiple values. If one contains multiple values, the other must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by-N vector of integers, then `Month` must be a 1-by-N vector of integers or a single integer. `Date` is then a 1-by-N vector of date numbers.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

`Date = lbusdate( ____,Holiday,Weekend,outputType)` returns the serial date number for the last business date of the given year and month using optional input arguments. The optional argument `Holiday` specifies nontrading days.

If neither `Holiday` nor `outputType` are specified, `Date` is returned as a serial date number. If `Holiday` is specified, but not `outputType`, then the type of the holiday variable controls the type of date. If `Holiday` is a serial date number or date character vector, then `Date` is returned as a serial date number.

## Examples

### Determine the Last Business Date of a Given Year and Month

Determine the `Date` using an input argument for `Year` and `Month`.

```
Date = lbusdate(2001, 5)
```

```
Date = 731002
```

```
datestr(Date)
```

```
ans =
'31-May-2001'
```

Determine the `Date` using the optional input argument for `outputType`.

```
Date = lbusdate(2001, 11,[],[],'datetime')
```

```
Date = datetime
      30-Nov-2001
```

Indicate that Saturday is a business day by appropriately setting the `Weekend` argument. May 31, 2003, is a Saturday. Use `lbusdate` to check that this Saturday is actually the last business day of the month.

```
Weekend = [1 0 0 0 0 0 0];
Date = datestr(lbusdate(2003, 5, [], Weekend))

Date =
'31-May-2003'
```

## Input Arguments

### **Year — Year to determine occurrence of weekday**

4-digit integer | vector of 4-digit integers

Year to determine occurrence of weekday, specified as a 4-digit integer or vector of 4-digit integers.

Data Types: `single` | `double`

### **Month — Month to determine occurrence of weekday**

integer with value 1 through 12 | vector of integers with values 1 through 12

Month to determine occurrence of weekday, specified as an integer or vector of integers with values 1 through 12.

Data Types: `single` | `double`

### **Holiday — Holidays and nontrading-day dates**

non-trading day vector is determined by the routine `holidays` (default) | serial date number | date character vector | datetime array

Holidays and nontrading-day dates, specified as vector.

All dates in `Holiday` must be the same format: either serial date numbers, or date character vectors, or datetime arrays. (Using serial date numbers improves performance.) The `holidays` function supplies the default vector.

If `Holiday` is a datetime array, then `Date` is returned as a datetime array. If `outputType` is specified, then its value determines the output type of `Date`. This overrides any influence of `Holiday`.

Data Types: `double` | `char` | `datetime`

### **Weekend — Weekend days**

[1 0 0 0 0 0 1] (Saturday and Sunday form the weekend) (default) | vector of length 7, containing 0 and 1, where 1 indicates weekend days

Weekend days, specified as a vector of length 7, containing 0 and 1, where 1 indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: `double`

### **outputType — Year to determine days**

'datenum' (default) | character vector with values 'datenum' or 'datetime'

A character vector specified as either 'datenum' or 'datetime'. The output `Date` is in serial date format if 'datenum' is specified, or datetime format if 'datetime' is specified. By default the output `Date` is in serial date format, or match the format of `Holiday`, if specified.

Data Types: char

## Output Arguments

### **Date — Date for the last business date of given year and month**

serial date number | date character vector | datetime array

Date for the last business date of a given year and month, returned as a serial date number, date character vector, or datetime array.

If neither `Holiday` nor `outputType` are specified, `Date` is returned as a serial date number. If `Holiday` is specified, but not `outputType`, then the type of the holiday variable controls the type of date:

- If `Holiday` is a serial date number or date character vector, then `Date` is returned as a serial date number
- If `Holiday` is a datetime array, then `Date` is returned as a datetime array.

.

## leadts

Lead time series object

---

**Note** `leadts` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = leadts(oldfts)
```

```
newfts = leadts(oldfts, leadperiod)
```

```
newfts = leadts(oldfts, leadperiod, padmode)
```

### Arguments

|                         |                                                                              |
|-------------------------|------------------------------------------------------------------------------|
| <code>oldfts</code>     | Financial time series object.                                                |
| <code>leadperiod</code> | Number of lead periods expressed in the frequency of the time series object. |
| <code>padmode</code>    | Data padding value.                                                          |

### Description

`leadts` advances a financial time series object by a specified time step.

`newfts = leadts(oldfts)` advances the data series in `oldfts` by one time series date entry and returns the result in the object `newfts`. The end will be padded with zeros, by default.

`newfts = leadts(oldfts, leadperiod)` shifts time series values to the left on an increasing time scale. `leadts` advances the data series to happen at an earlier time. `leadperiod` is the number of lead periods expressed in the frequency of the time series object `oldfts`. For example, if `oldfts` is a daily time series, `leadperiod` is specified in days. `leadts` pads the data with zeros (default).

`newfts = leadts(oldfts, leadperiod, padmode)` lets you pad the data with an arbitrary value, NaN, or Inf rather than zeros by setting `padmode` to the desired value.

# length

Get number of dates (rows)

---

**Note** `length` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
lenfts = length(tsobj)
```

## Description

`lenfts = length(tsobj)` returns the number of dates (rows) in the financial time series object `tsobj`. This is the same as issuing `lenfts = size(tsobj, 1)`.

## See Also

`length` | `size`

## lifetableconv

Convert life table series into life tables with forced termination

### Syntax

```
[qx, lx, dx] = lifetableconv(x0, lx0)
```

```
[qx, lx, dx] = lifetableconv(x0, y0, y0type)
```

### Description

`[qx, lx, dx] = lifetableconv(x0, lx0)` converts life table with ages `x0` and survival counts `lx0` into life tables with termination.

`[qx, lx, dx] = lifetableconv(x0, y0, y0type)` converts life table with ages `x0` and series `y0`, specified by the optional argument `y0type`, into life tables with termination.

### Examples

#### Convert Life Table Series into Life Tables with Forced Termination

Load the life table data file.

```
load us_lifetable_2009
```

Convert life table series into life tables with forced termination.

```
[qx, lx, dx] = lifetableconv(x, lx);
display(qx(1:20, :))
```

```

Plot the dx series and display the legend. The series dx is the number of people who die out of 100,000 alive at birth between age x and the next age in the series.

```

plot((0:119),dx(1:end-1,:));
legend(series, 'location', 'northwest');
title('\bfLife Table Yearly Decrements');
xlabel('Age');
ylabel('Number Dying within a Given Year');

```

## Input Arguments

### **x0** — Increasing ages for raw data

vector of nonnegative integer values

Increasing ages for raw data, specified as nonnegative integer values in an  $N0$  vector.

The vector of ages  $x$  must contain nonnegative integer values. If the input series is the discrete survival function  $l_x$ , then the starting age need only be nonnegative. Otherwise, the starting age must be 0.

Data Types: double

### **lx0** — Collection of num standardized survivor series

matrix

Collection of num standardized survivor series, specified as an  $N0$ -by-num matrix. The input  $lx0$  series is the number of people alive at age  $x$ , given 100,000 alive at birth. Values of 0 or NaN in the input table  $lx0$  are ignored.

Data Types: double

### **y0** — Collection of num life table series to be converted

matrix

Collection of num life table series to be converted, specified as an N0-by-num matrix. The default  $y_0$  series is  $lx_0$ .

Data Types: double

### **$y_0$ type — Type of mortality series for input $y_0$ with default 'lx'**

'lx' (default) | character vector with values 'qx', 'lx', 'dx'

(Optional) Type of mortality series for input  $y_0$ , specified as a character vector with one of the following values:

- 'qx' — Input is a table of discrete hazards ( $qx$ ).
- 'lx' — Input is a table of discrete survival counts ( $lx$ ).
- 'dx' — Input is a table of discrete decrements ( $dx$ ).

Whereas the output series have forced termination, the input series ( $y_0$ ) can have one of several types of termination:

- Natural termination runs out to the last person so that  $lx$  goes to 0,  $qx$  goes to 1, and  $dx$  goes to 0. For more information, see “Natural Termination” on page 19-920.
- Truncated termination stops at a terminal age so that  $lx$  is positive,  $qx$  is less than 1, and  $dx$  is positive. Any ages after the terminal age are NaN values. For more information, see “Truncated Termination” on page 19-921.

Data Types: char

## **Output Arguments**

### **qx — Discrete hazard function**

matrix

Discrete hazard function, returned as an N0-by-num matrix with forced termination. For more information, see “Forced Termination” on page 19-920.

The series  $qx$  is the conditional probability that a person at age  $x$  will die between age  $x$  and the next age in the series.

### **lx — Discrete survival function**

matrix

Discrete survival function, returned as an N0-by-num matrix with forced termination. For more information, see “Forced Termination” on page 19-920.

The series  $lx$  is the number of people alive at age  $x$ , given 100,000 alive at birth.

### **dx — Discrete decrements function**

matrix

Discrete decrements function, returned as an N0-by-num matrix with forced termination. For more information, see “Forced Termination” on page 19-920.

The series  $dx$  is the number of people who die out of 100,000 alive at birth, between age  $x$  and the next age in the series.

## More About

### Forced Termination

Most modern life tables have “forced” termination. Forced termination means that the last row of the life table applies for all persons with ages on or after the last age in the life table.

This sample illustrates forced termination.

#### United States Life Tables 2009

| $x$  | $l_x$ WM | $l_x$ WF | $l_x$ BM | $l_x$ BF | $q_x$ WM | $q_x$ WF | $q_x$ BM | $q_x$ BF |
|------|----------|----------|----------|----------|----------|----------|----------|----------|
| 93   | 9533     | 18368    | 6615     | 15685    | 0.219553 | 0.177156 | 0.200605 | 0.157858 |
| 94   | 7440     | 15114    | 5288     | 13209    | 0.23871  | 0.194852 | 0.214448 | 0.170868 |
| 95   | 5664     | 12169    | 4154     | 10952    | 0.258475 | 0.213411 | 0.229177 | 0.184624 |
| 96   | 4200     | 9572     | 3202     | 8930     | 0.27881  | 0.232971 | 0.24391  | 0.198992 |
| 97   | 3029     | 7342     | 2421     | 7153     | 0.299439 | 0.253337 | 0.259397 | 0.214036 |
| 98   | 2122     | 5482     | 1793     | 5622     | 0.320452 | 0.27417  | 0.274958 | 0.229634 |
| 99   | 1442     | 3979     | 1300     | 4331     | 0.341886 | 0.295803 | 0.291538 | 0.245671 |
| 100+ | 949      | 2802     | 921      | 3267     | 1        | 1        | 1        | 1        |

In this case, the last row of the life table applies for all persons aged 100 or older. Specifically,  $q_x$  probabilities are  ${}_1q_x$  for ages less than 100 and, technically,  ${}_{\infty}q_x$  for age 100.

Forced termination has terminal age values that apply to all ages after the terminal age so that  $l_x$  is positive,  $q_x$  is 1, and  $d_x$  is positive. Ages after the terminal age are NaN values, although  $l_x$  and  $d_x$  can be 0 and  $q_x$  can be 1 for input series. Forced termination is triggered by a naturally terminating series, the last age in a truncated series, or the first NaN value in a series.

### Natural Termination

Before 1970, life tables were often published with data that included all ages for which persons associated with a given series were still alive. Tables in this form have “natural” termination. In natural termination, the last row of the life table for each series counts the deaths or probabilities of deaths of the last remaining person at the corresponding age. Tables in this form can be problematic due to the granularity of the data and the fact that groups of series can terminate at distinct ages. Natural termination is illustrated in the following sample of the last few years of a life table.

#### United States Life Tables 1940

| $x$ | $l_x$ WM | $l_x$ WF | $l_x$ BM | $l_x$ BF | $q_x$ WM | $q_x$ WF | $q_x$ BM | $q_x$ BF |
|-----|----------|----------|----------|----------|----------|----------|----------|----------|
| 103 | 14       | 29       | 59       | 234      | 0.428571 | 0.413793 | 0.389831 | 0.333333 |
| 104 | 8        | 17       | 36       | 156      | 0.5      | 0.470588 | 0.416667 | 0.358974 |
| 105 | 4        | 9        | 21       | 100      | 0.5      | 0.444444 | 0.47619  | 0.38     |
| 106 | 2        | 5        | 11       | 62       | 0.5      | 0.4      | 0.454545 | 0.403226 |
| 107 | 1        | 3        | 6        | 37       | 0        | 0.666667 | 0.5      | 0.432432 |
| 108 | 1        | 1        | 3        | 21       | 1        | 0        | 0.666667 | 0.47619  |
| 109 |          | 1        | 1        | 11       |          | 1        | 1        | 0.454545 |
| 110 |          |          |          | 6        |          |          |          | 0.5      |
| 111 |          |          |          | 3        |          |          |          | 0.666667 |
| 112 |          |          |          | 1        |          |          |          | 0        |
| 113 |          |          |          | 1        |          |          |          | 1        |
| 114 |          |          |          |          |          |          |          |          |

This form for life tables poses a number of issues that go beyond the obvious statistical issues. First, the  $l_x$  table on the left terminates at ages 108, 109, 109, and 113 for the four series in the table. Technically, the numbers after these ages are 0, but can also be NaN values because no person is alive after these terminating ages. Second, the probabilities  $q_x$  on the right terminate with fluctuating probabilities that go from 0 to 1 in some cases. In this case, however, all probabilities are  ${}_1q_x$  probabilities (unlike the forced termination probabilities). You can argue that the probabilities after the ages of termination can be 1 (anyone alive at this age is expected to die in the next year), 0 (the age lies outside the support of the probability distribution), or NaN values.

### Truncated Termination

Truncated termination occurs with truncation of life tables at an arbitrary age. For example, from 1970–1990, United States life tables truncated at age 85. This format is problematic because life table probabilities must either terminate with probability 1 (forced termination) or discard data that exceeds the terminating age. This sample of the last few years of a life table illustrates truncated termination. The raw data for this table is the  $l_x$  series. The  $q_x$  series is derived from this series.

#### United States Life Tables 1980

| $x$ | $l_x$ WM | $l_x$ WF | $l_x$ BM | $l_x$ BF | $q_x$ WM | $q_x$ WF | $q_x$ BM | $q_x$ BF |
|-----|----------|----------|----------|----------|----------|----------|----------|----------|
| 78  | 38558    | 61100    | 25481    | 45776    | 0.078064 | 0.045221 | 0.082689 | 0.054789 |
| 79  | 35548    | 58337    | 23374    | 43268    | 0.084477 | 0.050037 | 0.088303 | 0.059351 |
| 80  | 32545    | 55418    | 21310    | 40700    | 0.091504 | 0.055542 | 0.094603 | 0.064619 |
| 81  | 29567    | 52340    | 19294    | 38070    | 0.099165 | 0.061922 | 0.101741 | 0.070607 |
| 82  | 26635    | 49099    | 17331    | 35382    | 0.107528 | 0.069935 | 0.109746 | 0.077356 |
| 83  | 23771    | 45694    | 15429    | 32645    | 0.116613 | 0.078194 | 0.118608 | 0.084822 |
| 84  | 20999    | 42121    | 13599    | 29876    | 0.126339 | 0.081788 | 0.128392 | 0.093018 |
| 85  | 18346    | 38676    | 11853    | 27097    |          |          |          |          |

This life table format poses problems for termination because, for example, over 27% of the population for the fourth  $l_x$  series is still alive at age 85. To claim that the probability of dying for all ages after age 85 is 100% might be true but is uninformative. Notwithstanding the statistical issues, however, tables in this form are completed by forced termination.

## lifetablefit

Calibrate life table from survival data with parametric models

### Syntax

```
[a,elx] = lifetablefit(x,lx)
[a,elx] = lifetablefit(___,lifemodel,objtype,interpmethod,a0)
```

### Description

`[a,elx] = lifetablefit(x,lx)` calibrates a life table, `x`, from survival data, `lx`, using parametric models.

`[a,elx] = lifetablefit(___,lifemodel,objtype,interpmethod,a0)` calibrates a life table, `x`, from survival data, `lx`, using parametric models using optional arguments for `lifemodel`, `objtype`, `interpmethod`, and `a0`.

### Examples

#### Calibrate Life Table from Survival Data Using a Heligman-Pollard Parametric Model

Load the life table data file.

```
load us_lifetable_2009
```

Calibrate the life table from survival data using the default heligman-pollard parametric model.

```
[a,elx] = lifetablefit(x,lx);
display(a)
```

```
a = 8×3
```

```

Plot the  $qx$  series and display the legend. The series  $qx$  is the conditional probability that a person at age  $x$  will die between age  $x$  and the next age in the series

```

plot(x, log(qx))
legend(series)

```

## Input Arguments

**x** — Increasing ages for raw data  
vector of nonnegative integers

Increasing ages for raw data, specified as a N vector for nonnegative integers.

Data Types: double

### **lx — Collection of num discrete survival counts**

matrix

Collection of num discrete survival counts, specified as an N-by-num matrix. The input lx series is the number of people alive at age x, given 100,000 alive at birth. Values of 0 or NaN in the input table lx are ignored.

Data Types: double

### **Lifemodel — Parametric mortality model type**

'heligman-pollard' (default) | character vector with values 'heligman-pollard', 'heligman-pollard-2', 'heligman-pollard-3', 'gompertz', 'makeham', 'siler'

(Optional) Parametric mortality model type, specified as a character vector with one of the following values:

- 'heligman-pollard' — Eight-parameter Heligman-Pollard model (version 1), specified in terms of the discrete hazard function:

$$\frac{q(x)}{1 - q(x)} = A^{(x+B)^C} + D \exp\left(-E \left(\log \frac{x}{F}\right)^2\right) + GH^X$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'heligman-pollard-2' — Eight-parameter Heligman-Pollard model (version 2), specified in terms of the discrete hazard function:

$$\frac{q(x)}{1 - q(x)} = A^{(x+B)^C} + D \exp\left(-E \left(\log \frac{x}{F}\right)^2\right) + \frac{GH^X}{1 + GH^X}$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'heligman-pollard-3' — Eight-parameter Heligman-Pollard model (version 3), specified in terms of the discrete hazard function:

$$q(x) = A^{(x+B)^C} + D \exp\left(-E \left(\log \frac{x}{F}\right)^2\right) + GH^X$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'gompertz' — Two-parameter Gompertz model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx)$$

for ages  $x \geq 0$ , with parameters  $A, B \geq 0$ .

- 'makeham' — Three-parameter Gompertz-Makeham model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx) + C$$

for ages  $x \geq 0$ , with parameters  $A, B, C \geq 0$ .

- 'siler' — Five-parameter Siler model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx) + C + D \exp(-Ex)$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E \geq 0$ .

Data Types: char

### **objtype — Objective for nonlinear least-squares estimation**

'ratio' (default) | character vector with values 'ratio' 'logratio'

(Optional) Objective for nonlinear least-squares estimation, specified as a character vector with the following values:

- 'ratio' — Given raw data  $q_x$  and model estimates  $\hat{q}_x$  for  $x = 1, \dots, N$ , the first objective (which is the preferred objective) has the form

$$\Phi = \sum_{x=1}^N \left(1 - \frac{\hat{q}_x}{q_x}\right)^2$$

- 'logratio' — Given raw data  $q_x$  and model estimates  $\hat{q}_x$  for  $x = 1, \dots, N$ , the second objective has the form

$$\Phi = \sum_{x=1}^N (\log(\hat{q}_x) - \log(q_x))^2$$

Data Types: char

### **interpmethod — Interpolation method to use for abridged life table inputs**

'cubic' (default) | character vector with values 'cubic', 'linear', 'none'

(Optional) Interpolation method to use for abridged life table inputs, specified as a character vector with the following values:

- 'cubic' — Cubic interpolation that uses 'pchip' method in `interp1`.
- 'linear' — Linear interpolation.
- 'none' — No interpolation.

---

**Note** If the ages in  $x$  are not consecutive years and interpolation is set to 'none', then the estimates for the parameters are suitable only for the age vector  $x$ .

If you use the parameter estimates to compute life table values for arbitrary years, interpolate using the default 'cubic' method.

Interpolation with abridged life tables forms internal interpolated full life tables, which usually improves model fits.

---

Data Types: char

### **a0 — Initial parameter estimate to be applied to all series**

vector

(Optional) Initial parameter estimate to be applied to all series, specified as a `numparam` vector. This vector must conform to the number of parameters in the model specified using the `lifemodel` argument.

Data Types: `double`

## Output Arguments

### **a** — Parameter estimates for each num series

`matrix`

Parameter estimates for each num series, returned as a `numparam-by-num` matrix.

### **eLx** — Estimated collection of num standardized survivor series

`matrix`

Estimated collection of num standardized survivor series, returned as an `N-by-num` matrix. The `eLx` output series is the number of people alive at age `x`, given 100,000 alive at birth. Values of `0` or `NaN` in the input table `Lx` are ignored.

# lifetablegen

Generate life table series from calibrated mortality model

## Syntax

```
[qx, lx, dx] = lifetablegen(x, a)
[qx, lx, dx] = lifetablegen(x, a, lifemodel)
```

## Description

`[qx, lx, dx] = lifetablegen(x, a)` generates a life table series from a calibrated mortality model.

`[qx, lx, dx] = lifetablegen(x, a, lifemodel)` generates a life table series from a calibrated mortality model using the optional argument for `lifemodel`.

## Examples

### Generate Life Table Series from a Calibrated Mortality Model for Heligman-Pollard

Load the life table data file.

```
load us_lifetable_2009
```

Calibrate the life table from survival data using the default heligman-pollard parametric model.

```
a = lifetablefit(x, lx)
```

```
a = 8×3
```

```
    0.0005    0.0006    0.0004

```

Plot the  $q_x$  series and display the legend. The series  $q_x$  is the conditional probability that a person at age  $x$  will die between age  $x$  and the next age in the series.

```

plot(x, log(qx))
legend(series)

```

### Prepare Life Table Data Using the $q_x$ Series and Generate the $q_x$ Life Table

Load the life table data file.

```
load us_lifetable_2009
```

Convert the life table series into life tables with forced termination.

```
[~, lx] = lifetableconv(x, qx, 'qx');
```

Calibrate the life table from survival data using the default heligman-pollard parametric model.

```
a = lifetablefit(x, lx)
```

```
a = 8×3
```

```
    0.0005    0.0006    0.0004

    :
```

Plot the qx series and display the legend. The series qx is the conditional probability that a person at age x will die between age x and the next age in the series.

```
plot((0:100), log(qx));
legend(series, 'location', 'southeast');
title('Conditional Probability of Dying within One Year of Current Age');
xlabel('Age');
ylabel('Log Probability');
```

## Input Arguments

### **x** — Increasing ages for raw data

vector of nonnegative integers

Increasing ages for raw data, specified as a N vector of nonnegative integer values. The ages must start at 0 (birth).

Data Types: double

### **a** — Model parameters for num models

matrix

Model parameters for num models, specified as a numparam-by-num matrix, where the number of parameters (numparam) depends on the model specified using the lifemodel argument.

Data Types: double

### **lifemodel** — Parametric mortality model type

'heligman-pollard' (default) | character vector with values 'heligman-pollard', 'heligman-pollard-2', 'heligman-pollard-3', 'gompertz', 'makeham', 'siler'

(Optional) Parametric mortality model type, specified as a character vector with one of the following values:

- 'heligman-pollard' — Eight-parameter Heligman-Pollard model (version 1), specified in terms of the discrete hazard function:

$$\frac{q(x)}{1 - q(x)} = A^{(x+B)^C} + D \exp\left(-E \left(\log \frac{x}{F}\right)^2\right) + GH^X$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'heligman-pollard-2' — Eight-parameter Heligman-Pollard model (version 2), specified in terms of the discrete hazard function:

$$\frac{q(x)}{1 - q(x)} = A^{(x+B)^C} + D \exp\left(-E \left(\log \frac{x}{F}\right)^2\right) + \frac{GH^X}{1 + GH^X}$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'heligman-pollard-3' — Eight-parameter Heligman-Pollard model (version 3), specified in terms of the discrete hazard function:

$$q(x) = A^{(x+B)^C} + D \exp\left(-E \left(\log \frac{x}{F}\right)^2\right) + GH^X$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'gompertz' — Two-parameter Gompertz model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx)$$

for ages  $x \geq 0$ , with parameters  $A, B \geq 0$ .

- 'makeham' — Three-parameter Gompertz-Makeham model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx) + C$$

for ages  $x \geq 0$ , with parameters  $A, B, C \geq 0$ .

- 'siler' — Five-parameter Siler model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx) + C + D \exp(-Ex)$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E \geq 0$ .

Data Types: char

## Output Arguments

### qx — Conditional probabilities of dying for N ages and num series

matrix

Conditional probabilities of dying for N ages and num series, returned as an N-by-num matrix. The series qx is the conditional probability that a person at age x will die between age x and the next age in the series. For the last age, qx represents probabilities or counts for all ages after the last age.

The last row of the N-by-num output for qx is the values for all ages on or after the last age in x (due to "Forced Termination" on page 19-932). Therefore, the last row of qx contains 1 (100% probability of dying on or after the last age).

**$l_x$  — Survival counts for N ages and num series**

matrix

Survival counts for N ages and num series, returned as an N-by-num matrix. The series  $l_x$  is the number of people alive at age  $x$ , given 100,000 alive at birth.

 **$dx$  — Decrement counts for N ages and num series**

matrix

Decrement counts for N ages and num series, returned as an N-by-num matrix. The series  $dx$  is the number of people out of 100,000 alive at birth who die between age  $x$  and the next age in the series. For the last age,  $dx$  represent probabilities or counts for all ages after the last age.

The last row of the N-by-num output for  $dx$  are values for all ages on or after the last age in  $x$  (due to “Forced Termination” on page 19-932). Therefore, the last row of  $dx$  contains the remaining count of 100,000 people alive at birth who have not died by the last age.

**More About****Forced Termination**

Most modern life tables have “forced” termination. Forced termination means that the last row of the life table applies for all persons with ages on or after the last age in the life table.

This sample illustrates forced termination.

**United States Life Tables 2009**

| $x$  | $l_x$ WM | $l_x$ WF | $l_x$ BM | $l_x$ BF | $q_x$ WM | $q_x$ WF | $q_x$ BM | $q_x$ BF |
|------|----------|----------|----------|----------|----------|----------|----------|----------|
| 93   | 9533     | 18368    | 6615     | 15685    | 0.219553 | 0.177156 | 0.200605 | 0.157858 |
| 94   | 7440     | 15114    | 5288     | 13209    | 0.23871  | 0.194852 | 0.214448 | 0.170868 |
| 95   | 5664     | 12169    | 4154     | 10952    | 0.258475 | 0.213411 | 0.229177 | 0.184624 |
| 96   | 4200     | 9572     | 3202     | 8930     | 0.27881  | 0.232971 | 0.24391  | 0.198992 |
| 97   | 3029     | 7342     | 2421     | 7153     | 0.299439 | 0.253337 | 0.259397 | 0.214036 |
| 98   | 2122     | 5482     | 1793     | 5622     | 0.320452 | 0.27417  | 0.274958 | 0.229634 |
| 99   | 1442     | 3979     | 1300     | 4331     | 0.341886 | 0.295803 | 0.291538 | 0.245671 |
| 100+ | 949      | 2802     | 921      | 3267     | 1        | 1        | 1        | 1        |

In this case, the last row of the life table applies for all persons aged 100 or older. Specifically,  $q_x$  probabilities are  ${}_1q_x$  for ages less than 100 and, technically,  ${}_{\infty}q_x$  for age 100.

Forced termination has terminal age values that apply to all ages after the terminal age so that  $l_x$  is positive,  $q_x$  is 1, and  $dx$  is positive. Ages after the terminal age are NaN values, although  $l_x$  and  $dx$  can be 0 and  $q_x$  can be 1 for input series. Forced termination is triggered by a naturally terminating series, the last age in a truncated series, or the first NaN value in a series.

## Introduced in R2015a

## linebreak

Line break chart

---

**Note** `linebreak` is updated to accept data input as a matrix, `timetable`, or `table`.

The syntax for `linebreak` has changed. Previously, when using `table` input, the first column of dates could be serial date numbers, date character vectors, or datetime arrays, and you were required to have specific number of columns.

When using `table` input, the new syntax for `linebreak` supports:

- No need for time information. If you want to pass in date information, use `timetable` input.
  - No requirement of specific number of columns. However, you must provide valid column names. `linebreak` must contain a column named `'price'` (case insensitive).
- 

### Syntax

```
linebreak(Data)
h = linebreak(ax,Data)
```

### Description

`linebreak(Data)` plots the asset data, in a line break chart.

`h = linebreak(ax,Data)` adds an optional argument for `ax`.

### Examples

#### Generate a Line Break Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock. This `Linebreak` chart is for closing prices of the stock TMW for the most recent 21 days. Note that the variable name of asset price is be renamed to `'Price'` (case insensitive).

```
load SimulatedStock.mat
TMW.Properties.VariableNames{'Close'} = 'Price';
linebreak(TMW(end-20:end,:))
title('Line Break Chart for TMW')
```

## Input Arguments

### Data — Data for a series of prices

matrix | table | timetable

Data for a series of prices, specified as a matrix, table, or timetable. Timetables and tables with M rows must contain a variable named 'Price' (case insensitive).

Data Types: double | table | timetable

### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The linebreak plot is created in the axes specified by ax instead of in the current axes (ax = gca). The option ax can precede any of the input argument combinations.

Data Types: object

## Output Arguments

### h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

**Introduced in R2008a**

# lloow

Lowest low

---

**Note** lloow has been partially removed and will no longer accept a fints object (tsobj) argument. Use a matrix, timetable, or table instead for financial time series.

Use fts2timetable to convert a fints object to a timetable object.

---

## Syntax

```
values = lloow(Data)
values = lloow(___,Name,Value)
```

## Description

values = lloow(Data) generates a vector of lowest low values from the series of low prices for the past  $n$  periods.

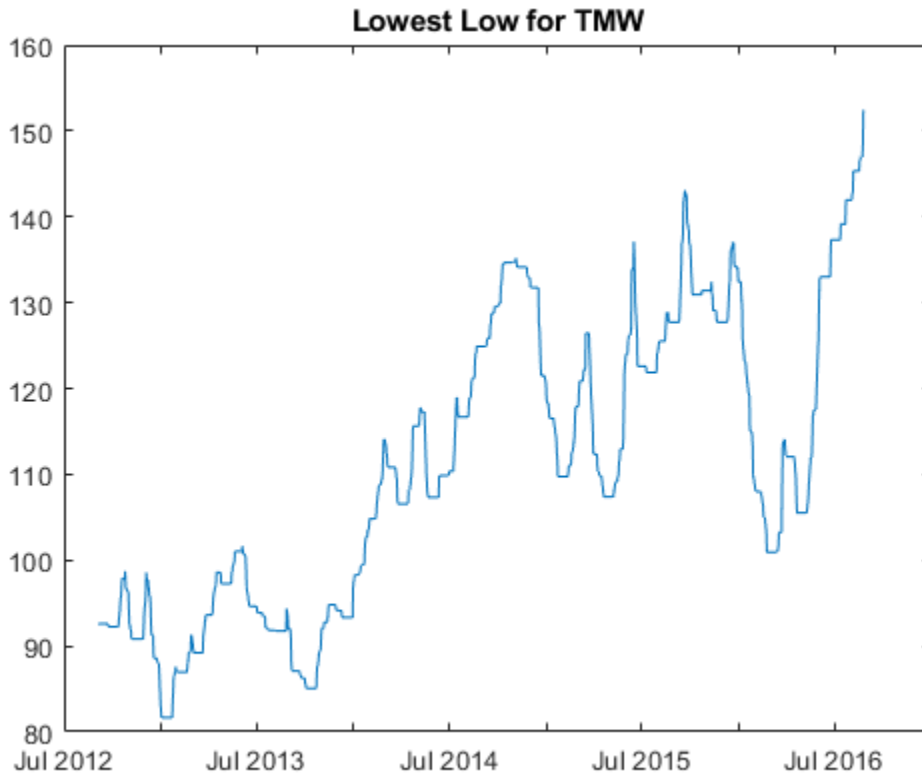

values = lloow(\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Calculate the Lowest Low for a Data Series for a Stock

Load the file SimulatedStock.mat, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
values = lloow(TMW);
plot(values.Time,values.LowestLow)
title('Lowest Low for TMW')
```

## Input Arguments

### Data — Data for low prices

matrix | table | timetable

Data for low prices, specified as a matrix, table, or timetable. Timetables and tables with M rows must contain a variable named 'Low' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `values = llow(TMW_LOW, 'NumPeriods', 10)`

### NumPeriods — Moving window for the lowest low calculation

14 (default) | positive integer

Moving window for the lowest low calculation, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

## Output Arguments

### values — Lowest low series

matrix | table | timetable

Lowest low series, returned with the same number of rows (**M**) and the same type (matrix, table, or timetable) as the input **Data**.

## log

Natural logarithm for financial times series object

---

**Note** `log` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = log(tsobj)
```

### Description

`newfts = log(tsobj)` calculates the natural logarithm (log base  $e$ ) of the data series in a financial time series object `tsobj`. It returns another time series object, `newfts`, containing the natural logarithms.

### See Also

# log10

Common logarithm for financial times series object

---

**Note** `log10` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = log10(tsobj)
```

## Description

`newfts = log10(tsobj)` calculates the common logarithm (base 10) of all the data in the data series of the financial time series object `tsobj` and returns the result in the object `newfts`.

## See Also

`exp` | `log` | `log2`

# lpm

Compute sample lower partial moments of data

## Syntax

`lpm(Data)`

`lpm(Data, MAR)`

`lpm(Data, MAR, Order)`

`Moment = lpm(Data, MAR, Order)`

## Arguments

|       |                                                                                                                                                                                                                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data  | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES observations of NUMSERIES asset returns.                                                                                                                                                                                                              |
| MAR   | (Optional) Scalar minimum acceptable return (default MAR = 0). This is a cutoff level of return such that all returns above MAR contribute nothing to the lower partial moment.                                                                                                                      |
| Order | (Optional) Either a scalar or a NUMORDERS vector of nonnegative integer moment orders. If no order specified, default Order = 0, which is the shortfall probability. Although this function works for noninteger orders and, in some cases, for negative orders, this falls outside customary usage. |

## Description

Given NUMSERIES assets with NUMSAMPLES returns in a NUMSAMPLES-by-NUMSERIES matrix `Data`, a scalar minimum acceptable return `MAR`, and one or more nonnegative moment orders in a NUMORDERS vector `Order`, `lpm` computes lower partial moments relative to `MAR` for each asset in a NUMORDERS  $\times$  NUMSERIES matrix `Moment`.

The output `Moment` is a NUMORDERS  $\times$  NUMSERIES matrix of lower partial moments with NUMORDERS Orders and NUMSERIES series, that is, each row contains lower partial moments for a given order.

**Note** To compute upper partial moments, reverse the signs of both `Data` and `MAR` (do not reverse the sign of the output). This function computes sample lower partial moments from data. To compute expected lower partial moments for multivariate normal asset returns with a specified mean and covariance, use `elpm`. With `lpm`, you can compute various investment ratios such as Omega ratio, Sortino ratio, and Upside Potential ratio, where:

- $\text{Omega} = \text{lpm}(-\text{Data}, -\text{MAR}, 1) / \text{lpm}(\text{Data}, \text{MAR}, 1)$
- $\text{Sortino} = (\text{mean}(\text{Data}) - \text{MAR}) / \text{sqrt}(\text{lpm}(\text{Data}, \text{MAR}, 2))$
- $\text{Upside} = \text{lpm}(-\text{Data}, -\text{MAR}, 1) / \text{sqrt}(\text{lpm}(\text{Data}, \text{MAR}, 2))$

## Examples

See “Sample Lower Partial Moments” on page 7-12.

## Introduced in R2006b

# lweekdate

Date of last occurrence of weekday in month

## Syntax

```
LastDate = lweekdate(Weekday,Year,Month)
LastDate = lweekdate( ____,NextDay,outputType)
```

## Description

`LastDate = lweekdate(Weekday,Year,Month)` returns the date number for the last occurrence of `Weekday` in the given year and month.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by-n vector of integers, then `Month` must be a 1-by-n vector of integers or a single integer. `LastDate` is then a 1-by-n vector of date numbers.

`LastDate = lweekdate( ____,NextDay,outputType)` returns the date of last occurrence of weekday in month using the optional arguments for `NextDay` and `outputType`.

The type of the output for `LastDate` depends on the input `outputType`. If this variable is 'datenum', `LastDate` is a serial date number. If `outputType` is 'datetime', then `LastDate` is a datetime array. By default, `outputType` is set to 'datenum'.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

## Examples

### Determine the Date of Last Occurrence of Weekday in a Month

Determine the last Monday in June 2001.

```
LastDate = lweekdate(2, 2001, 6); datestr>LastDate)
```

```
ans =
'25-Jun-2001'
```

Determine the last Monday in a week that also contains a Friday in June 2001 returned as a datetime array.

```
LastDate = lweekdate(2, 2001, 6,[],'datetime')
```

```
LastDate = datetime
25-Jun-2001
```

Determine the last Monday in a week that also contains a Friday in June 2001:

```
LastDate = lweekdate(2, 2001, 6, 6); datestr>LastDate)
```

```
ans =  
'25-Jun-2001'
```

Determine the last Monday in May for 2001, 2002, and 2003:

```
Year = [2001:2003];  
LastDate = lweekdate(2, Year, 5);  
datestr(LastDate)
```

```
ans = 3x11 char array  
    '28-May-2001'  
    '27-May-2002'  
    '26-May-2003'
```

## Input Arguments

### **Weekday** — Weekday whose date you seek

integer with value 1 through 7 | vector of integers with values 1 through 7

Weekday whose date you seek, specified as an integer or a vector of integers from 1 through 7.

- 1 — Sunday
- 2 — Monday
- 3 — Tuesday
- 4 — Wednesday
- 5 — Thursday
- 6 — Friday
- 7 — Saturday

Data Types: `single` | `double`

### **Year** — Year to determine occurrence of weekday

4-digit integer | vector of 4-digit integers

Year to determine occurrence of weekday, specified as a 4-digit integer or vector of 4-digit integers.

Data Types: `single` | `double`

### **Month** — Month to determine occurrence of weekday

integer with value 1 through 12 | vector of integers with values 1 through 12

Month to determine occurrence of weekday, specified as an integer or vector of integers with values 1 through 12.

Data Types: `single` | `double`

### **NextDay** — Weekday that must occur after Weekday in same week

0 = ignore (default) | integer with value 0 through 7 | vector of integers with values 0 through 7

Weekday that must occur after Weekday in same week, specified as an integer or a vector of integers from 0 through 7, where 0 = ignore (default) and 1 through 7 are the same as for Weekday.

Data Types: `single` | `double`

**outputType — Year to determine days**

'datenum' (default) | character vector with values 'datenum' or 'datetime'

A character vector specified as either 'datenum' or 'datetime'. The output `LastDate` is in serial date format if 'datenum' is specified, or datetime format if 'datetime' is specified. By default the output `LastDate` is in serial date format.

Data Types: char

## Output Arguments

**LastDate — Date for last occurrence of Weekday in given year and month**

serial date number | date character vector

Date for last occurrence of Weekday in given year and month, returned as a serial date number or date character vector.

The type of the output for `LastDate` depends on the optional input argument `outputType`. If this variable is 'datenum', `LastDate` is a serial date number. If `outputType` is 'datetime', then `LastDate` is a datetime array. By default, `outputType` is set to 'datenum'.

## m2xdate

MATLAB date to Excel serial date number

### Syntax

```
DateNum = m2xdate(MATLABDateNumber,Convention)
```

### Description

`DateNum = m2xdate(MATLABDateNumber,Convention)` converts MATLAB serial date numbers, date character vectors, or datetime arrays to Excel serial date numbers. MATLAB date numbers start with 1 = January 1, 0000 A.D., hence there is a difference of 693960 relative to the 1900 date system, or 695422 relative to the 1904 date system. This function is useful with Spreadsheet Link™ software.

### Examples

#### Convert MATLAB Serial Date Numbers Using 1900 Date System

This example shows how to convert MATLAB serial date numbers using the 1900 date system. Given MATLAB date numbers for Christmas 2001 through 2004, convert them to Excel date numbers in the 1900 system.

```
DateNum = datenum(2001:2004, 12, 25);  
ExDate = m2xdate(DateNum)
```

```
ExDate = 1×4
```

```
    37250    37615    37980    38346
```

#### Convert MATLAB Serial Date Numbers Using 1900 Date System With a datetime Array

This example shows how to convert MATLAB® date numbers using a datetime array with the 1900 date system. Given MATLAB date numbers for Christmas 2001 through 2004, convert them to Excel date numbers in the 1904 system.

```
DateNum = datetime(2001:2004, 12, 25, 'Locale', 'en_US');  
ExDate = m2xdate(DateNum)
```

```
ExDate = 1×4
```

```
    37250    37615    37980    38346
```

## Convert MATLAB Serial Date Numbers Using 1904 Date System

This example shows how to convert MATLAB serial date numbers using the 1904 date system. Given MATLAB date numbers for Christmas 2001 through 2004, convert them to Excel date numbers in the 1904 system.

```
DateNum = datenum(2001:2004, 12, 25);
ExDate = m2xdate(DateNum, 1)
```

```
ExDate = 1×4
```

```
    35788    36153    36518    36884
```

## Input Arguments

### MATLABDateNumber — MATLAB dates

serial date number | date character vector | datetime array

MATLAB dates, specified as a scalar or vector of MATLAB serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Convention — Flag for Excel date system

0 (Excel 1900 date system is in effect) (default) | numeric with value 0 or 1

Flag for Excel date system, specified as a scalar or vector as a numeric with a value 0 or 1.

When `Convention = 0` (default), the Excel 1900 date system is in effect. When `Convention = 1`, the Excel 1904 date system is used.

In the Excel 1900 date system, the Excel serial date number 1 corresponds to January 1, 1900 A.D. In the Excel 1904 date system, date number 0 is January 1, 1904 A.D.

Due to a software limitation in Excel software, the year 1900 is considered a leap year. As a result, all DATEVALUE's reported by Excel software between Jan. 1, 1900 and Feb. 28, 1900 (inclusive) differs from the values reported by 1. For example:

- In Excel software, Jan. 1, 1900 = 1
- In MATLAB, Jan. 1, 1900 - 693960 (for 1900 date system) = 2

```
datenum('Jan 1, 1900') - 693960
```

```
ans =
```

```
    2
```

Data Types: logical

## Output Arguments

### DateNum — Excel serial date number

array of serial date numbers

Excel serial date number, returned as an array of serial date numbers in Excel serial date number form.

**See Also**

`datenum` | `datestr` | `datetime` | `x2mdate`

# macd

Moving Average Convergence/Divergence (MACD)

---

**Note** `macd` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a `matrix`, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
[MACDLine,SignalLine] = macd(Data)
```

## Description

`[MACDLine,SignalLine] = macd(Data)` calculates the Moving Average Convergence/Divergence (MACD) line from the series of data and the nine-period exponential moving average from the `MACDLine`.

## Examples

### Calculate the Moving Average Convergence/Divergence for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
[MACDLine, signalLine]= macd(TMW);
plot(MACDLine.Time,MACDLine.Close,signalLine.Time,signalLine.Close);
legend('MACDLine','NinePerMA')
title('MACD for TMW')
```

## Input Arguments

### Data — Data with high, low, open, close information

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-4 matrix of high, low, opening, and closing prices. Timetables and tables with M rows must contain variables named 'High', 'Low', 'Open', and 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### MACDLine — MACD series

matrix | table | timetable

MACD series, returned with the same number of rows (M) and type (matrix, table, or timetable) as the input Data. The MACDLine is calculated by subtracting the 26-period (7.5%) exponential.

### SignalLine — Nine-period exponential series

matrix | table | timetable

Nine-period exponential series, returned with the same number of rows (M) and type (matrix, table, or timetable) as the input Data. The nine-period (20%) exponential moving average of the MACDLine is used as the SignalLine.

## More About

### MACD

The MACD is calculated by subtracting the 26-period (7.5%) exponential moving average from the 12-period (15%) moving average.

The nine-period (20%) exponential moving average of the MACD line is used as the "signal" line. When the two lines are plotted, they can give you indications on when to buy or sell a stock, when overbought or oversold is occurring, and when the end of trend may occur. For example, when the MACD and the 20-day moving average line have crossed and the MACD line becomes below the other line, it is time to sell.

## max

Maximum value

---

**Note** `max` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
tymax = max(tsoobj)
```

### Description

`tymax = max(tsoobj)` finds the maximum value in each data series in the financial time series object (`tsoobj`) and returns it in a structure `tymax`. The `tymax` structure contains field name(s) identical to the data series name(s).

---

**Note** `tymax` returns only the values and does not return the dates associated with the values. The maximum values are not necessarily from the same date.

---

# maxdrawdown

Compute maximum drawdown for one or more price series

## Syntax

```
MaxDD = maxdrawdown(Data)
MaxDD = maxdrawdown( ____, Format)
[MaxDD,MaxDDIndex] = maxdrawdown( ____ )
```

## Description

MaxDD = maxdrawdown(Data) computes maximum drawdown for each series in an N-vector MaxDD and identifies start and end indexes of maximum drawdown periods for each series in a 2-by-N matrix MaxDDIndex.

MaxDD = maxdrawdown( \_\_\_\_, Format) adds an optional argument for Format.

[MaxDD,MaxDDIndex] = maxdrawdown( \_\_\_\_ ) adds an optional output for MaxDDIndex.

## Examples

### Calculate Maximum Drawdown

Calculate the maximum drawdown (MaxDD) using example data with a fund, market, and cash series:

```
load FundMarketCash
MaxDD = maxdrawdown(TestData)
```

```
MaxDD = 1x3
    0.1658    0.3381    0
```

The maximum drop in the given time period was 16.58% for the fund series, and 33.81% for the market series. There was no decline in the cash series, as expected, because the cash account never loses value.

## Input Arguments

### Data — Total return price series

matrix

Total return price series, specified as a T-by-N matrix with T samples of N total return price series.

Data Types: double

### Format — (Optional) Format of Data

character vector with value of 'return', 'arithmetic', or 'geometric'

Format of Data, specified as character vector with the following possible values:

- 'return' (default) — Maximum drawdown in terms of maximum percentage drop from a peak.
- 'arithmetic'
  - Maximum drawdown of an arithmetic Brownian motion with drift (differences of data from peak to trough) using the equation

$$dX(t) = \mu dt + \sigma dW(t).$$

- 'geometric'
  - Maximum drawdown of a geometric Brownian motion with drift (differences of log of data from peak to trough) using the equation

$$dS(t) = \mu_0 S(t) dt + \sigma_0 S(t) dW(t)$$

Data Types: char

## Output Arguments

### MaxDD — Maximum drawdown

vector

Maximum drawdown, returned as a 1-by-N vector with maximum drawdown for each of N time series.

---

### Note

- Drawdown is the percentage drop in total returns from the start to the end of a period. If the total equity time series is increasing over an entire period, drawdown is 0. Otherwise, it is a positive number. Maximum drawdown is an ex-ante proxy for downside risk that computes the largest drawdown over all intervals of time that can be formed within a specified interval of time.
  - Maximum drawdown is sensitive to quantization error.
- 

### MaxDDIndex — Start and end indexes for each maximum drawdown period for each total equity time series

vector

Start and end indexes for each maximum drawdown period for each total equity time series, returned as a 2-by-N vector of start and end indexes. The first row of the vector contains the start indexes and the second row contains the end indexes of each maximum drawdown period.

## mean

Arithmetic average

---

**Note** `mean` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
tsmean = mean(tsobj)
```

### Description

`tsmean = mean(tsobj)` computes the arithmetic mean of all data in all series in the financial time series object (`tsobj`) and returns it in a structure `tsmean`. The `tsmean` structure contains field `name(s)` identical to the data series `name(s)`.

# medprice

Median price

---

**Note** `medprice` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
MedianPrice = medprice(Data)
```

## Description

`MedianPrice = medprice(Data)` calculates the median prices from the series of high and low prices. The median price is the average of the high and low prices for each period.

## Examples

### Calculate the Median Prices for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (`TMW`) for financial data for `TMW` stock.

```
load SimulatedStock.mat
MedianPrice = medprice(TMW);
plot(MedianPrice.Time,MedianPrice.MedianPrice)
title('Median Price for TMW')
```

## Input Arguments

### Data — Data for high, low, and close prices

matrix | table | timetable

Data for high, low, and close prices, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-3 matrix of high, low, and close prices stored in the corresponding columns. Timetables and tables with M rows must contain a variable named 'High', 'Low', 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### MedianPrice — Median price series

matrix | table | timetable

Median price series, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## References

## merge

Merge multiple financial time series objects

---

**Note** `merge` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = merge(fts1,fts2)
```

```
newfts = merge(fts1,fts2, ..., ftsx)
```

```
newfts = merge(fts1,fts2, ..., ftsx,'PARAM1',VALUE1,'PARAM2',VALUE2, ...)
```

### Arguments

|                 |                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fts1, fts2, ... | Comma-separated list of financial time series objects to merge.<br><br><b>Note</b> Multiple Financial Time Series objects can be merged at once. The merged objects must appear in a comma separated list before the optional inputs. The order of the inputs is significant.                                                                                                            |

Valid merge values are:<br><br>'union' — (Default) Returns the combined values of all merged objects.<br><br>'intersection' — Returns the values common to all merged objects.<br><br>RefObj — Maps all values to a reference time contained in a Financial Time Series object (RefObj) or vector of date numbers.                                      |
| 'DataSetMethod' | (Optional) Merge <i>method</i> . Valid merge values are:<br><br>'closest' — (Default) Returns data based on the order of the inputs. However, the first missing data point (NaN value) of a date will be replaced by the closest non-NaN data point that appears on the same date of subsequent merged objects.<br><br>'order' — Returns data based strictly on the order of the inputs. |
| 'SortColumns'   | (Optional) Sorts columns. Valid merge values are:<br><br>True/1 — (Default) Sorts the columns based on the headers (series names). The headers are sorted in alphabetical order.<br><br>False/0 — Columns are not sorted.                                                                                                                                                                |

## Description

`newfts = merge(fts1,fts2, ..., ftsx,'PARAM1',VALUE1,'PARAM2',VALUE2', ...)`  
 merges multiple financial time series objects. The optional parameter and value pair argument specifies the values contained in the output financial time series object `ftsout`.

## Examples

### Create Three Financial Time Series Objects and Merge into a Single Object

Create three financial time series objects and merged into a new time series object `t123`.

```
dates = {'jan-01-2001'; 'jan-02-2001'; 'jan-03-2001'; ...
        'jan-04-2001'; 'jan-06-2001'};
data = [1; 1; 1; 1; 1];
t1 = fints(dates, data);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
dates = {'jan-02-2001'; 'jan-03-2001'; 'jan-04-2001';
        'jan-05-2001'};
data = [2; 2; 2; 2];
t2 = fints(dates, data);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
dates = {'jan-03-2001'; 'jan-04-2001'; 'jan-05-2001';
        'jan-06-2001'};
data = [3; 3; 3; 3];
t3 = fints(dates, data);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
t123 = merge(t1, t2, t3)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
t123 =
```

```
desc:  ||  ||
freq:  Unknown (0)

{'dates: (6)'} {'series1: (6)'}
{'01-Jan-2001'} {[ 1]}
{'02-Jan-2001'} {[ 1]}
{'03-Jan-2001'} {[ 1]}
{'04-Jan-2001'} {[ 1]}
{'05-Jan-2001'} {[ 2]}
{'06-Jan-2001'} {[ 1]}
```

If you change the order of input time series, the output may contain different data when duplicate dates exist. Here, for example, is the result of using the same three time series defined above but with the order changed.

```
merge(t3, t2, t1)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [matlab.com/help/finance/fints](#).

```
ans =
```

```
desc:  ||  ||
freq:  Unknown (0)

{'dates: (6)'}   {'series1: (6)'}
{'01-Jan-2001'}  {[          1]}
{'02-Jan-2001'}  {[          2]}
{'03-Jan-2001'}  {[          3]}
{'04-Jan-2001'}  {[          3]}
{'05-Jan-2001'}  {[          3]}
{'06-Jan-2001'}  {[          3]}
```

t123 contains all 1's except on '05-Jan-2001' because t1 appears first in the list of inputs and takes precedence. The same logic can be applied to t321. By changing the order of inputs, you can overwrite old financial time series data with new data by placing the new time series ahead of the old one in the list of inputs to the merge function.

### Merge Financial Time Series Objects with Different Headers (Series Names)

Merge time series objects with different headers into a new time series object t45.

```
dates = {'jan-01-2001'; 'jan-02-2001'; 'jan-03-2001'; ...
'jan-04-2001'; 'jan-06-2001'};

# min

Minimum value

---

**Note** MIN is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
tsmin = min(tsobj)
```

## Description

`tsmin = min(tsobj)` finds the minimum value in each data series in the financial time series object (`tsobj`) and returns it in the structure `tsmin`. The `tsmin` structure contains field name(s) identical to the data series name(s).

---

**Note** `tsmin` returns only the values and does not return the dates associated with the values. The minimum values are not necessarily from the same date.

---

## See Also

`max`

## Topics

“Financial Time Series Operations” on page 13-6

**Introduced before R2006a**

## minus

Financial time series subtraction

---

**Note** `minus` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = tsojb_1 - tsojb_2
```

```
newfts = tsojb - array
```

```
newfts = array - tsojb
```

### Arguments

|                               |                                                                                                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsojb_1, tsojb_2</code> | A pair of financial time series objects .                                                                                                                                               |
| <code>array</code>            | A scalar value or array with the number of rows equal to the number of dates in <code>tsojb</code> and the number of columns equal to the number of data series in <code>tsojb</code> . |

### Description

`minus` is an element-by-element subtraction of the components.

`newfts = tsojb_1 - tsojb_2` subtracts financial time series objects. If an object is to be subtracted from another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when one financial time series object is subtracted from another, follows the order of the first object.

`newfts = tsojb - array` subtracts an array element by element from a financial time series object.

`newfts = array - tsojb` subtracts a financial time series object element by element from an array.

# minute

Minute of date or time

## Syntax

```
Minute = minute(Date)
Minute = minute( ___,F)
```

## Description

`Minute = minute(Date)` returns the minute of date or time given a serial date number or a character vector representing a date and time.

`Minute = minute( ___,F)` returns the minute of date or time given a serial date number or a date character vector, `Date`, using format defined by the optional input `F`. `Date` can be a character array where each row corresponds to one date character vector, or a one-dimensional cell array of character vectors. All the character vectors in `Date` must have the same format `F`. `F` must designate a supported date format symbol. For more information on supported date formats, see `datestr`.

## Examples

### Determine the Minutes of the Date for Various Dates

Find the minutes of the day for `Date` using a serial date number.

```
Minute = minute(731204.5591223380)
```

```
Minute = 25
```

Find the minutes of the day for `Date` using a character vector representing a date and time.

```
Minute = minute('19-dec-2001, 13:25:08.17')
```

```
Minute = 25
```

## Input Arguments

### Date — Date to determine minute

serial date number | character vector | cell array of character vectors

Date to determine minute, specified as a serial date number or a character vector representing a date and time.

`Date` can be an array of date character vectors, where each row corresponds to one date character vector, or a one-dimensional cell array of character vectors. All the character vectors in `Date` must have the same format `F`. `F` must designate a supported date format symbol. For more information on supported date formats, see `datestr`

Data Types: `single` | `double` | `char` | `cell`

**F — Date format symbol**

character vector designating date format

Date format symbol, specified as a character vector to designate the date format symbol for input argument `Date`. For more information on supported character vector formats, see `datestr`. Note, formats with 'Q' are not accepted.

Data Types: char

**Output Arguments****Minute — Minute of date or time**

nonnegative number

Minute of date or time, returned as a nonnegative number.

**See Also**

`datevec` | `hour` | `second`

# mirr

Modified internal rate of return

## Syntax

Return = mirr(CashFlow,FinRate,Reinvest)

## Arguments

|          |                                                                          |
|----------|--------------------------------------------------------------------------|
| CashFlow | Vector of cash flows. The first entry is the initial investment.         |
| FinRate  | Finance rate for negative cash flow values. Enter as a decimal fraction. |
| Reinvest | Reinvestment rate for positive cash flow values, as a decimal fraction.  |

## Description

Return = mirr(CashFlow,FinRate,Reinvest) calculates the modified internal rate of return for a series of periodic cash flows. This function calculates only positive rates of return; for nonpositive rates of return, Return = 0.

## Examples

This cash flow represents the yearly income from an initial investment of \$100,000. The finance rate is 9% and the reinvestment rate is 12%.

|        |            |
|--------|------------|
| Year 1 | \$20,000   |
| Year 2 | (\$10,000) |
| Year 3 | \$30,000   |
| Year 4 | \$38,000   |
| Year 5 | \$50,000   |

To calculate the modified internal rate of return on the investment

```
Return = mirr([-100000 20000 -10000 30000 38000 50000], 0.09, ...
0.12)
```

returns

```
Return =
0.0832 (8.32%)
```

# month

Month of date

## Syntax

```
[MonthNum,MonthString] = month(Date)
[MonthNum,MonthString] = month( ____,F)
```

## Description

[MonthNum,MonthString] = month(Date) returns the month of date given a serial date number or a date character vector.

[MonthNum,MonthString] = month( \_\_\_\_,F) returns the month of date given a serial date number or a date character vector, Date, using format defined by the optional input F. Date can be a character array where each row corresponds to one date character vector, or a one-dimensional cell array of character vectors. All the character vectors in Date must have the same format F. F must designate a supported date format symbol. For more information on supported date formats, see datestr.

## Examples

### Determine the Month for Various Dates

Find the month for Date using a serial date number.

```
[MonthNum, MonthString] = month(730368)
```

```
MonthNum = 9
```

```
MonthString =
'Sep'
```

Find the month for Date using a date character vector format.

```
[MonthNum, MonthString] = month('05-Sep-1999')
```

```
MonthNum = 9
```

```
MonthString =
'Sep'
```

Use the optional F argument to designate a country-specific date format for a given Date.

```
[MonthNum, MonthString] = month('1999/05/09','yyyy/dd/mm')
```

```
MonthNum = 9
```

```
MonthString =
'Sep'
```

## Input Arguments

### **Date — Date to determine month**

serial date number | date character vector | cell array of date character vectors

Date to determine month, specified as a serial date number or date character vector.

**Date** can be an array of date character vectors, where each row corresponds to one date character vector, or a one-dimensional cell array of character vectors. All the character vectors in **Date** must have the same format **F**. **F** must designate a supported date format symbol. For more information on supported date formats, see `datestr`

Data Types: `single` | `double` | `char` | `cell`

### **F — Date format symbol**

character vector designating date format

Date format symbol, specified as a character vector to designate the date format symbol for input argument **Date**. For more information on supported date character vector formats, see `datestr`. Note, formats with 'Q' are not accepted.

Data Types: `char`

## Output Arguments

### **MonthNum — Numeric representation of the month**

nonnegative integer

Month of date, returned as a nonnegative integer.

### **MonthString — Three letter abbreviation for month**

character vector

Three letter abbreviation for month, returned as a character vector.

## See Also

`datevec` | `day` | `year`

### Topics

“Handle and Convert Dates” on page 2-2

**Introduced before R2006a**

# months

Number of whole months between dates

## Syntax

```
MyMonths = months(StartDate,EndDate)
MyMonths = months( ____,EndMonthFlag)
```

## Description

`MyMonths = months(StartDate,EndDate)` returns the number of whole months between `StartDate` and `EndDate`. If `EndDate` is earlier than `StartDate`, `MyMonths` is negative.

Any input argument can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of character vector dates, then `EndDate` must be an  $n$ -row character array of character vector dates or a single date. `MyMonths` is then an  $N$ -by-1 vector of numbers.

`MyMonths = months( ____,EndMonthFlag)` returns the number of whole months between `StartDate` and `EndDate` using an optional argument for `EndMonthFlag`. If `EndDate` is earlier than `StartDate`, `MyMonths` is negative.

## Examples

### Determine the Number of Whole Months Between Dates

Find the number of whole months using date character vectors.

```
MyMonths = months('may 31 2000', 'jun 30 2000', 1)
```

```
MyMonths = 1
```

Find the number of whole months using date character vectors when the optional `EndMonthFlag` = 0.

```
MyMonths = months('may 31 2000','jun 30 2000', 0)
```

```
MyMonths = 0
```

Find the number of whole months using a cell array of date character vectors.

```
Dates = ['mar 31 2002'; 'apr 30 2002'; 'may 31 2002'];
MyMonths = months(Dates, 'jun 30 2002')
```

```
MyMonths = 3×1
```

```
3
2
1
```

## Input Arguments

### **StartDate** — Starting date for number of whole months between dates

serial date number | date character vector | cell array of date character vectors

Starting date for number of whole months between dates, specified as a serial date number or date character vector.

Any input argument can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of character vector dates, then `EndDate` must be an  $n$ -row character array of character vector dates or a single date. `MyMonths` is then an  $n$ -by-1 vector of numbers.

Data Types: `single` | `double` | `char` | `cell`

### **EndDate** — Ending date for number of whole months between dates

serial date number | date character vector | cell array of date character vectors

Ending date for number of whole months between dates, specified as a serial date number or date character vector.

Any input argument can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of character vector dates, then `EndDate` must be an  $n$ -row character array of character vector dates or a single date. `MyMonths` is then an  $n$ -by-1 vector of numbers.

Data Types: `single` | `double` | `char` | `cell`

### **EndMonthFlag** — Flag for end-of-month rule

1 (default) | nonnegative integer with values 0 or 1

Flag for end-of-month rule, specified as a nonnegative integer with values 0 or 1.

If `StartDate` and `EndDate` are end-of-month dates and `EndDate` has fewer days than `StartDate`, `EndMonthFlag` = 1. In this case, `EndDate` is treated as the end of a whole month, while `EndMonthFlag` = 0 does not.

Data Types: `logical`

## Output Arguments

### **MyMonths** — Number of whole months between dates

nonnegative integer

Number of whole months between dates, returned as a nonnegative integer.

## See Also

`yearfrac`

“Handle and Convert Dates” on page 2-2

**Introduced before R2006a**

## movavg

Moving average of a financial time series

---

**Note** movavg is updated to accept data input as a matrix, table, or timetable.

The syntax for movavg has changed. There is no longer support for the input arguments Lead and Lag, only a single windowSize is supported, and there is only one output argument (ma). If you want to compute the leading and lagging moving averages, you need to run movavg twice and adjust the windowSize.

---

### Syntax

```
ma = movavg(Data,type,windowSize)
```

```
ma = movavg( ___,Initialpoints)
```

```
ma = movavg(Data,type,weights)
```

```
ma = movavg( ___,Initialpoints)
```

### Description

ma = movavg(Data,type,windowSize) computes the moving average (MA) of a financial time series.

ma = movavg( \_\_\_,Initialpoints) adds an optional argument for Initialpoints.

ma = movavg(Data,type,weights) computes the moving average (MA) of a financial time series using a 'custom' type and weights.

ma = movavg( \_\_\_,Initialpoints) adds an optional argument for Initialpoints.

### Examples

#### Calculate the Moving Average for a Data Series

Load the file SimulatedStock.mat, which provides a timetable (TMW) for financial data.

```
load SimulatedStock.mat
type = 'linear';
windowSize = 14;
ma = movavg(TMW_CLOSE,type,windowSize)
```

```
ma = 1000×1
```

```
100.2500
100.3433
100.8700
100.4916
 99.9937
 99.3603
```

```

98.8769
98.6364
98.4348
97.8491
⋮

```

## Input Arguments

### Data — Data for a financial series

matrix | table | timetable

Data for a financial series, specified as a column-oriented matrix, table, or timetable. Timetables and tables must contain variables with only a numeric type.

Data Types: double | table | timetable

### type — Type of moving average to compute

character vector with value of 'simple', 'square-root', 'linear', 'square', 'exponential', 'triangular', 'modified', or 'custom' | string with value of "simple", "square-root", "linear", "square", "exponential", "triangular", "modified", or "custom"

Type of moving average to compute, specified as a character vector or string with an associated value.

Data Types: char | string

### windowSize — Number of observations of the input series to include in moving average

positive integer

Number of observations of the input series to include in moving average, specified as a scalar positive integer. The observations include (windowSize - 1) previous data points and the current data point.

---

**Note** The windowSize argument applies only to moving averages whose type is 'simple', 'square-root', 'linear', 'square', 'exponential', 'triangular', or 'modified'.

---

Data Types: double

### weights — Custom weights used to compute moving average

vector

Custom weights used to compute the moving average, specified as a vector.

---

**Note** The length of weights ( $N$ ) determines the size of the moving average window (windowSize). The weights argument applies only to a 'custom' type of moving average.

---

To compute moving average with custom weights, the weights ( $w$ ) are first normalized such that they sum to one:

$$W(i) = w(i)/\text{sum}(w), \text{ for } i = 1, 2, \dots, N$$

The normalized weights ( $W$ ) are then used to form the  $N$ -point weighted moving average ( $y$ ) of the input Data ( $x$ ):

$$y(t) = W(1)*x(t) + W(2)*x(t-1) + \dots + W(N)*x(t-N)$$

The initial moving average values within the window size are then adjusted according to the method specified in the name-value pair argument `Initialpoints`.

Data Types: `double`

### **Initialpoints** – Indicates how moving average is calculated at initial points

'shrink' (default) | character vector with values of 'shrink', 'fill', or 'zero' | string with values of "shrink", "fill", or "zero"

(Optional) Indicates how the moving average is calculated at initial points (before there is enough data to fill the window), specified as a character vector or string using one of the following values:

- 'shrink' - Initializes the moving average such that the initial points include only observed data
- 'zero' - Initializes the initial points with 0
- 'fill' - Fills initial points with NaNs

---

**Note** The `Initialpoints` argument applies to all type specifications except for the 'exponential' and 'modified' options.

---

Data Types: `char` | `string`

## **Output Arguments**

### **ma** – Moving average series

`matrix` | `table` | `timetable`

Moving average series, returned with the same number of rows ( $M$ ) and the same type (`matrix`, `table`, or `timetable`) as the input Data.

## mrdivide

Financial time series matrix division

---

**Note** `mrdivide` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = tsobj_1 / tsobj_2
```

```
newfts = tsobj / array
```

```
newfts = array / tsobj
```

### Arguments

|                               |                                                                                                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsobj_1, tsobj_2</code> | A pair of financial time series objects.                                                                                                                                        |
| <code>array</code>            | A scalar value or array with number of rows equal to the number of dates in <code>tsobj</code> and number of columns equal to the number of data series in <code>tsobj</code> . |

### Description

The `mrdivide` method divides element by element the components of one financial time series object (`tsobj`) by the components of the other. You can also divide the whole object by an array or divide a financial time series object into an array.

If an object is to be divided by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is divided by another object, follows the order of the first object.

`newfts = tsobj_1 / tsobj_2` divides financial time series objects element by element.

`newfts = tsobj / array` divides a financial time series object element by element by an array.

`newfts = array / tsobj` divides an array element by element by a financial time series object.

For financial time series objects, the `mrdivide` operation is identical to the `rdivide` operation.

## Syntax

```
newfts = tsojb_1 * tsojb_2
```

```
newfts = tsojb * array
```

```
newfts = array * tsojb
```

## Arguments

|                               |                                                                                                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsojb_1, tsojb_2</code> | A pair of financial time series objects.                                                                                                                                        |
| <code>array</code>            | A scalar value or array with number of rows equal to the number of dates in <code>tsojb</code> and number of columns equal to the number of data series in <code>tsojb</code> . |

## Description

The `mtimes` method multiplies element by element the components of one financial time series object (`tsojb`) by the components of the other. You can also multiply the entire object by an array.

If an object is to be multiplied by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is multiplied by another object, follows the order of the first object.

`newfts = tsojb_1 * tsojb_2` multiplies financial time series objects element by element.

`newfts = tsojb * array` multiplies a financial time series object element by element by an array.

`newfts = array * tsojb` and `newfts = array / tsojb` multiplies an array element by element by a financial time series object.

For financial time series objects, the `mtimes` operation is identical to the `times` operation.

## mvnrfish

Fisher information matrix for multivariate normal or least-squares regression

### Syntax

`Fisher = mvnrfish(Data,Design,Covariance,MatrixFormat,CovarFormat)`

### Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data         | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Design       | <p>A matrix or a cell array that handles two model structures:</p> <ul style="list-style-type: none"> <li>• If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>• If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> <p>If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.</p> |
| Covariance   | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the residuals of the regression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| MatrixFormat | <p>(Optional) Character vector that identifies parameters to be included in the Fisher information matrix:</p> <ul style="list-style-type: none"> <li>• <code>full</code> — Default format. Compute the full Fisher information matrix for both model and covariance parameter estimates.</li> <li>• <code>paramonly</code> — Compute only components of the Fisher information matrix associated with the model parameter estimates.</li> </ul>                                                                                                                                                                                                       |
| CovarFormat  | <p>(Optional) Character vector that specifies the format for the covariance matrix. The choices are:</p> <ul style="list-style-type: none"> <li>• <code>'full'</code> — Default method. The covariance matrix is a full matrix.</li> <li>• <code>'diagonal'</code> — The covariance matrix is a diagonal matrix.</li> </ul>                                                                                                                                                                                                                                                                                                                            |

### Description

`Fisher = mvnrfish(Data,Design,Covariance,MatrixFormat,CovarFormat)` computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates.

Fisher is a TOTALPARAMS-by-TOTALPARAMS Fisher information matrix. The size of TOTALPARAMS depends on MatrixFormat and on current parameter estimates. If MatrixFormat = 'full',

$$\text{TOTALPARAMS} = \text{NUMPARAMS} + \text{NUMSERIES} * (\text{NUMSERIES} + 1)/2$$

If MatrixFormat = 'paramonly',

$$\text{TOTALPARAMS} = \text{NUMPARAMS}$$

---

**Note** mvnrfish operates slowly if you calculate the full Fisher information matrix.

---

## Introduced in R2006a

## mvnrmle

Multivariate normal regression (ignore missing data)

### Syntax

[Parameters,Covariance,Resid,Info] = mvnrmle(Data,Design,MaxIterations,TolParam,TolObj,Covar0,Cov

### Arguments

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data          | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored. (Use mvnrmle to handle missing data.)                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Design        | <p>Matrix or a cell array that handles two model structures:</p> <ul style="list-style-type: none"> <li>• If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>• If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> <p>If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.</p> |
| MaxIterations | (Optional) Maximum number of iterations for the estimation algorithm. Default value is 100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| TolParam      | (Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates. Default value is sqrt(eps) which is about 1.0e-8 for double precision. The convergence test for changes in model parameters is                                                                                                                                                                                                                                                                                                                                                                                                              |
|               | $\ Param_k - Param_{k-1}\  < TolParam \times (1 + \ Param_k\ )$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|               | where Param represents the output Parameters, and iteration $k = 2, 3, \dots$ . Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.                                                                                                                                                                                                                                                                                                                                          |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TolObj      | (Optional) Convergence tolerance for estimation algorithm based on changes in the objective function. Default value is $\text{eps} \wedge 3/4$ which is about $1.0\text{e-}12$ for double precision. The convergence test for changes in the objective function is<br>$ Obj_k - Obj_{k-1}  < TolObj \times (1 +  Obj_k )$ for iteration $k = 2, 3, \dots$ . Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam $\leq 0$ and TolObj $\leq 0$ , do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests. |
| Covar0      | (Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied initial or known estimate for the covariance matrix of the regression residuals.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| CovarFormat | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"> <li>'full' — Default method. Compute the full covariance matrix.</li> <li>'diagonal' — Force the covariance matrix to be a diagonal matrix.</li> </ul>                                                                                                                                                                                                                                                                                                        |

## Description

`[Parameters, Covariance, Resid, Info] = mvnrmlc(Data, Design, MaxIterations, TolParam, TolObj, Covar0, CovarFormat)` estimates a multivariate normal regression model without missing data. The model has the form

$$Data_k \sim N(\text{Design}_k \times \text{Parameters}, \text{Covariance})$$

for samples  $k = 1, \dots, \text{NUMSAMPLES}$ .

`mvnrmlc` estimates a NUMPARAMS-by-1 column vector of model parameters called `Parameters`, and a NUMSERIES-by-NUMSERIES matrix of covariance parameters called `Covariance`.

`mvnrmlc(Data, Design)` with no output arguments plots the log-likelihood function for each iteration of the algorithm.

To summarize the outputs of `mvnrmlc`:

- `Parameters` is a NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.
- `Covariance` is a NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression model's residuals.
- `Resid` is a NUMSAMPLES-by-NUMSERIES matrix of residuals from the regression. For any row with missing values in `Data`, the corresponding row of residuals is represented as all NaN missing values, since this routine ignores rows with NaN values.

Another output, `Info`, is a structure that contains additional information from the regression. The structure has these fields:

- `Info.Obj` - A variable-extent column vector, with no more than `MaxIterations` elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last

value in this vector, `Obj(end)`, is the terminal estimate of the objective function. If you do maximum likelihood estimation, the objective function is the log-likelihood function.

- `Info.PrevParameters` - `NUMPARAMS`-by-1 column vector of estimates for the model parameters from the iteration just before the terminal iteration.
- `Info.PrevCovariance` - `NUMSERIES`-by-`NUMSERIES` matrix of estimates for the covariance parameters from the iteration just before the terminal iteration.

## Notes

`mvnrml` does not accept an initial parameter vector, because the parameters are estimated directly from the first iteration onward.

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a `NUMPARAMS` row vector.
- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix.

These points concern how `Design` handles missing data:

- Although `Design` should not have NaN values, ignored samples due to NaN values in `Data` are also ignored in the corresponding `Design` array.
- If `Design` is a 1-by-1 cell array, which has a single `Design` matrix for each sample, no NaN values are permitted in the array. A model with this structure must have `NUMSERIES ≥ NUMPARAMS` with `rank(Design{1}) = NUMPARAMS`.
- Two functions for handling missing data, `ecmmvnrml` and `ecmlsrml`, are stricter about the presence of NaN values in `Design`.

Use the estimates in the optional output structure `Info` for diagnostic purposes.

## mvnrobj

Log-likelihood function for multivariate normal regression without missing data

### Syntax

Objective = mvnrobj(Data,Design,Parameters,Covariance,CovarFormat)

### Arguments

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data        | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored. (Use <code>ecmmvnrml</code> to handle missing data.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Design      | <p>A matrix or a cell array that handles two model structures:</p> <ul style="list-style-type: none"> <li>• If <code>NUMSERIES = 1</code>, <code>Design</code> is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>• If <code>NUMSERIES ≥ 1</code>, <code>Design</code> is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> <p>If <code>Design</code> has a single cell, it is assumed to have the same <code>Design</code> matrix for each sample. If <code>Design</code> has more than one cell, each cell contains a <code>Design</code> matrix for each sample.</p> |
| Parameters  | NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Covariance  | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the residuals of the regression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| CovarFormat | <p>(Optional) Character vector that specifies the format for the covariance matrix. The choices are:</p> <ul style="list-style-type: none"> <li>• <code>'full'</code> — Default method. The covariance matrix is a full matrix.</li> <li>• <code>'diagonal'</code> — The covariance matrix is a diagonal matrix.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### Description

Objective = mvnrobj(Data,Design,Parameters,Covariance,CovarFormat) computes the log-likelihood function based on current maximum likelihood parameter estimates without missing data. Objective is a scalar that contains the log-likelihood function.

### Notes

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a NUMPARAMS row vector.

- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix.

Although `Design` should not have NaN values, ignored samples due to NaN values in `Data` are also ignored in the corresponding `Design` array.

## Introduced in R2006a

## mvnrstd

Evaluate standard errors for multivariate normal regression model

### Syntax

```
[StdParameters,StdCovariance] = mvnrstd(Data,Design,Covariance,CovarFormat)
```

### Arguments

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data        | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored. (Use <code>ecmmvnrml</code> to handle missing data.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Design      | A matrix or a cell array that handles two model structures: <ul style="list-style-type: none"> <li>• If <code>NUMSERIES = 1</code>, <code>Design</code> is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>• If <code>NUMSERIES ≥ 1</code>, <code>Design</code> is a cell array. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> <p>If <code>Design</code> has a single cell, it is assumed to have the same <code>Design</code> matrix for each sample. If <code>Design</code> has more than one cell, each cell contains a <code>Design</code> matrix for each sample.</p> |
| Covariance  | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression residuals.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| CovarFormat | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"> <li>• 'full' — Default method. The covariance matrix is a full matrix.</li> <li>• 'diagonal' — The covariance matrix is a diagonal matrix.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### Description

`[StdParameters,StdCovariance] = mvnrstd(Data,Design,Covariance,CovarFormat)` evaluates standard errors for a multivariate normal regression model without missing data. The model has the form

$$Data_k \sim N(\text{Design}_k \times \text{Parameters}, \text{Covariance})$$

for samples  $k = 1, \dots, \text{NUMSAMPLES}$ .

`mvnrstd` computes two outputs:

- `StdParameters` is a NUMPARAMS-by-1 column vector of standard errors for each element of `Parameters`, the vector of estimated model parameters.

- StdCovariance is a NUMSERIES-by-NUMSERIES matrix of standard errors for each element of Covariance, the matrix of estimated covariance parameters.

---

**Note** mvnrstd operates slowly when you calculate the standard errors associated with the covariance matrix Covariance.

---

## Notes

You can configure Design as a matrix if NUMSERIES = 1 or as a cell array if NUMSERIES ≥ 1.

- If Design is a cell array and NUMSERIES = 1, each cell contains a NUMPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

## nancov

Covariance ignoring NaNs

---

**Note** `nancov` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
c = nancov(X)
```

```
c = nancov(..., 'pairwise')
```

### Arguments

|   |                                |
|---|--------------------------------|
| X | Financial times series object. |
| Y | Financial times series object. |

### Description

`nancov` for financial times series objects is based on the Statistics and Machine Learning Toolbox function `nancov`. See `nancov`.

`c = nancov(X)`, if `X` is a financial time series object with one series and returns the sample variance of the values in `X`, treating NaNs as missing values. For a financial time series object containing more than one series, where each row is an observation and each series a variable, `nancov(X)` is the covariance matrix computing using rows of `X` that do not contain any NaN values. `nancov(X, Y)`, where `X` and `Y` are financial time series objects with the same number of elements, is equivalent to `nancov([X(:) Y(:)])`.

`nancov(X)` or `nancov(X, Y)` normalizes by  $(N-1)$  if  $N > 1$ , where  $N$  is the number of observations after removing missing values. This makes `nancov` the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For  $N = 1$ , `cov` normalizes by  $N$ .

`nancov(X, 1)` or `nancov(X, Y, 1)` normalizes by  $N$  and produces the second moment matrix of the observations about their mean. `nancov(X, Y, 0)` is the same as `nancov(X, Y)`, and `nancov(X, 0)` is the same as `nancov(X)`.

`c = nancov(..., 'pairwise')` computes  $c(i, j)$  using rows with no NaN values in columns  $i$  or  $j$ . The result may not be a positive definite matrix. `c = nancov(..., 'complete')` is the default, and it omits rows with any NaN values, even if they are not in column  $i$  or  $j$ . The mean is removed from each column before calculating the result.

### Examples

To generate random data having nonzero covariance between column 4 and the other columns:

```
x = randn(30, 4);           % uncorrelated data
x(:, 4) = sum(x, 2);       % introduce correlation
```

```
x(2, 3) = NaN; % introduce one missing value
f = fints('today:today+29', x); % create a fints object using x
c = nancov(f) % compute sample covariance
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

## nanmax

Maximum ignoring NaNs

---

**Note** `nanmax` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
m = nanmax(X)
```

```
[m,ndx] = nanmax(X)
```

```
m = nanmax(X,Y)
```

```
[m,ndx] = nanmax(X,[],DIM)
```

### Arguments

|     |                                          |
|-----|------------------------------------------|
| X   | Financial times series object.           |
| Y   | Financial times series object or scalar. |
| DIM | Dimension of X.                          |

### Description

`nanmax` for financial times series objects is based on the Statistics and Machine Learning Toolbox function `nanmax`. See `nanmax`.

`m = nanmax(X)` returns the maximum of a financial time series object `X` with NaNs treated as missing. `m` is the largest non-NaN element in `X`.

`[m,ndx] = nanmax(X)` returns the indices of the maximum values in `X`. If the values along the first nonsingleton dimension contain multiple maximal elements, the index of the first one is returned.

`m = nanmax(X,Y)` returns an array the same size as `X` and `Y` with the largest elements taken from `X` or `Y`. Only `Y` can be a scalar double.

`[m,ndx] = nanmax(X,[],DIM)` operates along the dimension `DIM`.

### Examples

To compute `nanmax` for the following dates:

```
dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;
```

```
[nmax, maxidx] = nanmax(f)
```

```

## nanmean

Mean ignoring NaNs

---

**Note** `nanmean` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
m = nanmean(X)
```

```
m = nanmean(X,DIM)
```

### Arguments

|     |                                                   |
|-----|---------------------------------------------------|
| X   | Financial times series object.                    |
| DIM | Dimension along which the operation is conducted. |

### Description

`nanmean` for financial times series objects is based on the Statistics and Machine Learning Toolbox function `nanmean`. See `nanmean`.

`m = nanmean(X)` returns the sample mean of a financial time series object `X`, treating NaNs as missing values. `m` is a row vector containing the mean value of the non-NaN elements in each series.

`m = nanmean(X,DIM)` takes the mean along dimension `DIM` of `X`.

### Examples

To compute `nanmean` for the following dates:

```
dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;
```

```
nmean = nanmean(f)
```

## nanmedian

Median ignoring NaNs

---

**Note** `nanmedian` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
m = nanmedian(X)
```

```
m = nanmedian(X,DIM)
```

### Arguments

|     |                                                   |
|-----|---------------------------------------------------|
| X   | Financial time series object.                     |
| DIM | Dimension along which the operation is conducted. |

### Description

`nanmedian` for financial time series objects is based on the Statistics and Machine Learning Toolbox function `nanmedian`. See `nanmedian`.

`m = nanmedian(X)` returns the sample median of a financial time series object `X`, treating NaNs as missing values. `m` is a row vector containing the median value of non-NaN elements in each column.

`m = nanmedian(X,DIM)` takes the median along the dimension `DIM` of `X`.

### Examples

To compute `nanmedian` for the following dates:

```
dates = {'01-Jan-2007'; '02-Jan-2007'; '03-Jan-2007'; '04-Jan-2007'};
f = fints(dates, magic(4));
f.series1(1) = nan;
f.series2(2) = nan;
f.series3([1 3]) = nan;
```

```
nmedian = nanmedian(f)
```

## nanmin

Minimum ignoring NaNs

---

**Note** `nanmin` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
m = nanmin(X)
[m,ndx] = nanmin(X)
m = nanmin(X,Y)
[m,ndx] = nanmin(X,[],DIM)
```

### Arguments

|     |                                                   |
|-----|---------------------------------------------------|
| X   | Financial times series object.                    |
| Y   | Financial times series object or scalar.          |
| DIM | Dimension along which the operation is conducted. |

### Description

`nanmin` for financial times series objects is based on the Statistics and Machine Learning Toolbox function `nanmin`. See `nanmin`.

`m = nanmin(X)` returns the minimum of a financial time series object `X` with NaNs treated as missing. `m` is the smallest non-NaN element in `X`.

`[m,ndx] = nanmin(X)` returns the indices of the minimum values in `X`. If the values along the first nonsingleton dimension contain multiple elements, the index of the first one is returned.

`m = nanmin(X,Y)` returns an array the same size as `X` and `Y` with the smallest elements taken from `X` or `Y`. Only `Y` can be a scalar double.

`[m,ndx] = nanmin(X, [], DIM)` operates along the dimension `DIM`.

### Examples

To compute `nanmin` for the following dates:

```
dates = {'01-Jan-2007'; '02-Jan-2007'; '03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;

[nmin, minidx] = nanmin(f)
```

## nanstd

Standard deviation ignoring NaNs

---

**Note** `nanstd` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
y = nanstd(X)
```

```
y = nanstd(X,1)
```

```
y = nanstd(X,FLAG,DIM)
```

### Arguments

|      |                                                   |
|------|---------------------------------------------------|
| X    | Financial times series object.                    |
| FLAG | Normalization flag.                               |
| DIM  | Dimension along which the operation is conducted. |

### Description

`nanstd` for financial times series objects is based on the Statistics and Machine Learning Toolbox function `nanstd`. See `nanstd`.

`y = nanstd(X)` returns the sample standard deviation of the values in a financial time series object `X`, treating NaNs as missing values. `y` is the standard deviation of the non-NaN elements of `X`.

`nanstd` normalizes `y` by  $(N - 1)$ , where  $N$  is the sample size. This is the square root of an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples and data are missing at random.

`y = nanstd(X,1)` normalizes by  $N$  and produces the square root of the second moment of the sample about its mean. `nanstd(X,0)` is the same as `nanstd(X)`.

`y = nanstd(X,flag,dim)` takes the standard deviation along the dimension `dim` of `X`. Set the value of `flag` to `0` to normalize the result by  $n - 1$ ; set the value of `flag` to `1` to normalize the result by  $n$ .

### Examples

To compute `nanstd` for the following dates:

```
dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;
```

```
nstd = nanstd(f)
```

### Description

`nanvar` for financial times series objects is based on the Statistics and Machine Learning Toolbox function `nanvar`. See `nanvar`.

`y = nanvar(X)` returns the sample variance of the values in a financial time series object `X`, treating NaNs as missing values. `y` is the variance of the non-NaN elements of each series in `X`.

`nanvar` normalizes `y` by  $N - 1$  if  $N > 1$ , where  $N$  is the sample size of the non-NaN elements. This is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples, and data are missing at random. For  $N = 1$ , `y` is normalized by  $N$ .

`y = nanvar(X,1)` normalizes by  $N$  and produces the second moment of the sample about its mean. `nanvar(X, 0)` is the same as `nanvar(X)`.

`y = nanvar(X,W)` computes the variance using the weight vector `W`. The length of `W` must equal the length of the dimension over which `nanvar` operates, and its non-NaN elements must be nonnegative. Elements of `X` corresponding to NaN elements of `W` are ignored.

`y = nanvar(X,W,DIM)` takes the variance along dimension `DIM` of `X`.

### Examples

To compute `nanvar`:

```
f = fints((today:today+1)', [4 -2 1; 9 5 7])
f.series1(1) = nan;
f.series3(2) = nan;
```

```
nvar = nanvar(f)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsasgn (line 118)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsasgn (line 118)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/nanvar (line 28)
```

```
nvar =
      0    24.5000      0
```

**Introduced before R2006a**

## negvalidx

Negative volume index

---

**Note** `negvalidx` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
volume = negvalidx(Data)
volume = negvalidx( ___,Name,Value)
```

### Description

`volume = negvalidx(Data)` calculates the negative volume index from the series of closing stock prices and trade volume.

`volume = negvalidx( ___,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Calculate the Negative Volume Index for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
volume = negvalidx(TMW);
plot(volume.Time,volume.NegativeVolume)
title('Negative Volume Index for TMW')
```

## Input Arguments

### Data — Data with closing prices and trade volume

matrix | table | timetable

Data with closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-2 with closing prices and trade volume stored in the first and second columns. Timetables and tables with M rows must contain variables named 'Close' and 'Volume' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `volume = negvalidx(TMW, 'InitialValue', 500)`

### InitialValue — Initial value for negative volume index

100 (default) | positive integer

Initial value for negative volume index, specified as the comma-separated pair consisting of 'InitialValue' and a scalar positive integer.

Data Types: double

## Output Arguments

### **volume — Negative volume index**

matrix | table | timetable

Negative volume index, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## More About

### **Negative Volume Index**

Negative volume index shows the days when the trading volume of a particular security is substantially lower than other days.

## nomrr

Nominal rate of return

### Syntax

Return = nomrr(Rate,NumPeriods)

### Arguments

|            |                                                                |
|------------|----------------------------------------------------------------|
| Rate       | Effective annual percentage rate. Enter as a decimal fraction. |
| NumPeriods | Number of compounding periods per year, an integer.            |

### Description

Return = nomrr(Rate,NumPeriods) calculates the nominal rate of return.

### Examples

#### Calculate the Nominal Rate of Return

This example shows how to calculate the nominal rate of return based on an effective annual percentage rate of 9.38% compounded monthly.

Return = nomrr(0.0938, 12)

Return = 0.0900

### See Also

**Introduced before R2006a**

## nweekdate

Date of specific occurrence of weekday in month

### Syntax

```
Date = nweekdate(n,Weekday,Year,Month)
Date = nweekdate( ____,Same,outputType)
```

### Description

`Date = nweekdate(n,Weekday,Year,Month)` returns the date number for the specific occurrence of the weekday in the given `Year` and `Month`.

Any input argument can contain multiple values, but if so, all other input arguments must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by-n vector of integers, then `Month` must be a 1-by-n vector of integers or a single integer. `Date` is then a 1-by-n vector of date numbers.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

`Date = nweekdate( ____,Same,outputType)` returns the date number for the specific occurrence of the weekday in the given `Year` and `Month` and also contains the optional arguments for weekday `Same` and `outputType`.

### Examples

#### Determine the Date of a Specific Occurrence of a Weekday in a Month

Find the first Thursday in May 2001.

```
Date = nweekdate(1, 5, 2001, 5);
datestr(Date)
```

```
ans =
'03-May-2001'
```

Find the first Thursday in May 2001 returned as a datetime array.

```
Date = nweekdate(1, 5, 2001, 5,[],'datetime')
```

```
Date = datetime
    03-May-2001
```

Find the first Thursday in a week that also contains a Wednesday in May 2001.

```
Date = nweekdate(2, 5, 2001, 5, 4);
datestr(Date)
```

```
ans =
'10-May-2001'
```

Find the third Monday in February for 2001, 2002, and 2003.

```
Year = [2001:2003];
Date = nweekdate(3, 2, Year, 2);
datestr(Date)
```

```
ans = 3x11 char array
    '19-Feb-2001'
    '18-Feb-2002'
    '17-Feb-2003'
```

## Input Arguments

### **n** — Nth occurrence of weekday in a month

integer with value 1 through 5 | vector of integers with values 1 through 5

Nth occurrence of the weekday in a month, specified as an integer or a vector of integers from 1 through 5.

If *n* is larger than the last occurrence of *Weekday*, the output *Date* = 0.

Data Types: single | double

### **Weekday** — Weekday whose date you seek

integer with value 1 through 7 | vector of integers with values 1 through 7

Weekday whose date you seek, specified as an integer or a vector of integers from 1 through 7.

- 1 — Sunday
- 2 — Monday
- 3 — Tuesday
- 4 — Wednesday
- 5 — Thursday
- 6 — Friday
- 7 — Saturday

Data Types: single | double

### **Year** — Year to determine occurrence of weekday

4-digit integer | vector of 4-digit integers

Year to determine occurrence of weekday, specified as a 4-digit integer or vector of 4-digit integers.

Data Types: single | double

### **Month** — Month to determine occurrence of weekday

integer with value 1 through 12 | vector of integers with values 1 through 12

Month to determine occurrence of weekday, specified as an integer or vector of integers with values 1 through 12.

Data Types: single | double

**Same — Weekday that must occur in same week with Weekday**

0 = ignore (default) | integer with value 0 through 7 | vector of integers with values 0 through 7

Weekday that must occur in the same week with `Weekday`, specified as an integer or a vector of integers from 0 through 7, where 0 = ignore (default) and 1 through 7 are as for `Weekday`.

Data Types: single | double

**outputType — Year to determine days**

'datenum' (default) | character vector with values 'datenum' or 'datetime'

A character vector specified as either 'datenum' or 'datetime'. The output `Date` is in serial date format if 'datenum' is specified, or datetime format if 'datetime' is specified. By default the output `Date` is in serial date format.

Data Types: single | double

**Output Arguments****Date — Date of specific occurrence of weekday in month**

serial date number | date character vector

Date of specific occurrence of weekday in month, returned as a serial date number or date character vector.

The type of the output for `Date` depends on the input `outputType`. If this variable is 'datenum', `Date` is a serial date number. If `outputType` is 'datetime', then `Date` is a datetime array. By default, `outputType` is set to 'datenum'.

# nyseclosures

New York Stock Exchange closures from 1885 to 2070

## Syntax

```
Closures = nyseclosures
[Closures, SatTransition] = nyseclosures(StartDate, EndDate, WorkWeekFormat)
```

## Description

`Closures = nyseclosures` returns a vector of serial date numbers for all known or anticipated closures from January 1, 1885 to December 31, 2070.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 1952 are based on a 6-day workweek. `nyseclosures` contains all holiday and special non-trading days for the New York Stock Exchange from 1885 through 2070 based on a six-day work week (always closed on Sundays).

`[Closures, SatTransition] = nyseclosures(StartDate, EndDate, WorkWeekFormat)`, using optional input arguments, returns a vector of serial date numbers corresponding to market closures between `StartDate` and `EndDate`, inclusive.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 1952 are based on a 6-day workweek. `nyseclosures` contains all holiday and special non-trading days for the New York Stock Exchange from 1885 through 2070 based on a six-day work week (always closed on Sundays). Use `WorkWeekFormat` to modify the list of dates.

## Examples

### Find NYSE Closures

Find the NYSE closures for 1899:

```
datestr(nyseclosures('1-jan-1899', '31-dec-1899'), 'dd-mmm-yyyy ddd')
```

```
ans = 16x15 char array
'02-Jan-1899 Mon'
'11-Feb-1899 Sat'
'13-Feb-1899 Mon'
'22-Feb-1899 Wed'
'31-Mar-1899 Fri'
'29-May-1899 Mon'
'30-May-1899 Tue'
'03-Jul-1899 Mon'
'04-Jul-1899 Tue'
'04-Sep-1899 Mon'
'29-Sep-1899 Fri'
'30-Sep-1899 Sat'
'07-Nov-1899 Tue'
'25-Nov-1899 Sat'
```

```
'30-Nov-1899 Thu'
'25-Dec-1899 Mon'
```

Find the NYSE closures for 1899 using a datetime array:

```
[Closures,SatTransition] = nyseclosures(datetime('1-jan-1899','Locale','en_US'),'30-Jun-1899')
```

```
Closures = 7x1 datetime
02-Jan-1899
11-Feb-1899
13-Feb-1899
22-Feb-1899
31-Mar-1899
29-May-1899
30-May-1899
```

```
SatTransition = datetime
29-Sep-1952
```

Find the NYSE closure dates using the 'Archaic' value for WorkWeekFormat:

```
datestr(nyseclosures('1-sep-1952','31-oct-1952','a'),1)
```

```
ans = 10x11 char array
'01-Sep-1952'
'06-Sep-1952'
'13-Sep-1952'
'20-Sep-1952'
'27-Sep-1952'
'04-Oct-1952'
'11-Oct-1952'
'13-Oct-1952'
'18-Oct-1952'
'25-Oct-1952'
```

The exchange was closed on Saturdays for much of 1952 before the official transition to a 5-day workweek.

## Input Arguments

### StartDate — Start date

start of default date range, January 1, 1885 (default) | serial date number | date character vector | datetime object

Start date, specified using a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### EndDate — End date

end of default date range, December 31, 2070 (default) | serial date number | date character vector | datetime object

End date, specified using a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### **WorkWeekFormat — Method to handle the workweek**

'Implicit' (default) | date character vector with values 'Modern', 'Implicit', or 'Archaic'

Method to handle the workweek, specified using a date character vector with values 'Modern', 'Implicit', or 'Archaic'. This function accepts the first letter for each method as input and is not case-sensitive. Acceptable values are:

- 'Modern' — 5-day workweek with all Saturday trading days removed.
- 'Implicit' — 6-day workweek until 1952 and 5-day week afterward (no need to exclude Saturdays).
- 'Archaic' — 6-day workweek throughout and Saturdays treated as closures after 1952.

Data Types: char

## **Output Arguments**

### **Closures — Market closures between StartDate and EndDate, inclusive**

vector

Market closures between the StartDate and EndDate, inclusive, returned as a vector of dates.

If StartDate or EndDate are all either serial date numbers or date character vectors, both Closures and SatTransition are returned as serial date numbers. If either StartDate or EndDate are datetime arrays, both Closures and SatTransition are returned as datetime arrays.

If both StartDate and EndDate are not specified or are empty, Closures contains all known or anticipated closures from January 1, 1885 to December 31, 2070 based on a WorkWeekFormat of 'implicit'.

### **SatTransition — Date of transition for New York Stock Exchange from 6-day workweek to 5-day workweek**

serial date number | datetime array

Date of transition for the New York Stock Exchange from a 6-day workweek to a 5-day workweek, returned as the date September 29, 1952 (serial date number 713226).

If StartDate or EndDate are all either serial date numbers or date character vectors, both Closures and SatTransition are returned as serial date numbers. If either StartDate or EndDate are datetime arrays, both Closures and SatTransition are returned as datetime arrays.

## **More About**

### **holidays**

The holidays function is based on a modern 5-day workweek.

This function contains all holidays and special nontrading days for the New York Stock Exchange from January 1, 1885 to December 31, 2070.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 2070 should include Saturday trading days. To capture these dates, use

nyseclosures. The results from holidays and nyseclosures are identical if the WorkWeekFormat in nyseclosures is 'Modern'.

# onbalvol

On-Balance Volume (OBV)

---

**Note** `onbalvol` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
volume = onbalvol(Data)
```

## Description

`volume = onbalvol(Data)` calculates the On-Balance Volume from the series of closing stock prices and trade volume.

## Examples

### Calculate the On-Balance Volume for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
volume = onbalvol(TMW);
plot(volume.Time,volume.OnBalanceVolume)
title('On-Balance Volume for TMW')
```

## Input Arguments

### Data — Data for closing prices and trade volume

matrix | table | timetable

Data for closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-2 matrix of closing prices and trade volume stored in the first and second columns. Timetables and tables with M rows must contain variables named 'Close' and 'Volume' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### volume — On-Balance Volume

matrix | table | timetable

On-Balance Volume, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## References

## oprofit

Option profit

### Syntax

```
Profit = oprofit(AssetPrice,Strike,Cost,PosFlag,OptType)
```

### Description

`Profit = oprofit(AssetPrice,Strike,Cost,PosFlag,OptType)` returns the profit of an option.

### Examples

#### Calculate the Profit of an Option

This example shows how to return the profit of an option. For example, consider buying (going long on) a call option with a strike price of \$90 on an underlying asset with a current price of \$100 for a cost of \$4.

```
Profit = oprofit(100, 90, 4, 0, 0)
```

```
Profit = 6
```

### Input Arguments

#### AssetPrice — Asset price

numeric

Asset price, specified as a scalar or a NINST-by-1 vector.

Data Types: double

#### Strike — Strike or exercise price

numeric

Strike or exercise price, specified as a scalar or a NINST-by-1 vector.

Data Types: double

#### Cost — Cost of option

numeric

Cost of the option, specified as a scalar or a NINST-by-1 vector.

Data Types: double

#### PosFlag — Option position

0 = long | 1 = short

Option position, specified as a scalar or a NINST-by-1 vector using the values 0 (long) or 1 (short).

Data Types: `logical`

**OptType – Option type**

0 = call option | 1 = put option

Option type, specified as a scalar or a NINST-by-1 vector using the values 0 (call option) or 1 (put option).

Data Types: `logical`

## Output Arguments

**Profit – Option profit**

vector

Option profit, returned as a scalar or a NINST-by-1 vector.

## See Also

## payadv

Periodic payment given number of advance payments

### Syntax

Payment = payadv(Rate, NumPeriods, PresentValue, FutureValue, Advance)

### Arguments

|              |                                                                                                        |
|--------------|--------------------------------------------------------------------------------------------------------|
| Rate         | Lending or borrowing rate per period. Enter as a decimal fraction. Must be greater than or equal to 0. |
| NumPeriods   | Number of periods in the life of the instrument.                                                       |
| PresentValue | Present value of the instrument.                                                                       |
| FutureValue  | Future value or target value to be attained after NumPeriods periods.                                  |
| Advance      | Number of advance payments. If the payments are made at the beginning of the period, add 1 to Advance. |

### Description

Payment = payadv(Rate, NumPeriods, PresentValue, FutureValue, Advance) returns the periodic payment given a number of advance payments.

### Examples

#### Compute the Periodic Payment

This example shows how to compute the periodic payment, given a number of advance payments. For example, the present value of a loan is \$1000.00 and it will be paid in full in 12 months. The annual interest rate is 10% and three payments are made at closing time.

```
Payment = payadv(0.1/12, 12, 1000, 0, 3)
```

```
Payment = 85.9389
```

### See Also

Introduced before R2006a

# payodd

Payment of loan or annuity with odd first period

## Syntax

Payment = payodd(Rate,NumPeriods,PresentValue,FutureValue,Days)

## Arguments

|              |                                                                       |
|--------------|-----------------------------------------------------------------------|
| rate         | Interest rate per period. Enter as a decimal fraction.                |
| NumPeriods   | Number of periods in the life of the instrument.                      |
| PresentValue | Present value of the instrument.                                      |
| FutureValue  | Future value or target value to be attained after NumPeriods periods. |
| Days         | Actual number of days until the first payment is made.                |

## Description

Payment = payodd(Rate,NumPeriods,PresentValue,FutureValue,Days) returns the payment for a loan or annuity with an odd first period.

## Examples

### Compute the Payment for a Loan or Annuity With an Odd First Period

This example shows how to return the payment for a loan or annuity with an odd first period. For example, consider a two-year loan for \$4000 that has an annual interest rate of 11% and the first payment will be made in 36 days.

```
Payment = payodd(0.11/12, 24, 4000, 0, 36)
```

```
Payment = 186.7731
```

## See Also

amortize | payadv | payper

## Topics

“Analyzing and Computing Cash Flows” on page 2-14

Introduced before R2006a

## payper

Periodic payment of loan or annuity

### Syntax

Payment = payper(Rate, NumPeriods, PresentValue, FutureValue, Due)

### Arguments

|              |                                                                                               |
|--------------|-----------------------------------------------------------------------------------------------|
| Rate         | Interest rate per period. Enter as a decimal fraction.                                        |
| NumPeriods   | Number of payment periods in the life of the instrument.                                      |
| PresentValue | Present value of the instrument.                                                              |
| FutureValue  | (Optional) Future value or target value to be attained after NumPeriods periods. Default = 0. |
| Due          | (Optional) When payments are due: 0 = end of period (default), or 1 = beginning of period.    |

### Description

Payment = payper(Rate, NumPeriods, PresentValue, FutureValue, Due) returns the periodic payment of a loan or annuity. An annuity is a series of payments over a period of time. The payments are usually in equal amounts and usually at regular intervals such as quarterly, semiannually, or annually.

### Examples

#### Compute the Periodic Payment of a Loan or Annuity

This example shows how to find the monthly payment for a three-year loan of \$9000 with an annual interest rate of 11.75%.

```
Payment = payper(0.1175/12, 36, 9000, 0, 0)
```

```
Payment = 297.8553
```

# payuni

Uniform payment equal to varying cash flow

## Syntax

```
Series = payuni(CashFlow,Rate)
```

## Arguments

|          |                                                                                                                    |
|----------|--------------------------------------------------------------------------------------------------------------------|
| CashFlow | A vector of varying cash flows. Include the initial investment as the initial cash flow value (a negative number). |
| Rate     | Periodic interest rate. Enter as a decimal fraction.                                                               |

## Description

Series = payuni(CashFlow,Rate) returns the uniform series value of a varying cash flow.

## Examples

This cash flow represents the yearly income from an initial investment of \$10,000. The annual interest rate is 8%.

|        |        |
|--------|--------|
| Year 1 | \$2000 |
| Year 2 | \$1500 |
| Year 3 | \$3000 |
| Year 4 | \$3800 |
| Year 5 | \$5000 |

To calculate the uniform series value

```
Series = payuni([-10000 2000 1500 3000 3800 5000], 0.08)
```

returns

```
Series =  
429.63
```

## pcalims

Linear inequalities for individual asset allocation

### Syntax

```
[A,b] = pcalims(AssetMin,AssetMax,NumAssets)
```

### Arguments

|           |                                                                                             |
|-----------|---------------------------------------------------------------------------------------------|
| AssetMin  | Scalar or NASSETS vector of minimum allocations in each asset. NaN indicates no constraint. |
| AssetMax  | Scalar or NASSETS vector of maximum allocations in each asset. NaN indicates no constraint. |
| NumAssets | (Optional) Number of assets. Default = length of AssetMin or AssetMax.                      |

### Description

As an alternative to `pcalims`, use the Portfolio object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see “Portfolio Object Workflow” on page 4-16.

`[A,b] = pcalims(AssetMin,AssetMax,NumAssets)` specifies the lower and upper bounds of portfolio allocations in each of `NumAssets` available asset investments.

`A` is a matrix and `b` is a vector such that  $A * \text{PortWts}' \leq b$ , where `PortWts` is a 1-by-NASSETS vector of asset allocations.

If `pcalims` is called with fewer than two output arguments, the function returns `A` concatenated with `b` `[A,b]`.

### Examples

Set the minimum weight in every asset to 0 (no short-selling), and set the maximum weight of IBM stock to 0.5 and CSCO to 0.8, while letting the maximum weight in INTC float.

| Asset          | IBM | INTC | CSCO |
|----------------|-----|------|------|
| Minimum Weight | 0   | 0    | 0    |
| Maximum Weight | 0.5 |      | 0.8  |

```
AssetMin = 0
AssetMax = [0.5 NaN 0.8]
[A,b] = pcalims(AssetMin, AssetMax)
```

```
A =
     1     0     0
     0     0     1
```

```

-1    0    0
 0    -1   0
 0     0   -1

```

b =

```

0.5000
0.8000
 0
 0
 0

```

Portfolio weights of 50% in IBM and 50% in INTC satisfy the constraints.

Set the minimum weight in every asset to 0 and the maximum weight to 1.

| Asset          | IBM | INTC | CSCO |
|----------------|-----|------|------|
| Minimum Weight | 0   | 0    | 0    |
| Maximum Weight | 1   | 1    | 1    |

```

AssetMin = 0
AssetMax = 1
NumAssets = 3

```

```
[A,b] = pcalims(AssetMin, AssetMax, NumAssets)
```

A =

```

 1    0    0
 0    1    0
 0    0    1
-1    0    0
 0   -1    0
 0    0   -1

```

b =

```

1
1
1
0
0
0

```

Portfolio weights of 50% in IBM and 50% in INTC satisfy the constraints.

## pcgcomp

Linear inequalities for asset group comparison constraints

### Syntax

`[A, b] = pcgcomp(GroupA, AtoBmin, AtoBmax, GroupB)`

### Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GroupA<br>GroupB   | Number of groups (NGROUPS) by number of assets (NASSETS) specifications of groups to compare. Each row specifies a group. For a specific group, $\text{Group}(i, j) = 1$ if the group contains asset $j$ ; otherwise, $\text{Group}(i, j) = 0$ .                                                                                                                 |
| AtoBmin<br>AtoBmax | Scalar or NGROUPS-long vectors of minimum and maximum ratios of allocations in GroupA to allocations in GroupB. NaN indicates no constraint between the two groups. Scalar bounds are applied to all group pairs. The total number of assets allocated to GroupA divided by the total number of assets allocated to GroupB is $\geq$ AtoBmin and $\leq$ AtoBmax. |

### Description

As an alternative to `pcgcomp`, use the Portfolio object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see “Portfolio Object Workflow” on page 4-16.

`[A, b] = pcgcomp(GroupA, AtoBmin, AtoBmax, GroupB)` specifies that the ratio of allocations in one group to allocations in another group is at least `AtoBmin` to 1 and at most `AtoBmax` to 1. Comparisons can be made between an arbitrary number of group pairs `NGROUPS` comprising subsets of `NASSETS` available investments.

`A` is a matrix and `b` a vector such that  $A * \text{PortWts}' \leq b$ , where `PortWts` is a 1-by-`NASSETS` vector of asset allocations.

If `pcgcomp` is called with fewer than two output arguments, the function returns `A` concatenated with `b` `[A, b]`.

### Examples

|               |               |               |        |
|---------------|---------------|---------------|--------|
| <b>Asset</b>  | INTC          | XOM           | RD     |
| <b>Region</b> | North America | North America | Europe |
| <b>Sector</b> | Technology    | Energy        | Energy |

| Group         | Min. Exposure | Max. Exposure |
|---------------|---------------|---------------|
| North America | 0.30          | 0.75          |

| Group      | Min. Exposure | Max. Exposure |
|------------|---------------|---------------|
| Europe     | 0.10          | 0.55          |
| Technology | 0.20          | 0.50          |
| Energy     | 0.20          | 0.80          |

Make the North American energy sector compose exactly 20% of the North American investment.

```
%
      INTC  XOM  RD
GroupA = [  0   1   0 ]; % North American Energy
GroupB = [  1   1   0 ]; % North America
```

```
AtoBmin = 0.20;
```

```
AtoBmax = 0.20;
```

```
[A,b] = pcgcomp(GroupA, AtoBmin, AtoBmax, GroupB)
```

```
A =
```

```
    0.2000    -0.8000     0
   -0.2000     0.8000     0
```

```
b =
```

```
    0
    0
```

Portfolio weights of 40% for INTC, 10% for XOM, and 50% for RD satisfy the constraints.

# pcglims

Linear inequalities for asset group minimum and maximum allocation

## Syntax

`[A,b] = pcglims(Groups,GroupMin,GroupMax)`

## Arguments

|          |                                                                                                                                                                                                                                                                |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Groups   | Number of groups (NGROUPS) by number of assets (NASSETS) specification of which assets belong to which group. Each row specifies a group. For a specific group, $\text{Group}(i,j) = 1$ if the group contains asset $j$ ; otherwise, $\text{Group}(i,j) = 0$ . |
| GroupMin | Scalar or NGROUPS-long vectors of minimum and maximum combined allocations in each group. NaN indicates no constraint. Scalar bounds are applied to all groups.                                                                                                |
| GroupMax |                                                                                                                                                                                                                                                                |

## Description

As an alternative to `pcglims`, use the Portfolio object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see “Portfolio Object Workflow” on page 4-16.

`[A,b] = pcglims(Groups, GroupMin, GroupMax)` specifies minimum and maximum allocations to groups of assets. An arbitrary number of groups, NGROUPS, comprising subsets of NASSETS investments, is allowed.

A is a matrix and b a vector such that  $A * \text{PortWts}' \leq b$ , where `PortWts` is a 1-by-NASSETS vector of asset allocations.

If `pcglims` is called with fewer than two output arguments, the function returns A concatenated with b `[A,b]`.

## Examples

|               |               |               |        |
|---------------|---------------|---------------|--------|
| <b>Asset</b>  | INTC          | XOM           | RD     |
| <b>Region</b> | North America | North America | Europe |
| <b>Sector</b> | Technology    | Energy        | Energy |

| Group         | Min. Exposure | Max. Exposure |
|---------------|---------------|---------------|
| North America | 0.30          | 0.75          |
| Europe        | 0.10          | 0.55          |
| Technology    | 0.20          | 0.50          |

| Group  | Min. Exposure | Max. Exposure |
|--------|---------------|---------------|
| Energy | 0.50          | 0.50          |

Set the minimum and maximum investment in various groups.

```
%
Groups = [ INTC  XOM  RD ; % North America
           1    1   0 ; % Europe
           0    0   1 ; % Technology
           1    0   0 ; % Energy
           0    1   1 ];
```

```
GroupMin = [0.30
            0.10
            0.20
            0.50];
```

```
GroupMax = [0.75
            0.55
            0.50
            0.50];
```

```
[A,b] = pcglims(Groups, GroupMin, GroupMax)
```

```
A =
```

```
-1    -1    0
 0     0   -1
-1     0    0
 0    -1   -1
 1     1    0
 0     0    1
 1     0    0
 0     1    1
```

```
b =
```

```
-0.3000
-0.1000
-0.2000
-0.5000
 0.7500
 0.5500
 0.5000
 0.5000
```

Portfolio weights of 50% in INTC, 25% in XOM, and 25% in RD satisfy the constraints.

## pcpval

Linear inequalities for fixing total portfolio value

### Syntax

```
[A,b] = pcpval(PortValue,NumAssets)
```

### Arguments

|           |                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PortValue | Scalar total value of asset portfolio (sum of the allocations in all assets). PortValue = 1 specifies weights as fractions of the portfolio and return and risk numbers as rates instead of value. |
| NumAssets | Number of available asset investments.                                                                                                                                                             |

### Description

As an alternative to `pcpval`, use the `Portfolio` object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-16.

`[A,b] = pcpval(PortValue,NumAssets)` scales the total value of a portfolio of `NumAssets` assets to `PortValue`. All portfolio weights, bounds, return, and risk values except `ExpReturn` and `ExpCovariance` (see `portopt`) are in terms of `PortValue`.

`A` is a matrix and `b` a vector such that  $A * \text{PortWts}' \leq b$ , where `PortWts` is a 1-by-`NumAssets` vector of asset allocations.

If `pcpval` is called with fewer than two output arguments, the function returns `A` concatenated with `b` `[A,b]`.

### Examples

Scale the value of a portfolio of three assets = 1, so all return values are rates and all weight values are in fractions of the portfolio.

```
PortValue = 1;
NumAssets = 3;
```

```
[A,b] = pcpval(PortValue, NumAssets)
```

```
A =
```

```
    1    1    1
   -1   -1   -1
```

```
b =
```

1  
-1

Portfolio weights of 40%, 10%, and 50% in the three assets satisfy the constraints.

## **Introduced before R2006a**

## peravg

Periodic average of FINTS object

---

**Note** `peravg` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
avgfts = peravg(tsobj)
```

```
avgfts = peravg(tsobj,numperiod)
```

```
avgfts = peravg(tsobj,daterange)
```

### Arguments

|                        |                                                                                                             |
|------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>tsobj</code>     | Financial time series object                                                                                |
| <code>numperiod</code> | (Optional) Integer specifying the number of data points over which each periodic average should be averaged |
| <code>daterange</code> | (Optional) Time period over which the data is averaged                                                      |

### Description

`peravg` calculates periodic averages of a financial time series object. Periodic averages are calculated from the values per period defined. If the period supplied is a character vector, it is assumed as a range of date character vector. If the period is entered as numeric, the number represents the number of data points (financial time series periods) to be included in a period for the calculation. For example, if you enter `'01/01/98: :01/01/99'` as the period input argument, `peravg` returns the average of the time series between those dates, inclusive. However, if you enter the number 5 as the period input, `peravg` returns a series of averages from the time series data taken 5 date points (financial time series periods) at a time.

`avgfts = peravg(tsobj,numperiod)` returns a structure `avgfts` that contains the periodic (per `numperiod` periods) average of the financial time series object. `avgfts` has field names identical to the data series names of `tsobj`.

`avgfts = peravg(tsobj,daterange)` returns a structure `avgfts` that contains the periodic (as specified by `daterange`) average of the financial time series object. `avgfts` has field names identical to the data series names of `tsobj`.

---

**Note** `peravg` calculates periodic averages of a FINTS object. Periodic averages are calculated from the values per period defined. If the period supplied is a character vector, it is assumed as a range of date character vectors. If the period is entered as numeric, the number represents the number of data points to be included in a period for the calculation.

---

## Examples

If you enter `01-Jan-2001:03-Jan-2001` as the period input argument, `peravg` returns the average of the time series between those dates, inclusive. However, if you enter the number 5 as the period input, `peravg` returns a series of averages from the time series data, taken 5 date points at a time.

```
%% Create the FINTS object %%
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates, 1), 1), times]);
data = [(1:6)', 2*(1:6)'];
myFts = fints(dates_times, data, {'Data1', 'Data2'}, 1, 'My first FINTS')
```

```
%% Create the FINTS object %%
[p, pFts] = peravg(myFts, 3)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

# periodicreturns

Periodic total returns from total return prices

## Syntax

```
TotalReturn = periodicreturns(TotalReturnPrices)
TotalReturn = periodicreturns( ____, Period)
```

## Description

`TotalReturn = periodicreturns(TotalReturnPrices)` calculates the daily total returns from a daily total return price series.

`TotalReturn = periodicreturns( ____, Period)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute TotalReturn Using datetime Input for TotalReturnPrices

Compute `TotalReturn` returned as a table using `datetime` input in a table for `TotalReturnPrices`.

```
Dates = datetime(2015,1,1:10,'Locale','en_US');
Prices = [0.01 0.03 0.1 -0.05 0.02 0.07 0.03 -0.01 -0.02 0.01]';
TotalReturnPrices = table(Dates,Prices);
TotalReturn = periodicreturns(TotalReturnPrices)
```

```
TotalReturn=9x2 table
      Dates      Prices
      _____  _____
      02-Jan-2015      2
      03-Jan-2015      2.3333
      04-Jan-2015      -1.5
      05-Jan-2015      -1.4
      06-Jan-2015      2.5
      07-Jan-2015     -0.57143
      08-Jan-2015     -1.3333
      09-Jan-2015      1
      10-Jan-2015     -1.5
```

## Input Arguments

**TotalReturnPrices** — Total return prices for a given security  
matrix | table

Total return prices for a given security, specified as an `NUMOBS-by-NASSETS + 1` matrix where Column 1 contains MATLAB serial date numbers. The remaining columns contain total return price data.

If you specify `TotalReturnPrices` as a table, the first column of the table represents the dates (as either serial date numbers, date character vectors, or datetime arrays) while the other columns represent the returns data. If a table is used, `TotalReturn` is returned as a table.

---

**Note** Although input returns can have dates in either ascending or descending order, output total returns in `TotalReturn` have dates in ascending order, with the earliest date in the first row of `TotalReturn`, and the most recent date in the last row of `TotalReturn`.

---

Data Types: `double` | `table`

### **Period — Periodicity flag used to compute total returns**

'd' (default) | character vector | numeric

(Optional) Periodicity flag used to compute total returns, specified as one of the following values:

- 'd' = daily values (default)
- 'w' = weekly values
- 'm' = monthly values
- $n$  = rolling return periodic values, where  $n$  is an integer

Data Types: `char` | `double`

## **Output Arguments**

### **TotalReturn — Total return values**

matrix | table

Total return values, returned as a `P-by-N` matrix or table consisting of either Dates in column 1 and daily return values in the remaining columns or period-end dates in column 1 and monthly return values in the remaining columns. The format of `TotalReturn` matches the format of the input `TotalReturnPrices`.

# plot

Plot data series

---

**Note** `plot` has been partially removed and will no longer accept a `fints` object (`tsobj`). Use `timetable` or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
plot(tsobj)
hp = plot(tsobj)
plot(tsobj, linefmt)
hp = plot(tsobj, linefmt)
plot(..., volumename, bar)
hp = plot(..., volumename, bar)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsobj</code>      | Financial time series object.                                                                                                                                                                                                                                             |
| <code>linefmt</code>    | (Optional) Line format.                                                                                                                                                                                                                                                   |
| <code>volumename</code> | (Optional) Specifies which data series is the volume series. <code>volumename</code> must be the exact data series name for the volume column (case sensitive).                                                                                                           |
| <code>bar</code>        | (Optional) <ul style="list-style-type: none"> <li><code>bar = 0</code> — (Default) Plot volume as a line.</li> <li><code>bar = 1</code> — Plot volume as a bar chart. The width of each bar is the same as the default in <code>bar</code>, <code>barh</code>.</li> </ul> |

## Description

`plot(tsobj)` plots the data series contained in the object `tsobj`. Each data series is a line. `plot` automatically generates a legend and dates on the x-axis. Grid is turned on by default. `plot` uses the default color order as if plotting a matrix.

The `plot` command automatically creates subplots when multiple time series are encountered, and they differ greatly on their decimal scales. For example, subplots are generated if one time series data set is in the 10s and another is in the 10,000s.

`hp = plot(tsobj)` also returns the handle(s) to the object(s) inside the plot figure. If there are multiple lines in the plot, `hp` is a vector of multiple handles.

`plot(tsobj, linefmt)` plots the data series in `tsobj` using the line format specified. For a list of possible line formats, see `plot`. The plot legend is not generated, but the dates on the x-axis and the

plot grid are. The specified line format is applied to all data series; that is, all data series have the same line type.

`hp = plot(tsoobj, linefmt)` plots the data series in `tsoobj` using the format specified. The plot legend is not generated, but the dates on the x-axis and the plot grid are. The specified line format is applied to all data series, that is, all data series can have the same line type. If there are multiple lines in the plot, `hp` is a vector of multiple handles.

`plot(..., volumename, bar)` also specifies which data series is the volume. The volume is plotted in a subplot below the other data series. If `bar = 1`, the volume is plotted as a bar chart. Otherwise, a line plot is used.

`hp = plot(..., volumename, bar)` returns handles for each line. If `bar = 1`, the handle to the patch for the bars is also returned.

---

**Note** To turn off the legend, enter `legend off` at the MATLAB command line. Once you turn it off, the legend is deleted. To turn it back on, recreate it using the `legend` command as if you are creating it for the first time. To turn off the grid, enter `grid off`. To turn it back on, enter `grid on`.

---

# plotFrontier

Plot efficient frontier

## Syntax

```
[prsk,pret] = plotFrontier(obj)
[prsk,pret] = plotFrontier(obj,NumPorts)
[prsk,pret] = plotFrontier(obj,PortWeights)
[prsk,pret] = plotFrontier(obj,PortRisk,PortReturn)
```

## Description

`[prsk,pret] = plotFrontier(obj)` estimates the efficient frontier with default number of 10 portfolios on the frontier, and plots the corresponding efficient frontier for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`[prsk,pret] = plotFrontier(obj,NumPorts)` estimates the efficient frontier with a specified number portfolios on the frontier, and plots the corresponding efficient frontier. The number of portfolios is defined by `NumPorts`.

`[prsk,pret] = plotFrontier(obj,PortWeights)` estimates efficient portfolio risks and returns with `PortWeights`, and plots the efficient frontier with those portfolios. This syntax assumes that you provide valid efficient portfolio weights as input. `PortWeights` is a `NumAsset-by-NumPorts` matrix.

`[prsk,pret] = plotFrontier(obj,PortRisk,PortReturn)` plots the efficient frontier with the given risks and returns. This syntax assumes that you provide valid inputs for efficient portfolio risks and returns. `PortRisk` and `PortReturn` are vectors with the same size.

---

**Note** `plotFrontier` handles multiple input formats as described above. Given an asset universe with `NumAssets` assets and an efficient frontier with `NumPorts` portfolios, remember that portfolio weights are `NumAsset-by-NumPorts` matrices and that portfolio risks and returns are `NumPorts` column vectors.

---

## Examples

### Plot the Efficient Frontier for the Portfolio Object

Given a portfolio `p`, plot the efficient frontier.

```
load CAPMuniverse
p = Portfolio('AssetList',Assets(1:12));
p = estimateAssetMoments(p, Data(:,1:12),'missingdata',true);
```

```
p = setDefaultConstraints(p);
plotFrontier(p);
```

### Plot the Efficient Frontier for the Portfolio Object with BoundType and MaxNumAssets Constraints

Create a Portfolio object for 12 stocks based on CAPMuniverse.mat.

```
load CAPMuniverse
p0 = Portfolio('AssetList',Assets(1:12));
p0 = estimateAssetMoments(p0, Data(:,1:12),'missingdata',true);
p0 = setDefaultConstraints(p0);
```

Use setMinMaxNumAssets to define a maximum number of 3 assets.

```
pWithMaxNumAssets = setMinMaxNumAssets(p0, [], 3);
```

Use setBounds to define a lower and upper bound and a BoundType of 'Conditional'.

```
pWithConditionalBound = setBounds(p0, 0.1, 0.5,'BoundType', 'Conditional');
```

Use plotFrontier to compare the different portfolio objects.

```
figure;
plotFrontier(p0); hold on;
```

```
plotFrontier(pWithMaxNumAssets); hold on;
plotFrontier(pWithConditionalBound); hold off;
legend('p0', 'with Max 3 assets invested', 'with each asset weight 0 or [0.1, 0.5]', 'location'
```

Define a target return and use `estimateFrontierByReturn` to compare the three portfolio objects.

```
targetRetn = 2.0e-3;
pwgt0 = estimateFrontierByReturn(p0, targetRetn);
pwgtWithMaxNumAssets = estimateFrontierByReturn(pWithMaxNumAssets, targetRetn);
pwgtConditionalBound = estimateFrontierByReturn(pWithConditionalBound, targetRetn);
```

The following table shows the final allocation for specified target return among the three portfolio objects. You can see that the small positions in 'AAPL' and 'HPQ' are avoided in `pwgtConditionalBound`, and only three assets are invested in `pwgtWithMaxNumAssets`.

```
result = table(p0.AssetList', pwgt0, pwgtWithMaxNumAssets, pwgtConditionalBound)
```

```
result=12x4 table
    Var1      pwgt0      pwgtWithMaxNumAssets      pwgtConditionalBound
-----
 {'AAPL'}    0.076791             0                        0.10002
 {'AMZN'}     0                   0                        0
 {'CSCO'}     0                   0                        0
 {'DELL'}     0                   0                        0
 {'EBAY'}     0                   0                        0
 {'GOOG'}    0.44841             0.47297                 0.44254
 {'HPQ'}     0.022406             0                        0
```

|           |         |         |         |
|-----------|---------|---------|---------|
| {'IBM' }  | 0.31139 | 0.34763 | 0.31591 |
| {'INTC' } | 0       | 0       | 0       |
| {'MSFT' } | 0.14101 | 0.1794  | 0.14153 |
| {'ORCL' } | 0       | 0       | 0       |
| {'YH00' } | 0       | 0       | 0       |

### Plot the Efficient Frontier for the PortfolioCVaR Object

Given a PortfolioCVaR p, plot the efficient frontier.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

plotFrontier(p);
```

### Plot Efficient Frontier for PortfolioMAD Object

Given a PortfolioMAD  $p$ , plot the efficient frontier.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

plotFrontier(p);

```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **NumPorts** — Number of points to obtain on efficient frontier

value from hidden property `defaultNumPorts` (default value is 10) (default) | scalar integer

Number of points to obtain on the efficient frontier, specified as a scalar integer.

---

**Note** If no value is specified for `NumPorts`, the default value is obtained from the hidden property `defaultNumPorts` (default value is 10). If `NumPorts = 1`, this function returns the portfolio specified by the hidden property `defaultFrontierLimit` (current default value is 'min').

---

Data Types: double

### **PortRisk — Standard deviations of portfolio returns for each portfolio**

[] (default) | vector

Standard deviations of portfolio returns for each portfolio, specified as a vector.

---

**Note** PortRisk and PortReturn must be vectors with the same size.

---

Data Types: double

### **PortReturn — Means of portfolio returns for each portfolio**

[] (default) | vector

Means of portfolio returns for each portfolio, specified as a vector.

---

**Note** PortRisk and PortReturn must be vectors with the same size.

---

Data Types: double

### **PortWeights — Optimal portfolios on the efficient frontier**

[] (default) | matrix

Optimal portfolios on the efficient frontier, specified as a NumAsset-by-NumPorts matrix.

Data Types: double

## **Output Arguments**

### **prsk — Estimated efficient portfolio risks (standard deviation of returns)**

vector

Estimated efficient portfolio risks (standard deviation of returns, returned as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj)).

---

#### **Note**

- If the portfolio object has a name in the Name property, the name is displayed as the title of the plot. Otherwise, the plot is labeled “Efficient Frontier.”
  - If the portfolio object has an initial portfolio in the InitPort property, the initial portfolio is plotted and labeled.
  - If portfolio risks and returns are inputs, make sure that risks come first in the calling sequence. In addition, if portfolio risks and returns are not sorted in ascending order, this method performs the sort. On output, the sorted moments are returned.
- 

### **pret — Estimated efficient portfolio returns**

vector

Estimated efficient portfolio returns, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note**

- If the portfolio object has a name in the `Name` property, the name is displayed as the title of the plot. Otherwise, the plot is labeled “Efficient Frontier.”
  - If the portfolio object has an initial portfolio in the `InitPort` property, the initial portfolio is plotted and labeled.
  - If portfolio risks and returns are inputs, make sure that risks come first in the calling sequence. In addition, if portfolio risks and returns are not sorted in ascending order, this method performs the sort. On output, the sorted moments are returned.
- 

**Tips**

You can also use dot notation to plot the efficient frontier.

```
[prsk, pret] = obj.plotFrontier;
```

# plus

Financial time series addition

---

**Note** `plus` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = tsobj_1 + tsobj_2
```

```
newfts = tsobj + array
```

```
newfts = array + tsobj
```

## Arguments

|                               |                                                                                                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsobj_1, tsobj_2</code> | A pair of financial time series objects.                                                                                                                                                |
| <code>array</code>            | A scalar value or array with the number of rows equal to the number of dates in <code>tsobj</code> and the number of columns equal to the number of data series in <code>tsobj</code> . |

## Description

`plus` is an element-by-element addition of the components.

`newfts = tsobj_1 + tsobj_2` adds financial time series objects. If an object is to be added to another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when one financial time series object is added to another, follows the order of the first object.

`newfts = tsobj + array` adds an array element by element to a financial time series object.

`newfts = array + tsobj` adds a financial time series object element by element to an array.

**Introduced before R2006a**

## pointfig

Point and figure chart

---

**Note** pointfig is updated to accept data input as a matrix, timetable, or table.

---

### Syntax

```
pointfig(Data)
h = pointfig(ax,Data)
```

### Description

pointfig(Data) plots a point and figure chart from a series of prices of a security. Upward price movements are plotted as X's and downward price movements are plotted as O's.

h = pointfig(ax,Data) adds an optional argument for ax.

### Examples

#### Generate a Point and Figure Chart for a Data Series for a Stock

Load the file SimulatedStock.mat, which provides a timetable (TMW) for financial data for TMW stock. This Point and Figure chart is for closing prices of the stock TMW for the most recent 21 days. Note that the variable name of asset price is be renamed to 'Price' (case insensitive).

```
load SimulatedStock.mat
TMW.Properties.VariableNames{'Close'} = 'Price';
pointfig(TMW(1:200,:))
title('Point and figure chart for TMW')
```

## Input Arguments

### Data — Data for a series of prices

matrix | table | timetable

Data for a series of prices, specified as a matrix, table, or timetable. Timetables and tables with M rows must contain a variable named 'Price' (case insensitive).

Data Types: double | table | timetable

### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The point and figure plot is created in the axes specified by ax instead of in the current axes (ax = gca). The option ax can precede any of the input argument combinations.

Data Types: object

## Output Arguments

### h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

# portalloc

Optimal capital allocation to efficient frontier portfolios

## Syntax

```
[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] =
portalloc(PortRisk,PortReturn,PortWts,RisklessRate)
```

```
[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] =
portalloc( __ ,BorrowRate,RiskAversion)
```

```
portalloc(PortRisk,PortReturn,PortWts,RisklessRate,BorrowRate,RiskAversion)
```

## Description

[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] = portalloc(PortRisk,PortReturn,PortWts,RisklessRate) calculates the optimal risky portfolio and the optimal allocation of funds between that risky portfolio of NASSETS and the risk-free asset.

[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] = portalloc( \_\_ ,BorrowRate,RiskAversion) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

portalloc(PortRisk,PortReturn,PortWts,RisklessRate,BorrowRate,RiskAversion) when invoked without any output arguments, a graph of the optimal capital allocation decision is displayed.

## Examples

### Compute the Optimal Risky Portfolio

This example shows how to compute the optimal risky portfolio by generating the efficient frontier from the asset data and then finding the optimal risky portfolio and allocate capital. The risk-free investment return is 8%, and the borrowing rate is 12%.

```
ExpReturn = [0.1 0.2 0.15];
```

```
ExpCovariance = [0.005   -0.010   0.004
                 -0.010   0.040   -0.002
                  0.004   -0.002   0.023];
```

```
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn,...
ExpCovariance);
```

```
RisklessRate = 0.08;
```

```
BorrowRate = 0.12;
```

```
RiskAversion = 3;
```

```
[RiskyRisk, RiskyReturn, RiskyWts, RiskyFraction, ...
OverallRisk, OverallReturn] = portalloc(PortRisk, PortReturn,...
PortWts, RisklessRate, BorrowRate, RiskAversion)
```

```
RiskyRisk = 0.1283
RiskyReturn = 0.1788
RiskyWts = 1×3
    0.0265    0.6023    0.3712

RiskyFraction = 1.1898
OverallRisk = 0.1527
OverallReturn = 0.1899
```

## Input Arguments

### **PortRisk** — Standard deviation of each risky asset efficient frontier portfolio

vector

Standard deviation of each risky asset efficient frontier portfolio, specified as an NPORTS-by-1 vector.

Data Types: double

### **PortReturn** — Expected return of each risky asset efficient frontier portfolio

vector

Expected return of each risky asset efficient frontier portfolio, specified an NPORTS-by-1 vector.

Data Types: double

### **PortWts** — Weights allocated to each asset

numeric

Weights allocated to each asset, specified as an NPORTS by number of assets (NASSETS) matrix of weights allocated to each asset. Each row represents an efficient frontier portfolio of risky assets. Total of all weights in a portfolio is 1.

Data Types: double

### **RisklessRate** — Risk-free lending rate

scalar decimal

Risk-free lending rate, specified as a scalar decimal.

Data Types: double

### **BorrowRate** — Borrowing rate

NaN (default) | scalar decimal

(Optional) Borrowing rate, specified as a scalar decimal. If borrowing is not desired, or not an option, set the BorrowRate to NaN (which is the default value).

Data Types: double

### **RiskAversion** — Coefficient of investor's degree of risk aversion

3 (default) | scalar numeric

(Optional) Coefficient of investor's degree of risk aversion, specified as a scalar numeric. Higher numbers indicate greater risk aversion. Typical coefficients range from 2.0 through 4.0. The default value of `RiskAversion` is 3.

---

**Note** Consider that a less risk-averse investor would be expected to accept much greater risk and, consequently, a more risk-averse investor would accept less risk for a given level of return. Therefore, making the `RiskAversion` argument higher reflects the risk-return tradeoff in the data.

---

Data Types: double

## Output Arguments

### **RiskyRisk** — Standard deviation of the optimal risky portfolio

numeric

Standard deviation of the optimal risky portfolio, returned as a scalar.

### **RiskyReturn** — Expected return of the optimal risky portfolio

numeric

Expected return of the optimal risky portfolio, returned as a scalar.

### **RiskyWts** — Weights allocated to the optimal risky portfolio

vector

Weights allocated to the optimal risky portfolio, returned a 1-by-NASSETS vector. The total of all weights in the portfolio is 1.

### **RiskyFraction** — Fraction of the complete portfolio allocated to the risky portfolio

numeric

Fraction of the complete portfolio (that is, the overall portfolio including risky and risk-free assets) allocated to the risky portfolio, returned as a scalar.

### **OverallRisk** — Standard deviation of the optimal overall portfolio

numeric

Standard deviation of the optimal overall portfolio, returned as a scalar.

### **OverallReturn** — Expected rate of return of the optimal overall portfolio

numeric

Expected rate of return of the optimal overall portfolio, returned as a scalar.

# portalalpha

Compute risk-adjusted alphas and returns for one or more assets

## Syntax

```
portalalpha(Asset,Benchmark)
```

```
portalalpha(Asset,Benchmark,Cash)
```

```
portalalpha(Asset,Benchmark,Cash,Choice)
```

```
Alpha = portalalpha(Asset,Benchmark,Cash,Choice)
```

```
[Alpha,RAReturn] = portalalpha(Asset,Benchmark,Cash,Choice)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Asset     | NUMSAMPLES × NUMSERIES matrix with NUMSAMPLES observations of asset returns for NUMSERIES asset return series.                                                                                                                                                                                                                                      |
| Benchmark | NUMSAMPLES vector of returns for a benchmark asset. The periodicity must be the same as the periodicity of Asset. For example, if Asset is monthly data, then Benchmark should be monthly returns.                                                                                                                                                  |
| Cash      | (Optional) Either a scalar return for a riskless asset or a vector of asset returns to be a proxy for a “riskless” asset. In either case, the periodicity must be the same as the periodicity of Asset. For example, if Asset is monthly data, then Cash must be monthly returns. If no value is supplied, the default value for Cash returns is 0. |

| Choice | <p>(Optional) A character vector, or cell array of character vectors to indicate one or more measures to be computed from among various risk-adjusted alphas and return measures. The number of choices selected in <code>Choice</code> is <code>NUMCHOICES</code>. The list of choices is given in the following table:</p> <table border="1" data-bbox="630 436 1479 1459"> <thead> <tr> <th data-bbox="630 436 889 478">Code</th> <th data-bbox="889 436 1479 478">Description</th> </tr> </thead> <tbody> <tr> <td data-bbox="630 478 889 520">'xs'</td> <td data-bbox="889 478 1479 520">Excess Return (no risk adjustment)</td> </tr> <tr> <td data-bbox="630 520 889 657">'sml'</td> <td data-bbox="889 520 1479 657">Security Market Line: The security market line shows that the relationship between risk and return is linear for individual securities (that is, increased risk = increased return).</td> </tr> <tr> <td data-bbox="630 657 889 856">'capm'</td> <td data-bbox="889 657 1479 856">Jensen's Alpha: Risk-adjusted performance measure that represents the average return on a portfolio or investment, above or below that predicted by the capital asset pricing model (CAPM), given the portfolio's or investment's beta and the average market return.</td> </tr> <tr> <td data-bbox="630 856 889 993">'mm'</td> <td data-bbox="889 856 1479 993">Modigliani &amp; Modigliani: Measures the returns of an investment portfolio for the amount of risk taken relative to some benchmark portfolio.</td> </tr> <tr> <td data-bbox="630 993 889 1234">'gh1'</td> <td data-bbox="889 993 1479 1234">Graham-Harvey 1: Performance measure developed by John Graham and Campbell Harvey. The idea is to lever a fund's portfolio to exactly match the volatility of the S&amp;P 500. The difference between the fund's levered return and the S&amp;P 500 return is the performance measure.</td> </tr> <tr> <td data-bbox="630 1234 889 1392">'gh2'</td> <td data-bbox="889 1234 1479 1392">Graham-Harvey 2: In this measure, the idea is to lever up or down the fund's recommended investment strategy (using a Treasury bill), so that the strategy has the same volatility as the S&amp;P 500.</td> </tr> <tr> <td data-bbox="630 1392 889 1459">'all'</td> <td data-bbox="889 1392 1479 1459">Compute all measures</td> </tr> </tbody> </table> <p>Choice is specified by using the code from the table (for example, to select the Modigliani &amp; Modigliani measure, <code>Choice = 'mm'</code>). A single choice is either a character vector or a scalar cell array with a single code from the table.</p> <p>Multiple choices can be selected with a cell array of character vectors for choice codes (for example, to select both Graham-Harvey measures, <code>Choice = {'gh1', 'gh2'}</code>). To select all choices, specify <code>Choice = 'all'</code>. If no value is supplied, the default choice is to compute the excess return with <code>Choice = 'xs'</code>. Choice is not case-sensitive.</p> | Code | Description | 'xs' | Excess Return (no risk adjustment) | 'sml' | Security Market Line: The security market line shows that the relationship between risk and return is linear for individual securities (that is, increased risk = increased return). | 'capm' | Jensen's Alpha: Risk-adjusted performance measure that represents the average return on a portfolio or investment, above or below that predicted by the capital asset pricing model (CAPM), given the portfolio's or investment's beta and the average market return. | 'mm' | Modigliani & Modigliani: Measures the returns of an investment portfolio for the amount of risk taken relative to some benchmark portfolio. | 'gh1' | Graham-Harvey 1: Performance measure developed by John Graham and Campbell Harvey. The idea is to lever a fund's portfolio to exactly match the volatility of the S&P 500. The difference between the fund's levered return and the S&P 500 return is the performance measure. | 'gh2' | Graham-Harvey 2: In this measure, the idea is to lever up or down the fund's recommended investment strategy (using a Treasury bill), so that the strategy has the same volatility as the S&P 500. | 'all' | Compute all measures |

| 'sml'  | Security Market Line: The security market line shows that the relationship between risk and return is linear for individual securities (that is, increased risk = increased return).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |      |             |      |                                    |       |                                                                                                                                                                                      |        |                                                                                                                                                                                                                                                                       |      |                                                                                                                                             |       |                                                                                                                                                                                                                                                                                |       |                                                                                                                                                                                                    |       |                      |
| 'capm' | Jensen's Alpha: Risk-adjusted performance measure that represents the average return on a portfolio or investment, above or below that predicted by the capital asset pricing model (CAPM), given the portfolio's or investment's beta and the average market return.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |      |             |      |                                    |       |                                                                                                                                                                                      |        |                                                                                                                                                                                                                                                                       |      |                                                                                                                                             |       |                                                                                                                                                                                                                                                                                |       |                                                                                                                                                                                                    |       |                      |
| 'mm'   | Modigliani & Modigliani: Measures the returns of an investment portfolio for the amount of risk taken relative to some benchmark portfolio.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |      |             |      |                                    |       |                                                                                                                                                                                      |        |                                                                                                                                                                                                                                                                       |      |                                                                                                                                             |       |                                                                                                                                                                                                                                                                                |       |                                                                                                                                                                                                    |       |                      |
| 'gh1'  | Graham-Harvey 1: Performance measure developed by John Graham and Campbell Harvey. The idea is to lever a fund's portfolio to exactly match the volatility of the S&P 500. The difference between the fund's levered return and the S&P 500 return is the performance measure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |      |             |      |                                    |       |                                                                                                                                                                                      |        |                                                                                                                                                                                                                                                                       |      |                                                                                                                                             |       |                                                                                                                                                                                                                                                                                |       |                                                                                                                                                                                                    |       |                      |
| 'gh2'  | Graham-Harvey 2: In this measure, the idea is to lever up or down the fund's recommended investment strategy (using a Treasury bill), so that the strategy has the same volatility as the S&P 500.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |      |             |      |                                    |       |                                                                                                                                                                                      |        |                                                                                                                                                                                                                                                                       |      |                                                                                                                                             |       |                                                                                                                                                                                                                                                                                |       |                                                                                                                                                                                                    |       |                      |

## Description

Given NUMSERIES assets with NUMSAMPLES returns in a NUMSAMPLES-by-NUMSERIES matrix *Asset*, a NUMSAMPLES vector of Benchmark returns, and either a scalar *Cash* return or a NUMSAMPLES vector of *Cash* returns, compute risk-adjusted alphas and returns for one or more methods specified by *Choice*.

To summarize the outputs of `portalalpha`:

- *Alpha* is a NUMCHOICES-by-NUMSERIES matrix of risk-adjusted alphas for each series in *Asset* with each row corresponding to a specified measure in *Choice*.
- *RAReturn* is a NUMCHOICES-by-NUMSERIES matrix of risk-adjusted returns for each series in *Asset* with each row corresponding to a specified measure in *Choice*.

---

**Note** NaN values in the data are ignored and, if NaNs are present, some results could be unpredictable. Although the alphas are comparable across measures, risk-adjusted returns depend on whether the *Asset* or *Benchmark* is levered or unlevered to match its risk with the alternative. If *Choice* = 'all', the order of rows in *Alpha* and *RAReturn* follows the order in the table. In addition, *Choice* = 'all' overrides all other choices.

---

## Examples

See “Risk-Adjusted Return” on page 7-10.

## portcons

Portfolio constraints

### Syntax

```
ConSet = portcons(varargin)
```

### Description

As an alternative to `portcons`, use the `Portfolio` object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-16.

Using linear inequalities, `portcons` generates a matrix of constraints for a portfolio of asset investments. The matrix `ConSet` is defined as  $\text{ConSet} = [A \ b]$ .  $A$  is a matrix and  $b$  a vector such that  $A * \text{PortWts}' \leq b$  sets the value, where `PortWts` is a 1-by-number of assets (`NASSETS`) vector of asset allocations.

`ConSet = portcons('ConstType',Data1, ..., DataN)` creates a matrix `ConSet`, based on the constraint type `ConstType`, and the constraint parameters `Data1, ..., DataN`.

`ConSet = portcons('ConstType1',Data11, ..., Data21, ..., Data2N, ...)` creates a matrix `ConSet`, based on the constraint types `ConstTypeN`, and the corresponding constraint parameters `DataN1, ..., DataNN`.

| Constraint Type        | Description                                                                                                       | Values                                                                                                                                                                                                                                                                                                                                |

| Custom          | Custom linear inequality constraints $A * PortWts' \leq b$ . | <p>A (required). NCONSTRAINTS-by-NASSETS matrix, specifying weights for each asset in each inequality equation.</p> <p>b (required). Vector of length NCONSTRAINTS specifying the right-hand sides of the inequalities.</p> <p><b>Note</b> For more information using Custom, see "Specifying Group Constraints" on page 3-30.</p>                                                                                                                                                                     |

## Examples

Constrain a portfolio of three assets:

| Asset                 | IBM | HPQ | XOM |
|-----------------------|-----|-----|-----|
| <b>Group</b>          | A   | A   | B   |
| <b>Minimum Weight</b> | 0   | 0   | 0   |
| <b>Maximum Weight</b> | 0.5 | 0.9 | 0.8 |

```
NumAssets = 3;
PVal = 1; % Scale portfolio value to 1.
AssetMin = 0;
AssetMax = [0.5 0.9 0.8];
```

```

GroupA = [1 1 0];
GroupB = [0 0 1];
AtoBmax = 1.5 % Value of assets in Group A at most 1.5 times value
              % in group B.

ConSet = portcons('PortValue', PVal, NumAssets, 'AssetLims', ...
AssetMin, AssetMax, NumAssets, 'GroupComparison', GroupA, NaN, ...
AtoBmax, GroupB)

```

```
ConSet =
```

```

    1.0000    1.0000    1.0000    1.0000
   -1.0000   -1.0000   -1.0000   -1.0000
    1.0000         0         0    0.5000
         0    1.0000         0    0.9000
         0         0    1.0000    0.8000
   -1.0000         0         0         0
         0   -1.0000         0         0
         0         0   -1.0000         0
    1.0000    1.0000   -1.5000         0

```

For instance, one possible solution for portfolio weights that satisfy the constraints is 30% in IBM, 30% in HPQ, and 40% in XOM.

# Portfolio

Create Portfolio object for mean-variance portfolio optimization and analysis

## Description

Use the `Portfolio` function to create a `Portfolio` object for mean-variance portfolio optimization.

The main workflow for portfolio optimization is to create an instance of a `Portfolio` object that completely specifies a portfolio optimization problem and to operate on the `Portfolio` object using supported functions to obtain and analyze efficient portfolios. For details on this workflow, see “Portfolio Object Workflow” on page 4-16.

You can use the `Portfolio` object in several ways. To set up a portfolio optimization problem in a `Portfolio` object, the simplest syntax is:

```
p = Portfolio;
```

This syntax creates a `Portfolio` object, `p`, such that all object properties are empty.

The `Portfolio` object also accepts collections of name-value pair arguments for properties and their values. The `Portfolio` object accepts inputs for properties with the general syntax:

```
p = Portfolio('property1',value1,'property2',value2, ... );
```

If a `Portfolio` object exists, the syntax permits the first (and only the first argument) of the `Portfolio` object to be an existing object with subsequent name-value pair arguments for properties to be added or modified. For example, given an existing `Portfolio` object in `p`, the general syntax is:

```
p = Portfolio(p,'property1',value1,'property2',value2, ... );
```

Input argument names are not case-sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see “Shortcuts for Property Names” on page 19-1082). The `Portfolio` object tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a `Portfolio` object is a value object so that, given portfolio `p`, the following code creates two objects, `p` and `q`, that are distinct:

```
q = Portfolio(p, ...)
```

After creating a `Portfolio` object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For more detailed information on the theoretical basis for mean-variance optimization, see “Portfolio Optimization Theory” on page 4-3.

## Creation

### Syntax

```
p = Portfolio
```

`p = Portfolio(Name,Value)`

`p = Portfolio(p,Name,Value)`

### Description

`p = Portfolio` creates an empty `Portfolio` object for mean-variance portfolio optimization and analysis. You can then add elements to the `Portfolio` object using the supported "add" and "set" functions. For more information, see "Creating the Portfolio Object" on page 4-22.

`p = Portfolio(Name,Value)` creates a `Portfolio` object (`p`) and sets Properties on page 19-1068 using name-value pairs. For example, `p = Portfolio('AssetList',Assets(1:12))`. You can specify multiple name-value pairs.

`p = Portfolio(p,Name,Value)` creates a `Portfolio` object (`p`) using a previously created `Portfolio` object `p` and sets Properties on page 19-1068 using name-value pairs. You can specify multiple name-value pairs.

### Input Arguments

#### **p** — Previously constructed Portfolio object

object

Previously constructed `Portfolio` object, specified using `Portfolio`.

## Properties

### Setting Up the Object

#### **AssetList** — Names or symbols of assets in universe

[] (default) | cell array of character vectors | string array

Names or symbols of assets in the universe, specified as a cell array of character vectors or a string array.

Data Types: `cell` | `string`

#### **InitPort** — Initial portfolio

[] (default) | vector

Initial portfolio, specified as a vector.

Data Types: `double`

#### **Name** — Name for instance of Portfolio object

[] (default) | character vector | string

Name for instance of the `Portfolio` object, specified as a character vector or a string.

Data Types: `char` | `string`

#### **NumAssets** — Number of assets in the universe

[] (default) | integer scalar

Number of assets in the universe, specified as an integer scalar.

Data Types: `double`

**Portfolio Object Constraints****AEquality — Linear equality constraint matrix**

[] (default) | matrix

Linear equality constraint matrix, specified as a matrix.

Data Types: double

**AInequality — Linear inequality constraint matrix**

[] (default) | matrix

Linear inequality constraint matrix, specified as a matrix.

Data Types: double

**bEquality — Linear equality constraint vector**

[] (default) | vector

Linear equality constraint vector, specified as a vector.

Data Types: double

**bInequality — Linear inequality constraint**

[] (default) | vector

Linear inequality constraint vector, specified as a vector.

Data Types: double

**GroupA — Group A weights to be bounded by weights in group B**

[] (default) | matrix

Group A weights to be bounded by weights in group B, specified as a matrix.

Data Types: double

**GroupB — Group B weights**

[] (default) | matrix

Group B weights, specified as a matrix.

Data Types: double

**GroupMatrix — Group membership matrix**

[] (default) | matrix

Group membership matrix, specified as a matrix.

Data Types: double

**LowerBound — Lower-bound constraint**

[] (default) | vector

Lower-bound constraint, specified as a vector.

Data Types: double

**LowerBudget — Lower-bound budget constraint**

[] (default) | scalar

Lower-bound budget constraint, specified as a scalar.

Data Types: double

**LowerGroup — Lower-bound group constraint**

[ ] (default) | vector

Lower-bound group constraint, specified as a vector.

Data Types: double

**LowerRatio — Minimum ratio of allocations between Groups A and B**

[ ] (default) | vector

Minimum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**TrackingError — Upper bound for tracking error constraint**

[ ] (default) | scalar

Upper bound for tracking error constraint, specified as a scalar.

Data Types: double

**TrackingPort — Tracking portfolio for tracking error constraint**

[ ] (default) | vector

Tracking portfolio for tracking error constraint, specified as a vector.

Data Types: double

**UpperBound — Upper-bound constraint**

[ ] (default) | vector

Upper-bound constraint, specified as a vector.

Data Types: double

**UpperBudget — Upper-bound budget constraint**

[ ] (default) | scalar

Upper-bound budget constraint, specified as a scalar.

Data Types: double

**UpperGroup — Upper-bound group constraint**

[ ] (default) | vector

Upper-bound group constraint, specified as a vector.

Data Types: double

**UpperRatio — Maximum ratio of allocations between Groups A and B**

[ ] (default) | vector

Maximum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**BoundType — Type of bounds for each asset weight**

'Simple' (default) | character vector with value 'Simple' or 'Conditional' | string with value "Simple" or "Conditional" | cell array of character vectors with values 'Simple' or 'Conditional' | string array with values "Simple" or "Conditional"

Type of bounds for each asset weight, specified as a scalar character vector or string, or a cell array of character vectors or a string array. For more information, see `setBounds`.

Data Types: `char` | `cell` | `string`

**MinNumAssets — Minimum number of assets allocated in portfolio**

[] (default) | numeric

Minimum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinNumAssets`.

Data Types: `double`

**MaxNumAssets — Maximum number of assets allocated in portfolio**

[] (default) | numeric

Maximum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinNumAssets`.

Data Types: `double`

**SellTurnover — Turnover constraint on sales**

[] (default) | scalar

Turnover constraint on sales, specified as a scalar.

Data Types: `double`

**BuyTurnover — Turnover constraint on purchases**

[] (default) | scalar

Turnover constraint on purchases, specified as a scalar.

Data Types: `double`

**Turnover — Turnover constraint**

[] (default) | scalar

Turnover constraint, specified as a scalar.

Data Types: `double`

**Portfolio Object Modeling****AssetCovar — Covariance of asset returns**

[] (default) | square matrix

Covariance of asset returns, specified as a square matrix. If `AssetCovar` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

Data Types: `double`

**AssetMean — Mean of asset returns**

[] (default) | vector

Mean of asset returns, specified as a vector.

Data Types: double

### **BuyCost — Proportional purchase costs**

[ ] (default) | vector

Proportional purchase costs, specified as a vector.

Data Types: double

### **RiskFreeRate — Risk-free rate**

[ ] (default) | scalar

Risk-free rate, specified as a scalar.

Data Types: double

### **SellCost — Proportional sales costs**

[ ] (default) | vector

Proportional sales costs, specified as a vector.

Data Types: double

## **Object Functions**

|                       |                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------|
| setAssetList          | Set up list of identifiers for assets                                                 |
| setInitPort           | Set up initial or current portfolio                                                   |
| setDefaultConstraints | Set up portfolio constraints with nonnegative weights that sum to 1                   |
| getAssetMoments       | Obtain mean and covariance of asset returns from Portfolio object                     |
| setAssetMoments       | Set moments (mean and covariance) of asset returns for Portfolio object               |
| estimateAssetMoments  | Estimate mean and covariance of asset returns from data                               |
| setCosts              | Set up proportional transaction costs                                                 |
| addEquality           | Add linear equality constraints for portfolio weights to existing constraints         |
| addGroupRatio         | Add group ratio constraints for portfolio weights to existing group ratio constraints |
| addGroups             | Add group constraints for portfolio weights to existing group constraints             |
| addInequality         | Add linear inequality constraints for portfolio weights to existing constraints       |
| getBounds             | Obtain bounds for portfolio weights from portfolio object                             |
| getBudget             | Obtain budget constraint bounds from portfolio object                                 |
| getCosts              | Obtain buy and sell transaction costs from portfolio object                           |
| getEquality           | Obtain equality constraint arrays from portfolio object                               |
| addGroupRatio         | Obtain group ratio constraint arrays from portfolio object                            |
| addGroups             | Obtain group constraint arrays from portfolio object                                  |
| getInequality         | Obtain inequality constraint arrays from portfolio object                             |
| getOneWayTurnover     | Obtain one-way turnover constraints from portfolio object                             |
| setGroups             | Set up group constraints for portfolio weights                                        |
| setInequality         | Set up linear inequality constraints for portfolio weights                            |
| setBounds             | Set up bounds for portfolio weights for a portfolio object                            |
| setBudget             | Set up budget constraints                                                             |
| setCosts              | Set up proportional transaction costs                                                 |
| setEquality           | Set up linear equality constraints for portfolio weights                              |

|                                       |                                                                                      |
|---------------------------------------|--------------------------------------------------------------------------------------|

| <code>estimateMaxSharpeRatio</code>   | Estimate efficient portfolio to maximize Sharpe ratio for Portfolio object           |
| <code>estimatePortMoments</code>      | Estimate moments of portfolio returns for Portfolio object                           |
| <code>estimatePortReturn</code>       | Estimate mean of portfolio returns                                                   |
| <code>estimatePortRisk</code>         | Estimate portfolio risk according to risk proxy associated with corresponding object |
| <code>setSolver</code>                | Choose main solver and specify associated solver options for portfolio optimization  |
| <code>setSolverMINLP</code>           | Choose mixed integer nonlinear programming (MINLP) solver for portfolio optimization |

## Examples

### Create an Empty Portfolio Object

You can create a Portfolio object, `p`, with no input arguments and display it using `disp`.

```
p = Portfolio;
disp(p);
```

Portfolio with properties:

```
    BuyCost: []
    SellCost: []
    RiskFreeRate: []
    AssetMean: []
    AssetCovar: []
    TrackingError: []
    TrackingPort: []
    Turnover: []
    BuyTurnover: []
    SellTurnover: []
    Name: []
    NumAssets: []
    AssetList: []
    InitPort: []
    AInequality: []
    bInequality: []
    AEquality: []
    bEquality: []
```

```
LowerBound: []
UpperBound: []
LowerBudget: []
UpperBudget: []
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
BoundType: []
```

This approach provides a way to set up a portfolio optimization problem with the `Portfolio` function. You can then use the associated set functions to set and modify collections of properties in the `Portfolio` object.

### Create a Portfolio Object Using a Single-Step Setup

You can use the `Portfolio` object directly to set up a “standard” portfolio optimization problem, given a mean and covariance of asset returns in the variables `m` and `C`.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio('assetmean', m, 'assetcovar', C, ...
             'lowerbudget', 1, 'upperbudget', 1, 'lowerbound', 0)

p =
Portfolio with properties:

    BuyCost: []
    SellCost: []
RiskFreeRate: []
  AssetMean: [4x1 double]
  AssetCovar: [4x4 double]
TrackingError: []
TrackingPort: []
    Turnover: []
  BuyTurnover: []
  SellTurnover: []
        Name: []
    NumAssets: 4
    AssetList: []
    InitPort: []
  AInequality: []
  bInequality: []
    AEquality: []
    bEquality: []
  LowerBound: [4x1 double]
```

```

UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
    GroupA: []
    GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
BoundType: []

```

Note that the `LowerBound` property value undergoes scalar expansion since `AssetMean` and `AssetCovar` provide the dimensions of the problem.

### Create a Portfolio Object Using a Sequence of Steps

Using a sequence of steps is an alternative way to accomplish the same task of setting up a “standard” portfolio optimization problem, given a mean and covariance of asset returns in the variables `m` and `C` (which also illustrates that argument names are not case sensitive).

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = Portfolio(p, 'assetmean', m, 'assetcovar', C);
p = Portfolio(p, 'lowerbudget', 1, 'upperbudget', 1);
p = Portfolio(p, 'lowerbound', 0);

plotFrontier(p);

```

This way works because the calls to `Portfolio` are in this particular order. In this case, the call to initialize `AssetMean` and `AssetCovar` provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the `LowerBound` property as follows:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = Portfolio(p, 'LowerBound', zeros(size(m)));
p = Portfolio(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = Portfolio(p, 'AssetMean', m, 'AssetCovar', C);

plotFrontier(p);
```

If you did not specify the size of LowerBound but, instead, input a scalar argument, the Portfolio object assumes that you are defining a single-asset problem and produces an error at the call to set asset moments with four assets.

### Create a Portfolio Object Using Shortcuts for Property Names

You can create a Portfolio object, `p` with Portfolio using shortcuts for property names.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio('mean', m, 'covar', C, 'budget', 1, 'lb', 0)
```

```
p =
Portfolio with properties:
    BuyCost: []
    SellCost: []
    RiskFreeRate: []
    AssetMean: [4x1 double]
    AssetCovar: [4x4 double]
    TrackingError: []
```

```
TrackingPort: []
  Turnover: []
  BuyTurnover: []
  SellTurnover: []
  Name: []
  NumAssets: 4
  AssetList: []
  InitPort: []
  AInequality: []
  bInequality: []
  AEquality: []
  bEquality: []
  LowerBound: [4x1 double]
  UpperBound: []
  LowerBudget: 1
  UpperBudget: 1
  GroupMatrix: []
  LowerGroup: []
  UpperGroup: []
  GroupA: []
  GroupB: []
  LowerRatio: []
  UpperRatio: []
  MinNumAssets: []
  MaxNumAssets: []
  BoundType: []
```

### Direct Setting of Portfolio Object Properties

Although not recommended, you can set properties directly, however no error-checking is done on your inputs.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio;
p.NumAssets = numel(m);
p.AssetMean = m;
p.AssetCovar = C;
p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
disp(p)
```

Portfolio with properties:

```
BuyCost: []
SellCost: []
RiskFreeRate: []
AssetMean: [4x1 double]
AssetCovar: [4x4 double]
```

```
TrackingError: []
TrackingPort: []
  Turnover: []
  BuyTurnover: []
  SellTurnover: []
  Name: []
  NumAssets: 4
  AssetList: []
  InitPort: []
  AInequality: []
  bInequality: []
  AEquality: []
  bEquality: []
  LowerBound: [4x1 double]
  UpperBound: []
  LowerBudget: 1
  UpperBudget: 1
  GroupMatrix: []
  LowerGroup: []
  UpperGroup: []
  GroupA: []
  GroupB: []
  LowerRatio: []
  UpperRatio: []
  MinNumAssets: []
  MaxNumAssets: []
  BoundType: []
```

### Create a Portfolio Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse

p = Portfolio('AssetList',Assets(1:12));
p = estimateAssetMoments(p, Data(:,1:12), 'missingdata', true);
p = setDefaultConstraints(p);
plotFrontier(p);
```

```

pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([pwgt],pnames,'obsnames',p.AssetList);

disp(Blotter);

```

|      | Port1     | Port2    | Port3    | Port4   | Port5 |
|------|-----------|----------|----------|---------|-------|
| AAPL | 0.017926  | 0.058247 | 0.097816 | 0.12955 | 0     |

## More About

### Mean-Variance Portfolio Optimization

A mean-variance optimization problem is completely specified with three elements.

The three elements for a mean-variance optimization problem are:

- A universe of assets with estimates for the prospective mean and covariance of asset total returns for a period of interest.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk, which, for mean-variance optimization, is either the gross or net mean of portfolio returns and the standard deviation of portfolio returns.

After you specify these three elements in an unambiguous way, you can solve and analyze portfolio optimization problems. The simplest mean-variance portfolio optimization problem has:

- A mean and covariance of asset total returns
- Nonnegative weights for all portfolios that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk that use the mean and covariance of asset total returns

For more information on the theory and definition of mean-variance optimization supported by portfolio optimization tools in Financial Toolbox, see “Portfolio Optimization Theory” on page 4-3.

### Portfolio Problem Sufficiency

A mean-variance portfolio optimization is completely specified with the Portfolio object if two conditions are met.

The following are the two conditions that must be met:

- The moments of asset returns must be specified such that the property `AssetMean` contains a valid finite mean vector of asset returns and the property `AssetCovar` contains a valid symmetric positive-semidefinite matrix for the covariance of asset returns.

The first condition is satisfied by setting the properties associated with the moments of asset returns.

- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded.

The second condition is satisfied by an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed, and several functions, such as `estimateBounds`, provide ways to ensure that your problem is properly formulated.

Given mean and covariance of asset returns in the variables `AssetMean` and `AssetCovar`, this problem is completely specified by:

```
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar, ...
'LowerBound', 0, 'UpperBudget', 1, 'LowerBudget', 1)
```

or equivalently by:

```
p = Portfolio;
p = setAssetMoments(p, AssetMean, AssetCovar);
p = setDefaultConstraints(p);
```

Although the general sufficiency conditions for mean-variance portfolio optimization go beyond these two conditions, the `Portfolio` object implemented in Financial Toolbox implicitly handles all these additional conditions. For more information on the Markowitz model for mean-variance portfolio optimization, see “Portfolio Optimization” on page A-5.

### Shortcuts for Property Names

The `Portfolio` object has shorter argument names that replace longer argument names associated with specific properties of the `Portfolio` object.

For example, rather than enter 'assetcovar', the `Portfolio` object accepts the case-insensitive name 'covar' to set the `AssetCovar` property in a `Portfolio` object. Every shorter argument name corresponds with a single property in the `Portfolio` object. The one exception is the alternative argument name 'budget', which signifies both the `LowerBudget` and `UpperBudget` properties. When 'budget' is used, then the `LowerBudget` and `UpperBudget` properties are set to the same value to form an equality budget constraint.

### Shortcuts for Property Names

| Shortcut Argument Name | Equivalent Argument / Property Name |
|------------------------|-------------------------------------|
| ae                     | AEquality                           |
| ai                     | AInequality                         |
| covar                  | AssetCovar                          |
| assetnames or assets   | AssetList                           |
| mean                   | AssetMean                           |
| be                     | bEquality                           |
| bi                     | bInequality                         |
| group                  | GroupMatrix                         |
| lb                     | LowerBound                          |
| n or num               | NumAssets                           |
| rfr                    | RiskFreeRate                        |
| ub                     | UpperBound                          |
| budget                 | UpperBudget and LowerBudget         |

## PortfolioCVaR

Creates PortfolioCVaR object for conditional value-at-risk portfolio optimization and analysis

### Description

Use `PortfolioCVaR` to create a `PortfolioCVaR` object for conditional value-at-risk portfolio optimization.

The main workflow for CVaR portfolio optimization is to create an instance of a `PortfolioCVaR` object that completely specifies a portfolio optimization problem and to operate on the `PortfolioCVaR` object using supported functions to obtain and analyze efficient portfolios. For details on this workflow, see “PortfolioCVaR Object Workflow” on page 5-14.

You can use the `PortfolioCVaR` object in several ways. To set up a portfolio optimization problem in a `PortfolioCVaR` object, the simplest syntax is:

```
p = PortfolioCVaR;
```

This syntax creates a `PortfolioCVaR` object, `p`, such that all object properties are empty.

The `PortfolioCVaR` object also accepts collections of name-value pair arguments for properties and their values. The `PortfolioCVaR` function accepts inputs for properties with the general syntax:

```
p = PortfolioCVaR('property1',value1,'property2',value2, ... );
```

If a `PortfolioCVaR` object already exists, the syntax permits the first (and only the first argument) of the `PortfolioCVaR` object to be an existing object with subsequent name-value pair arguments for properties to be added or modified. For example, given an existing `PortfolioCVaR` object in `p`, the general syntax is:

```
p = PortfolioCVaR(p,'property1',value1,'property2',value2, ... );
```

Input argument names are not case sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see “Shortcuts for Property Names” on page 19-1099). The `PortfolioCVaR` object tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a `PortfolioCVaR` object is a value object so that, given portfolio `p`, the following code creates two objects, `p` and `q`, that are distinct:

```
q = PortfolioCVaR(p, ...)
```

After creating a `PortfolioCVaR` object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For more detailed information on the theoretical basis for conditional value-at-risk portfolio optimization, see “Portfolio Optimization Theory” on page 5-2.

## Creation

### Syntax

```
p = PortfolioCVaR
p = PortfolioCVaR(Name,Value)

p = PortfolioCVaR(p,Name,Value)
```

### Description

`p = PortfolioCVaR` creates an empty `PortfolioCVaR` object for conditional value-at-risk portfolio optimization and analysis. You can then add elements to the `PortfolioCVaR` object using the supported "add" and "set" functions. For more information, see "Creating the PortfolioCVaR Object" on page 5-19.

`p = PortfolioCVaR(Name,Value)` creates a `PortfolioCVaR` object (`p`) and sets Properties on page 19-1085 using name-value pairs. For example, `p = PortfolioCVaR('AssetList',Assets(1:12))`. You can specify multiple name-value pairs.

`p = PortfolioCVaR(p,Name,Value)` creates a `PortfolioCVaR` object (`p`) using a previously created `PortfolioCVaR` object `p` and sets Properties on page 19-1085 using name-value pairs. You can specify multiple name-value pairs.

### Input Arguments

**p** — Previously constructed `PortfolioCVaR` object  
object

Previously constructed `PortfolioCVaR` object, specified using `PortfolioCVaR`.

## Properties

### Setting Up the Object

**AssetList** — Names or symbols of assets in universe

[] (default) | cell array of character vectors | string array

Names or symbols of assets in the universe, specified as a cell array of character vectors or a string array.

Data Types: cell | string

**InitPort** — Initial portfolio

[] (default) | vector

Initial portfolio, specified as a vector.

Data Types: double

**Name** — Name for instance of `PortfolioCVaR` object

[] (default) | character vector | string

Name for instance of the `PortfolioCVaR` object, specified as a character vector or string.

Data Types: char | string

**NumAssets — Number of assets in the universe**

[] (default) | integer scalar

Number of assets in the universe, specified as an integer scalar.

Data Types: double

**Portfolio Object Constraints**

**AEquality — Linear equality constraint matrix**

[] (default) | matrix

Linear equality constraint matrix, specified as a matrix.

Data Types: double

**AInequality — Linear inequality constraint matrix**

[] (default) | matrix

Linear inequality constraint matrix, specified as a matrix.

Data Types: double

**bEquality — Linear equality constraint vector**

[] (default) | vector

Linear equality constraint vector, specified as a vector.

Data Types: double

**bInequality — Linear inequality constraint**

[] (default) | vector

Linear inequality constraint vector, specified as a vector.

Data Types: double

**GroupA — Group A weights to be bounded by weights in group B**

[] (default) | matrix

Group A weights to be bounded by weights in group B, specified as a matrix.

Data Types: double

**GroupB — Group B weights**

[] (default) | matrix

Group B weights, specified as a matrix.

Data Types: double

**GroupMatrix — Group membership matrix**

[] (default) | matrix

Group membership matrix, specified as a matrix.

Data Types: double

**LowerBound — Lower-bound constraint**

[] (default) | vector

Lower-bound constraint, specified as a vector.

Data Types: double

**LowerBudget — Lower-bound budget constraint**

[] (default) | scalar

Lower-bound budget constraint, specified as a scalar.

Data Types: double

**LowerGroup — Lower-bound group constraint**

[] (default) | vector

Lower-bound group constraint, specified as a vector.

Data Types: double

**LowerRatio — Minimum ratio of allocations between Groups A and B**

[] (default) | vector

Minimum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**UpperBound — Upper-bound constraint**

[] (default) | vector

Upper-bound constraint, specified as a vector.

Data Types: double

**UpperBudget — Upper-bound budget constraint**

[] (default) | scalar

Upper-bound budget constraint, specified as a scalar.

Data Types: double

**UpperGroup — Upper-bound group constraint**

[] (default) | vector

Upper-bound group constraint, specified as a vector.

Data Types: double

**UpperRatio — Maximum ratio of allocations between Groups A and B**

[] (default) | vector

Maximum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**BoundType — Type of bounds for each asset weight**

'Simple' (default) | character vector with value 'Simple' or 'Conditional' | string with value "Simple" or "Conditional" | cell array of character vectors with values 'Simple' or 'Conditional' | string array with values "Simple" or "Conditional"

Type of bounds for each asset weight, specified as a scalar character vector or string, or a cell array of character vectors or a string array. For more information, see `setBounds`.

Data Types: `char` | `cell` | `string`

**MinNumAssets — Minimum number of assets allocated in portfolio**

[] (default) | numeric

Minimum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinNumAssets`.

Data Types: `double`

**MaxNumAssets — Maximum number of assets allocated in portfolio**

[] (default) | numeric

Maximum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinNumAssets`.

Data Types: `double`

**Turnover — Turnover constraint**

[] (default) | scalar

Turnover constraint, specified as a scalar.

Data Types: `double`

**SellTurnover — Turnover constraint on sales**

[] (default) | scalar

Turnover constraint on sales, specified as a scalar.

Data Types: `double`

**BuyTurnover — Turnover constraint on purchases**

[] (default) | scalar

Turnover constraint on purchases, specified as a scalar.

Data Types: `double`

**Portfolio Object Modeling****BuyCost — Proportional purchase costs**

[] (default) | vector

Proportional purchase costs, specified as a vector.

Data Types: `double`

**RiskFreeRate — Risk-free rate**

[] (default) | scalar

Risk-free rate, specified as a scalar.

Data Types: double

### **ProbabilityLevel — Value-at-risk probability level which is 1 – (loss probability)**

[ ] (default) | scalar

Value-at-risk probability level which is 1 – (loss probability), specified as a scalar.

Data Types: double

### **NumScenarios — Number of scenarios**

[ ] (default) | integer scalar

Number of scenarios, specified as an integer scalar.

Data Types: double

### **SellCost — Proportional sales costs**

[ ] (default) | vector

Proportional sales costs, specified as a vector.

Data Types: double

## **Object Functions**

|                       |                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------|
| setAssetList          | Set up list of identifiers for assets                                                 |
| setInitPort           | Set up initial or current portfolio                                                   |
| setDefaultConstraints | Set up portfolio constraints with nonnegative weights that sum to 1                   |
| estimateAssetMoments  | Estimate mean and covariance of asset returns from data                               |
| setCosts              | Set up proportional transaction costs                                                 |
| addEquality           | Add linear equality constraints for portfolio weights to existing constraints         |
| addGroupRatio         | Add group ratio constraints for portfolio weights to existing group ratio constraints |
| addGroups             | Add group constraints for portfolio weights to existing group constraints             |
| addInequality         | Add linear inequality constraints for portfolio weights to existing constraints       |
| getBounds             | Obtain bounds for portfolio weights from portfolio object                             |
| getBudget             | Obtain budget constraint bounds from portfolio object                                 |
| getCosts              | Obtain buy and sell transaction costs from portfolio object                           |
| getEquality           | Obtain equality constraint arrays from portfolio object                               |
| addGroupRatio         | Obtain group ratio constraint arrays from portfolio object                            |
| addGroups             | Obtain group constraint arrays from portfolio object                                  |
| getInequality         | Obtain inequality constraint arrays from portfolio object                             |
| getOneWayTurnover     | Obtain one-way turnover constraints from portfolio object                             |
| setGroups             | Set up group constraints for portfolio weights                                        |
| setInequality         | Set up linear inequality constraints for portfolio weights                            |
| setBounds             | Set up bounds for portfolio weights for a portfolio object                            |
| setMinMaxNumAssets    | Set cardinality constraints on the number of assets invested in a portfolio object    |
| setBudget             | Set up budget constraints                                                             |

|                                  |                                                                                               |
|----------------------------------|-----------------------------------------------------------------------------------------------|
| setCosts                         | Set up proportional transaction costs                                                         |
| setDefaultConstraints            | Set up portfolio constraints with nonnegative weights that sum to 1                           |
| setEquality                      | Set up linear equality constraints for portfolio weights                                      |
| setGroupRatio                    | Set up group ratio constraints for portfolio weights                                          |
| setInitPort                      | Set up initial or current portfolio                                                           |
| setOneWayTurnover                | Set up one-way portfolio turnover constraints                                                 |
| setTurnover                      | Set up maximum portfolio turnover constraint                                                  |
| checkFeasibility                 | Check feasibility of input portfolios against portfolio object                                |
| estimateBounds                   | Estimate global lower and upper bounds for set of portfolios                                  |
| estimateFrontier                 | Estimate specified number of optimal portfolios on the efficient frontier                     |
| estimateFrontierByReturn         | Estimate optimal portfolios with targeted portfolio returns                                   |
| estimateFrontierByRisk           | Estimate optimal portfolios with targeted portfolio risks                                     |
| estimateFrontierLimits           | Estimate optimal portfolios at endpoints of efficient frontier                                |
| plotFrontier                     | Plot efficient frontier                                                                       |
| estimatePortReturn               | Estimate mean of portfolio returns                                                            |
| estimatePortRisk                 | Estimate portfolio risk according to risk proxy associated with corresponding object          |
| setSolver                        | Choose main solver and specify associated solver options for portfolio optimization           |
| setProbabilityLevel              | Set probability level for VaR and CVaR calculations                                           |
| setScenarios                     | Set asset returns scenarios by direct matrix                                                  |
| getScenarios                     | Obtain scenarios from portfolio object                                                        |
| simulateNormalScenariosByData    | Simulate multivariate normal asset return scenarios from data                                 |
| simulateNormalScenariosByMoments | Simulate multivariate normal asset return scenarios from mean and covariance of asset returns |
| estimateScenarioMoments          | Estimate mean and covariance of asset return scenarios                                        |
| estimatePortVaR                  | Estimate value-at-risk for PortfolioCVaR object                                               |
| estimatePortStd                  |                                                                                               |

## Examples

### Create an Empty PortfolioCVaR Object

You can create a PortfolioCVaR object, `p`, with no input arguments and display it using `disp`.

```
p = PortfolioCVaR;
disp(p);
```

PortfolioCVaR with properties:

```
    BuyCost: []
    SellCost: []
    RiskFreeRate: []
    ProbabilityLevel: []
    Turnover: []
    BuyTurnover: []
    SellTurnover: []
    NumScenarios: []
    Name: []
```

```

    NumAssets: []
    AssetList: []
    InitPort: []
    AInequality: []
    bInequality: []
    AEquality: []
    bEquality: []
    LowerBound: []
    UpperBound: []
    LowerBudget: []
    UpperBudget: []
    GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
    GroupA: []
    GroupB: []
    LowerRatio: []
    UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
    BoundType: []

```

This approach provides a way to set up a portfolio optimization problem with the `PortfolioCVaR` function. You can then use the associated set functions to set and modify collections of properties in the `PortfolioCVaR` object.

### Create a PortfolioCVaR Object Using a Single-Step Setup

You can use the `PortfolioCVaR` object directly to set up a “standard” portfolio optimization problem. Given scenarios of asset returns in the variable `AssetScenarios`, this problem is completely specified as follows:

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR('Scenarios', AssetScenarios, ...
    'LowerBound', 0, 'LowerBudget', 1, 'UpperBudget', 1, ...
    'ProbabilityLevel', 0.95)

p =
    PortfolioCVaR with properties:

        BuyCost: []
        SellCost: []
    RiskFreeRate: []
    ProbabilityLevel: 0.9500
        Turnover: []
    BuyTurnover: []

```

```

SellTurnover: []
NumScenarios: 20000
    Name: []
    NumAssets: 4
    AssetList: []
    InitPort: []
AInequality: []
bInequality: []
    AEquality: []
    bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
        GroupA: []
        GroupB: []
    LowerRatio: []
    UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
BoundType: []

```

Note that the `LowerBound` property value undergoes scalar expansion since `AssetScenarios` provides the dimensions of the problem.

### Create a PortfolioCVaR Object Using a Sequence of Steps

Using a sequence of steps is an alternative way to accomplish the same task of setting up a “standard” CVaR portfolio optimization problem, given `AssetScenarios` variable is:

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = PortfolioCVaR(p, 'LowerBound', 0);
p = PortfolioCVaR(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setProbabilityLevel(p, 0.95);

plotFrontier(p);

```

This way works because the calls to `PortfolioCVaR` are in this particular order. In this case, the call to initialize `AssetScenarios` provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the `LowerBound` property as follows:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = PortfolioCVaR(p, 'LowerBound', zeros(size(m)));
p = PortfolioCVaR(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setProbabilityLevel(p, 0.95);
p = setScenarios(p, AssetScenarios);

plotFrontier(p);
```

If you did not specify the size of `LowerBound` but, instead, input a scalar argument, the `PortfolioCVaR` object assumes that you are defining a single-asset problem and produces an error at the call to set asset scenarios with four assets.

### Create a PortfolioCVaR Object Using Shortcuts for Property Names

You can create a `PortfolioCVaR` object, `p` with the `PortfolioCVaR` object using shortcuts for property names.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
```

```
m = m/12;
C = C/12;
```

```
AssetScenarios = mvnrnd(m, C, 20000);
```

```
p = PortfolioCVaR('scenario', AssetScenarios, 'lb', 0, 'budget', 1, 'plevel', 0.95)
```

```
p =
PortfolioCVaR with properties:
```

```

        BuyCost: []
        SellCost: []
    RiskFreeRate: []
    ProbabilityLevel: 0.9500
        Turnover: []
        BuyTurnover: []
        SellTurnover: []
    NumScenarios: 20000
        Name: []
        NumAssets: 4
        AssetList: []
        InitPort: []
    AInequality: []
    bInequality: []
        AEquality: []
        bEquality: []
    LowerBound: [4x1 double]
    UpperBound: []
    LowerBudget: 1
    UpperBudget: 1
    GroupMatrix: []
        LowerGroup: []
        UpperGroup: []
            GroupA: []
            GroupB: []
        LowerRatio: []
        UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
    BoundType: []

```

### Direct Setting of PortfolioCVaR Object Properties

Although not recommended, you can set properties directly, however no error-checking is done on your inputs.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;

p = setScenarios(p, AssetScenarios);
p.ProbabilityLevel = 0.95;

p.LowerBudget = 1;
p.UpperBudget = 1;

```

```
p.LowerBound = zeros(size(m));
disp(p)
```

PortfolioCVaR with properties:

```
    BuyCost: []
    SellCost: []
    RiskFreeRate: []
    ProbabilityLevel: 0.9500
    Turnover: []
    BuyTurnover: []
    SellTurnover: []
    NumScenarios: 20000
        Name: []
    NumAssets: 4
    AssetList: []
    InitPort: []
    AInequality: []
    bInequality: []
    AEquality: []
    bEquality: []
    LowerBound: [4x1 double]
    UpperBound: []
    LowerBudget: 1
    UpperBudget: 1
    GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
        GroupA: []
        GroupB: []
    LowerRatio: []
    UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
    BoundType: []
```

Scenarios cannot be assigned directly to a PortfolioCVaR object. Scenarios must always be set through either the `PortfolioCVaR` function, the `setScenarios` function, or any of the scenario simulation functions.

### Construct a PortfolioCVaR Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse

p = PortfolioCVaR('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 , 'missingdata', true);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

plotFrontier(p);
```

```

pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([pwgt],pnames,'obsnames',p.AssetList);

disp(Blotter);

```

|      | Port1    | Port2     | Port3    | Port4   | Port5 |
|------|----------|-----------|----------|---------|-------|
| AAPL | 0.010562 | 0.07364   | 0.11931  | 0.13073 | 0     |

## More About

### Conditional Value-at-Risk Portfolio Optimization

A CVaR optimization problem is completely specified with four elements.

The four elements for a CVaR optimization problem are:

- A universe of assets with scenarios of asset total returns for a period of interest, where scenarios comprise a collection of samples from the underlying probability distribution for asset total returns. This collection must be sufficiently large for asymptotic convergence of sample statistics. Asset return moments and related statistics are derived exclusively from the scenarios.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk proxies, which, for CVaR optimization, is either the gross or net mean of portfolio returns and the conditional value-at-risk of portfolio returns.
- A probability level that specifies the probability that a loss is less than or equal to the value-at-risk. Typical values are 0.9 and 0.95, which indicate 10% and 5% loss probabilities.

After these four elements have been specified in an unambiguous way, it is possible to solve and analyze CVaR portfolio optimization problems.

The simplest CVaR portfolio optimization problem has:

- Scenarios of asset total returns
- A requirement that all portfolios have nonnegative weights that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk proxies that use scenarios of asset total returns
- A probability level of 0.95

Given scenarios of asset returns in the variable `AssetScenarios`, this problem is completely specified by:

```
p = PortfolioCVaR('Scenarios', AssetScenarios, 'LowerBound', 0, 'Budget', 1, ...
'ProbabilityLevel', 0.95);
```

or equivalently by:

```
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
```

To confirm that this is a valid portfolio optimization problem, the following function determines whether the set of `PortfolioCVaR` choices is bounded (a necessary condition for portfolio optimization).

```
[lb, ub, isbounded] = estimateBounds(p);
```

Given the problem specified in the `PortfolioCVaR` object `p`, the efficient frontier for this problem can be displayed with:

```
plotFrontier(p);
```

and efficient portfolios can be obtained with:

```
pwgt = estimateFrontier(p);
```

For more information on the theory and definition of conditional value-at-risk optimization supported by portfolio optimization tools in Financial Toolbox, see “Portfolio Optimization Theory” on page 5-2.

### PortfolioCVaR Problem Sufficiency

A CVaR portfolio optimization problem is completely specified with the `PortfolioCVaR` object if three conditions are met.

The following are the three conditions that must be met:

- You must specify a collection of asset returns or prices known as scenarios such that all scenarios are finite asset returns or prices. These scenarios are meant to be samples from the underlying probability distribution of asset returns. This condition can be satisfied by the `setScenarios` function or with several canned scenario simulation functions.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded. You can satisfy this condition using an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed and several tools, such as the `estimateBounds` function, provide ways to ensure that your problem is properly formulated.
- You must specify a probability level to locate the level of tail loss above which the conditional value-at-risk is to be minimized. This condition can be satisfied by the `setProbabilityLevel` function.

Although the general sufficient conditions for CVaR portfolio optimization go beyond the first three conditions, the `PortfolioCVaR` object handles all these additional conditions.

### Shortcuts for Property Names

The `PortfolioCVaR` object has shorter argument names that replace longer argument names associated with specific properties of the `PortfolioCVaR` object.

For example, rather than enter `'ProbabilityLevel'`, the `PortfolioCVaR` object accepts the case-insensitive name `'plevel'` to set the `ProbabilityLevel` property in a `PortfolioCVaR` object. Every shorter argument name corresponds with a single property in the `PortfolioCVaR` object. The one exception is the alternative argument name `'budget'`, which signifies both the `LowerBudget` and `UpperBudget` properties. When `'budget'` is used, then the `LowerBudget` and `UpperBudget` properties are set to the same value to form an equality budget constraint.

**Shortcuts for Property Names**

| Shortcut Argument Name      | Equivalent Argument / Property Name |
|-----------------------------|-------------------------------------|
| ae                          | AEquality                           |
| ai                          | AInequality                         |
| assetnames or assets        | AssetList                           |
| be                          | bEquality                           |
| bi                          | bInequality                         |
| budget                      | UpperBudget and LowerBudget         |
| group                       | GroupMatrix                         |
| lb                          | LowerBound                          |
| n or num                    | NumAssets                           |
| level, problevel, or plevel | ProbabilityLevel                    |
| rfr                         | RiskFreeRate                        |
| scenario or assetscenarios  | Scenarios                           |
| ub                          | UpperBound                          |

## PortfolioMAD

Create PortfolioMAD object for mean-absolute deviation portfolio optimization and analysis

### Description

The PortfolioMAD object implements mean-absolute deviation portfolio optimization, where MAD stands for “mean-absolute deviation.” PortfolioMAD objects support functions that are specific to MAD portfolio optimization.

The main workflow for MAD portfolio optimization is to create an instance of a PortfolioMAD object that completely specifies a portfolio optimization problem and to operate on the PortfolioMAD object to obtain and analyze efficient portfolios. For more information on the workflow when using PortfolioMAD objects, see “PortfolioMAD Object Workflow” on page 6-14.

You can use the PortfolioMAD object in several ways. To set up a portfolio optimization problem in a PortfolioMAD object, the simplest syntax is:

```
p = PortfolioMAD;
```

This syntax creates a PortfolioMAD object, p, such that all object properties are empty.

The PortfolioMAD object also accepts collections of name-value pair arguments for properties and their values. The PortfolioMAD object accepts inputs for properties with the general syntax:

```
p = PortfolioMAD('property1',value1,'property2',value2, ... );
```

If a PortfolioMAD object exists, the syntax permits the first (and only the first argument) of the PortfolioMAD object to be an existing object with subsequent name-value pair arguments for properties to be added or modified. For example, given an existing PortfolioMAD object in p, the general syntax is:

```
p = PortfolioMAD(p,'property1',value1,'property2',value2, ... );
```

Input argument names are not case-sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see “Shortcuts for Property Names” on page 19-1117). The PortfolioMAD object tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a PortfolioMAD object is a value object so that, given portfolio p, the following code creates two objects, p and q, that are distinct:

```
q = PortfolioMAD(p, ...)
```

After creating a PortfolioMAD object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For more detailed information on the theoretical basis for conditional value-at-risk portfolio optimization, see “Portfolio Optimization Theory” on page 6-2.

## Creation

### Syntax

```
p = PortfolioMAD
p = PortfolioMAD(Name,Value)

p = PortfolioMAD(p,Name,Value)
```

### Description

`p = PortfolioMAD` creates an empty `PortfolioMAD` object for mean-absolute deviation portfolio optimization and analysis. You can then add elements to the `PortfolioMAD` object using the supported "add" and "set" functions. For more information, see "Creating the PortfolioMAD Object" on page 6-19.

`p = PortfolioMAD(Name,Value)` creates a `PortfolioMAD` object (`p`) and sets Properties on page 19-1103 using name-value pairs. For example, `p = PortfolioMAD('AssetList',Assets(1:12))`. You can specify multiple name-value pairs.

`p = PortfolioMAD(p,Name,Value)` creates a `PortfolioMAD` object (`p`) using a previously created `PortfolioMAD` object `p` and sets Properties on page 19-1103 using name-value pairs. You can specify multiple name-value pairs.

### Input Arguments

**p** — Previously constructed `PortfolioMAD` object  
object

Previously constructed `PortfolioMAD` object, specified using `PortfolioMAD`.

## Properties

### Setting Up the Object

#### **AssetList** — Names or symbols of assets in universe

[] (default) | cell array of character vectors | string array

Names or symbols of assets in the universe, specified as a cell array of character vectors or a string array.

Data Types: `cell` | `string`

#### **InitPort** — Initial portfolio

[] (default) | vector

Initial portfolio, specified as a vector.

Data Types: `double`

#### **Name** — Name for instance of `PortfolioMAD` object

[] (default) | character vector | string

Name for instance of the `PortfolioMAD` object, specified as a character vector.

Data Types: char | string

**NumAssets — Number of assets in the universe**

[] (default) | integer scalar

Number of assets in the universe, specified as an integer scalar.

Data Types: double

**Portfolio Object Constraints**

**AEquality — Linear equality constraint matrix**

[] (default) | matrix

Linear equality constraint matrix, specified as a matrix.

Data Types: double

**AInequality — Linear inequality constraint matrix**

[] (default) | matrix

Linear inequality constraint matrix, specified as a matrix.

Data Types: double

**bEquality — Linear equality constraint vector**

[] (default) | vector

Linear equality constraint vector, specified as a vector.

Data Types: double

**bInequality — Linear inequality constraint**

[] (default) | vector

Linear inequality constraint vector, specified as a vector.

Data Types: double

**GroupA — Group A weights to be bounded by weights in group B**

[] (default) | matrix

Group A weights to be bounded by weights in group B, specified as a matrix.

Data Types: double

**GroupB — Group B weights**

[] (default) | matrix

Group B weights, specified as a matrix.

Data Types: double

**GroupMatrix — Group membership matrix**

[] (default) | matrix

Group membership matrix, specified as a matrix.

Data Types: double

**LowerBound — Lower-bound constraint**

[] (default) | vector

Lower-bound constraint, specified as a vector.

Data Types: double

**LowerBudget — Lower-bound budget constraint**

[] (default) | scalar

Lower-bound budget constraint, specified as a scalar.

Data Types: double

**LowerGroup — Lower-bound group constraint**

[] (default) | vector

Lower-bound group constraint, specified as a vector.

Data Types: double

**LowerRatio — Minimum ratio of allocations between Groups A and B**

[] (default) | vector

Minimum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**UpperBound — Upper-bound constraint**

[] (default) | vector

Upper-bound constraint, specified as a vector.

Data Types: double

**UpperBudget — Upper-bound budget constraint**

[] (default) | scalar

Upper-bound budget constraint, specified as a scalar.

Data Types: double

**UpperGroup — Upper-bound group constraint**

[] (default) | vector

Upper-bound group constraint, specified as a vector.

Data Types: double

**UpperRatio — Maximum ratio of allocations between Groups A and B**

[] (default) | vector

Maximum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**BoundType — Type of bounds for each asset weight**

'Simple' (default) | character vector with value 'Simple' or 'Conditional' | string with value "Simple" or "Conditional" | cell array of character vectors with values 'Simple' or 'Conditional' | string array with values "Simple" or "Conditional"

Type of bounds for each asset weight, specified as a scalar character vector or string, or a cell array of character vectors or a string array. For more information, see `setBounds`.

Data Types: `char` | `cell` | `string`

**MinNumAssets — Minimum number of assets allocated in portfolio**

[] (default) | numeric

Minimum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinNumAssets`.

Data Types: `double`

**MaxNumAssets — Maximum number of assets allocated in portfolio**

[] (default) | numeric

Maximum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMaxNumAssets`.

Data Types: `double`

**BuyTurnover — Turnover constraint on purchases**

[] (default) | scalar

Turnover constraint on purchases, specified as a scalar.

Data Types: `double`

**SellTurnover — Turnover constraint on sales**

[] (default) | scalar

Turnover constraint on sales, specified as a scalar.

Data Types: `double`

**Turnover — Turnover constraint**

[] (default) | scalar

Turnover constraint, specified as a scalar.

Data Types: `double`

**Portfolio Object Modeling****BuyCost — Proportional purchase costs**

[] (default) | vector

Proportional purchase costs, specified as a vector.

Data Types: `double`

**RiskFreeRate — Risk-free rate**

[] (default) | scalar

Risk-free rate, specified as a scalar.

Data Types: double

### **ProbabilityLevel — Value-at-risk probability level which is 1 – (loss probability)**

[ ] (default) | scalar

Value-at-risk probability level which is 1 – (loss probability), specified as a scalar.

Data Types: double

### **NumScenarios — Number of scenarios**

[ ] (default) | integer scalar

Number of scenarios, specified as an integer scalar.

Data Types: double

### **SellCost — Proportional sales costs**

[ ] (default) | vector

Proportional sales costs, specified as a vector.

Data Types: double

## **Object Functions**

|                       |                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------|
| setAssetList          | Set up list of identifiers for assets                                                 |
| setInitPort           | Set up initial or current portfolio                                                   |
| setDefaultConstraints | Set up portfolio constraints with nonnegative weights that sum to 1                   |
| estimateAssetMoments  | Estimate mean and covariance of asset returns from data                               |
| setCosts              | Set up proportional transaction costs                                                 |
| addEquality           | Add linear equality constraints for portfolio weights to existing constraints         |
| addGroupRatio         | Add group ratio constraints for portfolio weights to existing group ratio constraints |
| addGroups             | Add group constraints for portfolio weights to existing group constraints             |
| addInequality         | Add linear inequality constraints for portfolio weights to existing constraints       |
| getBounds             | Obtain bounds for portfolio weights from portfolio object                             |
| getBudget             | Obtain budget constraint bounds from portfolio object                                 |
| getCosts              | Obtain buy and sell transaction costs from portfolio object                           |
| getEquality           | Obtain equality constraint arrays from portfolio object                               |
| addGroupRatio         | Obtain group ratio constraint arrays from portfolio object                            |
| addGroups             | Obtain group constraint arrays from portfolio object                                  |
| getInequality         | Obtain inequality constraint arrays from portfolio object                             |
| getOneWayTurnover     | Obtain one-way turnover constraints from portfolio object                             |
| setGroups             | Set up group constraints for portfolio weights                                        |
| setInequality         | Set up linear inequality constraints for portfolio weights                            |
| setBounds             | Set up bounds for portfolio weights for a portfolio object                            |
| setMinMaxNumAssets    | Set cardinality constraints on the number of assets invested in a portfolio object    |
| setBudget             | Set up budget constraints                                                             |

|                                  |                                                                                               |
|----------------------------------|-----------------------------------------------------------------------------------------------|
| setCosts                         | Set up proportional transaction costs                                                         |
| setDefaultConstraints            | Set up portfolio constraints with nonnegative weights that sum to 1                           |
| setEquality                      | Set up linear equality constraints for portfolio weights                                      |
| setGroupRatio                    | Set up group ratio constraints for portfolio weights                                          |
| setInitPort                      | Set up initial or current portfolio                                                           |
| setOneWayTurnover                | Set up one-way portfolio turnover constraints                                                 |
| setTurnover                      | Set up maximum portfolio turnover constraint                                                  |
| checkFeasibility                 | Check feasibility of input portfolios against portfolio object                                |
| estimateBounds                   | Estimate global lower and upper bounds for set of portfolios                                  |
| estimateFrontier                 | Estimate specified number of optimal portfolios on the efficient frontier                     |
| estimateFrontierByReturn         | Estimate optimal portfolios with targeted portfolio returns                                   |
| estimateFrontierByRisk           | Estimate optimal portfolios with targeted portfolio risks                                     |
| estimateFrontierLimits           | Estimate optimal portfolios at endpoints of efficient frontier                                |
| plotFrontier                     | Plot efficient frontier                                                                       |
| estimatePortReturn               | Estimate mean of portfolio returns                                                            |
| estimatePortRisk                 | Estimate portfolio risk according to risk proxy associated with corresponding object          |
| setSolver                        | Choose main solver and specify associated solver options for portfolio optimization           |
| setProbabilityLevel              | Set probability level for VaR and CVaR calculations                                           |
| setScenarios                     | Set asset returns scenarios by direct matrix                                                  |
| getScenarios                     | Obtain scenarios from portfolio object                                                        |
| simulateNormalScenariosByData    | Simulate multivariate normal asset return scenarios from data                                 |
| simulateNormalScenariosByMoments | Simulate multivariate normal asset return scenarios from mean and covariance of asset returns |
| estimateScenarioMoments          | Estimate mean and covariance of asset return scenarios                                        |
| estimatePortStd                  | Estimate standard deviation of portfolio returns                                              |

## Examples

### Create an Empty PortfolioMAD Object

You can create a PortfolioMAD object, `p`, with no input arguments and display it using `disp`.

```
p = PortfolioMAD;
disp(p);
```

PortfolioMAD with properties:

```
BuyCost: []
SellCost: []
RiskFreeRate: []
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: []
Name: []
NumAssets: []
AssetList: []
InitPort: []
```

```

AInequality: []
bInequality: []
  AEquality: []
  bEquality: []
  LowerBound: []
  UpperBound: []
LowerBudget: []
UpperBudget: []
GroupMatrix: []
  LowerGroup: []
  UpperGroup: []
    GroupA: []
    GroupB: []
  LowerRatio: []
  UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
  BoundType: []

```

This approach provides a way to set up a portfolio optimization problem with the `PortfolioMAD` function. You can then use the associated set functions to set and modify collections of properties in the `PortfolioMAD` object.

### Create a PortfolioMAD Object Using a Single-Step Setup

You can use the `PortfolioMAD` object directly to set up a “standard” portfolio optimization problem. Given scenarios of asset returns in the variable `AssetScenarios`, this problem is completely specified as follows:

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD('Scenarios', AssetScenarios, ...
  'LowerBound', 0, 'LowerBudget', 1, 'UpperBudget', 1)

p =
PortfolioMAD with properties:

  BuyCost: []
  SellCost: []
RiskFreeRate: []
  Turnover: []
  BuyTurnover: []
  SellTurnover: []
NumScenarios: 20000
  Name: []
  NumAssets: 4
  AssetList: []

```

```

    InitPort: []
    AInequality: []
    bInequality: []
    AEquality: []
    bEquality: []
    LowerBound: [4x1 double]
    UpperBound: []
    LowerBudget: 1
    UpperBudget: 1
    GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
    GroupA: []
    GroupB: []
    LowerRatio: []
    UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
    BoundType: []

```

Note that the `LowerBound` property value undergoes scalar expansion since `AssetScenarios` provides the dimensions of the problem.

### Create a PortfolioMAD Object Using a Sequence of Steps

Using a sequence of steps is an alternative way to accomplish the same task of setting up a “standard” MAD portfolio optimization problem, given `AssetScenarios` variable is:

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = PortfolioMAD(p, 'LowerBound', 0);
p = PortfolioMAD(p, 'LowerBudget', 1, 'UpperBudget', 1);

plotFrontier(p);

```

This way works because the calls to PortfolioMAD are in this particular order. In this case, the call to initialize AssetScenarios provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the LowerBound property as follows:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = PortfolioMAD(p, 'LowerBound', zeros(size(m)));
p = PortfolioMAD(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setScenarios(p, AssetScenarios);

plotFrontier(p);
```

If you did not specify the size of LowerBound but, instead, input a scalar argument, the PortfolioMAD object assumes that you are defining a single-asset problem and produces an error at the call to set asset scenarios with four assets.

### Create a PortfolioMAD Object Using Shortcuts for Property Names

You can create a PortfolioMAD object, `p` with the PortfolioMAD object using shortcuts for property names.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD('scenario', AssetScenarios, 'lb', 0, 'budget', 1)

p =
PortfolioMAD with properties:
```

```

    BuyCost: []
    SellCost: []
    RiskFreeRate: []
    Turnover: []
    BuyTurnover: []
    SellTurnover: []
    NumScenarios: 20000
        Name: []
    NumAssets: 4
    AssetList: []
    InitPort: []
    AInequality: []
    bInequality: []
    AEquality: []
    bEquality: []
    LowerBound: [4x1 double]
    UpperBound: []
    LowerBudget: 1
    UpperBudget: 1
    GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
        GroupA: []
        GroupB: []
    LowerRatio: []
    UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
    BoundType: []

```

### Direct Setting of PortfolioMAD Object Properties

Although not recommended, you can set properties directly, however no error-checking is done on your inputs.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;

p = setScenarios(p, AssetScenarios);

p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
disp(p);

```

PortfolioMAD with properties:

```
    BuyCost: []
    SellCost: []
    RiskFreeRate: []
    Turnover: []
    BuyTurnover: []
    SellTurnover: []
    NumScenarios: 20000
    Name: []
    NumAssets: 4
    AssetList: []
    InitPort: []
    AInequality: []
    bInequality: []
    AEquality: []
    bEquality: []
    LowerBound: [4x1 double]
    UpperBound: []
    LowerBudget: 1
    UpperBudget: 1
    GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
    GroupA: []
    GroupB: []
    LowerRatio: []
    UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
    BoundType: []
```

Scenarios cannot be assigned directly to a PortfolioMAD object. Scenarios must always be set through either the PortfolioMAD function, the setScenarios function, or any of the scenario simulation functions.

### Create a PortfolioMAD Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse

p = PortfolioMAD('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000, 'missingdata',true);
p = setDefaultConstraints(p);

plotFrontier(p);
```

```

pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([pwgt],pnames,'obsnames',p.AssetList);

disp(Blotter);

```

|      | Port1     | Port2    | Port3    | Port4   | Port5 |
|------|-----------|----------|----------|---------|-------|

## More About

### Mean-Absolute Deviation Portfolio Optimization

A MAD optimization problem is completely specified with three elements.

The three elements for a A MAD optimization problem are:

- A universe of assets with scenarios of asset total returns for a period of interest, where scenarios comprise a collection of samples from the underlying probability distribution for asset total returns. This collection must be sufficiently large for asymptotic convergence of sample statistics. Asset return moments and related statistics are derived exclusively from the scenarios.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk proxies, which, for MAD optimization, is either the gross or net mean of portfolio returns and the mean-absolute deviation of portfolio returns.

After these three elements have been specified unambiguously, it is possible to solve and analyze MAD portfolio optimization problems.

The simplest MAD portfolio optimization problem has:

- Scenarios of asset total returns
- A requirement that all portfolios have nonnegative weights that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk proxies that use scenarios of asset total returns

Given scenarios of asset returns in the variable `AssetScenarios`, this problem is completely specified by:

```
p = PortfolioMAD('Scenarios', AssetScenarios, 'LowerBound', 0, 'Budget', 1);
```

or equivalently by:

```
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
```

To confirm that this is a valid portfolio optimization problem, the following function determines whether the set of `PortfolioMAD` choices is bounded (a necessary condition for portfolio optimization).

```
[lb, ub, isbounded] = estimateBounds(p);
```

Given the problem specified in the `PortfolioMAD` object `p`, the efficient frontier for this problem can be displayed with:

```
plotFrontier(p);
```

and efficient portfolios can be obtained with:

```
pwgt = estimateFrontier(p);
```

For more detailed information on the theoretical basis for mean-absolute deviation optimization, see “Portfolio Optimization Theory” on page 6-2.

## PortfolioMAD Problem Sufficiency

A MAD portfolio optimization problem is completely specified with the `PortfolioMAD` object if three conditions are met.

The following are the three conditions that must be met:

- You must specify a collection of asset returns or prices known as scenarios such that all scenarios are finite asset returns or prices. These scenarios are meant to be samples from the underlying probability distribution of asset returns. This condition can be satisfied by the `setScenarios` function or with several canned scenario simulation functions.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded. You can satisfy this condition using an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed and several tools, such as the `estimateBounds` function, provide ways to ensure that your problem is properly formulated.

Although the general sufficient conditions for MAD portfolio optimization go beyond these conditions, the `PortfolioMAD` object handles all these additional conditions.

## Shortcuts for Property Names

The `PortfolioMAD` object has shorter argument names that replace longer argument names associated with specific properties of the `PortfolioMAD` object.

For example, rather than enter `'AInequality'`, `PortfolioMAD` accepts the case-insensitive name `'ai'` to set the `AInequality` property in a `PortfolioMAD` object. Every shorter argument name corresponds with a single property in the `PortfolioMAD` function. The one exception is the alternative argument name `'budget'`, which signifies both the `LowerBudget` and `UpperBudget` properties. When `'budget'` is used, then the `LowerBudget` and `UpperBudget` properties are set to the same value to form an equality budget constraint.

## Shortcuts for Property Names

| Shortcut Argument Name     | Equivalent Argument / Property Name |
|----------------------------|-------------------------------------|
| ae                         | AEquality                           |
| ai                         | AInequality                         |
| assetnames or assets       | AssetList                           |
| be                         | bEquality                           |
| bi                         | bInequality                         |
| budget                     | UpperBudget and LowerBudget         |
| group                      | GroupMatrix                         |
| lb                         | LowerBound                          |
| n or num                   | NumAssets                           |
| rfr                        | RiskFreeRate                        |
| scenario or assetscenarios | Scenarios                           |
| ub                         | UpperBound                          |

## Introduced in R2013b

## portopt

Portfolios on constrained efficient frontier

---

**Note** portopt has been partially removed and will no longer accept `ConSet` or `varargin` arguments. Use `Portfolio` instead to solve portfolio problems that are more than a long-only fully-invested portfolio. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow”. For more information on migrating portopt code to `Portfolio`, see “portopt Migration to Portfolio Object”.

---

### Syntax

```
[PortRisk,PortReturn,PortWts] = portopt(ExpReturn,ExpCovariance)
```

```
[PortRisk,PortReturn,PortWts] = portopt(ExpReturn,ExpCovariance,NumPorts)
```

```
[PortRisk,PortReturn,PortWts] = portopt(ExpReturn,ExpCovariance,NumPorts,PortReturn)
```

### Arguments

|               |                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ExpReturn     | 1 by number of assets (NASSETS) vector specifying the expected (mean) return of each asset.                                                                                                                                                 |
| ExpCovariance | NASSETS-by-NASSETS matrix specifying the covariance of the asset returns.                                                                                                                                                                   |
| NumPorts      | (Optional) Number of portfolios generated along the efficient frontier. Returns are equally spaced between the maximum possible return and the minimum risk point. If NumPorts is empty (entered as []), computes 10 equally spaced points. |
| PortReturn    | (Optional) Expected return of each portfolio. A number of portfolios (NPORTS-by-1 vector). If not entered or empty, NumPorts equally spaced returns between the minimum and maximum possible values are used.                               |

### Description

`[PortRisk,PortReturn,PortWts] = portopt(ExpReturn,ExpCovariance)` sets up the most basic portfolio problem with weights greater than or equal to 0 that must sum to 1. All that is necessary to solve this problem is the mean and covariance of asset returns. The problem returns 10 equally-spaced points on the efficient frontier by return.

`[PortRisk,PortReturn,PortWts] = portopt(ExpReturn,ExpCovariance,NumPorts)` sets up the basic portfolio problem but lets you specify how many equally-spaced points on the efficient frontier that you want in `NumPorts`. If you specify 1, it returns the minimum-risk portfolio.

`[PortRisk,PortReturn,PortWts] = portopt(ExpReturn,ExpCovariance,NumPorts,PortReturn)` sets up the basic portfolio problem but lets you specify target returns on the efficient frontier in the vector `PortReturn`. This functionality requires that if you set `PortReturn`, `NumPorts` should be empty.

**Note** portopt generates a warning if have returns outside the range and returns the portfolios at the endpoints of the efficient frontier.

---

The outputs for portopt are:

PortRisk is an NPORTS-by-1 vector of the standard deviation of each portfolio.

PortReturn is an NPORTS-by-1 vector of the expected return of each portfolio.

PortWts is an NPORTS-by-NASSETS matrix of weights allocated to each asset. Each row represents a portfolio. The total of all weights in a portfolio is 1.

If portopt is invoked without output arguments, it writes to the current figure window.

## Examples

### Plot the Risk-Return Efficient Frontier

Use portopt to connect 20 portfolios along the efficient frontier having evenly spaced returns. By default, choose among portfolios without short-selling and scale the value of the portfolio to 1.

```
ExpReturn = [0.1 0.2 0.15];
```

```
ExpCovariance = [0.005   -0.010   0.004  
                -0.010   0.040  -0.002  
                0.004   -0.002   0.023];
```

```
NumPorts = 20;  
portopt(ExpReturn, ExpCovariance, NumPorts)
```

Introduced before R2006a

## portrand

Randomized portfolio risks, returns, and weights

### Syntax

```
[PortRisk,PortReturn,PortWts] = portrand(Asset,Return,Points,Method)
```

```
portrand(Asset,Return,Points,Method)
```

### Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Asset  | Matrix of time series data. Each row is an observation and each column represents a single security.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Return | (Optional) Row vector where each column represents the rate of return for the corresponding security in Asset. By default, Return is computed by taking the average value of each column of Asset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Points | (Optional) Scalar that specifies how many random points should be generated. Default = 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Method | <p>(Optional) A character vector that specifies how to generate random portfolios from the set of portfolios with two possible methods:</p> <ul style="list-style-type: none"> <li>'uniform' - Uniformly distributed portfolio weights (default method). The 'uniform' method generates portfolio weights that are uniformly distributed on the set of portfolio weights.</li> <li>'geometric' - Concentrated portfolio weights around the geometric center of the set of portfolios. The 'geometric' method generates portfolio weights that are concentrated around the geometric center of the set of portfolio weights.</li> </ul> <p><b>Note</b> The 'uniform' and 'geometric' methods generate weights that are distributed symmetrically around the geometric center of the set of weights.</p> |

### Description

[PortRisk,PortReturn,PortWts] = portrand(Asset,Return,Points,Method) returns the risks, rates of return, and weights of random portfolio configurations.

|            |                                                                                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------|
| PortRisk   | Points-by-1 vector of standard deviations.                                                                          |
| PortReturn | Points-by-1 vector of expected rates of return.                                                                     |
| PortWts    | Points by number of securities matrix of asset weights. Each row of PortWts is a different portfolio configuration. |

portrand(Asset, Return, Points, Method) plots the points representing each portfolio configuration. It does not return any data to the MATLAB workspace.

---

**Note** Portfolios are selected at random from a set of portfolios such that portfolio weights are nonnegative and sum to 1. The sample mean and covariance of asset returns are used to compute portfolio returns for each random portfolio.

## portror

Portfolio expected rate of return

### Syntax

```
R = portror(Return,Weight)
```

### Arguments

|        |                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------|
| Return | 1-by-N matrix of rates of return. Each column of Return represents the rate of return for a single security               |
| Weight | M-by-N matrix of weights. Each row of Weight represents a different weighting combination of the assets in the portfolio. |

### Description

`R = portror(Return,Weight)` returns a 1-by-M vector for the expected rate of return.

### Examples

#### Portfolio Expected Rate of Return

This example shows a portfolio that is made up of two assets ABC and XYZ having expected rates of return of 10% and 14%, respectively. If 40% percent of the portfolio's funds are allocated to asset ABC and the remaining funds are allocated to asset XYZ, the portfolio's expected rate of return is:

```
r = portror([.1 .14],[.4 .6])
```

```
r = 0.1240
```

# portsim

Monte Carlo simulation of correlated asset returns

## Syntax

```
RetSeries = portsim(ExpReturn,ExpCovariance,NumObs)
RetSeries = portsim( ____,RetIntervals,NumSim,Method)
```

## Description

`RetSeries = portsim(ExpReturn,ExpCovariance,NumObs)` simulates correlated returns of NASSETS assets over NUMOBS consecutive observation intervals. Asset returns are simulated as the proportional increments of constant drift, constant volatility stochastic processes, thereby approximating continuous-time geometric Brownian motion.

`RetSeries = portsim( ____,RetIntervals,NumSim,Method)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Distinction Between Simulation Methods

This example shows the distinction between the Exact and Expected methods of simulation.

Consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on daily asset returns (where `ExpReturn` and `Sigmas` are divided by 100 to convert percentages to returns).

```
ExpReturn      = [0.0246  0.0189  0.0273  0.0141  0.0311]/100;
Sigmas         = [0.9509  1.4259  1.5227  1.1062  1.0877]/100;
Correlations   = [1.0000  0.4403  0.4735  0.4334  0.6855
                  0.4403  1.0000  0.7597  0.7809  0.4343
                  0.4735  0.7597  1.0000  0.6978  0.4926
                  0.4334  0.7809  0.6978  1.0000  0.4289
                  0.6855  0.4343  0.4926  0.4289  1.0000];
```

Convert the correlations and standard deviations to a covariance matrix.

```
ExpCovariance = corr2cov(Sigmas, Correlations)
```

```
ExpCovariance = 5x5
10-3 x
```

```
    0.0904    0.0597    0.0686    0.0456    0.0709
    0.0597    0.2033    0.1649    0.1232    0.0674
    0.0686    0.1649    0.2319    0.1175    0.0816
    0.0456    0.1232    0.1175    0.1224    0.0516
    0.0709    0.0674    0.0816    0.0516    0.1183
```

Assume that there are 252 trading days in a calendar year, and simulate two sample paths (realizations) of daily returns over a two-year period. Since `ExpReturn` and `ExpCovariance` are expressed daily, set `RetIntervals = 1`.

```
StartPrice    = 100;
NumObs        = 504; % two calendar years of daily returns
NumSim        = 2;
RetIntervals  = 1;   % one trading day
NumAssets     = 5;
```

To illustrate the distinction between methods, simulate two paths by each method, starting with the same random number state.

```
rng('default');
RetExact = portsim(ExpReturn, ExpCovariance, NumObs, ...
  RetIntervals, NumSim, 'Exact');
rng(0);
RetExpected = portsim(ExpReturn, ExpCovariance, NumObs, ...
  RetIntervals, NumSim, 'Expected');
```

Compare the mean and covariance of `RetExact` with the inputs (`ExpReturn` and `ExpCovariance`), you will observe that they are almost identical.

At this point, `RetExact` and `RetExpected` are both 504-by-5-by-2 arrays. Now assume an equally weighted portfolio formed from the five assets and create arrays of portfolio returns in which each column represents the portfolio return of the corresponding sample path of the simulated returns of the five assets. The portfolio arrays `PortRetExact` and `PortRetExpected` are 504-by-2 matrices.

```
Weights       = ones(NumAssets, 1)/NumAssets;
PortRetExact  = zeros(NumObs, NumSim);
PortRetExpected = zeros(NumObs, NumSim);

for i = 1:NumSim
    PortRetExact(:,i) = RetExact(:, :, i) * Weights;
    PortRetExpected(:,i) = RetExpected(:, :, i) * Weights;
end
```

Finally, convert the simulated portfolio returns to prices and plot the data. In particular, note that since the `Exact` method matches expected return and covariance, the terminal portfolio prices are virtually identical for each sample path. This is not true for the `Expected` simulation method. Although this example examines portfolios, the same methods apply to individual assets as well. Thus, `Exact` simulation is most appropriate when unique paths are required to reach the same terminal prices.

```
PortExact = ret2tick(PortRetExact, ...
  repmat(StartPrice, 1, NumSim));
PortExpected = ret2tick(PortRetExpected, ...
  repmat(StartPrice, 1, NumSim));
subplot(2,1,1), plot(PortExact, '-r')
ylabel('Portfolio Prices')
title('Exact Method')
subplot(2,1,2), plot(PortExpected, '-b')
ylabel('Portfolio Prices')
title('Expected Method')
```

### Interaction Between ExpReturn, ExpCovariance, and RetIntervals

This example shows the interplay among ExpReturn, ExpCovariance, and RetIntervals. Recall that portsim simulates correlated asset returns over an interval of length  $dt$ , given by the equation

$$\frac{dS}{S} = \mu dt + \sigma dz = \mu dt + \sigma \varepsilon \sqrt{dt},$$

where  $S$  is the asset price,  $\mu$  is the expected rate of return,  $\sigma$  is the volatility of the asset price, and  $\varepsilon$  represents a random drawing from a standardized normal distribution.

The time increment  $dt$  is determined by the optional input RetIntervals, either as an explicit input argument or as a unit time increment by default. Regardless, the periodicity of ExpReturn, ExpCovariance, and RetIntervals must be consistent. For example, if ExpReturn and ExpCovariance are annualized, then RetIntervals must be in years. This point is often misunderstood.

To illustrate the interplay among ExpReturn, ExpCovariance, and RetIntervals, consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on daily asset returns.

```
ExpReturn    = [0.0246  0.0189  0.0273  0.0141  0.0311]/100;
Sigmas      = [0.9509  1.4259  1.5227  1.1062  1.0877]/100;
```

```

Correlations = [1.0000 0.4403 0.4735 0.4334 0.6855
               0.4403 1.0000 0.7597 0.7809 0.4343
               0.4735 0.7597 1.0000 0.6978 0.4926
               0.4334 0.7809 0.6978 1.0000 0.4289
               0.6855 0.4343 0.4926 0.4289 1.0000];

```

Convert the correlations and standard deviations to a covariance matrix of daily returns.

```
ExpCovariance = corr2cov(Sigmas, Correlations);
```

Assume 252 trading days per calendar year, and simulate a single sample path of daily returns over a four-year period. Since the `ExpReturn` and `ExpCovariance` inputs are expressed daily, set `RetIntervals = 1`.

```

StartPrice = 100;
NumObs = 1008; % four calendar years of daily returns
RetIntervals = 1; % one trading day
NumAssets = length(ExpReturn);
randn('state',0);
RetSeries1 = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, 1, 'Expected');

```

Now annualize the daily data, thereby changing the periodicity of the data, by multiplying `ExpReturn` and `ExpCovariance` by 252 and dividing `RetIntervals` by 252 (`RetIntervals = 1/252` of a year). Resetting the random number generator to its initial state, you can reproduce the results.

```

rng('default');
RetSeries2 = portsim(ExpReturn*252, ExpCovariance*252, ...
NumObs, RetIntervals/252, 1, 'Expected');

```

Assume an equally weighted portfolio and compute portfolio returns associated with each simulated return series.

```
Weights = ones(NumAssets, 1)/NumAssets;
```

```

PortRet1 = RetSeries2 * Weights;
PortRet2 = RetSeries2 * Weights;

```

Comparison of the data reveals that `PortRet1` and `PortRet2` are identical.

### Univariate Geometric Brownian Motion

This example shows how to simulate a univariate geometric Brownian motion process. It is based on an example found in Hull, *Options, Futures, and Other Derivatives*, 5th Edition (see example 12.2 on page 236). In addition to verifying Hull's example, it also graphically illustrates the lognormal property of terminal stock prices by a rather large Monte Carlo simulation.

Assume that you own a stock with an initial price of \$20, an annualized expected return of 20% and volatility of 40%. Simulate the daily price process for this stock over the course of one full calendar year (252 trading days).

```

StartPrice = 20;
ExpReturn = 0.2;
ExpCovariance = 0.4^2;
NumObs = 252;
NumSim = 10000;
RetIntervals = 1/252;

```

RetIntervals is expressed in years, consistent with the fact that ExpReturn and ExpCovariance are annualized. Also, ExpCovariance is entered as a variance rather than the more familiar standard deviation (volatility).

Set the random number generator state, and simulate 10,000 trials (realizations) of stock returns over a full calendar year of 252 trading days.

```
rng('default');
RetSeries = squeeze(portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, NumSim, 'Expected'));
```

The squeeze function reformats the output array of simulated returns from a 252-by-1-by-10000 array to more convenient 252-by-10000 array. (Recall that portsim is fundamentally a multivariate simulation engine).

In accordance with Hull's equations 12.4 and 12.5 on page 236

$$E(S_T) = S_0 e^{\mu T}$$

$$\text{var}(S_T) = S_0^2 e^{2\mu T} (e^{\sigma^2 T} - 1)$$

convert the simulated return series to a price series and compute the sample mean and the variance of the terminal stock prices.

```
StockPrices = ret2tick(RetSeries, repmat(StartPrice, 1, NumSim));
```

```
SampMean = mean(StockPrices(end,:))
SampVar = var(StockPrices(end,:))
```

```
SampMean =
    24.4489
```

```
SampVar =
    101.4243
```

Compare these values with the values you obtain by using Hull's equations.

```
ExpValue = StartPrice*exp(ExpReturn)
ExpVar = ...
StartPrice*StartPrice*exp(2*ExpReturn)*(exp((ExpCovariance)) - 1)
```

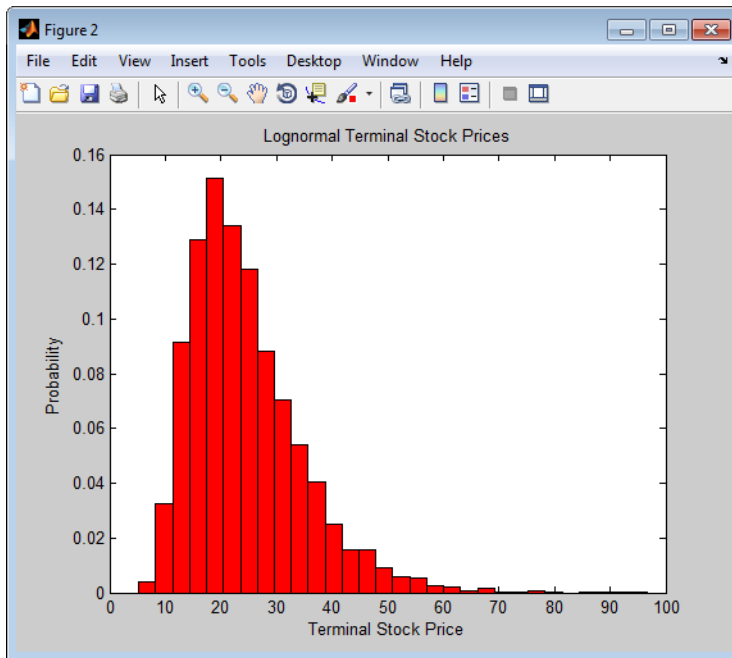

```
ExpValue =
    24.4281
```

```
ExpVar =
    103.5391
```

These results are very close to the results shown in Hull's example 12.2.

Display the sample density function of the terminal stock price after one calendar year. From the sample density function, the lognormal distribution of terminal stock prices is apparent.

```
[count, BinCenter] = hist(StockPrices(end,:), 30);
figure
bar(BinCenter, count/sum(count), 1, 'r')
xlabel('Terminal Stock Price')
ylabel('Probability')
title('Lognormal Terminal Stock Prices')
```

## Input Arguments

**ExpReturn** — Expected (mean) return of each asset  
vector

Expected (mean) return of each asset, specified as a 1-by-NASSETS vector.

Data Types: double

**ExpCovariance** — Asset return covariances  
matrix

Asset return covariances, specified as an NASSETS-by-NASSETS matrix. ExpCovariance must be symmetric and positive semidefinite (no negative eigenvalues). The standard deviations of the returns are  $\text{ExpSigma} = \text{sqrt}(\text{diag}(\text{ExpCovariance}))$ . If ExpCovariance is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

Data Types: double

**NumObs** — Number of consecutive observations in the return time series  
positive scalar integer

number of consecutive observations in the return time series, specified as a positive scalar integer. If NumObs is entered as the empty matrix `[]`, the length of RetIntervals is used.

Data Types: double

**RetIntervals** — Interval times between observations  
1 (default) | positive scalar | vector

(Optional) Interval times between observations, specified as a positive scalar or a number of observations NUMOBS-by-1 vector. If RetIntervals is not specified, all intervals are assumed to have length 1.

Data Types: double

**NumSim — Number of simulated sample paths (realizations) of NUMOBS observations**

1 (default) | positive scalar integer

(Optional) Number of simulated sample paths (realizations) of NUMOBS observations, specified as a positive scalar integer. The default value for NumSim is 1 (single realization of NUMOBS correlated asset returns).

Data Types: double

**Method — Type of Monte Carlo simulation**

'Exact' (default) | character vector

(Optional) Type of Monte Carlo simulation, specified as a character vector with one of the following values:

- 'Exact' (default) generates correlated asset returns in which the sample mean and covariance match the input mean (ExpReturn) and covariance (ExpCovariance) specifications.
- 'Expected' generates correlated asset returns in which the sample mean and covariance are statistically equal to the input mean and covariance specifications. (The expected values of the sample mean and covariance are equal to the input mean (ExpReturn) and covariance (ExpCovariance) specifications.)

For either Method, the sample mean and covariance returned are appropriately scaled by RetIntervals.

Data Types: char

**Output Arguments**

**RetSeries — Three-dimensional array of correlated, normally distributed, proportional asset returns**

array

Three-dimensional array of correlated, normally distributed, proportional asset returns, returned as a NUMOBS-by-NASSETS-by-NUMSIM three-dimensional array.

Asset returns over an interval of length  $dt$  are given by

$$\frac{dS}{S} = \mu dt + \sigma dz = \mu dt + \sigma \varepsilon \sqrt{dt},$$

where  $S$  is the asset price,  $\mu$  is the expected rate of return,  $\sigma$  is the volatility of the asset price, and  $\varepsilon$  represents a random drawing from a standardized normal distribution.

**Notes**

- When Method is 'Exact', the sample mean and covariance of all realizations (scaled by RetIntervals) match the input mean and covariance. When the returns are then converted to asset prices, all terminal prices for a given asset are in close agreement. Although all realizations are drawn independently, they produce similar terminal asset prices. Set Method to 'Expected' to avoid this behavior.

- The returns from the portfolios in `PortWts` are given by  $\text{PortReturn} = \text{PortWts} * \text{RetSeries}(:, :, 1)'$ , where `PortWts` is a matrix in which each row contains the asset allocations of a portfolio. Each row of `PortReturn` corresponds to one of the portfolios identified in `PortWts`, and each column corresponds to one of the observations taken from the first realization (the first plane) in `RetSeries`. See `portopt` and `portstats` for portfolio specification and optimization.

## portstats

Portfolio expected return and risk

### Syntax

```
[PortRisk,PortReturn] = portstats(ExpReturn,ExpCovariance)
[PortRisk,PortReturn] = portstats( ____,Wts)
```

### Description

[PortRisk,PortReturn] = portstats(ExpReturn,ExpCovariance) computes the expected rate of return and risk for a portfolio of assets.

[PortRisk,PortReturn] = portstats( \_\_\_\_,Wts) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Computes the Expected Rate of Return and Risk for a Portfolio of Assets

This example shows how to calculate the expected rate of return and risk for a portfolio of assets.

```
ExpReturn = [0.1 0.2 0.15];
```

```
ExpCovariance = [0.0100    -0.0061    0.0042
                 -0.0061    0.0400   -0.0252
                  0.0042   -0.0252    0.0225 ];
```

```
PortWts=[0.4 0.2 0.4; 0.2 0.4 0.2];
```

```
[PortRisk, PortReturn] = portstats(ExpReturn, ExpCovariance,...
PortWts)
```

```
PortRisk = 2×1
```

```
    0.0560
    0.0550
```

```
PortReturn = 2×1
```

```
    0.1400
    0.1300
```

### Input Arguments

**ExpReturn** — Expected (mean) return of each asset  
vector

Expected (mean) return of each asset, specified as a 1-by-NASSETS vector.

Data Types: double

### **ExpCovariance — Asset return covariances**

matrix

Asset return covariances, specified as an NASSETS-by-NASSETS matrix.

Data Types: double

### **Wts — Weights allocated to each asset**

1/NASSETS (equally weighted) (default) | matrix

(Optional) Weights allocated to each asset, specified as an NPORTS-by-NASSETS matrix. Each row represents a different weighting combination of the assets in the portfolio. If Wts is not entered, weights of 1/NASSETS are assigned to each security.

Data Types: double

## **Output Arguments**

### **PortRisk — Standard deviation of each portfolio**

vector

Standard deviation of each portfolio, returned as an NPORTS-by-1 vector.

### **PortReturn — Expected return of each portfolio**

vector

Expected return of each portfolio, returned an NPORTS-by-1 vector.

# portvar

Variance for portfolio of assets

## Syntax

```
V = portvar(Asset,Weight)
```

## Arguments

|        |                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------|
| Asset  | M-by-N matrix of M asset returns for N securities.                                                                        |
| Weight | R-by-N matrix of R portfolio weights for N securities. Each row of Weight constitutes a portfolio of securities in Asset. |

## Description

`V = portvar(Asset,Weight)` returns the portfolio variance as an R-by-1 vector (assuming Weight is a matrix of size R-by-N) with each row representing a variance calculation for each row of Weight.

`V = portvar(Asset)` assigns each security an equal weight when calculating the portfolio variance.

## portvrisk

Portfolio value at risk (VaR)

### Syntax

```
ValueAtRisk = portvrisk(PortReturn,PortRisk)
ValueAtRisk = portvrisk( ____,RiskThreshold,PortValue)
```

### Description

`ValueAtRisk = portvrisk(PortReturn,PortRisk)` returns the maximum potential loss in the value of a portfolio over one period of time (that is, monthly, quarterly, yearly, and so on) given the loss probability level. `portvrisk` calculates `ValueAtRisk` using a normal distribution.

`ValueAtRisk = portvrisk( ____,RiskThreshold,PortValue)` adds optional arguments for `RiskThreshold` and `PortValue`.

### Examples

#### Compute the Maximum Potential Loss in the Value of a Portfolio Over One Period of Time

This example shows how to return the maximum potential loss in the value of a portfolio over one period of time, where `ValueAtRisk` is computed on a per-unit basis.

```
PortReturn = 0.29/100;
PortRisk = 3.08/100;
RiskThreshold = [0.01;0.05;0.10];
PortValue = 1;
ValueAtRisk = portvrisk(PortReturn,PortRisk,...
RiskThreshold,PortValue)
```

```
ValueAtRisk = 3×1
```

```
0.0688
0.0478
0.0366
```

#### Compute the Maximum Potential Loss in the Value of a Portfolio Over One Period of Time Using Actual Values

This example shows how to return the maximum potential loss in the value of a portfolio over one period of time, where `ValueAtRisk` is computed with actual values.

```
PortReturn = [0.29/100;0.30/100];
PortRisk = [3.08/100;3.15/100];
RiskThreshold = 0.10;
PortValue = [1000000000;500000000];
```

```
ValueAtRisk = portvrisk(PortReturn,PortRisk,...
RiskThreshold,PortValue)
```

```
ValueAtRisk = 2×1
107 ×
```

```
3.6572
1.8684
```

## Input Arguments

### PortReturn — Expected return of each portfolio over period

scalar numeric | vector

Expected return of each portfolio over the period, specified as a scalar numeric or an NPORTS-by-1 vector.

Data Types: double

### PortRisk — Standard deviation of each portfolio over period

scalar numeric | vector

Standard deviation of each portfolio over period, specified as a scalar numeric or NPORTS-by-1 vector.

Data Types: double

### RiskThreshold — Loss probability

0.05 (5%) (default) | scalar decimal | vector

(Optional) Loss probability, specified as a scalar decimal or an NPORTS-by-1 vector.

Data Types: double

### PortValue — Total value of asset portfolio

1 (default) | scalar numeric | vector

(Optional) Total value of asset portfolio, specified as a scalar numeric or an NPORTS-by-1 vector.

---

**Note** If PortReturn and PortRisk are in dollar units, then PortValue should be 1. If PortReturn and PortRisk are on a percentage basis, then PortValue should be the total value of the portfolio.

---

Data Types: double

## Output Arguments

### ValueAtRisk — Estimated maximum loss in portfolio

vector

Estimated maximum loss in the portfolio, returned as an NPORTS-by-1 vector. ValueAtRisk is predicted with a confidence probability of  $1 - \text{RiskThreshold}$ .

---

**Note** If PortValue is not given, ValueAtRisk is presented on a per-unit basis. A value of 0 indicates no losses.

---

# posvalidx

Positive volume index

---

**Note** posvalidx has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a `matrix`, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
volume = posvalidx(Data)
volume = posvalidx( ___,Name,Value)
```

## Description

`volume = posvalidx(Data)` calculates the positive volume index from the series of closing stock prices and trade volume.

`volume = posvalidx( ___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Positive Volume Index for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
volume = posvalidx(TMW);
plot(volume.Time,volume.PositiveVolume)
title('Positive Volume Index for TMW')
```

## Input Arguments

### Data — Data with closing prices and trade volume

matrix | table | timetable

Data with closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-2 with closing prices and trade volume stored in the first and second columns. Timetables and tables with M rows must contain variables named 'Close' and 'Volume' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `volume = posvolidx(TMW, 'InitialValue', 500)`

### InitialValue — Initial value for positive volume index

100 (default) | positive integer

Initial value for positive volume index, specified as the comma-separated pair consisting of 'InitialValue' and a scalar positive integer.

Data Types: double

## Output Arguments

### volume — Positive volume index

matrix | table | timetable

Positive volume index, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## More About

### Positive Volume Index

Positive volume index shows the days when the trading volume of a particular security is substantially higher than other days.

## power

Financial time series power

---

**Note** `power` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = tsubj .^ array
```

```
newfts = array .^tsubj
```

```
newfts = tsubj_1 .^ tsubj_2
```

### Arguments

|                               |                                                                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsubj</code>            | Financial time series object.                                                                                                                                                         |
| <code>array</code>            | Scalar value or array with the number of rows equal to the number of dates in <code>tsubj</code> and the number of columns equal to the number of data series in <code>tsubj</code> . |
| <code>tsubj_1, tsubj_2</code> | Pair of financial time series objects.                                                                                                                                                |

### Description

`newfts = tsubj .^ array` raises all values in the data series of the financial time series object `tsubj` element by element to the power indicated by the array value. The results are stored in another financial time series object `newfts`. The `newfts` object contains the same data series names as `tsubj`.

`newfts = array .^ tsubj` raises the array values element by element to the values contained in the data series of the financial time series object `tsubj`. The results are stored in another financial time series object `newfts`. The `newfts` object contains the same data series names as `tsubj`.

`newfts = tsubj_1 .^ tsubj_2` raises the values in the object `tsubj_1` element by element to the values in the object `tsubj_2`. The data series names, the dates, and the number of data points in both series must be identical. `newfts` contains the same data series names as the original time series objects.

## prbyzero

Price bonds in portfolio by set of zero curves

### Syntax

```
BondPrices = prbyzero(Bonds,Settle,ZeroRates,ZeroDates)
BondPrices = prbyzero( ____,Compounding)
```

### Description

`BondPrices = prbyzero(Bonds,Settle,ZeroRates,ZeroDates)` computes the bond prices in a portfolio using a set of zero curves.

`BondPrices = prbyzero( ____,Compounding)` adds an optional argument for Compounding.

### Examples

#### Compute the Bond Prices in a Portfolio Using a Set of Zero Curves

This example uses the function `zbtprice` to compute a zero curve given a portfolio of coupon bonds and their prices. It then reverses the process, using the zero curve as input to the function `prbyzero` to compute the prices.

```
Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;
          datenum('7/1/2000') 0.06 100 2 0 0;
          datenum('7/1/2000') 0.09375 100 6 1 0;
          datenum('6/30/2001') 0.05125 100 1 3 1;
          datenum('4/15/2002') 0.07125 100 4 1 0;
          datenum('1/15/2000') 0.065 100 2 0 0;
          datenum('9/1/1999') 0.08 100 3 3 0;
          datenum('4/30/2001') 0.05875 100 2 0 0;
          datenum('11/15/1999') 0.07125 100 2 0 0;
          datenum('6/30/2000') 0.07 100 2 3 1;
          datenum('7/1/2001') 0.0525 100 2 3 0;
          datenum('4/30/2002') 0.07 100 2 0 0];
```

```
Prices = [ 99.375;
           99.875;
           105.75 ;
           96.875;
           103.625;
           101.125;
           103.125;
           99.375;
           101.0 ;
           101.25 ;
           96.375;
           102.75 ];
```

```
Settle = datenum('12/18/1997');
```

Set semiannual compounding for the zero curve, on an actual/365 basis.

```
OutputCompounding = 2;
```

Execute the function `zbtprice` which returns the zero curve at the maturity dates.

```
[ZeroRates, ZeroDates] = zbtprice(Bonds, Prices, Settle, ...  
OutputCompounding)
```

```
ZeroRates = 11x1
```

```
0.0616  
0.0609  
0.0658  
0.0590  
0.0647  
0.0655  
0.0606  
0.0601  
0.0642  
0.0621  
⋮
```

```
ZeroDates = 11x1
```

```
729907  
730364  
730439  
730500  
730667  
730668  
730971  
731032  
731033  
731321  
⋮
```

Execute the function `prbyzero`.

```
BondPrices = prbyzero(Bonds, Settle, ZeroRates, ZeroDates)
```

```
BondPrices = 12x1
```

```
99.3750  
98.7980  
106.8270  
96.8750  
103.6249  
101.1250  
103.1250  
99.3637  
101.0000  
101.2500  
⋮
```

In this example `zbtprice` and `prbyzero` do not exactly reverse each other. Many of the bonds have the end-of-month rule off (`EndMonthRule = 0`). The rule subtly affects the time factor computation.

If you set the rule on (`EndMonthRule = 1`) everywhere in the Bonds matrix, then `prbyzero` returns the original prices, except when the two incompatible prices fall on the same maturity date.

### Compute the Bond Prices in a Portfolio Using a Set of Zero Curves and datetime Inputs

This example uses the function `zbtprice` to compute a zero curve given a portfolio of coupon bonds and their prices. It then reverses the process, using the zero curve as input to the function `prbyzero` with `datetime` inputs to compute the prices.

```
Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;
         datenum('7/1/2000') 0.06 100 2 0 0;
         datenum('7/1/2000') 0.09375 100 6 1 0;
         datenum('6/30/2001') 0.05125 100 1 3 1;
         datenum('4/15/2002') 0.07125 100 4 1 0;
         datenum('1/15/2000') 0.065 100 2 0 0;
         datenum('9/1/1999') 0.08 100 3 3 0;
         datenum('4/30/2001') 0.05875 100 2 0 0;
         datenum('11/15/1999') 0.07125 100 2 0 0;
         datenum('6/30/2000') 0.07 100 2 3 1;
         datenum('7/1/2001') 0.0525 100 2 3 0;
         datenum('4/30/2002') 0.07 100 2 0 0];

Prices = [ 99.375;
          99.875;
          105.75 ;
          96.875;
          103.625;
          101.125;
          103.125;

## Input Arguments

### Bonds — Coupon bond information to compute prices

table | matrix

Coupon bond information to compute prices, specified as a 6-column table or a NumBonds-by-6 matrix of bond information where the table columns or matrix columns contains:

- **Maturity (Required)** Maturity date of the bond, as a serial date number. Use `datenum` to convert date character vectors to serial date numbers. If the input `Bonds` is a table, the `Maturity` dates can be serial date numbers, date character vectors, or datetime arrays.
- **CouponRate (Required)** Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
- **Face (Optional)** Face or par value of the bond. Default = 100.
- **Period (Optional)** Coupons per year of the bond. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
- **Basis (Optional)** Day-count basis of the bond. A vector of integers.
  - 0 = actual/actual (default)
  - 1 = 30/360 (SIA)
  - 2 = actual/360
  - 3 = actual/365
  - 4 = 30/360 (BMA)
  - 5 = 30/360 (ISDA)
  - 6 = 30/360 (European)
  - 7 = actual/365 (Japanese)
  - 8 = actual/actual (ICMA)
  - 9 = actual/360 (ICMA)
  - 10 = actual/365 (ICMA)
  - 11 = 30/360E (ICMA)
  - 12 = actual/365 (ISDA)
  - 13 = BUS/252
  - For more information, see “Basis” on page 2-18.
- **EndMonthRule (Optional)** End-of-month rule. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month

:

---

**Note**

- If **Bonds** is a table, the table columns have the same meaning as when a matrix is used, but the **Maturity** dates can be serial date numbers, date character vectors, or datetime arrays.
  - If **Bonds** is a matrix, it is a **NUMBONDS**-by-6 matrix of bonds where each row describes one bond. The first two columns are required; the remaining columns are optional but must be added in order. All rows in **Bonds** must have the same number of columns. The columns are **Maturity**, **CouponRate**, **Face**, **Period**, **Basis**, and **EndMonthRule**.
- 

.

Data Types: double | table

**Settle — Settlement date**

serial date number | date character vector | datetime

Settlement date, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

**ZeroRates — Observed zero rates**

decimal fractions

Observed zero rates, specified as **NUMDATES**-by-**NUMCURVES** matrix of decimal fractions. Each column represents a rate curve. Each row represents an observation date.

Data Types: double | datetime | char

**ZeroDates — Observed dates for ZeroRates**

serial date number | date character vector | datetime

Observed dates for **ZeroRates**, specified as a **NUMDATES**-by-1 column using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

**Compounding — Compounding frequency of input ZeroRates when annualized**

2 (default) | numeric values: 1, 2, 3, 4, 6, 12,

(Optional) Compounding frequency of input **ZeroRates** when annualized, specified using the allowed values:

- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

Data Types: double

## Output Arguments

### **BondPrices** — Clean bond prices

numeric

Clean bond prices, returned as a NUMBONDS-by-NUMCURVES matrix. Each column is derived from the corresponding zero curve in `ZeroRates`.

In addition, you can use the Financial Instruments Toolbox method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `prbyzero`. For more information, see “Converting an `IRDataCurve` or `IRFunctionCurve` Object” (Financial Instruments Toolbox).

## prcroc

Price rate of change

---

**Note** `prcroc` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
PriceChangeRate = prcroc(Data)
PriceChangeRate = prcroc( ___,Name,Value)
```

### Description

`PriceChangeRate = prcroc(Data)` calculates the price rate-of-change, `PriceChangeRate`, from the series of closing stock prices. By default, the volume rate-of-change is calculated between the current closing price and the closing price 12 periods ago.

`PriceChangeRate = prcroc( ___,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Calculate the Price Rate-of-Change for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
PriceChangeRate = prcroc(TMW);
plot(PriceChangeRate.Time,PriceChangeRate.PriceRoc)
title('Price Rate of Change for TMW')
```

## Input Arguments

### Data — Data for closing prices

matrix | table | timetable

Data for closing prices, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-1 matrix of closing prices. Timetables and tables with `M` rows must contain a variable named 'Close' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `PriceChangeRate = prcroc(TMW, 'NumPeriods', 18)`

### NumPeriods — Period difference

12 (default) | positive integer

Period difference, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

## Output Arguments

### PriceChangeRate — Closing price rate-of-change

matrix | table | timetable

Closing price rate-of-change, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## prdisc

Price of discounted security

### Syntax

```
Price = prdisc(Settle,Maturity,FaceDiscount)
Price = prdisc( ____,Basis)
```

### Description

Price = prdisc(Settle,Maturity,FaceDiscount) returns the price of a security whose yield is quoted as a bank discount rate (for example, U. S. Treasury bills).

Price = prdisc( \_\_\_\_,Basis) adds an optional argument for Basis.

### Examples

#### Calculate the Price of a Security Whose Yield is Quoted as a Bank Discount Rate

This example shows how to return the price of a security whose yield is quoted as a bank discount rate (for example, U. S. Treasury bills).

```
Settle = '10/14/2000';
Maturity = '03/17/2001';
Face = 100;
Discount = 0.087;
Basis = 2;
```

```
Price = prdisc(Settle, Maturity, Face, Discount, Basis)
```

```
Price = 96.2783
```

#### Calculate the Price of a Security Whose Yield is Quoted as a Bank Discount Rate Using datetime Inputs

This example shows how to use datetime inputs to return the price of a security whose yield is quoted as a bank discount rate (for example, U. S. Treasury bills).

```
Settle = '10/14/2000';
Maturity = '03/17/2001';
Face = 100;
Discount = 0.087;
Basis = 2;
```

```
Price = prdisc(datetime(Settle,'Locale','en_US'),datetime(Maturity,'Locale','en_US'), Face, Disc
```

```
Price = 96.2783
```

## Input Arguments

### Settle — Settlement date

serial date number | date character vector | datetime

Settlement date, specified as serial date numbers, date character vectors, or datetime arrays.

Settle must be earlier than Maturity.

Data Types: double | datetime | char

### Maturity — Maturity date

serial date number | date character vector | datetime

Maturity date, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

### Face — Redemption (par, face) value

numeric

Redemption (par, face) value, specified as a numeric value.

Data Types: double

### Discount — Bank discount rate of the security

decimal fraction

Bank discount rate of the security, specified as a decimal fraction value.

Data Types: double

### Basis — Day-count basis of instrument

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

(Optional) Day-count basis of the instrument, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `double`

## **Output Arguments**

### **Price — Price of discounted security**

`numeric`

Price of discounted security, returned as a numeric value.

# priceandvol

Price and Volume chart

---

**Note** priceandvol is updated to accept data input as a matrix, timetable, or table.

The syntax for priceandvol has changed. Previously, when using table input, the first column of dates could be serial date numbers, date character vectors, or datetime arrays, and you were required to have specific number of columns.

When using table input, the new syntax for priceandvol supports:

- No need for time information. If you want to pass in date information, use timetable input.
- No requirement of specific number of columns. However, you must provide valid column names. linebreak must contain columns named 'open', 'high', 'low', 'close', and 'volume' (case insensitive).

---

## Syntax

```
priceandvol(Data)
h = priceandvol(Data)
```

## Description

priceandvol(Data) plots two charts from a series of opening, high, low, closing prices, and traded volume. Opening, high, low, and closing prices are on one axis and the volume series are on a second axis.

h = priceandvol(Data) adds a Graphic handle for the figure.

## Examples

### Generate a Price and Volume Chart for a Data Series for a Stock

Load the file SimulatedStock.mat, which provides a timetable (TMW) for financial data for TMW stock. This price and volume chart for the TMW stock contains the open, high, low, close, and volume for the most recent 21 days.

```
load SimulatedStock.mat
priceandvol(TMW(end-20:end,:));
```

## Input Arguments

**Data** — Data for opening, high, low, closing prices, and volume traded

matrix | table | timetable

Data for opening, high, low, closing prices, and volume traded, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-5 matrix of opening, high, low, closing prices and traded volume. Timetables and tables with M rows must contain variables named 'Open', 'High', 'Low', 'Close', and 'Volume' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

**h** — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

## prmat

Price with interest at maturity

### Syntax

```
[Price,AccruInterest] = prmat(Settle,Maturity,Issue,Face,CouponRateYield)
[Price,AccruInterest] = prmat( ____,Basis)
```

### Description

[Price,AccruInterest] = prmat(Settle,Maturity,Issue,Face,CouponRateYield) returns the price and accrued interest of a security that pays interest at maturity. This function also applies to zero coupon bonds or pure discount securities by setting CouponRate = 0.

[Price,AccruInterest] = prmat( \_\_\_\_,Basis) adds an optional argument for Basis.

### Examples

#### Find the Yield of a Security Paying Interest at Maturity

This example shows how to find the yield of a security paying interest at maturity for the following.

```
Settle = '02/07/2000';
Maturity = '04/13/2000';
Issue = '10/11/1999';
Face = 100;
Price = 99.98;
CouponRate = 0.0608;
Basis = 1;
```

```
Yield = yldmat(Settle, Maturity, Issue, Face, Price, ...
CouponRate, Basis)
```

```
Yield = 0.0607
```

#### Find the Yield of a Security Paying Interest at Maturity Using datetime Inputs

This example shows how to use datetime inputs find the yield of a security paying interest at maturity for the following:

```
Settle = '7-Feb-2000';
Maturity = '13-Apr-2000';
Issue = '11-Oct-1999';
Face = 100;
Price = 99.98;
CouponRate = 0.0608;
Basis = 1;
```

```

Settle = datetime(Settle, 'Locale', 'en_US');
Maturity = datetime(Maturity, 'Locale', 'en_US');
Issue = datetime(Issue, 'Locale', 'en_US');

Yield = yldmat(Settle, Maturity, Issue, Face, Price, ...
CouponRate, Basis)

Yield = 0.0607

```

## Input Arguments

### **Settle** — Settlement date of security

serial date number | date character vector | datetime

Settlement date of the security, specified as serial date numbers, date character vectors, or datetime arrays. The `Settle` date must be before the `Maturity` date.

Data Types: double | char | datetime

### **Maturity** — Maturity date of security

serial date number | date character vector | datetime

Maturity date of the security, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Issue** — Issue date

serial date number | date character vector | datetime

Issue date of the security, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Face** — Redemption value

numeric

Redemption value (par value), specified as a numeric value.

Data Types: double

### **CouponRate** — Coupon rate

decimal fraction

Coupon rate, specified as a decimal fraction value.

Data Types: double

### **Yield** — Annual yield

decimal fraction

Annual yield, specified as a decimal fraction value.

Data Types: double

**Basis – Day-count basis**

0 (actual/actual) (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

(Optional) Day-count basis of the security, specified using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

**Output Arguments****Price – Security price**

numeric

Security price, returned as a numeric value.

**AccruInterest – Accrued interest**

numeric

Accrued interest for security, returned as a numeric value.

## prtbill

Price of Treasury bill

### Syntax

```
Price = prtbill(Settle,Maturity,Face,Discount)
```

### Description

Price = prtbill(Settle,Maturity,Face,Discount) returns the price for a Treasury bill.

### Examples

#### Calculate the Price for a Treasury Bill

This example shows how to return the price for a Treasury bill, where the settlement date of a Treasury bill is February 10, 2002, the maturity date is August 6, 2002, the discount rate is 3.77%, and the par value is \$1000.

```
Price = prtbill('2/10/2002', '8/6/2002', 1000, 0.0377)
```

```
Price = 981.4642
```

#### Calculate the Price for a Treasury Bill Using datetime Inputs

This example shows how to use `datetime` inputs to return the price for a Treasury bill, where the settlement date of a Treasury bill is February 10, 2002, the maturity date is August 6, 2002, the discount rate is 3.77%, and the par value is \$1000.

```
Price = prtbill(datetime('10-Feb-2002','Locale','en_US'), datetime('6-Aug-2002','Locale','en_US'))
```

```
Price = 981.4642
```

### Input Arguments

#### Settle — Settlement date for Treasury bill

serial date number | date character vector | datetime

Settlement date for the Treasury bill, specified as serial date numbers, date character vectors, or datetime arrays. The `Settle` date must be before the `Maturity` date.

Data Types: double | char | datetime

#### Maturity — Maturity date for Treasury bill

serial date number | date character vector | datetime

Maturity date for the Treasury bill, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `char` | `datetime`

### **Face — Redemption value of Treasury bill**

numeric

Redemption value (par value) of the Treasury bill, specified as a numeric value.

Data Types: `double`

### **Discount — Discount rate of Treasury bill**

decimal fraction

Discount rate of the Treasury bill, specified as a decimal fraction value.

Data Types: `double`

## **Output Arguments**

### **Price — Treasury bill price**

numeric

Treasury bill price, returned as a numeric value.

## pvfix

Present value with fixed periodic payments

### Syntax

`PresentVal = pvfix(Rate, NumPeriods, Payment, ExtraPayment, Due)`

### Arguments

|              |                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------|
| rate         | Periodic interest rate, as a decimal fraction.                                                     |
| NumPeriods   | Number of periods.                                                                                 |
| Payment      | Periodic payment.                                                                                  |
| ExtraPayment | (Optional) Payment received other than Payment in the last period. Default = 0.                    |
| Due          | (Optional) When payments are due or made: 0 = end of period (default), or 1 = beginning of period. |

### Description

`PresentVal = pvfix(Rate, NumPeriods, Payment, ExtraPayment, Due)` returns the present value of a series of equal payments.

### Examples

#### Calculate the Present Value of a Series of Equal Payments

This example shows how to return the present value of a series of equal payments, where \$200 is paid monthly into a savings account earning 6%. The payments are made at the end of the month for five years.

```
PresentVal = pvfix(0.06/12, 5*12, 200, 0, 0)
```

```
PresentVal = 1.0345e+04
```

# pvtrend

Price and Volume Trend (PVT)

---

**Note** pvtrend has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
trend = pvtrend(Data)
```

## Description

`trend = pvtrend(Data)` calculates the Price and Volume Trend (PVT) from the series of closing stock prices and trade volume.

## Examples

### Calculate the Price and Volume Trend for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
trend = pvtrend(TMW);
plot(trend.Time,trend.PriceVolumeTrend)
title('Price and Volume Trend for TMW')
```

## Input Arguments

### Data — Data for closing prices and trade volume

matrix | table | timetable

Data for closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-2 matrix of closing prices and trade volume. Timetables and tables with M rows must contain variables named 'Close' and 'Volume' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### trend — Price and volume trend

matrix | table | timetable

Price and volume trend (PVT), returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## References

## pvvar

Present value of varying cash flow

### Syntax

`PresentVal = pvvar(CashFlow,Rate,CFDates)`

### Arguments

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CashFlow | A vector of varying cash flows. Include the initial investment as the initial cash flow value (a negative number). If <code>CashFlow</code> is a matrix, each column is treated as a separate cash-flow stream.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Rate     | Periodic interest rate. Enter as a decimal fraction. If <code>CashFlow</code> is a matrix, a scalar <code>Rate</code> is allowed when the same rate applies to all cash-flow streams in <code>CashFlow</code> . When multiple cash-flow streams require different discount rates, <code>Rate</code> must be a vector whose length equals the number of columns in <code>CashFlow</code> .                                                                                                                                                                                                                                                   |
| CFDates  | (Optional) A vector of serial date numbers, date character vectors, or datetime arrays on which the cash flows occur. Specify <code>CFDates</code> when there are irregular (nonperiodic) cash flows. The default assumes that <code>CashFlow</code> contains regular (periodic) cash flows. If <code>CashFlow</code> is a matrix, and all cash-flow streams share the same dates, <code>CFDates</code> can be a vector whose length matches the number of rows in <code>CashFlow</code> . When different cash-flow streams have different payment dates, specify <code>CFDates</code> as a matrix the same size as <code>CashFlow</code> . |

### Description

`PresentVal = pvvar(CashFlow,Rate,CFDates)` returns the net present value of a varying cash flow. Present value is calculated at the time the first cash flow occurs.

### Examples

This cash flow represents the yearly income from an initial investment of \$10,000. The annual interest rate is 8%.

|        |        |
|--------|--------|
| Year 1 | \$2000 |
| Year 2 | \$1500 |
| Year 3 | \$3000 |
| Year 4 | \$3800 |
| Year 5 | \$5000 |

To calculate the net present value of this regular cash flow

```
PresentVal = pvvar([-10000 2000 1500 3000 3800 5000], 0.08)
```

returns

PresentVal =

1715.39

An investment of \$10,000 returns this irregular cash flow. The original investment and its date are included. The periodic interest rate is 9%.

| Cash Flow | Dates             |
|-----------|-------------------|
| (\$10000) | January 12, 1987  |
| \$2500    | February 14, 1988 |
| \$2000    | March 3, 1988     |
| \$3000    | June 14, 1988     |
| \$4000    | December 1, 1988  |

To calculate the net present value of this irregular cash flow

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
```

```
CFDates = ['01/12/1987'
           '02/14/1988'
           '03/03/1988'
           '06/14/1988'
           '12/01/1988'];
```

```
PresentVal = pvvar(CashFlow, 0.09, CFDates)
```

returns

PresentVal =

142.16

The net present value of the same investment under different discount rates of 7%, 9%, and 11% is obtained in a single call:

```
PresentVal = pvvar(repmat(CashFlow,3,1)', [.07 .09 .11], CFDates)
```

pv =

419.0136 142.1648 -122.1275

## pyld2zero

Zero curve given par yield curve

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: `InputCompounding`, `InputBasis`, `OutputCompounding`, and `OutputBasis`.

---

### Syntax

```
[ZeroRates, CurveDates] = pyld2zero(ParRates, CurveDates, Settle)
[ZeroRates, CurveDates] = pyld2zero( ____, Name, Value)
```

### Description

`[ZeroRates, CurveDates] = pyld2zero(ParRates, CurveDates, Settle)` returns a zero curve given a par yield curve and its maturity dates. If either input for `CurveDates` or `Settle` is a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` is returned as a serial date number.

`[ZeroRates, CurveDates] = pyld2zero( ____, Name, Value)` adds optional name-value pair arguments

### Examples

#### Compute Zero Curve Given Par Yield Curve

Define the settlement date, maturity, and zero rates.

```
Settle = datenum('01-Feb-2013');
CurveDates = datemnth(Settle, 12*[1 2 3 5 7 10 20 30]');
ZeroRates = [.11 0.30 0.64 1.44 2.07 2.61 3.29 3.55]'/100;
InputCompounding = 2;
InputBasis = 1;
OutputCompounding = 2;
OutputBasis = 1;
```

Compute par yield curve from zero rates.

```
ParRates = zero2pyld(ZeroRates, CurveDates, Settle, 'InputCompounding', 2, ...
    'InputBasis', 1, 'OutputCompounding', 2, 'OutputBasis', 1)
```

```
ParRates = 8×1
```

```
0.0011
0.0030
0.0064
0.0142
0.0201
```

```
0.0251
0.0309
0.0330
```

Compute zero curve from the par yield curve.

```
ZeroRates = pyld2zero(ParRates, CurveDates, Settle, 'InputCompounding', 2, ...
'InputBasis', 1, 'OutputCompounding', 2, 'OutputBasis', 1)
```

ZeroRates = 8×1

```

### Compute Zero Curve Given Par Yield Curve Using datetime Inputs

Use datetime inputs to compute the zero curve given the par yield curve.

```
Settle = datenum('01-Feb-2013');
```

```
CurveDates = [datenum('01-Feb-2014')
datenum('01-Feb-2015')
datenum('01-Feb-2016')
datenum('01-Feb-2018')
datenum('01-Feb-2020')
datenum('01-Feb-2023')
datenum('01-Feb-2033')
datenum('01-Feb-2043')];
```

```
OriginalParRates = [0.11 0.30 0.64 1.42 2.02 2.51 3.10 3.31]'/100;
```

```
InputCompounding = 1;
InputBasis = 0;
OutputCompounding = 1;
OutputBasis = 0;
```

```
Settle = datetime(Settle, 'ConvertFrom', 'datenum', 'Locale', 'en_US');
CurveDates = datetime(CurveDates, 'ConvertFrom', 'datenum', 'Locale', 'en_US');
[ZeroRates Dates] = pyld2zero(OriginalParRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)
```

ZeroRates = 8×1

```
0.0011
0.0030
0.0064
0.0144
```

```
0.0207
0.0261
0.0329
0.0356
```

```
Dates = 8x1 datetime
01-Feb-2014
01-Feb-2015
01-Feb-2016
01-Feb-2018
01-Feb-2020
01-Feb-2023
01-Feb-2033
01-Feb-2043
```

### Demonstrate a Roundtrip From pyld2zero to zero2pyld

Given the following a par yield curve and its maturity dates, return the ZeroRates.

```
Settle = datenum('01-Feb-2013');
```

```
CurveDates = [datenum('01-Feb-2014')
datenum('01-Feb-2015')
datenum('01-Feb-2016')
datenum('01-Feb-2018')
datenum('01-Feb-2020')
datenum('01-Feb-2023')
datenum('01-Feb-2033')
datenum('01-Feb-2043')];
```

```
OriginalParRates = [0.11 0.30 0.64 1.42 2.02 2.51 3.10 3.31]'/100;
```

```
InputCompounding = 1;
InputBasis = 0;
OutputCompounding = 1;
OutputBasis = 0;
```

```
ZeroRates = pyld2zero(OriginalParRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)
```

```
ZeroRates = 8x1
```

```
0.0011
0.0030
0.0064
0.0144
0.0207
0.0261
0.0329
0.0356
```

With the `ZeroRates`, use the `zero2pyld` function to return the `ParRatesOut` and determine the roundtrip error.

```
ParRatesOut = zero2pyld(ZeroRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)
```

```
ParRatesOut = 8×1
```

```
0.0011
0.0030
0.0064
0.0142
0.0202
0.0251
0.0310
0.0331
```

```
max(abs(OriginalParRates - ParRatesOut)) % Roundtrip error
```

```
ans = 1.2750e-16
```

## Input Arguments

### ParRates — Annualized par yields

decimal fraction

Annualized par yields (coupon rates), specified as a `NUMBONDS`-by-1 vector using decimal fractions. In aggregate, the rates constitute an implied zero curve for the investment horizon represented by `CurveDates`.

Data Types: `double`

### CurveDates — Maturity dates

serial date number | date character vector | `datetime`

Maturity dates which correspond to the input `ParRates`, specified as a `NUMBONDS`-by-1 vector using serial date numbers, date character vectors, or `datetime` arrays.

Data Types: `double` | `datetime` | `char`

### Settle — Common settlement date for ZeroRates

serial date number | date character vector | `datetime`

Common settlement date for input `ParRates`, specified as serial date numbers, date character vectors, or `datetime` arrays.

Data Types: `double` | `datetime` | `char`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

```
Example: [ZeroRates, CurveDates] =  
pyld2zero(ParRates, CurveDates, Settle, 'OutputCompounding', 3, 'OutputBasis', 5, 'InputCompounding', 4, 'InputBasis', 5)
```

**OutputCompounding — Compounding frequency of output ZeroRates**

2 (default) | numeric values: 0, 1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of output ZeroRates, specified using the allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

---

**Note**

- If `OutputCompounding` is set to 0 (simple), -1 (continuous), or 365 (daily), the `InputCompounding` must also be specified using a valid value.
  - If `OutputCompounding` is not specified, then `OutputCompounding` is assigned the value specified for `InputCompounding`.
  - If either `OutputCompounding` or `InputCompounding` are not specified, the default is 2 (semiannual) for both.
- 

Data Types: double

**OutputBasis — Day-count basis of output ZeroRates**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of output ZeroRates, specified using allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If `OutputBasis` is not specified, then `OutputBasis` is assigned the value specified for `InputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

### **InputCompounding — Compounding frequency of input ParRates**

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of input `ParRates`, specified using allowed values:

- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

### **Note**

- If `OutputCompounding` is 1, 2, 3, 4, 6, or 12 and `InputCompounding` is not specified, the value of `OutputCompounding` is used.
  - If `OutputCompounding` is 0 (simple), -1 (continuous), or 365 (daily), a valid `InputCompounding` value must also be specified.
  - If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2 (semiannual) for both.
- 

Data Types: double

### **InputBasis — Day-count basis of input ParRates**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of the input `ParRates`, specified using allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If `InputBasis` is not specified, then `InputBasis` is assigned the value specified for `OutputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

## Output Arguments

### ZeroRates — Zero rates

numeric

Zero rates, returned as a `NUMBONDS`-by-1 numeric vector. In aggregate, the rates in `ZeroRates` constitute a zero curve for the investment horizon represented by `CurveDates`. `ZeroRates` are ordered by ascending maturity.

### CurveDates — Maturity dates that correspond to ZeroRates

serial date number | date character vector | datetime

Maturity dates that correspond to the `ZeroRates`, returned as a `NUMBONDS`-by-1 vector of maturity dates that correspond to each par rate contained in `ZeroRates`. `CurveDates` are ordered by ascending maturity.

If either input for `CurveDates` or `Settle` is a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` are returned as a serial date numbers.

## quarter

Returns the quarter of given date

### Syntax

```
q = quarter(date)
q = quarter( ____, month1)
q = quarter(date, month1, dateformat)
```

### Description

`q = quarter(date)` returns the quarter of the given `date`, assuming the standard calendar (starting on January 1st).

`q = quarter( ____, month1)` returns the quarter of the date for a calendar which starts on the month specified by `month1`. `month1` must be an integer between 1-12 representing Jan-Dec respectively.

`q = quarter(date, month1, dateformat)` returns the quarter of the date for a calendar which starts on the month specified by `month1`. `month1` must be an integer between 1-12 representing January to December respectively. The `dateformat` input is a character vector to specify the format of your date character vector in case it is not normally recognized by the `datenum` function.

### Examples

#### Determine the Quarter for a Given Date

`quarter` returns the quarter of the given `date`, assuming the standard calendar that starts on Jan 1st.

```
quarter('7-Apr-2013')
```

```
ans = 2
```

#### Determine the Quarter for a Given Date for an Off-Cycle Calendar

`quarter` returns the quarter of the date for a calendar which starts on the month specified by `month1`.

```
quarter('7-Apr-2013', 5)
```

```
ans = 4
```

If the financial calendar starts in May (where `month1 = 5`), April would be the last month and fall in the last quarter.

## Determine the Quarter for a Given Date When the Date is Not Recognized by datenum

When using `quarter`, the optional input argument for `dateformat` is a character vector which lets you specify the format of your date character vector in case it isn't normally recognized by the `datenum` function.

```
quarter('07-04-2013',1)
```

```
ans = 3
```

This gives the quarter 3 because by default `datenum` interprets the date as July 7th, 2013.

If you really meant April 7th, 2013, you can use `dateformat` to specify the intended format.

```
quarter('07-04-2013',1,'dd-mm-yyyy')
```

```
ans = 2
```

## Input Arguments

### **date** — Date in a quarter

serial date number | date character vector

Date in a quarter, specified as serial date numbers or date character vectors.

Data Types: `double` | `char`

### **month1** — First month in a calendar

integer with value between 1-12

First month in a calendar, specified as an integer with a value between 1-12, representing January to December respectively. Use `month1` when the standard calendar that starts on January 1st does not apply.

Data Types: `double`

### **dateformat** — Format of date

character vector

Format of date, specified as a character vector. `dateformat` input is a character vector to specify the format of your date character vector in case it is not normally recognized by the `datenum` function.

Data Types: `char`

## Output Arguments

### **q** — Quarter for given date

integer

Quarter for given date, returned as an integer between 1-4.

`datenum`

**Introduced in R2016a**

# rdivide

Financial time series division

---

**Note** `rdivide` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = tsoj_1 ./ tsoj_2
```

```
newfts = tsoj ./ array
```

```
newfts = array ./ tsoj
```

## Arguments

|                                           |                                                                                                                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsoj_1</code> , <code>tsoj_2</code> | Pair of financial time series objects.                                                                                                                                              |
| <code>array</code>                        | Scalar value or array with the number of rows equal to the number of dates in <code>tsoj</code> and the number of columns equal to the number of data series in <code>tsoj</code> . |

## Description

The `rdivide` method divides, element by element, the components of one financial time series object by the components of the other. You can also divide the whole object by an array or divide a financial time series object into an array.

If an object is to be divided by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is divided by another object, follows the order of the first object.

`newfts = tsoj_1 ./ tsoj_2` divides financial time series objects element by element.

`newfts = tsoj ./ array` divides a financial time series object element by element by an array.

`newfts = array ./ tsoj` divides an array element by element by a financial time series object.

For financial time series objects, the `rdivide` operation is identical to the `mrdivide` operation.

**Introduced before R2006a**

## renko

Renko

---

**Note** `renko` is updated to accept data input as a matrix, `timetable`, or `table`.

The syntax for `renko` has changed. Previously, when using `table` input, the first column of dates could be serial date numbers, date character vectors, or datetime arrays, and you were required to have specific number of columns.

When using `table` input, the new syntax for `renko` supports:

- No need for time information. If you want to pass in date information, use `timetable` input.
  - No requirement of specific number of columns. However, you must provide valid column names. `renko` must contain a column named `'price'` (case insensitive).
- 

### Syntax

```
renko(Data)
renko(Data,Threshold,)
h = renko(ax, ___)
```

### Description

`renko(Data)` plots a Renko chart from a series of prices of a security.

`renko(Data,Threshold,)` adds an optional argument for `Threshold`.

`h = renko(ax, ___)` adds an optional argument for `ax`.

### Examples

#### Generate a Renko Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (`TMW`) for financial data for `TMW` stock. This example shows how to plot a Renko chart for the most recent 21 days. Note that the variable name of asset price is renamed to `'Price'` (case insensitive).

```
load SimulatedStock.mat
TMW.Properties.VariableNames{'Close'} = 'Price';
renko(TMW(end-8:end,:),2)
title('Renko Chart for TMW')
```

## Input Arguments

### Data — Data for a series of prices

matrix | table | timetable

Data for a series of prices, specified as a matrix, table, or timetable. Timetables and tables with  $M$  rows must contain a variable named 'Price' (case insensitive).

Data Types: double | table | timetable

### Threshold — (Optional) Least price change value when adding a new box

1 (default) | positive numeric

Least price change value when adding a new box, specified as a scalar positive numeric value.

Data Types: double

### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The renko plot is created in the axes specified by **ax** instead of in the current axes (ax = gca). The option **ax** can precede any of the input argument combinations.

Data Types: object

## Output Arguments

### **h** — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

## Topics

“Using Timetables in Finance”

“Convert Financial Time Series Objects fints to Timetables” on page 12-2

**Introduced in R2008a**

# resamplets

Downsample data

---

**Note** `resamplets` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = resamplets(oldfts, samplestep)
```

## Description

`newfts = resamplets(oldfts, samplestep)` downsamples the data contained in the financial time series object `oldfts` every `samplestep` periods. For example, to have the new financial time series object contain every other data element from `oldfts`, set `samplestep` to 2.

`newfts` is a financial time series object containing the same data series (names) as the input `oldfts`.

## ret2tick

Convert return series to price series

### Syntax

```
[TickSeries, TickTimes] = ret2tick(Data)
[TickSeries, TickTimes] = ret2tick( ____, Name, Value)
```

### Description

[TickSeries, TickTimes] = ret2tick(Data) computes prices from the start prices of NASSET assets and NUMOBS return observations.

[TickSeries, TickTimes] = ret2tick( \_\_\_\_, Name, Value) adds optional name-value pair arguments.

### Examples

#### Convert a Return Series to a Price Series

Compute the price increase of two stocks over a year's time based on three incremental return observations.

```
RetSeries = [0.10 0.12
             0.05 0.04
            -0.05 0.05];
```

```
RetIntervals = [182
                91
                92];
```

```
StartTime = datetime('18-Dec-2000', 'Locale', 'en_US');
```

```
[TickSeries, TickTimes] = ret2tick(RetSeries, 'ReturnIntervals', RetIntervals, ...
    'StartTime', StartTime)
```

```
TickSeries = 4x2
```

```
    1.0000    1.0000
    1.1000    1.1200
    1.1550    1.1648
    1.0973    1.2230
```

```
TickTimes = 4x1 datetime
```

```
18-Dec-2000
18-Jun-2001
17-Sep-2001
18-Dec-2001
```

## Convert a Price Series to a Return Series Using timetable Input

Use `timetable` input to convert a price series to a return series, given periodic returns of two stocks observed in the first, second, third, and fourth quarters.

```
RetSeries = [0.10 0.12
             0.05 0.04
            -0.05 0.05];
```

```
RetTimes = datetime({'6/18/2001','9/17/2001','12/18/2001'},'InputFormat','MM/dd/yyyy','Locale','en_US');
RetSeries = array2timetable(RetSeries,'RowTimes',RetTimes);
StartTime = datetime('12/18/2000','InputFormat','MM/dd/yyyy','Locale','en_US');
```

```
[TickSeries, TickTimes] = ret2tick(RetSeries, 'StartTime', StartTime)
```

```
TickSeries=4x2 timetable
      Time      RetSeries1      RetSeries2
      _____  _____  _____
      18-Dec-2000           1           1
      18-Jun-2001          1.1          1.12
      17-Sep-2001         1.155         1.1648
      18-Dec-2001         1.0973         1.223
```

```
TickTimes = 4x1 datetime
      18-Dec-2000
      18-Jun-2001
      17-Sep-2001
      18-Dec-2001
```

## Input Arguments

### Data — Data for asset returns

matrix | table | timetable

Data for asset returns, specified as a `NUMOBSNASSETS` matrix, `table`, or `timetable`. The returns are not normalized by the time increments between successive price observations.

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[TickSeries, TickTimes] = ret2tick(RetSeries, 'StartTime', StartTime)`

### StartPrice — Initial prices for each asset

1 for all assets (default) | numeric

Initial prices for each asset, specified as the comma-separated pair consisting of 'StartPrice' and a NASSETS-by-1 vector indicating initial prices for each asset, or a single scalar initial price applied to all assets.

Data Types: double

### ReturnIntervals — Return interval between prices

1 for all assets (default) | numeric | duration | calendar duration

Return interval between prices, specified as the comma-separated pair consisting of 'ReturnIntervals' and a scalar return interval applied to all returns, or a vector of length NUMOBS return intervals between successive returns. ReturnIntervals is defined as:

$$\text{ReturnIntervals}(t) = \text{TickTimes}(t) - \text{TickTimes}(t-1).$$

---

**Note** If the type of Data is a timetable, ReturnIntervals is ignored.

---

Data Types: double

### StartTime — Starting time for first observation applied to the prices of all assets

0 if ReturnIntervals is numeric (default) | numeric | duration | calendar duration

Starting time for first observation applied to the price series of all assets, specified as the comma-separated pair consisting of 'StartTime' and a scalar string, character vector, double, or datetime.

---

**Note** If ReturnIntervals is a duration or calendar duration value, the default for StartTime is datetime('today').

---

If Data is a timetable and StartTime is not specified, the resulting asset prices in the first period are not reported.

---

Data Types: double | string | char | datetime

### Method — Method to convert asset returns to prices

'Simple' (default) | character vector with value of 'Simple' or 'Continuous' | string with value of "Simple" or "Continuous"

Method to convert asset returns to prices, specified as the comma-separated pair consisting of 'Method' and a string or character vector indicating the method to convert asset prices to returns.

If the method is 'Simple', then simple periodic returns are used:

$$\text{TTickSeries}(t) = \text{TickSeries}(t-1) * (1 + \text{ReturnSeries}(t)).$$

If the method is 'Continuous', then continuous returns are used:

$$\text{TickSeries}(t) = \text{TickSeries}(t-1) * \exp(\text{ReturnSeries}(t)).$$

Data Types: char | string

## Output Arguments

### TickSeries — Time series array of asset prices

matrix | table | timetable

Time series array of asset prices, returned as NUMBOBS+1-by-NASSETS time series of asset prices of the same type (matrix, table, or timetable) as the input `Data`. The first row contains the oldest prices and the last row contains the most recent. Prices across a given row are assumed to occur at the same time for all columns, and each column is a price series of an individual asset.

### TickTimes — Observation times associated with prices in TickSeries

vector

Observation times associated with the prices in `TickSeries`, returned as a NUMBOBS+1 length column vector of monotonically increasing observation times associated with the prices in `TickSeries`. The initial time is `StartTime`. For matrix and table `Data`, sequential observations occur at increments specified in `ReturnIntervals` and for `Data` timetables, sequential observations are derived from times and dates in `Data`.

## Extended Capabilities

### Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports input `Data` that is specified as a tall column vector, a tall table, or a tall timetable. For more information, see `tall` and “Tall Arrays” (MATLAB).

## ret2tick (fts)

Convert return series to price series for time series object

---

**Note** `ret2tick (fts)` is not recommended. Use `ret2tick` instead.

---

### Syntax

```
priceFts = ret2tick(returnFts)
```

```
priceFts = ret2tick(returnFts, 'PARAM1', VALUE1, 'PARAM2', VALUE2', ...)
```

### Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| returnFts | Financial time series object of returns.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 'PARAM1 ' | (Optional) <i>StartPrice</i> is a Numeric value and is a scalar or 1-by-N vector of initial prices for each asset. If <i>StartPrice</i> is unspecified or empty, the initial price of all assets is 1.                                                                                                                                                                                                                                                                         |
| 'PARAM2 ' | (Optional) <i>StartTime</i> is Date value for a scalar date number or a single date character vector specifying the starting time for the first observation. This date is applied to the price series of all assets.<br><br><b>Note</b> The first period price value of the resulting price series will not be reported if <i>StartTime</i> is not specified. The resulting price series are scaled based on the <i>StartPrice</i> , even if <i>StartTime</i> is not supplied. |
| 'PARAM3 ' | (Optional) <i>Method</i> is a character vector indicating the method to convert asset returns to prices. The value must be defined as 'Simple' (default) or 'Continuous'. If <i>Method</i> is 'Simple', <code>ret2tick</code> uses simple periodic returns. If <i>Method</i> is 'Continuous', the function uses continuously compounded returns. Case is ignored for <i>Method</i> .                                                                                           |

### Description

`priceFts = ret2tick(returnFts, 'PARAM1', VALUE1, 'PARAM2', VALUE2', ...)` generates a financial time series object of prices.

If *Method* is unspecified or 'Simple', the prices are

$$\text{PriceSeries}(i+1) = \text{PriceSeries}(i) * [1 + \text{ReturnSeries}(i)]$$

If *Method* is 'Continuous', the prices are

$$\text{PriceSeries}(i+1) = \text{PriceSeries}(i) * \exp[\text{ReturnSeries}(i)]$$

## Examples

Compute the price series from the following return series:

```
RetSeries = [0.10 0.12
             0.05 0.04
            -0.05 0.05]
```

Use the following dates:

```
Dates = {'18-Jun-2001'; '17-Sep-2001'; '18-Dec-2001'}
```

where

```
ret = fints(Dates, RetSeries)
```

```
ret =
desc: (none)
freq: Unknown (0)

'dates: (3)'      'series1: (3)'      'series2: (3)'
'18-Jun-2001'    [      0.1000]      [      0.1200]
'17-Sep-2001'    [      0.0500]      [      0.0400]
'18-Dec-2001'    [     -0.0500]      [      0.0500]
```

PriceFts is computed as:

```
PriceFts = ret2tick(ret, 'StartPrice', 100, 'StartTime', '18-Dec-2000')
```

```
PriceFts =
desc: (none)
freq: Unknown (0)

'dates: (4)'      'series1: (4)'      'series2: (4)'
'18-Dec-2000'     [      100]         [      100]
'18-Jun-2001'     [  110.0000]        [  112.0000]
'17-Sep-2001'     [  115.5000]        [  116.4800]
'18-Dec-2001'     [  109.7250]        [  122.3040]
```

## rmfield

Remove data series

---

**Note** `rmfield` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
fts = rmfield(tsoobj,fieldname)
```

### Arguments

|                        |                                                                                                                                                                                                                        |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsoobj</code>    | Financial time series object.                                                                                                                                                                                          |
| <code>fieldname</code> | Character vector containing the data series name to remove a single series from the object. Cell array of character vectors for the data series names to remove multiple data series from the object at the same time. |

### Description

`fts = rmfield(tsoobj,fieldname)` removes the data series `fieldname` and its contents from the financial time series object `tsoobj`.

### See Also

`chfield` | `extfield` | `fieldnames` | `getfield` | `isfield`

### Topics

# rsindex

Relative Strength Index (RSI)

---

**Note** `rsindex` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
index = rsindex(Data)
index = rsindex(___,Name,Value)
```

## Description

`index = rsindex(Data)` calculates the Relative Strength Index (RSI) from the series of closing stock prices.

`index = rsindex(___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Relative Strength Index for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
index = rsindex(TMW);
plot(index.Time,index.RelativeStrengthIndex)
title('Relative Strength Index for TMW')
```

## Input Arguments

### Data — Data with closing prices

matrix | table | timetable

Data with closing prices, specified as a matrix, table, or timetable. For matrix input, `Data` is M-by-1 with closing prices. Timetables and tables with M rows must contain a variable named 'Close' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `index = rsindex(TMW, 'WindowSize', 10)`

### WindowSize — Moving window size for relative strength index

14 (default) | positive integer

Moving window size for relative strength index, specified as the comma-separated pair consisting of 'WindowSize' and a scalar positive integer.

Data Types: double

## Output Arguments

### **index — Relative strength index**

matrix | table | timetable

Relative strength index, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## More About

### **Relative Strength Index**

Relative strength index is calculated by dividing the average of the gains by the average of the losses within a specified period.

$$RS = (\text{average gains}) / (\text{average losses})$$

## second

Seconds of date or time

### Syntax

```
Seconds = second(Date)
Seconds = second( ____, F)
```

### Description

`Seconds = second(Date)` returns the seconds given a serial date number or a character vector representing a date and time.

`Seconds = second( ____, F)` returns the second of one or more character vectors, `Date`, using a format defined by the optional input `F`. `Date` can be a character array where each row corresponds to one character vector, or a one-dimensional cell array of character vectors. All the character vectors in `Date` must have the same format `F`. `F` must designate a supported date format symbol. For more information on supported date formats, see `datestr`.

### Examples

#### Determine the Seconds of the Date for Various Dates

Find the seconds of the day (`Date`) using a serial date number.

```
Seconds = second(738647.558427893)
```

```
Seconds = 8.1700
```

Find the seconds of the day (`Date`) using a character vector representing a date and time.

```
Seconds = second('06-May-2022, 13:24:08.17')
```

```
Seconds = 8.1700
```

### Input Arguments

#### Date — Date to determine second

serial date number | character vector | cell array of character vectors

Date to determine second, specified as a serial date number or a character vector representing a date and time.

`Date` can be an array of character vectors representing a date and time, where each row corresponds to one character vector, or a one-dimensional cell array of character vectors. All the character vectors in `Date` must have the same format `F`. `F` must designate a supported date format symbol. For more information on supported date formats, see `datestr`

Data Types: `single` | `double` | `char` | `cell`

**F — Date format symbol**

character vector designating date format

Date format symbol, specified as a character vector to designate the date format symbol for input argument `Date`. For more information on supported character vector formats, see `datestr`. Note, formats with 'Q' are not accepted.

Data Types: char

**Output Arguments****Seconds — Seconds of date or time**

nonnegative number

Seconds of date or time, returned as a nonnegative number.

**See Also**

`datevec` | `minute`

## selectreturn

Portfolio configurations from 3-D efficient frontier

### Syntax

```
PortConfigs = selectreturn(AllMean,AllCovariance,Target)
```

### Arguments

|               |                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AllMean       | Number of curves (NCURVES-by-1 cell array), where each element is a 1-by-NASSETS (number of assets) vector of the expected asset returns used to generate each curve on the surface. |
| AllCovariance | NCURVES-by-1 cell array where each element is an NASSETS-by-NASSETS vector of the covariance matrix used to generate each curve on the surface.                                      |
| Target        | Target return value for each curve in the frontier.                                                                                                                                  |

### Description

`PortConfigs = selectreturn(AllMean,AllCovariance,Target)` returns the portfolio configurations for a target return given the average return and covariance for a rolling efficient frontier.

`PortConfigs` is a NASSETS-by-NCURVES matrix of asset allocation weights needed to obtain the target rate of return.

## setAssetList

Set up list of identifiers for assets

### Syntax

```
obj = setAssetList(obj,AssetList)
obj = setAssetList(obj,'asset1','asset2',asset3',...)
```

### Description

`obj = setAssetList(obj,AssetList)` sets up the list of identifiers for assets for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setAssetList(obj,'asset1','asset2',asset3',...)` sets up a list of asset identifiers, specified as a comma-separated list of character vectors, a cell array of character vectors, or string array where each character vector or string is an asset identifier.

---

### Note

- If an asset list is entered as an input, this function overwrites an existing asset list in the object if one exists.
  - If no asset list is entered as an input, three actions can occur:
    - If `NumAssets` is nonempty and `AssetList` is empty, `AssetList` becomes a numbered list of assets with default names according to the hidden property in `defaultforAssetList` ('Asset').
    - If `NumAssets` is nonempty and `AssetList` is nonempty, nothing happens.
    - If `NumAssets` is empty and `AssetList` is empty, the default `NumAssets = 1` is set and a default asset list is created ('Asset1').
- 

### Examples

#### Create a Default List of Asset Names with Three Assets for a Portfolio Object

Create a default list of asset names with three assets.

```
p = Portfolio('NumAssets',3);
p = setAssetList(p);
disp(p.AssetList);

{'Asset1'}    {'Asset2'}    {'Asset3'}
```

**Create an Explicitly Named List of Asset Names with Three Assets for a Portfolio Object**

Create a list of asset names for three equities AGG, EEM, and VEU.

```
p = Portfolio;
p = setAssetList(p, 'AGG', 'EEM', 'VEU');
disp(p.AssetList);

    {'AGG'}    {'EEM'}    {'VEU'}
```

**Create a Default List of Asset Names with Three Assets for a PortfolioCVaR Object**

Create a default list of asset names with three assets.

```
p = PortfolioCVaR('NumAssets',3);
p = setAssetList(p);
disp(p.AssetList);

    {'Asset1'}    {'Asset2'}    {'Asset3'}
```

**Create an Explicitly Named List of Asset Names with Three Assets for a PortfolioCVaR Object**

Create a list of asset names for three equities AGG, EEM, and VEU.

```
p = PortfolioCVaR;
p = setAssetList(p, 'AGG', 'EEM', 'VEU');
disp(p.AssetList);

    {'AGG'}    {'EEM'}    {'VEU'}
```

**Create a Default List of Asset Names with Three Assets for a PortfolioMAD Object**

Create a default list of asset names with three assets.

```
p = PortfolioMAD('NumAssets',3);
p = setAssetList(p);
disp(p.AssetList);

    {'Asset1'}    {'Asset2'}    {'Asset3'}
```

**Create an Explicitly Named List of Asset Names with Three Assets for a PortfolioMAD Object**

Create a list of asset names for three equities AGG, EEM, and VEU.

```
p = PortfolioMAD;
p = setAssetList(p, 'AGG', 'EEM', 'VEU');
disp(p.AssetList);

    {'AGG'}    {'EEM'}    {'VEU'}
```

## Input Arguments

### obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### AssetList — List of assets

character vector | cell array of character vectors | string array

List of assets, specified using a character vector, cell array of character vectors, or string array where each character vector or string is an asset identifier.

Data Types: char | cell | string

## Output Arguments

### obj — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

The underlying object (`obj`) has a number of public hidden properties to format the asset list:

- `defaultforAssetList` — Default name for assets ('Asset'). Change this name to create default asset names such as 'ETF', 'Bond'.
- `sortAssetList` — Reserved for future implementation.
- `uppercaseAssetList` — If `true`, make all asset identifiers uppercase character vectors. Otherwise do nothing. Default is `false`.

## Tips

- You can also use dot notation to set up list of identifiers for assets.

```
obj = obj.setAssetList(AssetList);
```

- To clear an `AssetList`, call this function with `[]` or `{[]}`.

### **Introduced in R2011a**

# setAssetMoments

Set moments (mean and covariance) of asset returns for Portfolio object

## Syntax

```
obj = setAssetMoments(obj, AssetMean)
obj = setAssetMoments(obj, AssetMean, AssetCovar, NumAssets)
```

## Description

`obj = setAssetMoments(obj, AssetMean)` obtains mean and covariance of asset returns for a Portfolio object. For details on the workflow, see “Portfolio Object Workflow” on page 4-16.

`obj = setAssetMoments(obj, AssetMean, AssetCovar, NumAssets)` obtains mean and covariance of asset returns for a Portfolio object with additional options for AssetCovar and NumAssets.

## Examples

### Set Asset Moments for a Portfolio Object

Set the asset moment properties, given the mean and covariance of asset returns in the variables `m` and `C`.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

p = Portfolio;
p = setAssetMoments(p, m, C);
[assetmean, assetcovar] = getAssetMoments(p)
```

assetmean = 4×1

```
0.0042
0.0083
0.0100
0.0150
```

assetcovar = 4×4

```
0.0005    0.0003    0.0002         0
0.0003    0.0024    0.0017    0.0010
0.0002    0.0017    0.0048    0.0028
         0    0.0010    0.0028    0.0102
```

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using a `Portfolio` object. For more information on creating a portfolio object, see

- `Portfolio`

Data Types: `object`

### **AssetMean — Mean of asset returns**

vector

Mean of asset returns, specified as a vector.

---

**Note** If `AssetMean` is a scalar and the number of assets is known, scalar expansion occurs. If the number of assets cannot be determined, this method assumes that `NumAssets = 1`.

---

Data Types: `double`

### **AssetCovar — Covariance of asset returns**

symmetric positive semidefinite matrix

Covariance of asset returns, specified as a symmetric positive semidefinite matrix.

---

#### **Note**

- If `AssetCovar` is a scalar and the number of assets is known, a diagonal matrix is formed with the scalar value along the diagonals. If it is not possible to determine the number of assets, this method assumes that `NumAssets = 1`.
  - If `AssetCovar` is a vector, a diagonal matrix is formed with the vector along the diagonal.
  - If `AssetCovar` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.
- 

Data Types: `double`

### **NumAssets — Number of assets**

integer

Number of assets, specified as an integer.

---

**Note** If `NumAssets` is not already set in the object, `NumAssets` can be entered to resolve array expansions with `AssetMean` or `AssetCovar`.

---

Data Types: `double`

## Output Arguments

### **obj** — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio` object. For more information on creating a portfolio object, see

- `Portfolio`

## Tips

- You can also use dot notation to set moments (mean and covariance) of the asset returns.  
`obj = obj.setAssetMoments(obj, AssetMean, AssetCovar, NumAssets);`
- To clear `NumAssets` and `AssetCovar`, use this function to set these respective inputs to `[]`.

## Introduced in R2011a

## setBounds

Set up bounds for portfolio weights for a portfolio object

### Syntax

```
obj = setBounds(obj, LowerBound)
obj = setBounds( ____, Name, Value)
```

```
obj = setBounds(obj, LowerBound, UpperBound)
obj = setBounds( ____, Name, Value)
```

### Description

`obj = setBounds(obj, LowerBound)` sets up bounds for portfolio weights for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setBounds( ____, Name, Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax, including `BoundType` as 'Simple' or 'Conditional'.

`obj = setBounds(obj, LowerBound, UpperBound)` sets up bounds for portfolio weights for portfolio objects with an additional option for `UpperBound`.

Given bound constraints `LowerBound` and `UpperBound` and 'Simple' `BoundType`, every weight in a portfolio `Port` must satisfy the following:

$$\text{LowerBound} \leq \text{Port} \leq \text{UpperBound}$$

Given bound constraints `LowerBound` and `UpperBound`, and 'Conditional' `BoundType`, every weight in a portfolio `Port` must satisfy the following:

$$\text{Port} = 0 \text{ or } \text{LowerBound} \leq \text{Port} \leq \text{UpperBound}$$

`obj = setBounds( ____, Name, Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax, including `BoundType` as 'Simple' or 'Conditional'.

### Examples

#### Set Bound Constraints for a Portfolio Object

Suppose you have a balanced fund with stocks that can range from 50% to 75% of your portfolio and bonds that can range from 25% to 50% of your portfolio. Use `setBounds` to set the bound constraints for a balanced fund. Note that this sets default 'Simple' `BoundType`, which enforces  $0.5 \leq x_1 \leq 0.75$ ,  $0.25 \leq x_2 \leq 0.5$ .

```
lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
```

```
p = Portfolio;
p = setBounds(p, lb, ub);
disp(p.NumAssets);
```

```
2
```

```
disp(p.LowerBound);
```

```
0.5000
0.2500
```

```
disp(p.UpperBound);
```

```
0.7500
0.5000
```

### Set Bound Constraints to Define 'Conditional' BoundType Constraints for a Portfolio Object

Suppose you have the mean and covariance of the asset returns for a three asset portfolio:

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
```

The following uses `setBounds` with 'Conditional' BoundType (semicontinuous) constraints to set  $x_i = 0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i = 1, \dots, \text{NumAssets}$ .

```
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setBounds(p, 0.02, 0.5, 'BoundType', 'Conditional', 'NumAssets', 3)
```

```
p =
Portfolio with properties:
    BuyCost: []
    SellCost: []
    RiskFreeRate: []
    AssetMean: [3x1 double]
    AssetCovar: [3x3 double]

### Set Bound Constraints to Define Mixed BoundTypes for a Portfolio Object

Suppose you have the mean and covariance of the asset returns for a three asset portfolio:

```

AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];

```

The following uses `setBounds` with both 'Simple' and 'Conditional' BoundType constraints for all  $i = 1, \dots, \text{NumAssets}$ .

```

p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setBounds(p, 0.1, 0.5, 'BoundType', ["simple"; "conditional"; "conditional"])

```

```

p =
Portfolio with properties:

```

```

    BuyCost: []
    SellCost: []
RiskFreeRate: []
    AssetMean: [3x1 double]
    AssetCovar: [3x3 double]
TrackingError: []
TrackingPort: []

```

```

    Turnover: []
    BuyTurnover: []
    SellTurnover: []
    Name: []
    NumAssets: 3
    AssetList: []
    InitPort: []
    AInequality: []
    bInequality: []
    AEquality: []
    bEquality: []
    LowerBound: [3x1 double]
    UpperBound: [3x1 double]
    LowerBudget: []
    UpperBudget: []
    GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
    GroupA: []
    GroupB: []
    LowerRatio: []
    UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
    BoundType: [3x1 categorical]

```

```
disp(p.LowerBound);
```

```

0.1000
0.1000

```

```
disp(p.UpperBound);
```

```

0.5000
0.5000
0.5000

```

```
disp(p.BoundType);
```

```

simple
conditional
conditional

```

You can use supply lower and upper bounds as vectors, which defines different values for each asset. The following have  $-0.8 \leq x_1 \leq 0.2$ ;  $x_2 = 0$  or  $0.1 \leq x_2 \leq 0.5$ ;  $x_3 = 0$  or  $0.1 \leq x_3 \leq 0.5$ . Note that as 'Simple' BoundType, the assets can be held as short or long positions. However, when using 'Conditional' BoundType, the assets can only be long positions.

```
p = setBounds(p, [-0.8, 0.1, 0.1], [-0.2,0.5,0.5], 'BoundType',["simple"; "conditional"; "conditi
disp(p.LowerBound);
```

```

-0.8000
0.1000
0.1000

```

```
disp(p.UpperBound);
```

```

-0.2000
 0.5000
 0.5000

disp(p.BoundType);

simple
conditional
conditional

```

### Set MinNumAssets Constraint for a Portfolio Object

Set the minimum cardinality constraint for a three-asset portfolio for which you have the mean and covariance values of the asset returns.

```

AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];

p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);

```

When working with a `Portfolio` object, the `setMinNumAssets` function enables you to set up limits on the number of assets invested. These limits are also known as cardinality constraints. When managing a portfolio, it is common that you want to invest in at least a certain number of assets. In addition, you should also clearly define the weight requirement for each invested asset. You can do this using `setBounds` with a `'Conditional'` `BoundType`. If you do not specify a `'Conditional'` `BoundType`, the optimizer cannot understand which assets are invested assets and cannot formulate the `MinNumAssets` constraint.

The following example specifies that at least two assets should be invested and the investments should be greater than 16%.

```

p = setMinNumAssets(p, 2, []);
p = setBounds(p, 0.16, 'BoundType', 'conditional');

```

Use `estimateFrontierByReturn` to estimate optimal portfolios with targeted portfolio returns.

```

pwgt = estimateFrontierByReturn(p,[ 0.008, 0.01 ])

pwgt = 3×2

    0.2861    0.3967
    0.5001    0.2438
    0.2138    0.3595

```

### Set Bound Constraints for a PortfolioCVaR Object

Suppose you have a balanced fund with stocks that can range from 50% to 75% of your portfolio and bonds that can range from 25% to 50% of your portfolio. To set the bound constraints for a balanced fund.

```

lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];

p = PortfolioCVaR;
p = setBounds(p, lb, ub);
disp(p.NumAssets);

    2

disp(p.LowerBound);

    0.5000
    0.2500

disp(p.UpperBound);

    0.7500
    0.5000

```

### Set Bound Constraints to Define 'Conditional' BoundType Constraints for a PortfolioCVaR Object

Suppose you have a balanced fund with stocks that can range from 50% to 75% of your portfolio and bonds that can range from 25% to 50% of your portfolio. To set the bound constraints for a balanced fund with semicontinuous constraints, use `setBounds` with 'Conditional' BoundType constraints to set  $x_i = 0.25$  or  $0.5 \leq x_i \leq 0.5$  or  $0.75$  for all  $i = 1, \dots, \text{NumAssets}$ .

```

lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];

p = PortfolioCVaR;
p = setBounds(p, lb, ub, 'BoundType', ["conditional"; "conditional"]);
disp(p.NumAssets);

    2

disp(p.LowerBound);

    0.5000
    0.2500

disp(p.UpperBound);

    0.7500
    0.5000

```

### Set Bound Constraints for a PortfolioMAD Object

Suppose you have a balanced fund with stocks that can range from 50% to 75% of your portfolio and bonds that can range from 25% to 50% of your portfolio. To set the bound constraints for a balanced fund.

```

lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];

```

```
p = PortfolioMAD;  
p = setBounds(p, lb, ub);  
disp(p.NumAssets);
```

```
2
```

```
disp(p.LowerBound);
```

```
0.5000  
0.2500
```

```
disp(p.UpperBound);
```

```
0.7500  
0.5000
```

### Set Bound Constraints to Define 'Conditional' BoundType Constraints for a PortfolioMAD Object

Suppose you have a balanced fund with stocks that can range from 50% to 75% of your portfolio and bonds that can range from 25% to 50% of your portfolio. To set the bound constraints for a balanced fund with semicontinuous constraints, use `setBounds` with 'Conditional' BoundType constraints to set  $x_i = 0.25$  or  $0.5 \leq x_i \leq 0.5$  or  $0.75$  for all  $i = 1, \dots, \text{NumAssets}$ .

```
lb = [ 0.5; 0.25 ];  
ub = [ 0.75; 0.5 ];
```

```
p = PortfolioMAD;  
p = setBounds(p, lb, ub, 'BoundType', ["conditional"; "conditional"]);  
disp(p.NumAssets);
```

```
2
```

```
disp(p.LowerBound);
```

```
0.5000  
0.2500
```

```
disp(p.UpperBound);
```

```
0.7500  
0.5000
```

### Input Arguments

#### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`

- PortfolioMAD

Data Types: object

### LowerBound — Lower-bound weight for each asset

scalar | vector

Lower-bound weight for each asset, specified as a scalar or vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

---

#### Note

- If either LowerBound or UpperBound are input as empties with [], the corresponding attributes in the Portfolio, PortfolioCVaR, or PortfolioMAD object are cleared and set to [].
  - If LowerBound or UpperBound are specified as scalars and NumAssets exists or can be computed, then they undergo scalar expansion. The default value for NumAssets is 1.
  - If both LowerBound and UpperBound exist and they are not ordered correctly, the setBounds function switches bounds if necessary.
  - If 'Conditional' BoundType is specified, the LowerBound cannot be a negative value.
- 

Data Types: double

### UpperBound — Upper-bound weight for each asset

scalar | vector

(Optional) Upper-bound weight for each asset, specified as a scalar or vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

---

#### Note

- If either LowerBound or UpperBound are input as empties with [], the corresponding attributes in the Portfolio, PortfolioCVaR, or PortfolioMAD object are cleared and set to [].
  - If LowerBound or UpperBound are specified as scalars and NumAssets exists or can be computed, then they undergo scalar expansion. The default value for NumAssets is 1.
  - If both LowerBound and UpperBound exist and they are not ordered correctly, the setBounds function switches bounds if necessary.
  - If 'Conditional' BoundType is specified, the UpperBound cannot be a negative value.
- 

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: obj = setBounds(p,0.02,'BoundType','Conditional');

**BoundType — Type of bounds for each asset weight**

'Simple' (default) | character vector with value 'Simple' or 'Conditional' | string with value "Simple" or "Conditional" | cell array of character vectors with values 'Simple' or 'Conditional' | string array with values "Simple" or "Conditional"

Type of bounds for each asset weight, specified as the comma-separated pair consisting of 'BoundType' and a scalar character vector or string with a value of 'Simple' or 'Conditional' or a cell array of character vectors with values of 'Simple' or 'Conditional'.

- 'Simple' is LowerBound <= AssetWeight <= UpperBound.
- 'Conditional' is LowerBound <= AssetWeight <= UpperBound or AssetWeight = 0.

---

**Warning** If you specify the Bound range to be inclusive of zero (using either a 'Simple' or 'Conditional' BoundType), when you use `setMinMaxNumAssets` to specify the `MinNumAssets` constraint, and then use one of the `estimate` functions, it is ambiguous for the optimizer to define the minimum requirement for an allocated asset. In this case, the optimizer considers that an asset with zero weight is a valid allocated asset and the optimization proceeds, but with the warning that the allocation has less than the `MinNumAssets` required. For more information, see “Troubleshooting for Setting 'Conditional' BoundType, `MinNumAssets`, and `MaxNumAssets` Constraints” on page 4-122.

---

Data Types: char | cell | string

**NumAssets — Number of assets in portfolio**

1 (default) | scalar numeric

Number of assets in portfolio, specified as the comma-separated pair consisting of 'NumAssets' and a scalar numeric value.

---

**Note** `NumAssets` cannot be used to change the dimension of a `Portfolio`, `PortfolioCvAR`, or `PortfolioMAD` object.

- If either `LowerBound` or `UpperBound` are input as empties with `[]`, the corresponding attributes in the `Portfolio`, `PortfolioCvAR`, or `PortfolioMAD` object are cleared and set to `[]`.
  - If `LowerBound` or `UpperBound` are specified as scalars and `NumAssets` exists or can be imputed, then they undergo scalar expansion. The default value for `NumAssets` is 1.
  - If both `LowerBound` and `UpperBound` exist and they are not ordered correctly, the `setBounds` function switches bounds if necessary.
- 

Data Types: double

**Output Arguments****obj — Updated portfolio object**

object

Updated portfolio object, returned as a `Portfolio`, `PortfolioCvAR`, or `PortfolioMAD` object.

## Tips

You can also use dot notation to set up the bounds for portfolio weights.

```
obj = obj.setBounds(LowerBound, UpperBound, Name, Value);
```

If any of `LowerBound`, `UpperBound`, or `BoundType` are input as empties with `[]`, the corresponding attributes in the portfolio object are cleared and set to `[]`. If `BoundType` is cleared as `[]`, the bound type defaults to `'Simple'`.

```
p = setBounds(p, LowerBound, [], 'BoundType', []);
```

To reset a portfolio object to be a continuous problem, run the following:

```
p = setMinMaxNumAssets(p, [], []);
p = setBounds(p, p.LowerBound, p.UpperBound, 'BoundType', 'Simple');
```

## Introduced in R2011a

## setBudget

Set up budget constraints

### Syntax

```
obj = setBudget(obj,LowerBudget)
obj = setBudget(obj,LowerBudget,UpperBudget)
```

### Description

`obj = setBudget(obj,LowerBudget)` sets up budget constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setBudget(obj,LowerBudget,UpperBudget)` sets up budget constraints for portfolio objects with an additional option for `UpperBudget`.

### Examples

#### Set Budget Constraint for a Portfolio Object

Assume you have a fund that permits up to 10% leverage, which means that your portfolio can be from 100% to 110% invested in risky assets. Given a `Portfolio` object `p`, set the budget constraint.

```
p = Portfolio;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
```

```
1
```

```
disp(p.UpperBudget);
```

```
1.1000
```

#### Set Budget Constraint for a PortfolioCVaR Object

Assume you have a fund that permits up to 10% leverage, which means that your portfolio can be from 100% to 110% invested in risky assets. Given a `CVaR` portfolio object `p`, set the budget constraint.

```
p = PortfolioCVaR;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
```

```
1
```

```
disp(p.UpperBudget);
```

```
1.1000
```

### Set Budget Constraint for a PortfolioMAD Object

Assume you have a fund that permits up to 10% leverage, which means that your portfolio can be from 100% to 110% invested in risky assets. Given PortfolioMAD object `p`, set the budget constraint.

```
p = PortfolioMAD;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
```

```
1
```

```
disp(p.UpperBudget);
```

```
1.1000
```

### Control the Allocation of a Risk-Free Asset Using setBudget

Define mean and covariance of risk asset returns.

```
m = [ 0.05; 0.1; 0.12; 0.18; ];
C = [ 0.0064 0.00408 0.00192 0,;
      0.00408 0.0289 0.0204 0.0119,;
      0.00192 0.0204 0.0576 0.0336,;
      0 0.0119 0.0336 0.1225];
```

Create a Portfolio object defining the risk-free rate.

```
p = Portfolio('RiskFreeRate',0.03, 'assetmean', m, 'assetcovar', C, ...
'lowerbudget', 1, 'upperbudget', 1, 'lowerbound', 0);
```

Create multiple Portfolio objects with different budgets on risky assets. By defining the risky assets, you can control how much is invested in a risk-free asset.

```
p = setBudget(p, 1, 1); % allow 0% risk-free asset allocation, meaning fully invested in risky assets
p1 = setBudget(p, 0, 1); % allow 0 to 100% risk-free asset allocation
p2 = setBudget(p, 0.7, 1); % allow 0 to 30% risk-free asset allocation
```

```
plotFrontier(p); hold on;
plotFrontier(p1);hold on;
plotFrontier(p2);
legend('Without risk-free asset', 'With risk-free asset in range [0,1]', 'With risk-free asset in range [0,1]');
```

`setBudget` defines the bound for total weights for the allocated risky assets, and the remaining is automatically the bound for a risk-free asset. Use `setBudget` to control the level of allowed allocation to a risk-free asset. For additional information on using `setBudget` with a risk-free asset, see “Leverage in Portfolio Optimization with a Risk-Free Asset”.

## Input Arguments

### **obj** – Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **LowerBudget** – Lower-bound for budget constraint

scalar

Lower-bound for budget constraint, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** Given bounds for a budget constraint in either `LowerBudget` or `UpperBudget`, budget constraints require any portfolio in `Port` to satisfy:

$$\text{LowerBudget} \leq \text{sum}(\text{Port}) \leq \text{UpperBudget}$$

One or both constraints may be specified. The usual budget constraint for a fully invested portfolio is to have `LowerBudget = UpperBudget = 1`. However, if the portfolio has allocations in cash, the budget constraints can be used to specify the cash constraints. For example, if the portfolio can hold between 0% and 10% in cash, the budget constraint would be set up with

```
obj = setBudget(obj, 0.9, 1)
```

---

Data Types: double

### **UpperBudget — Upper-bound for budget constraint**

scalar

Upper-bound for budget constraint, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** Given bounds for a budget constraint in either `LowerBudget` or `UpperBudget`, budget constraints require any portfolio in `Port` to satisfy:

$$\text{LowerBudget} \leq \text{sum}(\text{Port}) \leq \text{UpperBudget}$$

One or both constraints may be specified. The usual budget constraint for a fully invested portfolio is to have `LowerBudget = UpperBudget = 1`. However, if the portfolio has allocations in cash, the budget constraints can be used to specify the cash constraints. For example, if the portfolio can hold between 0% and 10% in cash, the budget constraint would be set up with

```
obj = setBudget(obj, 0.9, 1)
```

---

Data Types: double

## **Output Arguments**

### **obj — Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## **Tips**

You can also use dot notation to set up the budget constraints.

```
obj = obj.setBudget(LowerBudget, UpperBudget);
```

**See Also**

getBudget

## setCosts

Set up proportional transaction costs

### Syntax

```
obj = setCosts(obj,BuyCost)
```

```
obj = setCosts(obj,BuyCost,SellCost,InitPort,NumAssets)
```

### Description

`obj = setCosts(obj,BuyCost)` sets up proportional transaction costs for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setCosts(obj,BuyCost,SellCost,InitPort,NumAssets)` sets up proportional transaction costs for portfolio objects with additional options specified for `SellCost`, `InitPort`, and `NumAssets`.

Given proportional transaction costs and an initial portfolio in the variables `BuyCost`, `SellCost`, and `InitPort`, the transaction costs for any portfolio `Port` reduce expected portfolio return by:

$$\text{BuyCost}' * \max\{0, \text{Port} - \text{InitPort}\} + \text{SellCost}' * \max\{0, \text{InitPort} - \text{Port}\}$$

### Examples

#### Set Up Transaction Costs for a Portfolio Object

Given a `Portfolio` object `p` with an initial portfolio already set, use the `setCosts` function to set up transaction costs.

```
bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
```

```
p = Portfolio('InitPort', x0);
p = setCosts(p, bc, sc);
```

```
disp(p.NumAssets);
```

```
5
```

```
disp(p.BuyCost);
```

```
0.0013
0.0013
0.0013
0.0013
0.0013
```

```
disp(p.SellCost);
```

0.2000
0.1000
0.1000
```

### Set Up Transaction Costs for a PortfolioCVaR Object

Given a CVaR portfolio object `p` with an initial portfolio already set, use the `setCosts` function to set up transaction costs.

```
bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
```

```
p = PortfolioCVaR('InitPort', x0);
p = setCosts(p, bc, sc);
```

```
disp(p.NumAssets);
```

```

## Set Up Transaction Costs for a PortfolioMAD Object

Given PortfolioMAD object `p` with an initial portfolio already set, use the `setCosts` function to set up transaction costs.

```
bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
```

```
p = PortfolioMAD('InitPort', x0);
p = setCosts(p, bc, sc);
```

```
disp(p.NumAssets);
```

```
5
```

```
disp(p.BuyCost);
```

```
0.0013
0.0013
0.0013
0.0013
0.0013

0.0024
```

```
disp(p.InitPort);
```

```
0.4000
0.2000
0.2000
0.1000
0.1000
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **BuyCost** — Proportional transaction cost to purchase each asset

vector

Proportional transaction cost to purchase each asset, specified as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note**

- If `BuyCost`, `SellCost`, or `InitPort` are specified as scalars and `NumAssets` exists or can be imputed, then these values undergo scalar expansion. The default value for `NumAssets` is 1.
  - Transaction costs in `BuyCost` and `SellCost` are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.
- 

Data Types: double

**SellCost — Proportional transaction cost to sell each asset**

vector

Proportional transaction cost to sell each asset, specified as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note**

- If `BuyCost`, `SellCost`, or `InitPort` are specified as scalars and `NumAssets` exists or can be imputed, then these values undergo scalar expansion. The default value for `NumAssets` is 1.
  - Transaction costs in `BuyCost` and `SellCost` are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.
- 

Data Types: double

**InitPort — Initial or current portfolio weights**

vector

Initial or current portfolio weights, specified as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** If no `InitPort` is specified, that value is assumed to be 0.

- If `BuyCost`, `SellCost`, or `InitPort` are specified as scalars and `NumAssets` exists or can be imputed, then these values undergo scalar expansion. The default value for `NumAssets` is 1.
  - Transaction costs in `BuyCost` and `SellCost` are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.
- 

Data Types: double

**NumAssets — Number of assets in portfolio**

scalar

Number of assets in portfolio, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** NumAssets cannot be used to change the dimension of a portfolio object.

- If BuyCost, SellCost, or InitPort are specified as scalars and NumAssets exists or can be imputed, then these values undergo scalar expansion. The default value for NumAssets is 1.
  - Transaction costs in BuyCost and SellCost are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.
- 

Data Types: double

## Output Arguments

### obj — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

## Tips

- You can also use dot notation to set up proportional transaction costs.

```
obj = obj.setCosts(BuyCost, SellCost, InitPort, NumAssets);
```

- If BuyCost or SellCost are input as empties with [], the corresponding attributes in the portfolio object are cleared and set to []. If InitPort is set to empty with [], it will only be cleared and set to [] if BuyCost, SellCost, and Turnover are also empty. Otherwise, it is an error.

## Introduced in R2011a

## setDefaultConstraints

Set up portfolio constraints with nonnegative weights that sum to 1

### Syntax

```
obj = setDefaultConstraints(obj)
obj = setDefaultConstraints(obj, NumAssets)
```

### Description

`obj = setDefaultConstraints(obj)` sets up portfolio constraints with nonnegative weights that sum to 1 for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setDefaultConstraints(obj, NumAssets)` sets up portfolio constraints with nonnegative weights that sum to 1 with an additional option for `NumAssets`.

A "default" portfolio set has `LowerBound = 0` and `LowerBudget = UpperBudget = 1` such that a portfolio `Port` must satisfy `sum(Port) = 1` with `Port >= 0`.

### Examples

#### Define Default Constraints for the Portfolio Object

Assuming you have 20 assets, you can define the "default" portfolio set.

```
p = Portfolio('NumAssets', 20);
p = setDefaultConstraints(p);
disp(p);
```

Portfolio with properties:

```

    bInequality: []
    AEquality: []
    bEquality: []
```

```

LowerBound: [20x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
    GroupA: []
    GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
BoundType: [20x1 categorical]

```

### Define Default Constraints for the PortfolioCVaR Object

Assuming you have 20 assets, you can define the "default" portfolio set.

```

p = PortfolioCVaR('NumAssets', 20);
p = setDefaultConstraints(p);
disp(p);

```

PortfolioCVaR with properties:

```

    BuyCost: []
    SellCost: []
    RiskFreeRate: []
ProbabilityLevel: []
    Turnover: []
    BuyTurnover: []
    SellTurnover: []

    AEquality: []
    bEquality: []
    LowerBound: [20x1 double]
    UpperBound: []
    LowerBudget: 1
    UpperBudget: 1
    GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
    GroupA: []
    GroupB: []
    LowerRatio: []
    UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
    BoundType: [20x1 categorical]
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

**NumAssets — Number of assets in portfolio**

scalar

Number of assets in portfolio, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** `NumAssets` cannot be used to change the dimension of a portfolio object. The default for `NumAssets` is 1.

---

Data Types: double

**Output Arguments****obj — Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

**Tips**

- You can also use dot notation to set up the default portfolio set.  

```
obj = obj.setDefaultConstraints(NumAssets);
```
- This function does not modify any existing constraints in a portfolio object other than the bound and budget constraints. If an `UpperBound` constraint exists, it is cleared and set to `[]`.

## setEquality

Set up linear equality constraints for portfolio weights

### Syntax

```
obj= setEquality(obj,AEquality,bEquality)
```

### Description

`obj= setEquality(obj,AEquality,bEquality)` sets up linear equality constraints for portfolio weights for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

Given linear equality constraint matrix `AEquality` and vector `bEquality`, every weight in a portfolio `Port` must satisfy the following:

$$AEquality * Port = bEquality$$

### Examples

#### Set Linear Equality Constraints for a Portfolio Object

Suppose you have a portfolio of five assets, and you want to ensure that the first three assets are 50% of your portfolio. Given a `Portfolio` object `p`, set the linear equality constraints with the following.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setEquality(p, A, b);

disp(p.NumAssets);

5

disp(p.AEquality);

1 1 1 0 0

disp(p.bEquality);

0.5000
```

#### Set Linear Equality Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are 50% of your portfolio. Given a `PortfolioCVaR` object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```

A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioCVaR;
p = setEquality(p, A, b);
disp(p.NumAssets);

5

disp(p.AEquality);

1 1 1 0 0

disp(p.bEquality);

0.5000

```

### Set Linear Equality Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are 50% of your portfolio. Given a PortfolioMAD object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```

A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)

AEquality = 1x5

1 1 1 0 0

bEquality = 0.5000

```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **AEquality** — Matrix to form linear equality constraints

matrix

Matrix to form linear equality constraints, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** An error results if `AEquality` is empty and `bEquality` is nonempty.

---

Data Types: double

### **bEquality** – Vector to form linear equality constraints

vector

Vector to form linear equality constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** An error results if `AEquality` is nonempty and `bEquality` is empty.

---

Data Types: double

## **Output Arguments**

### **obj** – Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## **Tips**

- You can also use dot notation to set up linear equality constraints for portfolio weights.
 

```
obj = obj.setEquality(AEquality, bEquality);
```
- Linear equality constraints can be removed from a portfolio object by entering `[]` for each property you want to remove.

## **See Also**

## setGroupRatio

Set up group ratio constraints for portfolio weights

### Syntax

```
obj = setGroupRatio(obj,GroupA,GroupB,LowerRatio)
obj = setGroupRatio( ____,UpperRatio)
```

### Description

`obj = setGroupRatio(obj,GroupA,GroupB,LowerRatio)` sets up group ratio constraints for portfolio weights for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setGroupRatio( ____,UpperRatio)` sets up group ratio constraints for portfolio weights for portfolio objects with an additional optional argument for `UpperRatio`.

Given base and comparison group matrices `GroupA` and `GroupB` and `LowerRatio` or `UpperRatio` bounds, group ratio constraints require any portfolio in `Port` to satisfy the following:

$$(\text{GroupB} * \text{Port}) .* \text{LowerRatio} \leq \text{GroupA} * \text{Port} \leq (\text{GroupB} * \text{Port}) .* \text{UpperRatio}$$

---

**Caution** This collection of constraints usually requires that portfolio weights be nonnegative and that the products `GroupA * Port` and `GroupB * Port` are always nonnegative. Although negative portfolio weights and non-Boolean group ratio matrices are supported, use with caution.

---

### Examples

#### Set Group Ratio Constraints for a Portfolio Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolio never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). Group ratio constraints can be set with:

```
GA = [ true true true false false false ];    % financial companies
GB = [ false false false true true true ];    % nonfinancial companies
p = Portfolio;
p = setGroupRatio(p, GA, GB, [], 0.5);

disp(p.NumAssets);

    6

disp(p.GroupA);

    1    1    1    0    0    0

disp(p.GroupB);
```

```

0 0 0 1 1 1
disp(p.UpperRatio);
0.5000

```

### Set Group Ratio Constraints for a PortfolioCVaR Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolio never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). Group ratio constraints can be set with:

```

GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = PortfolioCVaR;
p = setGroupRatio(p, GA, GB, [], 0.5);

disp(p.NumAssets);
6

disp(p.GroupA);
1 1 1 0 0 0

disp(p.GroupB);
0 0 0 1 1 1

disp(p.UpperRatio);
0.5000

```

### Set Group Ratio Constraints for a PortfolioMAD Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolio never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). Group ratio constraints can be set with:

```

GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = PortfolioMAD;
p = setGroupRatio(p, GA, GB, [], 0.5);

disp(p.NumAssets);
6

disp(p.GroupA);
1 1 1 0 0 0

disp(p.GroupB);
0 0 0 1 1 1

```

```
disp(p.UpperRatio);
    0.5000
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

### **GroupA** — Matrix that forms base groups for comparison

matrix

Matrix that forms base groups for comparison, specified as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** The group matrices `GroupA` and `GroupB` are usually indicators of membership in groups, which means that their elements are usually either 0 or 1. Because of this interpretation, `GroupA` and `GroupB` matrices can be either logical or numerical arrays.

---

Data Types: `double` | `logical`

### **GroupB** — Matrix that forms comparison groups

matrix

Matrix that forms comparison groups, specified as a matrix `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** The group matrices `GroupA` and `GroupB` are usually indicators of membership in groups, which means that their elements are usually either 0 or 1. Because of this interpretation, `GroupA` and `GroupB` matrices can be either logical or numerical arrays.

---

Data Types: `double` | `logical`

### **LowerRatio** — Lower bound for ratio of GroupB groups to GroupA groups

vector

Lower bound for ratio of GroupB groups to GroupA groups, specified as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** If input is scalar, `LowerRatio` undergoes scalar expansion to be conformable with the group matrices.

---

Data Types: double

**UpperRatio — Upper bound for ratio of GroupB groups to GroupA groups**  
vector

Upper bound for ratio of GroupB groups to GroupA groups, specified as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** If input is scalar, `UpperRatio` undergoes scalar expansion to be conformable with the group matrices.

---

Data Types: double

## Output Arguments

**obj — Updated portfolio object**  
object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## Tips

- You can also use dot notation to set up group ratio constraints for portfolio weight.  
`obj = obj.setGroupRatio(GroupA, GroupB, LowerRatio, UpperRatio);`
- To remove group ratio constraints, enter empty arrays for the corresponding arrays. To add to existing group ratio constraints, use `addGroupRatio`.

## setGroups

Set up group constraints for portfolio weights

### Syntax

```
obj = setGroups(obj,GroupMatrix,LowerGroup)
obj = setGroups(obj,GroupMatrix,LowerGroup,UpperGroup)
```

### Description

`obj = setGroups(obj,GroupMatrix,LowerGroup)` sets up group constraints for portfolio weights for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setGroups(obj,GroupMatrix,LowerGroup,UpperGroup)` sets up group constraints for portfolio weights for portfolio objects with an additional option specified for `UpperGroup`.

Given `GroupMatrix` and either `LowerGroup` or `UpperGroup`, a portfolio `Port` must satisfy the following:

$$\text{LowerGroup} \leq \text{GroupMatrix} * \text{Port} \leq \text{UpperGroup}$$

### Examples

#### Set Group Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given a `Portfolio` object `p`, set the group constraints with the following.

```
G = [ true true true false false ];
p = Portfolio;
p = setGroups(p, G, [], 0.3);
```

```
disp(p.NumAssets);
```

```
5
```

```
disp(p.GroupMatrix);
```

```
1 1 1 0 0
```

```
disp(p.UpperGroup);
```

```
0.3000
```

### Set Group Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given a CVaR portfolio object `p`, set the group constraints with the following.

```
G = [ true true true false false ];
p = PortfolioCVaR;
p = setGroups(p, G, [], 0.3);

disp(p.NumAssets);

    5

disp(p.GroupMatrix);

    1    1    1    0    0

disp(p.UpperGroup);

    0.3000
```

### Set Group Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given PortfolioMAD object `p`, set the group constraints with the following.

```
G = [ true true true false false ];
p = PortfolioMAD;
p = setGroups(p, G, [], 0.3);

disp(p.NumAssets);

    5

disp(p.GroupMatrix);

    1    1    1    0    0

disp(p.UpperGroup);

    0.3000
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`

- PortfolioMAD

Data Types: object

**GroupMatrix — Group constraint matrix**

logical or numeric matrix

Group constraint matrix, specified as a matrix for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

---

**Note** The group matrix GroupMatrix is usually an indicator of membership in groups, which means that its elements are usually either 0 or 1. Because of this interpretation, GroupMatrix can be either a logical or numerical matrix.

---

Data Types: double

**LowerGroup — Lower bound for group constraints**

vector

Lower bound for group constraints, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

---

**Note** If input is scalar, LowerGroup undergoes scalar expansion to be conformable with GroupMatrix.

---

Data Types: double

**UpperGroup — Upper bound for group constraints**

vector

Upper bound for group constraints, returned as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

---

**Note** If input is scalar, UpperGroup undergoes scalar expansion to be conformable with GroupMatrix.

---

Data Types: double

**Output Arguments****obj — Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR

- PortfolioMAD

## Tips

- You can also use dot notation to set up group constraints for portfolio weights.

```
obj = obj.setGroups(GroupMatrix, LowerGroup, UpperGroup);
```

- To remove group constraints, enter empty arrays for the corresponding arrays. To add to existing group constraints, use `addGroups`.

## Introduced in R2011a

## setInequality

Set up linear inequality constraints for portfolio weights

### Syntax

```
obj = setInequality(obj,AInequality,bInequality)
```

### Description

`obj = setInequality(obj,AInequality,bInequality)` sets up linear inequality constraints for portfolio weights for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

Given a linear inequality constraint matrix `AInequality` and vector `bInequality`, every weight in a portfolio `Port` must satisfy the following:

$$\text{AInequality} * \text{Port} \leq \text{bInequality}$$

### Examples

#### Set Linear Inequality Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than 50% of your portfolio. Given a `Portfolio` object `p`, set the linear inequality constraints with the following.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setInequality(p, A, b);

disp(p.NumAssets);

    5

disp(p.AInequality);

    1    1    1    0    0

disp(p.bInequality);

    0.5000
```

### Set Linear Inequality Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than 50% of your portfolio. Given a CVaR portfolio object `p`, set the linear inequality constraints with the following.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioCVaR;
p = setInequality(p, A, b);

disp(p.NumAssets);

5

disp(p.AInequality);

1 1 1 0 0

disp(p.bInequality);

0.5000
```

### Set Linear Inequality Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than 50% of your portfolio. Given PortfolioMAD object `p`, set the linear inequality constraints with the following.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD;
p = setInequality(p, A, b);

disp(p.NumAssets);

5

disp(p.AInequality);

1 1 1 0 0

disp(p.bInequality);

0.5000
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Data Types: object

### **AInequality – Matrix to form linear inequality constraints**

matrix

Matrix to form linear inequality constraints, specified as a matrix for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

---

**Note** An error results if AInequality is empty and bInequality is nonempty.

---

Data Types: double

### **bInequality – Vector to form linear inequality constraints**

vector

Vector to form linear inequality constraints, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

---

**Note** An error results if AInequality is nonempty and bInequality is empty.

---

Data Types: double

## **Output Arguments**

### **obj – Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

## **Tips**

- You can also use dot notation to set up linear inequality constraints for portfolio weights.
 

```
obj = obj.setInequality(AInequality, bInequality);
```
- To remove inequality constraints, enter empty arguments. To add to existing inequality constraints, use addInequality.

## setInitPort

Set up initial or current portfolio

### Syntax

```
obj = setInitPort(obj,InitPort)
obj = setInitPort(obj,InitPort,NumAssets)
```

### Description

`obj = setInitPort(obj,InitPort)` sets up initial or current portfolio for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setInitPort(obj,InitPort,NumAssets)` sets up initial or current portfolio for portfolio objects with an additional options specified for `NumAssets`.

### Examples

#### Set the InitPort Property for a Portfolio Object

Given an initial portfolio in `x0`, use the `setInitPort` function to set the `InitPort` property.

```
p = Portfolio('NumAssets', 4);
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = setInitPort(p, x0);
disp(p.InitPort);
```

```
0.3000
0.2000
0.2000
0
```

#### Set InitPort to Create an Equally-Weighted Portfolio of Four Assets for a Portfolio Object

Create an equally weighted portfolio of four assets using the `setInitPort` function.

```
p = Portfolio('NumAssets', 4);
p = setInitPort(p, 1/4, 4);
disp(p.InitPort);
```

```
0.2500
0.2500
0.2500
0.2500
```

### Set the InitPort Property for a PortfolioCvAR Object

Given an initial portfolio in `x0`, use the `setInitPort` function to set the `InitPort` property.

```
p = PortfolioCvAR('NumAssets', 4);
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = setInitPort(p, x0);
disp(p.InitPort);
```

```
0.3000
0.2000
0.2000
0
```

### Set InitPort to Create an Equally-Weighted Portfolio of Four Assets for a PortfolioCvAR Object

Create an equally weighted portfolio of four assets using the `setInitPort` function.

```
p = PortfolioCvAR('NumAssets', 4);
p = setInitPort(p, 1/4, 4);
disp(p.InitPort);
```

```
0.2500
0.2500
0.2500
0.2500
```

### Set the InitPort Property for a PortfolioMAD Object

Given an initial portfolio in `x0`, use the `setInitPort` function to set the `InitPort` property.

```
p = PortfolioMAD('NumAssets', 4);
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = setInitPort(p, x0);
disp(p.InitPort);
```

```
0.3000
0.2000
0.2000
0
```

### Set InitPort to Create an Equally-Weighted Portfolio of Four Assets for a PortfolioMAD Object

Create an equally weighted portfolio of four assets using the `setInitPort` function.

```
p = PortfolioMAD('NumAssets', 4);
p = setInitPort(p, 1/4, 4);
disp(p.InitPort);
```

```
0.2500  
0.2500  
0.2500  
0.2500
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

### **InitPort** — Initial or current portfolio weights

vector

Initial or current portfolio weights, specified as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** If `InitPort` is specified as a scalar and `NumAssets` exists, then `InitPort` undergoes scalar expansion.

---

Data Types: `double`

### **NumAssets** — Number of assets in portfolio

1 (default) | scalar

Number of assets in portfolio, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** If it is not possible to obtain a value for `NumAssets`, it is assumed that `NumAssets` is 1.

---

Data Types: `double`

## Output Arguments

### **obj** — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`

- PortfolioCVaR
- PortfolioMAD

## Tips

- You can also use dot notation to set up an initial or current portfolio.  
`obj = obj.setInitPort(InitPort, NumAssets);`
- To remove an initial portfolio, call this function with an empty argument [] for InitPort.

## Introduced in R2011a

## setMinMaxNumAssets

Set cardinality constraints on the number of assets invested in a portfolio object

### Syntax

```
obj = setMinMaxNumAssets(obj, MinNumAssets, MaxNumAssets)
```

### Description

`obj = setMinMaxNumAssets(obj, MinNumAssets, MaxNumAssets)` sets cardinality constraints for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object.

`MinNumAssets` and `MaxNumAssets` are the minimum and maximum number of assets invested in the portfolio, respectively. The total number of allocated assets satisfying the Bound constraints is between `[MinNumAssets, MaxNumAssets]`. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

### Examples

#### Set MaxNumAssets Constraint for a Portfolio Object

Set the maximum cardinality constraint for a three-asset portfolio for which you have the mean and covariance values of the asset returns.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];

p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested. Use `setMinMaxNumAssets` to limit the total number of allocated assets to no more than two.

```
p = setMinMaxNumAssets(p, [], 2);
```

Use `estimateFrontierByReturn` to estimate optimal portfolios with targeted portfolio returns.

```
pwgt = estimateFrontierByReturn(p, [ 0.008, 0.01 ])
```

```
pwgt = 3×2
```

```
      0      0
0.6101  0.3962
0.3899  0.6038
```

### Set MinNumAssets Constraint for a Portfolio Object

Set the minimum cardinality constraint for a three-asset portfolio for which you have the mean and covariance values of the asset returns.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];

p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up limits on the number of assets invested. These limits are also known as cardinality constraints. When managing a portfolio, it is common that you want to invest in at least a certain number of assets. In addition, you should also clearly define the weight requirement for each invested asset. You can do this using `setBounds` with a 'Conditional' `BoundType`. If you do not specify a 'Conditional' `BoundType`, the optimizer cannot understand which assets are invested assets and cannot formulate the `MinNumAssets` constraint.

The following example specifies that at least two assets should be invested and the investments should be greater than 16%.

```
p = setMinMaxNumAssets(p, 2, []);
p = setBounds(p, 0.16, 'BoundType', 'conditional');
```

Use `estimateFrontierByReturn` to estimate optimal portfolios with targeted portfolio returns.

```
pwgt = estimateFrontierByReturn(p,[ 0.008, 0.01 ])

pwgt = 3×2

    0.2861    0.3967
    0.5001    0.2438
    0.2138    0.3595
```

### Set 'Conditional' BoundType, MinNumAssets, and MaxNumAssets Constraints for a Portfolio Object

Set the minimum and maximum cardinality constraints and a 'Conditional' `BoundType` for a three-asset portfolio for which you have the mean and covariance values of the asset returns.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];

p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested. The following example specifies that exactly two assets

should be invested using `setMinMaxNumAssets` and the investment should be equally allocated among the two assets using `setBounds`.

```
p = setMinMaxNumAssets(p, 2, 2);
p = setBounds(p, 0.5, 0.5, 'BoundType', 'conditional');
```

Use `estimateFrontierByReturn` to estimate optimal portfolios with targeted portfolio returns.

```
pwgt = estimateFrontierByReturn(p,[ 0.008, 0.01 ])
```

```
pwgt = 3×2
```

```
      0      0.5000
0.5000      0
0.5000      0.5000
```

### Set 'Conditional' BoundType, MinNumAssets, and MaxNumAssets Constraints for a PortfolioCVaR Object

Suppose you have a universe of 12 stocks where you want to find the optimal portfolios with targeted returns and you want to set semicontinuous and cardinality constraints for the portfolio.

```
load CAPMuniverse
p = PortfolioCVaR('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000, 'missingdata',true);
p = setProbabilityLevel(p, 0.80);
```

When working with a `PortfolioCVaR` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested. The following example specifies that a minimum of five assets and a maximum of 10 assets should be invested using `setMinMaxNumAssets` and the investments should be greater than 4% and less than 45% using `setBounds`.

```
p = setMinMaxNumAssets(p, 5, 10);
p = setBounds(p, 0.04, 0.45, 'BoundType', 'conditional');
```

Use `estimateFrontierByReturn` to estimate optimal portfolios with targeted portfolio returns.

```
pwgt = estimateFrontierByReturn(p,[ 0.00026, 0.00038 ])
```

```
pwgt = 12×2
```

```
0.0400      0.0400
      0      0
      0      0
      0      0
      0      0
0.0507      0.0786
0.0400      0.0400
0.0400      0.0400
      0      0
0.0400      0.0400
      ⋮
```

## Set 'Conditional' BoundType, MinNumAssets, and MaxNumAssets Constraints for a PortfolioMAD Object

Suppose you have a universe of 12 stocks where you want to find the optimal portfolios with targeted returns and you want to set semicontinuous and cardinality constraints for the portfolio.

```
load CAPMuniverse
p = PortfolioMAD('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 , 'missingdata', true);
```

When working with a PortfolioMAD object, the setMinMaxNumAssets function enables you to set up the limits on the number of assets invested. The following example specifies that a minimum of five assets and a maximum of 10 assets should be invested using setMinMaxNumAssets and the investments should be greater than 4% and less than 45% using setBounds.

```
p = setMinMaxNumAssets(p, 5, 10);
p = setBounds(p, 0.04, 0.45, 'BoundType', 'conditional');
```

Use estimateFrontierByReturn to estimate optimal portfolios with targeted portfolio returns.

```
pwgt = estimateFrontierByReturn(p,[ 0.00026, 0.00038 ])
```

```
pwgt = 12x2
```

```
    0.0400    0.0400
         0         0
         0         0
         0         0
         0         0
    0.0507    0.0786
    0.0400    0.0400
    0.0400    0.0400
         0         0
    0.0400    0.0400
         ⋮
```

## Input Arguments

### obj — Object for portfolio

object

Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Data Types: object

### MinNumAssets — Minimum number of assets allocated in portfolio

scalar numeric

Minimum number of assets allocated in the portfolio, specified using a scalar numeric.

Data Types: `double`

### **MaxNumAssets** — Maximum number of assets allocated in portfolio

scalar numeric

Maximum number of assets allocated in the portfolio, specified using a scalar numeric.

Data Types: `double`

## **Output Arguments**

### **obj** — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object.

## **Tips**

- You can also use dot notation to set up a list of identifiers for assets.  

```
obj = obj.setMinMaxNumAssets(MinNumAssets,MaxNumAssets);
```
- Specifying empty values (`[]`) for `MinNumAssets` and `MaxNumAssets` removes limit constraints from the `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object.

## **Introduced in R2018b**

# setOneWayTurnover

Set up one-way portfolio turnover constraints

## Syntax

```
obj = setOneWayTurnover(obj, BuyTurnover)
obj = setOneWayTurnover(obj, BuyTurnover, SellTurnover, InitPort, NumAssets)
```

## Description

`obj = setOneWayTurnover(obj, BuyTurnover)` sets up one-way portfolio turnover constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setOneWayTurnover(obj, BuyTurnover, SellTurnover, InitPort, NumAssets)` sets up one-way portfolio turnover constraints for portfolio objects with additional options specified for `SellTurnover`, `InitPort`, and `NumAssets`.

Given an initial portfolio in `InitPort` and an upper bound for portfolio turnover on purchases in `BuyTurnover` or sales in `SellTurnover`, the one-way turnover constraints require any portfolio `Port` to satisfy the following:

$$1' * \max\{0, \text{Port} - \text{InitPort}\} \leq \text{BuyTurnover}$$

$$1' * \max\{0, \text{InitPort} - \text{Port}\} \leq \text{SellTurnover}$$

---

**Note** If `Turnover = BuyTurnover = SellTurnover`, the constraint is not equivalent to:

$$1' * |\text{Port} - \text{InitPort}| \leq \text{Turnover}$$

To set this constraint, use `setTurnover`.

---

## Examples

### Set One-Way Turnover Constraints for a Portfolio Object

Set one-way turnover constraints.

```
p = Portfolio('AssetMean', [0.1, 0.2, 0.15], 'AssetCovar', ...
[ 0.005, -0.010, 0.004; -0.010, 0.040, -0.002; 0.004, -0.002, 0.023]);
p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0); %130-30 portfolio
plotFrontier(p);
```

### Set One-Way Turnover Constraints for a PortfolioCVaR Object

Set one-way turnover constraints.

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioCVaR('InitPort', x0);
p = setOneWayTurnover(p, 0.3, 0.2);
disp(p.NumAssets);

10

disp(p.BuyTurnover)

0.3000

disp(p.SellTurnover)

0.2000

disp(p.InitPort);

0.1200
0.0900
0.0800
0.0700
0.1000
```

```

0.1000
0.1500
0.1100
0.0800
0.1000

```

## Set One-Way Turnover Constraints for a PortfolioMAD Object

Set one-way turnover constraints.

```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioMAD('InitPort', x0);
p = setOneWayTurnover(p, 0.3, 0.2);
disp(p.NumAssets);

    10

disp(p.BuyTurnover)

    0.3000

disp(p.SellTurnover)

    0.2000

disp(p.InitPort);

    0.1200
    0.0900
    0.0800
    0.0700
    0.1000
    0.1000
    0.1500
    0.1100
    0.0800
    0.1000

```

## Input Arguments

### obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### BuyTurnover — Turnover constraint on purchases

nonnegative and finite scalar

Turnover constraint on purchases, specified as a nonnegative and finite scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **SellTurnover** — Turnover constraint on sales

nonnegative and finite scalar

Turnover constraint on sales, specified as a nonnegative and finite scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **InitPort** — Initial or current portfolio weights

0 (default) | finite vector with `NumAssets > 0` elements

Initial or current portfolio weights, specified as a finite vector with `NumAssets > 0` elements for a `Portfolio`, `PortfolioCVaR`, `PortfolioMAD` input object (`obj`).

---

**Note** If no `InitPort` is specified, that value is assumed to be 0.

If `InitPort` is specified as a scalar and `NumAssets` exists, then `InitPort` undergoes scalar expansion.

---

Data Types: double

### **NumAssets** — Number of assets in portfolio

1 (default) | scalar

Number of assets in portfolio, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** If it is not possible to obtain a value for `NumAssets`, it is assumed that `NumAssets` is 1.

---

Data Types: double

## **Output Arguments**

### **obj** — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## **More About**

### **One-way Turnover Constraint**

One-way turnover constraints ensure that estimated optimal portfolios differ from an initial portfolio by no more than specified amounts according to whether the differences are purchases or sales.

The constraints take the form

$$1^T \max\{0, x - x_0\} \leq \tau_B$$

$$1^T \max\{0, x_0 - x\} \leq \tau_S$$

with

- $x$  — The portfolio (*NumAssets* vector)
- $x_0$  — Initial portfolio (*NumAssets* vector)
- $\tau_B$  — Upper-bound for turnover constraint on purchases (scalar)
- $\tau_S$  — Upper-bound for turnover constraint on sales (scalar)

Specify one-way turnover constraints using the following properties in a supported portfolio object: `BuyTurnover` for  $\tau_B$ , `SellTurnover` for  $\tau_S$ , and `InitPort` for  $x_0$ .

---

**Note** The average turnover constraint (which is set using `setTurnover`) is not just the combination of the one-way turnover constraints with the same value for the constraint.

---

## Tips

You can also use dot notation to set up one-way portfolio turnover constraints.

```
obj = obj.setOneWayTurnover(BuyTurnover, SellTurnover, InitPort, NumAssets)
```

## Introduced in R2011a

## setProbabilityLevel

Set probability level for VaR and CVaR calculations

### Syntax

```
obj = setProbabilityLevel(obj,ProbabilityLevel)
```

### Description

`obj = setProbabilityLevel(obj,ProbabilityLevel)` sets probability level for VaR and CVaR calculations for a `PortfolioCVaR` object. For details on the workflow, see “PortfolioCVaR Object Workflow” on page 5-14.

### Examples

#### Set Probability Level for a PortfolioCVaR Object

Set the `ProbabilityLevel` for a CVaR portfolio object.

```
p = PortfolioCVaR;  
p = setProbabilityLevel(p, 0.95);  
disp(p.ProbabilityLevel)
```

```
0.9500
```

### Input Arguments

#### **obj** — Object for portfolio

object

Object for portfolio, specified using a `PortfolioCVaR` object.

For more information on creating a `PortfolioCVaR` object, see

- `PortfolioCVaR`

Data Types: object

#### **ProbabilityLevel** — Probability level which is 1 minus the probability of losses greater than the value-at-risk

scalar with value from 0 to 1

Probability level which is 1 minus the probability of losses greater than the value-at-risk, specified as a scalar with value from 0 to 1.

---

**Note** `ProbabilityLevel` must be a value from 0 to 1 and, in most cases, should be a value from 0.9 to 0.99.

---

Data Types: double

## Output Arguments

### **obj** — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `PortfolioCVaR` object. For more information on creating a portfolio object, see

- `PortfolioCVaR`

## Tips

You can also use dot notation to set the probability level for VaR and CVaR calculations:

```
obj = obj.setProbabilityLevel(ProbabilityLevel)
```

### Introduced in R2012b

## setSolver

Choose main solver and specify associated solver options for portfolio optimization

### Syntax

```
obj = setSolver(obj,solverType)
```

```
obj = setSolver(obj,solverType,Name,Value)
```

```
obj = setSolver(obj,solverType,optioptions)
```

### Description

`obj = setSolver(obj,solverType)` selects the main solver and enables you to specify associated solver options for portfolio optimization for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setSolver(obj,solverType,Name,Value)` selects the main solver and enables you to specify associated solver options for portfolio optimization for portfolio objects with additional options specified by using one or more `Name,Value` pair arguments.

`obj = setSolver(obj,solverType,optioptions)` selects the main solver and enables you to specify associated solver options for portfolio optimization for portfolio objects with an `optioptions` object.

### Examples

#### Set Solver Type for a Portfolio Object

If you use the `quadprog` function as the `solverType`, the default is the interior-point-convex version of `quadprog`.

```
load CAPMuniverse
p = Portfolio('AssetList',Assets(1:12));
p = setDefaultConstraints(p);
p = setSolver(p, 'quadprog');
display(p.solverType);
```

```
quadprog
```

You can switch back to `lcp prog` with:

```
p = setSolver(p, 'lcp prog');
display(p.solverType);
```

```
lcp prog
```

### Set the Solver Type as 'fmincon' for a PortfolioCVaR Object

Use 'fmincon' as the solverType.

```
p = PortfolioCVaR;
p = setSolver(p, 'fmincon');
display(p.solverType);
```

```
fmincon
```

### Set the Solver Type as 'fmincon' and Use Name-Value Pair Arguments to Set the Algorithm for a PortfolioCVaR Object

Use 'fmincon' as the solverType and use name-value pair arguments to set the algorithm to 'interior-point' and to turn off the display.

```
p = PortfolioCVaR;
p = setSolver(p, 'fmincon', 'Algorithm', 'interior-point', 'Display', 'off');
display(p.solverOptions.Algorithm);
```

```
interior-point
```

```
display(p.solverOptions.Display);
```

```
off
```

### Set the Solver Type as 'fmincon' and Use an optimoptions Object to Set the Algorithm for a PortfolioCVaR Object

Use 'fmincon' as the solverType and use an optimoptions object to set the algorithm to 'interior-point' and to turn off the display.

```
p = PortfolioCVaR;
options = optimoptions('fmincon', 'Algorithm', 'interior-point', 'Display', 'off');
p = setSolver(p, 'fmincon', options);
display(p.solverOptions.Algorithm);
```

```
interior-point
```

```
display(p.solverOptions.Display);
```

```
off
```

### Set 'TrustRegionCP' as the Solver Type with Default Options for a PortfolioCVaR Object

Use 'TrustRegionCP' as the solverType with default options.

```
p = PortfolioCVaR;
p = setSolver(p, 'TrustRegionCP');
display(p.solverType);
```

```

trustregioncp
display(p.solverOptions);

        MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    MasterSolverOptions: [1x1 optim.options.Linprog]
        Display: 'off'
        CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
        ActiveCutTolerance: 1.0000e-07
        ShrinkRatio: 0.7500
    TrustRegionStartIteration: 2
        DeltaLimit: 1

```

### Set 'TrustRegionCP' as the Solver Type with 'ShrinkRatio' for a PortfolioCVaR Object

Use the name-value pair 'ShrinkRatio' to shrink the size of the trust region by 0.75.

```

p = PortfolioCVaR;
p = setSolver(p,'TrustRegionCP','ShrinkRatio',0.75);
display(p.solverType);

```

```

trustregioncp
display(p.solverOptions);

        MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    MasterSolverOptions: [1x1 optim.options.Linprog]
        Display: 'off'
        CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
        ActiveCutTolerance: 1.0000e-07
        ShrinkRatio: 0.7500
    TrustRegionStartIteration: 2
        DeltaLimit: 1

```

### Set 'TrustRegionCP' as the Solver Type and Change the Master Solver Option for a PortfolioCVaR Object

For the master solver, continue using the dual - simplex algorithm with no display, but tighten its termination tolerance to 1e-8.

```

p = PortfolioCVaR;
options = optimoptions('linprog','Algorithm','Dual-Simplex','Display','off','OptimalityTolerance

```

```
p = setSolver(p, 'TrustRegionCP', 'MasterSolverOptions', options);
display(p.solverType)
```

```
trustregioncp
```

```
display(p.solverOptions)
```

```

        MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    MasterSolverOptions: [1x1 optim.options.Linprog]
        Display: 'off'
        CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    ShrinkRatio: 0.7500
    TrustRegionStartIteration: 2
    DeltaLimit: 1

```

```
display(p.solverOptions.MasterSolverOptions.Algorithm)
```

```
dual-simplex
```

```
display(p.solverOptions.MasterSolverOptions.Display)
```

```
off
```

```
display(p.solverOptions.MasterSolverOptions.TolFun)
```

```
1.0000e-08
```

For the master solver, use the interior-point algorithm with no display, and with a termination tolerance of  $1e-7$ .

```
p = PortfolioCVaR;
options = optimoptions('linprog', 'Algorithm', 'interior-point', 'Display', 'off', 'OptimalityTolerance', 1e-7);
p = setSolver(p, 'TrustRegionCP', 'MasterSolverOptions', options);
display(p.solverType)
```

```
trustregioncp
```

```
display(p.solverOptions)
```

```

        MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    MasterSolverOptions: [1x1 optim.options.Linprog]
        Display: 'off'
        CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    ShrinkRatio: 0.7500
    TrustRegionStartIteration: 2
    DeltaLimit: 1

```

```
display(p.solverOptions.MasterSolverOptions.Algorithm)
```

```
interior-point
display(p.solverOptions.MasterSolverOptions.Display)
off
display(p.solverOptions.MasterSolverOptions.TolFun)
    1.0000e-07
```

### **Set Solver Type as 'fmincon' for a PortfolioMAD Object**

Use 'fmincon' as the solverType.

```
p = PortfolioMAD;
p = setSolver(p, 'fmincon');
display(p.solverType);

fmincon
```

### **Set the Solver Type as 'fmincon' and Use Name-Value Pair Arguments to Set the Algorithm for a PortfolioMAD Object**

Use 'fmincon' as the solverType and use name-value pair arguments to set the algorithm to 'sqp' and to turn on the display.

```
p = PortfolioMAD;
p = setSolver(p, 'fmincon', 'Algorithm', 'sqp', 'Display', 'final');
display(p.solverOptions.Algorithm);

sqp

display(p.solverOptions.Display);

final
```

### **Set Solver Type as 'fmincon' and Use an optimoptions Structure to Set the Algorithm for a PortfolioMAD Object**

Use 'fmincon' as the solverType and use an optimoptions object to set the algorithm to 'trust-region-reflective' and to turn off the display.

```
p = PortfolioMAD;
options = optimoptions('fmincon', 'Algorithm', 'trust-region-reflective', 'Display', 'off');
p = setSolver(p, 'fmincon', options);
display(p.solverOptions.Algorithm);

trust-region-reflective

display(p.solverOptions.Display);

off
```

## Set the Solver Type as 'fmincon' and Use an optimoptions Structure to Set the Algorithm and Use of Gradients for a PortfolioMAD Object

Use 'fmincon' as the solverType and use an optimoptions object to set the algorithm to 'active-set' and to set the gradients flag 'on' for 'GradObj' and turn off the display.

```
p = PortfolioMAD;
options = optimoptions('fmincon','algorithm','active-set','display','off','gradobj','on');
p = setSolver(p, 'fmincon', options);
display(p.solverOptions.Algorithm);
```

```
active-set
```

```
display(p.solverOptions.Display);
```

```
off
```

## Input Arguments

### obj — Object for portfolio

object

Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Data Types: object

### solverType — Solver to use for portfolio optimization

character vector | string

Solver to use for portfolio optimization, specified using a character vector or string for the supported solverType.

The solverType input argument depends on which type of object (obj) is being used for a portfolio optimization.

For a Portfolio object, the supported solverType are:

- 'lcprog' (Default).
  - The 'lcprog' solver uses linear complementary programming with Lemke's algorithm with control variables name-value pair arguments for 'maxiter', 'tiebreak', 'tolpiv'. For more information about 'lcprog' name-value pair options, see "Portfolio Object Name-Value Pair Arguments" on page 19-1269.
- 'fmincon'
  - The default algorithm for 'fmincon' is 'sqp'. For more information about 'fmincon' name-value pair options, see "Portfolio Object Name-Value Pair Arguments" on page 19-1269.

- 'quadprog'
  - The default algorithm for 'quadprog' is `interior-point-convex`. For more information about 'quadprog' name-value pair options, see “Portfolio Object Name-Value Pair Arguments” on page 19-1269.

For a `PortfolioCVaR` object, the supported `solverType` are:

- 'TrustRegionCP' (Default)
  - 'TrustRegionCP' is an implementation of Kelley's [1] cutting-plane method for convex optimization. For more information about 'TrustRegionCP' name-value pair options, see “Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'” on page 19-1270.
- 'ExtendedCP'
  - 'ExtendedCP' is an implementation of Kelley's [1] cutting-plane method for convex optimization. For more information about 'ExtendedCP' name-value pair options, see “Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'” on page 19-1270.
- 'fmincon'
  - The default algorithm for 'fmincon' is 'sqp'. For more information about 'fmincon' name-value pair options, see “PortfolioCVaR Object Name-Value Pair Arguments” on page 19-1270.
- 'cuttingplane'
  - The 'cuttingplane' solver is an implementation of Kelley's [1] cutting-plane method for convex optimization with name-value pair arguments for 'MaxIter', 'Abstol', 'Reltol' and 'MasterSolverOptions'. For more information about 'cuttingplane' name-value pair options, see “PortfolioCVaR Object Name-Value Pair Arguments” on page 19-1270.

For a `PortfolioMAD` object, the supported `solverType` are:

- 'TrustRegionCP' (Default)
  - 'TrustRegionCP' is an implementation of Kelley's [1] cutting-plane method for convex optimization. For more information about 'TrustRegionCP' name-value pair options, see “Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'” on page 19-1270.
- 'ExtendedCP'
  - 'ExtendedCP' is an implementation of Kelley's [1] cutting-plane method for convex optimization. For more information about 'ExtendedCP' name-value pair options, see “Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'” on page 19-1270.
- 'fmincon'
  - The default algorithm for 'fmincon' is the 'sqp' algorithm and 'GradObj' set to 'on'. For more information about 'fmincon' name-value pair options, see “PortfolioMAD Object Name-Value Pair Arguments” on page 19-1270.

**Note** `setSolver` can also configure solver options for 'linprog'. `linprog` is a helper solver used in estimating efficient frontier problems for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. The default algorithm for 'linprog' is 'dual-simplex'. For more information about 'linprog' name-value pair options, see “Name-Value Pair Arguments” on page 19-1269. For more details on using a helper solver, see “Solver Guidelines for Portfolio Objects” on page 4-104, “Solver Guidelines

for PortfolioCVaR Objects” on page 5-92, or “Solver Guidelines for PortfolioMAD Objects” on page 6-89.

Data Types: char | string

### optimoptions – optimoptions object

object

(Optional) `optimoptions` object, specified as an `optimoptions` object that is created using `optimoptions` from Optimization Toolbox. For example:

```
p = setSolver(p,'fmincon',optimoptions('fmincon','Display','iter'));
```

**Note** `optimoptions` is the default and recommended method to set solver options, however `optimset` is also supported.

Data Types: object

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `p = setSolver(p,'cuttingplane','MasterSolverOptions',options)` sets `cuttingplane` options for a `PortfolioCVaR` object.

Depending on the `obj` type (`Portfolio`, `PortfolioCVaR`, or `PortfolioMAD`) and the specified `solverType`, the options for the associated name-value pair arguments are different.

### Portfolio Object Name-Value Pair Arguments

- For a `Portfolio` object using a `solverType` of `lcprog`, choose a name-value value in this table.

| Value      | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'maxiter'  | Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer. The default value is $1 + n^3$ , where $n$ is the dimension of the input.                                                                                                                                                                                                                      |
| 'tiebreak' | Method to break ties for pivot selection, specified as the comma-separated pair consisting of 'tiebreak' and one of the following options: <ul style="list-style-type: none"> <li><code>first</code> - Select pivot with lowest index.</li> <li><code>last</code> - Select pivot with highest index.</li> <li><code>random</code> - Select a pivot at random.</li> </ul> The default value is <code>first</code> . |
| 'tolpiv'   | Pivot tolerance below which a number is considered to be zero, specified as the comma-separated pair consisting of 'tolpiv' and a numeric value. The default value is $1.0e-9$ .                                                                                                                                                                                                                                   |

- For a `Portfolio` object using a `solverType` of `fmincon`, see “options” (Optimization Toolbox) to choose name-value pair arguments.

- For a Portfolio object using a solverType of linprog, see “options” (Optimization Toolbox) to choose name-value pair arguments.
- For a Portfolio object using a solverType of quadprog, see “options” (Optimization Toolbox) to choose name-value pair arguments.

#### PortfolioCVaR Object Name-Value Pair Arguments

- For a PortfolioCVaR object using a solverType of fmincon, see “options” (Optimization Toolbox) to choose name-value pair arguments.
- For a PortfolioCVaR object using a solverType of 'TrustRegionCP' or 'ExtendedCP', see “Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'” on page 19-1270 to choose name-value pair arguments.
- For a PortfolioCVaR object using a solverType of 'cuttingplane', choose a name-value pair value in this table.

| Value                 | Description                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'MaxIter'             | Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer. The default value is 1000.                                                                                  |
| 'AbsTol'              | Absolute stopping tolerance, specified as the comma-separated pair consisting of 'AbsTol' and a positive scalar. The default value is 1e-6.                                                                                     |
| 'RelTol'              | Relative stopping tolerance, specified as the comma-separated pair consisting of 'RelTol' and a positive scalar. The default value is 1e-5.                                                                                     |
| 'MasterSolverOptions' | Options for the master solver linprog, specified as the comma-separated pair consisting of 'MasterSolverOptions' and an optimoptions object. The default is optimoptions('linprog','Algorithm','Dual-Simplex','Display','off'). |

- For a PortfolioCVaR object using a solverType of linprog, see “options” (Optimization Toolbox) to choose name-value pair arguments.

#### PortfolioMAD Object Name-Value Pair Arguments

- For a PortfolioMAD object using a solverType of fmincon, see “options” (Optimization Toolbox) to choose name-value pair arguments.
- For a PortfolioMAD object using a solverType of 'TrustRegionCP' or 'ExtendedCP', see “Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'” on page 19-1270 to choose name-value pair arguments.
- For a PortfolioMAD object using a solverType of linprog, see “options” (Optimization Toolbox) to choose name-value pair arguments.

#### Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'

For a PortfolioCVaR or PortfolioMAD object using a solverType of 'TrustRegionCP' or 'ExtendedCP', choose a name-value pair value in this table.

| Value                      | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'MaxIterations'            | Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIterations' and a positive real number. The default value is 1e-3.                                                                                                                                                                                                                                           |
| 'NonlinearScalingFactor'   | Scales the nonlinear function and its gradient by a factor, specified as the comma-separated pair consisting of 'NonlinearScalingFactor' and a positive real number. The default value is 1e-3.                                                                                                                                                                                                    |
| 'ObjectiveScalingFactor'   | Scales the objective function by a factor, specified as the comma-separated pair consisting of 'ObjectiveScalingFactor' and a positive real number. The default value is 1e-3.                                                                                                                                                                                                                     |
| 'AbsoluteGapTolerance'     | Solver stops if the absolute difference between the approximated nonlinear function value and its true value is less than or equal to <b>AbsoluteGapTolerance</b> , specified as the comma-separated pair consisting of 'AbsoluteGapTolerance' and a positive real number. The default value is 1e-7.                                                                                              |
| 'RelativeGapTolerance'     | Solver stops if the relative difference between the approximated nonlinear function value and its true value is less than or equal to <b>RelativeGapTolerance</b> , specified as the comma-separated pair consisting of 'RelativeGapTolerance' and a positive real number. The default value is 1e-5.                                                                                              |
| 'Display'                  | Level of display, specified as the comma-separated pair consisting of 'Display' and a supported value of: <ul style="list-style-type: none"> <li>• 'iter' displays output at each iteration and gives the technical exit message.</li> <li>• 'final' displays just the final output and gives the final technical exit message.</li> <li>• 'off' is the default and displays no output.</li> </ul> |
| 'CutGeneration'            | Method to add the cut, specified as the comma-separated pair consisting of 'CutGeneration' and a supported value of: <ul style="list-style-type: none"> <li>• 'basic' is the default and the new cut is added at the latest solution found.</li> <li>• 'midway' is where the new cut is added at the mid point between the latest and previous solution found.</li> </ul>                          |
| 'MaxIterationsInactiveCut' | Removes constraints that are not active for the last <b>MaxIterationsInactiveCut</b> iterations, specified as the comma-separated pair consisting of 'MaxIterationsInactiveCut' and a positive integer. The default value is 30.                                                                                                                                                                   |
| 'ActiveCutTolerance'       | Determines if the cuts are active and is used together with <b>MaxIterationsInactiveCut</b> to decide which cuts to remove from the LP subproblem, specified as the comma-separated pair consisting of 'ActiveCutTolerance' and a real number. The default value is 1e-7.                                                                                                                          |

| Value                       | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'MasterSolverOptions'       | Options for the master solver <code>linprog</code> , specified as the comma-separated pair consisting of 'MasterSolverOptions' and an <code>optimoptions</code> object. The default is <code>optimoptions('linprog','Algorithm','Dual-Simplex','Display','off')</code> .                                                                                                                                        |
| 'TrustRegionStartIteration' | Use this parameter only for a <code>solverType</code> of 'TrustRegionCP'. Solver starts to apply the trust region heuristic at <code>TrustRegionStartIteration</code> . Nonnegative integer. Default is 2.                                                                                                                                                                                                      |
| 'ShrinkRatio'               | Use this parameter only for a <code>solverType</code> of 'TrustRegionCP'. If the approximated functions are not agreeing well in the previous iterations, the algorithm will shrink the size of trust region by the <code>ShrinkRatio</code> . Nonnegative real between 0 and 1. Default is 0.75.                                                                                                               |
| 'DeltaLimit'                | Use this parameter only for a <code>solverType</code> of 'TrustRegionCP'. The trust region of the approximated functions is bounded by <code>DeltaLimit</code> during the iterations. <code>DeltaLimit</code> is also used to initialize the trust region. For portfolio problems, 1 is generally a good <code>DeltaLimit</code> , since portfolio weights are between 0 and 1. Nonnegative real. Default is 1. |

## Output Arguments

### **obj** — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## Tips

You can also use dot notation to choose the solver and specify associated solver options.

```
obj = obj.setSolver(solverType,Name,Value);
```

## Algorithms

To solve the efficient frontier of a portfolio, one version of the portfolio optimization problem minimizes the portfolio risk  $Risk(x)$ , subject to a target return, and other linear constraints specified for the `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For the definition of portfolio risk and return, see “Risk Proxy” on page 4-5 and “Return Proxy” on page 4-4.

$$\text{Minimize}_x Risk(x)$$

$$\text{subject to } Return(x) \geq TargetReturn$$

$$Ax \leq b$$

$$A_{eq}x = b_{eq}$$

$$lb \leq x \leq ub$$

An alternative version of the portfolio optimization problem maximizes the expected return of the portfolio, subject to a target risk and other linear constraints specified for the Portfolio, PortfolioCVaR, or PortfolioMAD object.

$$\begin{aligned} & \text{Maximize}_x \text{Return}(x) \\ & \text{subject to } \text{Risk}(x) \leq \text{TargetRisk} \\ & Ax \leq b \\ & A_{eq}x = b_{eq} \\ & lb \leq x \leq ub \end{aligned}$$

The return proxy is always a linear function. Therefore, depending on the risk proxy and whether it is used as the objective or constraints, the problem needs to be solved by different solvers. For example, `quadprog` is appropriate for problems with a quadratic function as the objective and only linear constraints, and `fmincon` is appropriate for problems with nonlinear objective or constraints. In addition, there are solvers in Financial Toolbox suitable for certain special types of problems, such as the solverType `lcprog`, `'TrustRegionCP'`, or `'ExtendedCP'`.

## Introduced in R2011a

## setSolverMINLP

Choose mixed integer nonlinear programming (MINLP) solver for portfolio optimization

### Syntax

```
obj = setSolverMINLP(obj,solverTypeMINLP)
```

```
obj = setSolverMINLP( ___,Name,Value)
```

### Description

`obj = setSolverMINLP(obj,solverTypeMINLP)` selects the mixed integer nonlinear programming (MINLP) solver and enables you to specify associated solver options for portfolio optimization for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object.

When any one or any combination of 'Conditional' `BoundType`, `MinNumAssets`, or `MaxNumAssets` constraints are active, the portfolio problem is formulated by adding `NumAssets` binary variables. The binary variable 0 indicates that an asset is not invested and the binary variable 1 indicates that an asset is invested. For more information on using 'Conditional' `BoundType`, see `setBounds`. For more information on specifying `MinNumAssets` and `MaxNumAssets`, see `setMinMaxNumAssets`.

If you use the `estimate` functions with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object for which any of the 'Conditional' `BoundType`, `MinNumAssets`, or `MaxNumAssets` constraints are active, MINLP solver is automatically used. For details on MINLP, see “Algorithms” on page 19-1284.

`obj = setSolverMINLP( ___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Configure MINLP Solver and Options When Using a Portfolio Object

Configure the MINLP solver for a three-asset portfolio for which you have the mean and covariance values of the asset returns.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
```

When working with a `Portfolio` object, use `setBounds` with a 'Conditional' `BoundType` constraint to set  $x_i = 0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i = 1, \dots, \text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.5, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, use `setMinMaxNumAssets` function to set up `MinNumAssets` and `MaxNumAssets` constraints for a portfolio. This sets limit constraints for the `Portfolio` object, where the total number of allocated assets satisfying the constraints is between

MinNumAssets and MaxNumAssets. Setting MinNumAssets = MaxNumAssets = 2, specifies that only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Three different MINLP solvers (OuterApproximation, ExtendedCP, TrustRegionCP) use the cutting plane method. Use the setSolverMINLP function to configure the OuterApproximation solver and options.

```
pint = setSolverMINLP(p, 'OuterApproximation', 'NonlinearScalingFactor', 1e4, 'Display', 'iter',
pint.solverTypeMINLP
```

```
ans =
'OuterApproximation'
```

```
pint.solverOptionsMINLP
```

```
ans = struct with fields:
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 10000
    ObjectiveScalingFactor: 1000
    Display: 'iter'
    CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

You can also configure the options for intlinprog, which is the Master solver for mixed integer linear programming problems in the MINLP solver.

```
pint = setSolverMINLP(p, 'OuterApproximation', 'IntMasterSolverOptions', optimoptions('intlinprog',
pint.solverOptionsMINLP.IntMasterSolverOptions
```

```
ans =
intlinprog options:
```

```
Set properties:
    Display: 'off'
```

```
Default properties:
```

```
    AbsoluteGapTolerance: 0
    BranchRule: 'reliability'
    ConstraintTolerance: 1.0000e-04
    CutGeneration: 'basic'
    CutMaxIterations: 10
    Heuristics: 'basic'
    HeuristicsMaxNodes: 50
    IntegerPreprocess: 'basic'
    IntegerTolerance: 1.0000e-05
    LPMaxIterations: 'max(30000, 10*(numberOfEqualities+numberOfInequalities+numberOfIntegers))'
    LPOptimalityTolerance: 1.0000e-07
    MaxFeasiblePoints: Inf
    MaxNodes: 10000000
    MaxTime: 7200
    NodeSelection: 'simplebestproj'
```

```

ObjectiveCutoff: Inf
ObjectiveImprovementThreshold: 0
OutputFcn: []
PlotFcn: []
RelativeGapTolerance: 1.0000e-04
RootLPAlgorithm: 'dual-simplex'
RootLPMaxIterations: 'max(30000,10*(numberOfEqualities+numberOfInequalities+number

```

### Configure MINLP Solver and Options When Using a PortfolioCVaR Object

Configure the MINLP solver for a 12 asset portfolio that is using semicontinuous and cardinality constraints.

```

load CAPMuniverse
p = PortfolioCVaR('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 , 'missingdata', true);
p = setProbabilityLevel(p, 0.95);

```

When working with a PortfolioCVaR object, the setMinMaxNumAssets function enables you to set up the limits on the number of assets invested. The following example specifies that a minimum of five assets and a maximum of 10 assets should be invested using setMinMaxNumAssets and the investments should be greater than 4% and less than 45% using setBounds.

```

p = setMinMaxNumAssets(p, 5, 10);
p = setBounds(p, 0.04, 0.45, 'BoundType', 'conditional');

```

Three different MINLP solvers (OuterApproximation, ExtendedCP, TrustRegionCP) use the cutting plane method. Use the setSolverMINLP function to configure the OuterApproximation solver and options.

```

pint = setSolverMINLP(p, 'OuterApproximation', 'NonlinearScalingFactor', 1e4, 'Display', 'iter',
pint.solverTypeMINLP

```

```

ans =
'OuterApproximation'

```

```

pint.solverOptionsMINLP

```

```

ans = struct with fields:
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 10000
    ObjectiveScalingFactor: 1000
    Display: 'iter'
    CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30

```

You can also configure the options for intlinprog, which is the Master solver for mixed integer linear programming problems in the MINLP solver.

```

pint = setSolverMINLP(p, 'OuterApproximation', 'IntMasterSolverOptions', optimoptions('intlinprog',
pint.solverOptionsMINLP.IntMasterSolverOptions

ans =
  intlinprog options:

    Set properties:
                Display: 'off'

    Default properties:
      AbsoluteGapTolerance: 0
                BranchRule: 'reliability'
      ConstraintTolerance: 1.0000e-04
                CutGeneration: 'basic'
      CutMaxIterations: 10
                Heuristics: 'basic'
      HeuristicsMaxNodes: 50
      IntegerPreprocess: 'basic'
      IntegerTolerance: 1.0000e-05

      ObjectiveImprovementThreshold: 0
                OutputFcn: []
                PlotFcn: []
      RelativeGapTolerance: 1.0000e-04
      RootLPAlgorithm: 'dual-simplex'
      RootLPMaxIterations: 'max(30000,10*(numberOfEqualities+numberOfInequalities+numberOf

```

### Configure MINLP Solver and Options When Using a PortfolioMAD Object

Configure the MINLP solver for a 12 asset portfolio that is using semicontinuous and cardinality constraints.

```

load CAPMuniverse
p = PortfolioMAD('AssetList', Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000, 'missingdata', true);

```

When working with a PortfolioMAD object, the setMinMaxNumAssets function enables you to set up the limits on the number of assets invested. The following example specifies that a minimum of five assets and a maximum of 10 assets should be invested using setMinMaxNumAssets and the investments should be greater than 4% and less than 45% using setBounds.

```

p = setMinMaxNumAssets(p, 5, 10);
p = setBounds(p, 0.04, 0.45, 'BoundType', 'conditional');

```

Three different MINLP solvers (OuterApproximation, ExtendedCP, TrustRegionCP) use the cutting plane method. Use the setSolverMINLP function to configure the OuterApproximation solver and options.

```

pint = setSolverMINLP(p, 'OuterApproximation', 'NonlinearScalingFactor', 1e4, 'Display', 'iter',
pint.solverTypeMINLP

ans =
'OuterApproximation'

pint.solverOptionsMINLP

ans = struct with fields:
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 10000
    ObjectiveScalingFactor: 1000
    Display: 'iter'
    CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30

```

You can also configure the options for `intlinprog`, which is the Master solver for mixed integer linear programming problems in the MINLP solver.

```

pint = setSolverMINLP(p, 'OuterApproximation', 'IntMasterSolverOptions', optimoptions('intlinprog',
pint.solverOptionsMINLP.IntMasterSolverOptions

ans =
intlinprog options:

Set properties:
    Display: 'off'

Default properties:
    AbsoluteGapTolerance: 0

    NodeSelection: 'simplebestproj'
    ObjectiveCutoff: Inf
    ObjectiveImprovementThreshold: 0
    OutputFcn: []
    PlotFcn: []
    RelativeGapTolerance: 1.0000e-04
    RootLPAlgorithm: 'dual-simplex'
    RootLPMaxIterations: 'max(30000,10*(numberOfEqualities+numberOfInequalities+numberOfIntegers))'

```

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **solverTypeMINLP — MINLP solver for portfolio optimization**

character vector with a value of `'OuterApproximation'`, `'ExtendedCP'`, or `'TrustRegionCP'` | string with a value of `"OuterApproximation"`, `"ExtendedCP"`, or `"TrustRegionCP"`

MINLP solver for portfolio optimization when any one or any combination of `'Conditional'` `BoundType`, `MinNumAssets`, or `MaxNumAssets` constraints are active. Specify `solverTypeMINLP` using a character vector or string with a value of `'OuterApproximation'`, `'ExtendedCP'`, or `'TrustRegionCP'`.

For a `Portfolio` object, the default value of the `solverTypeMINLP` is `'OuterApproximation'` with the following default settings for name-value pairs for `setSolverMINLP`:

- `MaxIterations` - 1000
- `AbsoluteGapTolerance` - 1.0000e-07
- `RelativeGapTolerance` - 1.0000e-05
- `Display` - 'off'
- `NonlinearScalingFactor` - 1000
- `ObjectiveScalingFactor` - 1000
- `CutGeneration` - 'basic'
- `MaxIterationsInactiveCut` - 30
- `NumIterationsEarlyIntegerConvergence` - 30
- `ActiveCutTolerance` - 1.0000e-07
- `IntMasterSolverOptions` - `optimoptions('intlinprog','Algorithm','Dual-Simplex','Display','off')`

For a `PortfolioCVaR` and `PortfolioMAD` object, the default value of the `solverTypeMINLP` is `'TrustRegionCP'` with the following default settings for name-value pairs for `setSolverMINLP`:

- `MaxIterations` - 1000
- `AbsoluteGapTolerance` - 1.0000e-07
- `RelativeGapTolerance` - 1.0000e-05
- `Display` - 'off'
- `NonlinearScalingFactor` - 1000
- `ObjectiveScalingFactor` - 1000

- `CutGeneration` - 'basic'
- `MaxIterationsInactiveCut` - 30
- `NumIterationsEarlyIntegerConvergence` - 30
- `ActiveCutTolerance` - 1.0000e-07
- `TrustRegionStartIteration` - 2
- `ShrinkRatio` - 0.75
- `DeltaLimit` - 1
- `IntMasterSolverOptions` - `optioptions('intlinprog','Algorithm','Dual-Simplex','Display','off')`

Data Types: char | string

### Name-Value Pair Arguments or `optioptions` Object

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `p =`

```
setSolverMINLP(p, 'ExtendedCP', 'MaxIterations', 10000, 'NonlinearScalingFactor', 1000)
```

### **MaxIterations** — Maximum number of iterations

1000 (default) | nonnegative integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIterations' and a nonnegative integer value.

Data Types: double

### **NonlinearScalingFactor** — Scaling factor for nonlinear function and gradient

1000 (default) | nonnegative real

Scaling factor for nonlinear function and gradient, specified as the comma-separated pair consisting of 'NonlinearScalingFactor' and a nonnegative real value.

Data Types: double

### **ObjectiveScalingFactor** — Scales the objective function used by MasterSolver by a factor

1000 (default) | nonnegative real

Scales the objective function used by MasterSolver by a factor, specified as the comma-separated pair consisting of 'ObjectiveScalingFactor' and a nonnegative real value.

Data Types: double

### **AbsoluteGapTolerance** — Solver stops if absolute difference between approximated nonlinear function value and its true value is less than or equal to AbsoluteGapTolerance

0.00000001 (default) | nonnegative real

The solver stops if the absolute difference between the approximated nonlinear function value and its true value is less than or equal to AbsoluteGapTolerance. AbsoluteGapTolerance is specified as the comma-separated pair consisting of 'AbsoluteGapTolerance' and a nonnegative real value.

Data Types: double

**RelativeGapTolerance — Solver stops if the relative difference between approximated nonlinear function value and its true value is less than or equal to RelativeGapTolerance**

0.00001 (default) | nonnegative real

The solver stops if the relative difference between the approximated nonlinear function value and its true value is less than or equal to `RelativeGapTolerance`. `RelativeGapTolerance` is specified as the comma-separated pair consisting of `'AbsoluteGapTolerance'` and a nonnegative real value.

Data Types: double

**Display — Display output format**

'off' (default) | character vector with value of 'iter', 'final', or 'off'

Display output format, specified as the comma-separated pair consisting of `'Display'` and a character vector with a value of:

- 'off' - Display no output
- 'iter' - Display output at each iteration and the technical exit message
- 'final' - Display only the final output and the final technical exit message

Data Types: char

**CutGeneration — Cut specification**

'basic' (default) | character vector with value of 'midway' or 'basic'

Cut specification, specified as the comma-separated pair consisting of `'CutGeneration'` and a character vector with one of these values:

- 'midway' - Add the new cut at the midpoint between the latest and previous solutions found.
- 'basic' - Add the new cut at the latest solution found.

Data Types: char

**MaxIterationsInactiveCut — Removes constraints that are not active for last MaxIterationsInactiveCut iterations**

30 (default) | nonnegative integer

Removes constraints that are not active for the last `MaxIterationsInactiveCut` iterations, specified as the comma-separated pair consisting of `'MaxIterationsInactiveCut'` and a nonnegative integer value. Generally, the `MaxIterationsInactiveCut` value is larger than 10.

Data Types: double

**NumIterationsEarlyIntegerConvergence — When integer variable solution is stable for the last NumIterationsEarlyIntegerConvergence iterations, the solver computes a final NLP by using latest integer variable solution in the MILP**

30 (default) | nonnegative integer

When the integer variable solution is stable for the last `NumIterationsEarlyIntegerConvergence` iterations, the solver computes a final NLP by using the latest integer variable solution in the MILP. `NumIterationsEarlyIntegerConvergence` is specified as the comma-separated pair consisting of `'NumIterationsEarlyIntegerConvergence'` and a nonnegative integer value.

Data Types: double

**ActiveCutTolerance — Determines if the cuts are active**

0.0000001 (default) | nonnegative real

Determines if the cuts are active, specified as the comma-separated pair consisting of 'ActiveCutTolerance' and a nonnegative real value. ActiveCutTolerance is used together with MaxIterationsInactiveCut to decide which cuts to remove from the MILP subproblem.

Data Types: double

**TrustRegionStartIteration — Solver starts to apply trust region heuristic at TrustRegionStartIteration**

2 (default) | nonnegative integer

Solver starts to apply the trust region heuristic at TrustRegionStartIteration, specified as the comma-separated pair consisting of 'TrustRegionStartIteration' and a nonnegative integer.

---

**Note** The TrustRegionStartIteration name-value pair argument can only be used with a solverTypeMINLP of 'TrustRegionCP'.

---

Data Types: double

**ShrinkRatio — Ratio to shrink size of trust region**

0.75 (default) | nonnegative real between 0 and 1

Ratio to shrink size of trust region, specified as the comma-separated pair consisting of 'ShrinkRatio' and a nonnegative real value between 0 and 1. If the approximated functions do not have good agreement in the previous iterations, the algorithm uses this ratio to shrink the trust-region size.

---

**Note** The ShrinkRatio name-value pair argument can only be used with a solverTypeMINLP of 'TrustRegionCP'.

---

Data Types: double

**DeltaLimit — Trust region of the approximated functions is bounded by DeltaLimit during iterations**

1 (default) | nonnegative real

Trust region of the approximated functions is bounded by DeltaLimit during the iterations, specified as the comma-separated pair consisting of 'DeltaLimit' and a nonnegative real value. For portfolio problems, 1 is generally a good value for DeltaLimit, since portfolio weights are between 0 and 1.

---

**Note** The DeltaLimit name-value pair argument can only be used with a solverTypeMINLP of 'TrustRegionCP'.

---

Data Types: double

**IntMasterSolverOptions — Options for master solver**

```
optimoptions('intlinprog', 'Display', 'off',
'ConstraintTolerance', 1e-5, 'MaxTime', 1000, 'IPPreprocess', 'none',
```

```
'CutGeneration', 'advanced', 'Heuristics', 'rins', 'IntegerTolerance', 1e-5,
'NodeSelection', 'mininfeas', 'LPPreprocess', 'none') (default) | optimoptions
object
```

Options for the master solver `intlinprog`, specified as the comma-separated pair consisting of `'IntMasterSolverOptions'` and an `optimoptions` object.

Example: `'IntMasterSolverOptions', optimoptions('intlinprog','Display','off')`

## Output Arguments

### **obj** — Updated portfolio object

object

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object.

## More About

### MINLP Solvers

All three MINLP solvers (`'OuterApproximation'`, `'ExtendedCP'`, and `'TrustRegionCP'`) defined by `solverTypeMINLP` rely on the cutting plane concept.

These MINLP solvers approximate the nonlinear convex function  $f(x)$  by a piecewise linear approximation, which is a sequence of linear cuts around the original function. In this way, the original MINLP is reduced to a sequence of MILP subproblems, each one with a more refined approximation to  $f(x)$  than previous MILPs, and yields a more optimal solution. The process continues until the solution found from MILP converges to the true function value within a certain tolerance.

- The `'ExtendedCP'` solver iteratively adds a linear cut at the latest solution found to approximate  $f(x)$ .
- The `'OuterApproximation'` solver is similar to `'ExtendedCP'`, but they differ in where to add the cut. Instead of using the solution from the latest MILP, `OuterApproximation` uses the values of integer variables from the latest MILP solution and fixes them to reduce the MINLP to a nonlinear programming (NLP) problem. The cut is added at the solution from this NLP problem.
- The `'TrustRegionCP'` solver is a version of `'ExtendedCP'` that is modified to speed up the optimization process. In general, the trust region method uses a model to approximate the true function within a region at each iteration. In the context of the MINLP solver, the model is the maximum of all the added cuts. The true function is the nonlinear function  $f(x)$  in the optimization problem. The region of the model is updated based on how well the model approximates the true function for the iteration. This approximation is the comparison of the predicted reduction of the objective function using the model vs. the true reduction.

## Tips

You can also use dot notation to specify associated name-value pair options.

```
obj = obj.setSolverMINLP(Name,Value);
```

---

**Note** The `solverTypeMINLP` and `solverOptionsMINLP` properties cannot be set using dot notation because they are hidden properties. To set the `solverTypeMINLP` and `solverOptionsMINLP` properties, use the `setSolverMINLP` function directly.

---

## Algorithms

When any one, or any combination of 'Conditional' BoundType, MinNumAssets, or MaxNumAssets constraints is active, the portfolio problem is formulated by adding NumAssets binary variables. The binary variable  $\theta$  indicates that an asset is not invested and the binary variable  $1$  indicates that an asset is invested.

The MinNumAssets and MaxNumAssets constraints narrow down the number of active positions in a portfolio to the range of  $[minN, maxN]$ . In addition, the 'Conditional' BoundType constraint is to set a lower and upper bound so that the position is either  $\theta$  or lies in the range  $[minWgt, maxWgt]$ . These two types of constraints are incorporated into the portfolio optimization model by introducing  $n$  variables,  $v_i$ , which only take binary values  $\theta$  and  $1$  to indicate whether the corresponding asset is invested ( $1$ ) or not invested ( $\theta$ ). Here  $n$  is the total number of assets and the constraints can be formulated as the following linear inequality constraints:

$$\begin{aligned} minN &\leq \sum_{i=1}^n v_i \leq maxN \\ minWgt * v_i &\leq x_i \leq maxWgt * v_i \\ 0 &\leq v \leq 1 \\ v_i &\text{ are integers} \end{aligned}$$

In this equation,  $minN$  and  $maxN$  are representations for MinNumAsset and MaxNumAsset that are set using `setMinMaxNumAssets`. Also,  $minWgt$  and  $maxWgt$  are representations for LowerBound and UpperBound that are set using `setBounds`.

The portfolio optimization problem to minimize the variance of the portfolio, subject to achieving a target expected return and some additional linear constraints on the portfolio weights, is formulated as

$$\begin{aligned} & \text{minimize}_x \quad x^T H x \\ & \text{s.t.} \quad m^T x \geq \text{TargetReturn} \\ & \quad Ax \leq b \\ & \quad A_{eq} x = b_{eq} \\ & \quad lb \leq x \leq ub \end{aligned}$$

In this equation,  $H$  represents the covariance and  $m$  represents the asset returns.

The portfolio optimization problem to maximize the return, subject to an upper limit on the variance of the portfolio return and some additional linear constraints on the portfolio weights, is formulated as

$$\begin{aligned} & \text{maximize}_x \quad m^T x \\ & \text{s.t.} \quad x^T H x \leq \text{TargetRisk} \\ & \quad Ax \leq b \\ & \quad A_{eq} x = b_{eq} \\ & \quad lb \leq x \leq ub \end{aligned}$$

When the 'Conditional' BoundType, MinNumAssets, and MaxNumAssets constraints are added to the two optimization problems, the problems become:

$$\begin{aligned} & \text{minimize}_{x,v} \quad x^T H x \\ & \text{s. t.} \quad m^T x \geq \text{TargetReturn} \\ & \quad A[x; v] \leq b' \\ & \quad A_{eq} x = b_{eq} \\ & \quad \min N \leq \sum_{i=1}^n v_i \leq \max N \\ & \quad \min Wgt(v_i) \leq x_i \leq \max Wgt(v_i) \\ & \quad lb \leq x \leq ub \\ & \quad 0 \leq v \leq 1 \\ & \quad v_i \text{ are integers} \end{aligned}$$

$$\begin{aligned} & \text{maximize}_{x,v} \quad m^T x \\ & \text{s. t.} \quad x^T H x \geq \text{TargetRisk} \\ & \quad A[x; v] \leq b' \\ & \quad A_{eq} x = b_{eq} \\ & \quad \min N \leq \sum_{i=1}^n v_i \leq \max N \\ & \quad \min Wgt * v_i \leq x_i \leq \max Wgt(v_i) \\ & \quad 0 \leq v \leq 1 \\ & \quad v_i \text{ are integers} \end{aligned}$$

## setScenarios

Set asset returns scenarios by direct matrix

---

**Note** setScenarios has been partially removed and will no longer accept a `fints` object for the `GetAssetList` argument. Use `timetable` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
obj = setScenarios(obj,AssetScenarios)
obj = setScenarios(obj,AssetScenarios,Name,Value)
```

### Description

`obj = setScenarios(obj,AssetScenarios)` sets asset returns scenarios by direct matrix for `PortfolioCVaR` or `PortfolioMAD` objects. For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setScenarios(obj,AssetScenarios,Name,Value)` set asset returns scenarios by direct matrix for `PortfolioCVaR` or `PortfolioMAD` objects using additional options specified by one or more `Name,Value` pair arguments.

### Examples

#### Set Asset Returns Scenarios for a PortfolioCVaR Object

Given a `PortfolioCVaR` object `p`, use the `setScenarios` function to set asset return scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
disp(p)
```

```

### Set Asset Returns Scenarios for a PortfolioCvAR Object Using Timetable Data

To illustrate using the `setScenarios` function with `AssetScenarios` data continued in a `timetable` object, use the `CAPMuniverse.mat` which contains a `timetable` object (`AssetsTimeTable`) for returns data.

```

load CAPMuniverse;
AssetsTimeTable.Properties;
head(AssetsTimeTable,5)

```

ans=5x14 timetable

| Time        | AAPL      | AMZN      | CSCO      | DELL      | EBAY      | GOOG | HP   |
|-------------|-----------|-----------|-----------|-----------|-----------|------|------|
| 03-Jan-2000 | 0.088805  | 0.1742    | 0.008775  | -0.002353 | 0.12829   | NaN  | 0.0  |
| 04-Jan-2000 | -0.084331 | -0.08324  | -0.05608  | -0.08353  | -0.093805 | NaN  | -0.0 |
| 05-Jan-2000 | 0.014634  | -0.14877  | -0.003039 | 0.070984  | 0.066875  | NaN  | -0.0 |
| 06-Jan-2000 | -0.086538 | -0.060072 | -0.016619 | -0.038847 | -0.012302 | NaN  | -0.0 |
| 07-Jan-2000 | 0.047368  | 0.061013  | 0.0587    | -0.037708 | -0.000964 | NaN  | 0.0  |

`setScenarios` accepts a name-value pair argument name `'DataFormat'` with a corresponding value set to `'prices'` to indicate that the input to the function is in the form of asset prices and not returns (the default value for the `'DataFormat'` argument is `'returns'`).

```

r = PortfolioCvAR;
r = setScenarios(r,AssetsTimeTable,'dataformat','returns');

```

In addition, the `setScenarios` function also extracts asset names or identifiers from a `timetable` object when the name-value argument `'GetAssetList'` set to `true` (its default value is `false`). If

the 'GetAssetList' value is true, the timetable column identifiers are used to set the AssetList property of the PortfolioCVaR object. To show this, the formation of the PortfolioCVaR object r is repeated with the 'GetAssetList' flag set to true.

```
r = setScenarios(r,AssetsTimeTable,'GetAssetList',true);
disp(r.AssetList')
```

```
{ 'AAPL' }
{ 'AMZN' }
{ 'CSCO' }
{ 'DELL' }
{ 'EBAY' }
{ 'GOOG' }
{ 'HPQ' }
{ 'IBM' }
{ 'INTC' }
{ 'MSFT' }
{ 'ORCL' }
{ 'YHOO' }
{ 'MARKET' }
{ 'CASH' }
```

## Input Arguments

### obj — Object for portfolio

object

Object for portfolio, specified using a PortfolioCVaR or PortfolioMAD object.

For more information on creating a PortfolioCVaR or PortfolioMAD object, see

- PortfolioCVaR
- PortfolioMAD

Data Types: object

### AssetScenarios — Scenarios for asset returns or prices

matrix | table | timetable

Scenarios for asset returns or prices, specified as a matrix, table, or timetable that contains asset data that can be converted into asset returns ([NumSamples-by-NumAssets] matrix).

AssetReturns data can be:

- NumSamples-by-NumAssets matrix.
- Table of NumSamples prices or returns at a given periodicity for a collection of NumAssets assets
- Timetable object with NumSamples observations and NumAssets time series

If the input data are prices, they can be converted into returns with the DataFormat name-value pair argument, where the default format is assumed to be 'Returns'. Be careful using price data because portfolio optimization usually requires total returns and not simply price returns.

This function sets up a function handle to indirectly access input AssetScenarios without needing to make a copy of the data.

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `p = setScenarios(p, AssetScenarios, 'DataFormat', 'Returns', 'GetAssetList', false);`

#### DataFormat — Flag to convert input data as prices into returns

'Returns' (default) | character vector with values 'Returns' or 'Prices'

Flag to convert input data as prices into returns, specified as the comma-separated pair consisting of 'DataFormat' and a character vector with the values:

- 'Returns' — Data in `AssetReturns` contains asset total returns.
- 'Prices' — Data in `AssetReturns` contains asset total return prices.

Data Types: char

#### GetAssetList — Flag indicating which asset names to use for the asset list

false (default) | logical with value true or false

Flag indicating which asset names to use for the asset list, specified as the comma-separated pair consisting of 'GetAssetList' and a logical with a value of true or false. Acceptable values for `GetAssetList` are:

- false — Do not extract or create asset names.
- true — Extract or create asset names from table or timetable.

If a table or timetable is passed into this function as `AssetScenarios` and the `GetAssetList` flag is true, the column names from the table or timetable are used as asset names in `obj.AssetList`.

If a matrix is passed and the `GetAssetList` flag is true, default asset names are created based on the `AbstractPortfolio` property `defaultforAssetList`, which is currently 'Asset'.

If the `GetAssetList` flag is false, no action occurs, which is the default behavior.

Data Types: logical

## Output Arguments

### obj — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `PortfolioCVaR` or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `PortfolioCVaR`
- `PortfolioMAD`

**Tips**

You can also use dot notation to set asset return scenarios.

```
obj = obj.setScenarios(AssetScenarios);
```

# setTrackingError

Set up maximum portfolio tracking error constraint

## Syntax

```
obj = setTrackingError(obj,TrackingError)
obj = setTrackingError( ____,TrackingPort,NumAssets)
```

## Description

`obj = setTrackingError(obj,TrackingError)` sets up a maximum portfolio tracking error constraint for a `Portfolio` object. For details on the workflow when using a `Portfolio` object, see “Portfolio Object Workflow” on page 4-16.

`obj = setTrackingError( ____,TrackingPort,NumAssets)` sets up a maximum portfolio tracking error constraint using optional arguments for `TrackingPort` and `NumAssets`.

## Examples

### Set up a Tracking Error Constraint

Create a `Portfolio` object.

```
AssetMean = [ 0.05; 0.1; 0.12; 0.18 ];
AssetCovar = [ 0.0064 0.00408 0.00192 0;
               0.00408 0.0289 0.0204 0.0119;
               0.00192 0.0204 0.0576 0.0336;
               0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio('mean', AssetMean, 'covar', AssetCovar, 'lb', 0, 'budget', 1)
```

```
p =
Portfolio with properties:
```

```
    BuyCost: []
    SellCost: []
    RiskFreeRate: []
    AssetMean: [4x1 double]
    AssetCovar: [4x4 double]
    TrackingError: []
    TrackingPort: []
    Turnover: []

```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using a `Portfolio` object. For more information on creating a portfolio object, see `Portfolio`.

Data Types: object

### **TrackingError** — Upper bound for portfolio tracking error

nonnegative and finite scalar

Upper bound for portfolio tracking error, specified using a nonnegative and finite scalar.

Given an upper bound for portfolio tracking error in `TrackingError` and a tracking portfolio in `TrackingPort`, the tracking error constraint requires any portfolio in `Port` to satisfy

$$(\text{Port} - \text{TrackingPort})' * \text{AssetCovar} * (\text{Port} - \text{TrackingPort}) \leq \text{TrackingError}^2 .$$

For more information, see “Tracking Error Constraints” on page 4-13.

Data Types: double

### **TrackingPort — Tracking portfolio weights**

finite vector

Tracking portfolio weights, specified using a vector. `TrackingPort` must be a finite vector with `NumAssets > 0` elements.

If no `TrackingPort` is specified, it is assumed to be  $\mathbf{0}$ . If `TrackingPort` is specified as a scalar and `NumAssets` exists, then `TrackingPort` undergoes scalar expansion.

Data Types: double

### **NumAssets — Number of assets in portfolio**

scalar

Number of assets in portfolio, specified using a scalar. If it is not possible to obtain a value for `NumAssets`, it is assumed that `NumAssets` is 1.

Data Types: double

## **Output Arguments**

### **obj — Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a `Portfolio` object. For more information on creating a portfolio object, see `Portfolio`.

---

**Note** The tracking error constraints can be used with any of the other supported constraints in the `Portfolio` object without restrictions. However, since the portfolio set necessarily and sufficiently must be a non-empty compact set, the application of a tracking error constraint can result in an empty portfolio set. Use `estimateBounds` to confirm that the portfolio set is non-empty and compact.

---

## **Tips**

You can also use dot notation to set up a maximum portfolio tracking error constraint.

```
obj = obj.setTrackingError(TrackingError, NumAssets);
```

To remove a tracking portfolio, call this function with an empty argument (`[]`) for `TrackingError`.

```
obj = setTrackingError(obj, [ ]);
```

# setTrackingPort

Set up benchmark portfolio for tracking error constraint

## Syntax

```
obj = setTrackingPort(obj,TrackingPort)
obj = setTrackingPort( ____,NumAssets)
```

## Description

`obj = setTrackingPort(obj,TrackingPort)` sets up a benchmark portfolio for a tracking error constraint for a `Portfolio` object. For details on the workflow when using a `Portfolio` object, see “Portfolio Object Workflow” on page 4-16.

`obj = setTrackingPort( ____,NumAssets)` sets up a benchmark portfolio for a tracking error constraint using an optional input argument for `NumAssets`.

## Examples

### Set up a Tracking Port

Create a `Portfolio` object.

```
AssetMean = [ 0.05; 0.1; 0.12; 0.18 ];
AssetCovar = [ 0.0064 0.00408 0.00192 0;
               0.00408 0.0289 0.0204 0.0119;
               0.00192 0.0204 0.0576 0.0336;
               0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio('mean', AssetMean, 'covar', AssetCovar, 'lb', 0, 'budget', 1)

### Introduced in R2015b

## setTurnover

Set up maximum portfolio turnover constraint

### Syntax

```
obj = setTurnover(obj,Turnover)
obj = setTurnover(obj,Turnover,InitPort,NumAssets)
```

### Description

`obj = setTurnover(obj,Turnover)` sets up maximum portfolio turnover constraint for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-16, “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = setTurnover(obj,Turnover,InitPort,NumAssets)` sets up maximum portfolio turnover constraint for portfolio objects with additional options specified for `Turnover`, `InitPort`, and `NumAssets`.

Given an upper bound for portfolio turnover in `Turnover` and an initial portfolio in `InitPort`, the turnover constraint requires any portfolio in `Port` to satisfy the following:

$$| \text{Port} - \text{InitPort} | \leq \text{Turnover}$$

### Examples

#### Set Turnover Constraint for a Portfolio Object

Given a `Portfolio` object `p`, to ensure that average turnover is no more than 30% with an initial portfolio of 10 assets in a variable `x0`, use the `setTurnover` method to set the turnover constraint.

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = Portfolio('InitPort', x0);
p = setTurnover(p, 0.3);
```

```
disp(p.NumAssets);
```

```
10
```

```
disp(p.Turnover);
```

```
0.3000
```

```
disp(p.InitPort);
```

```

```

0.1500
0.1100
0.0800
0.1000

```

### Set Turnover Constraint for a CVaR Portfolio Object

Given a CVaR portfolio object `p`, to ensure that average turnover is no more than 30% with an initial portfolio of 10 assets in a variable `x0`, use the `setTurnover` method to set the turnover constraint.

```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioCVaR('InitPort', x0);
p = setTurnover(p, 0.3);

```

```

disp(p.NumAssets);

```

```

10

```

```

disp(p.Turnover);

```

```

0.3000

```

```

disp(p.InitPort);

```

```

0.1200
0.0900
0.0800
0.0700
0.1000
0.1000
0.1500
0.1100
0.0800
0.1000

```

### Set Turnover Constraint for a MAD Portfolio Object

Given PortfolioMAD object `p`, to ensure that average turnover is no more than 30% with an initial portfolio of 10 assets in a variable `x0`, use the `setTurnover` method to set the turnover constraint.

```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioMAD('InitPort', x0);
p = setTurnover(p, 0.3);

```

```

disp(p.NumAssets);

```

```

10

```

```

disp(p.Turnover);

```

```

0.3000

```

```

disp(p.InitPort);

```

```
0.1200  
0.0900  
0.0800  
0.0700  
0.1000  
0.1000  
0.1500  
0.1100  
0.0800  
0.1000
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **Turnover** — Portfolio turnover constraint

nonnegative and finite scalar

Portfolio turnover constraint, specified as a nonnegative and finite scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **InitPort** — Initial or current portfolio weights

0 (default) | finite vector with `NumAssets > 0` elements.

Initial or current portfolio weights, specified as a finite vector with `NumAssets > 0` elements for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** If no `InitPort` is specified, that value is assumed to be 0.

If `InitPort` is specified as a scalar and `NumAssets` exists, then `InitPort` undergoes scalar expansion.

---

Data Types: double

### **NumAssets** — Number of assets in portfolio

1 (default) | scalar

Number of assets in portfolio, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** If it is not possible to obtain a value for `NumAssets`, it is assumed that `NumAssets` is 1.

---

Data Types: double

## Output Arguments

### **obj** — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## Tips

You can also use dot notation to set up the maximum portfolio turnover constraint.

```
obj = obj.setTurnover(Turnover, InitPort, NumAssets);
```

## Introduced in R2011a

## simulateNormalScenariosByData

Simulate multivariate normal asset return scenarios from data

---

**Note** `simulateNormalScenariosByData` has been partially removed and will no longer accept a `fints` object for the `AssetReturns` argument. Use `timetable` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
obj = simulateNormalScenariosByData(obj,AssetReturns)
```

```
obj = simulateNormalScenariosByData(obj,AssetReturns,NumScenarios,Name,Value)
```

### Description

`obj = simulateNormalScenariosByData(obj,AssetReturns)` simulates multivariate normal asset return scenarios from data for portfolio object for `PortfolioCVaR` or `PortfolioMAD` objects. For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = simulateNormalScenariosByData(obj,AssetReturns,NumScenarios,Name,Value)` simulates multivariate normal asset return scenarios from data for portfolio object for `PortfolioCVaR` or `PortfolioMAD` objects using additional options specified by one or more `Name,Value` pair arguments.

This function estimates the mean and covariance of asset returns from either price or return data and then uses these estimates to generate the specified number of scenarios with the function `mvnrnd`.

Data can be in a `NumSamples-by-NumAssets` matrix of `NumSamples` prices or returns at a given periodicity for a collection of `NumAssets` assets, a `table` or a `timetable`.

---

**Note** If you want to use the method multiple times and you want to simulate identical scenarios each time the function is called, precede each function call with `rng(seed)` using a specified integer seed.

---

### Examples

#### Simulate Multivariate Normal Asset Return Scenarios from Data for a PortfolioCVaR Object

Given a `PortfolioCVaR` object `p`, use the `simulateNormalScenariosByData` function to simulate multivariate normal asset return scenarios from data.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
```

```

m = m/12;
C = C/12;

RawData = mvnrnd(m, C, 240);
NumScenarios = 2000;

p = PortfolioCVaR;
p = simulateNormalScenariosByData(p, RawData, NumScenarios)

p =

```

### Estimate Mean and Covariance of Asset Returns from Market Data for a PortfolioCVaR Object

Create a PortfolioCVaR object `p` and use the `simulateNormalScenariosByData` function with market data loaded from `CAPMuniverse.mat` to simulate multivariate normal asset return scenarios. The market data, `AssetsTimeTable`, is a timetable of asset returns.

```
load CAPMuniverse
```

```
p = PortfolioCVaR('AssetList',Assets);
disp(p);
```

PortfolioCVaR with properties:

```

        BuyCost: []
        SellCost: []
        RiskFreeRate: []
        ProbabilityLevel: []
        Turnover: []
        BuyTurnover: []
        SellTurnover: []
        NumScenarios: []
        Name: []
        NumAssets: 14
        AssetList: {1x14 cell}
        InitPort: []
        AInequality: []
        bInequality: []
        AEquality: []
        bEquality: []
        LowerBound: []
        UpperBound: []

```

```

LowerBudget: []
UpperBudget: []
GroupMatrix: []
LowerGroup: []
UpperGroup: []
    GroupA: []
    GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
BoundType: []

```

Simulate the scenarios from the timetable data for each of the assets from `CAPMuniverse.mat` and plot the efficient frontier.

```

p = simulateNormalScenariosByData(p,AssetsTimeTable,10000,'missingdata',true);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.9);
plotFrontier(p);

```

### Estimate Mean and Covariance of Asset Returns from Data for a PortfolioMAD Object

Given a PortfolioMAD object `p`, use the `simulateNormalScenariosByData` function to simulate multivariate normal asset return scenarios from data.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

RawData = mvnrnd(m, C, 240);
NumScenarios = 2000;

p = PortfolioMAD;
p = simulateNormalScenariosByData(p, RawData, NumScenarios);
p = setDefaultConstraints(p);

disp(p);

```

PortfolioMAD with properties:

```

    MaxNumAssets: []
    BoundType: [4x1 categorical]

```

### Estimate Mean and Covariance of Asset Returns from Market Data for a PortfolioMAD Object

Create a PortfolioMAD object `p` and use the `simulateNormalScenariosByData` function with market data loaded from `CAPMuniverse.mat` to simulate multivariate normal asset return scenarios. The market data, `AssetsTimeTable`, is a timetable of asset returns.

```

load CAPMuniverse

p = PortfolioMAD('AssetList',Assets);
disp(p.AssetList');

    {'AAPL' }
    {'AMZN' }
    {'CSCO' }
    {'DELL' }
    {'EBAY' }
    {'GOOG' }
    {'HPQ'  }
    {'IBM'  }
    {'INTC' }
    {'MSFT' }
    {'ORCL' }
    {'YHOO' }
    {'MARKET'}
    {'CASH' }

```

Simulate the scenarios from the timetable data for each of the assets from CAPMuniverse.mat and plot the efficient frontier.

```

p = simulateNormalScenariosByData(p,AssetsTimeTable,10000,'missingdata',true);
p = setDefaultConstraints(p);
plotFrontier(p);

```

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using a `PortfolioCVaR` or `PortfolioMAD` object.

For more information on creating a `PortfolioCVaR` or `PortfolioMAD` object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **AssetReturns — Asset data that can be converted into asset returns**

matrix | table | timetable

Asset data that can be converted into asset returns (`[NumSamples-by-NumAssets]` matrix), specified as a matrix, table, or timetable.

AssetReturns data can be:

- `NumSamples-by-NumAssets` matrix.
- Table of `NumSamples` prices or returns at a given periodicity for a collection of `NumAssets` assets
- Timetable object with `NumSamples` observations and `NumAssets` time series

Data Types: double | table | timetable

### **NumScenarios — Number of scenarios to simulate**

positive integer

Number of scenarios to simulate, specified as a positive integer.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `p =`

```
simulateNormalScenariosByData(p,RawData,NumScenarios,'DataFormat','Returns','MissingData',true,'GetAssetList',true)
```

### **DataFormat — Flag to convert input data as prices into returns**

'Returns' (default) | character vector with values 'Returns' or 'Prices'

Flag to convert input data as prices into returns, specified as the comma-separated pair consisting of `'DataFormat'` and a character vector with the values:

- `'Returns'` — Data in `AssetReturns` contains asset total returns.
- `'Prices'` — Data in `AssetReturns` contains asset total return prices.

Data Types: char

**MissingData — Flag to use ECM algorithm to handle NaN values**

false (default) | logical with values true or false

Flag to use ECM algorithm to handle NaN values, specified as the comma-separated pair consisting of 'MissingData' and a logical with a value of true or false.

- false — Do not use ECM algorithm to handle NaN values (exclude NaN values).
- true — Use ECM algorithm to handle NaN values.

Data Types: logical

**GetAssetList — Flag indicating which asset names to use for the asset list**

false (default) | logical with values true or false

Flag indicating which asset names to use for the asset list, specified as the comma-separated pair consisting of 'GetAssetList' and a logical with a value of true or false.

- false — Do not extract or create asset names.
- true — Extract or create asset names from the table or timetable.

If a table or timetable is passed into this function using the AssetReturns argument and the GetAssetList flag is true, the column names from the table or timetable are used as asset names in obj.AssetList.

If a matrix is passed and the GetAssetList flag is true, default asset names are created based on the AbstractPortfolio property defaultforAssetList, which is 'Asset'.

If the GetAssetList flag is false, no action occurs, which is the default behavior.

Data Types: logical

**Output Arguments****obj — Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a PortfolioCVaR or PortfolioMAD object. For more information on creating a portfolio object, see

- PortfolioCVaR
- PortfolioMAD

**Tips**

You can also use dot notation to simulate multivariate normal asset return scenarios from data for a PortfolioCVaR or PortfolioMAD object.

```
obj = obj.simulateNormalScenariosByData(AssetReturns, NumScenarios, Name, Value);
```

# simulateNormalScenariosByMoments

Simulate multivariate normal asset return scenarios from mean and covariance of asset returns

## Syntax

```
obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovar,NumScenarios)
obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovarNumScenarios,
NumAssets)
```

## Description

`obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovar,NumScenarios)` simulates multivariate normal asset return scenarios from mean and covariance of asset returns for `PortfolioCVaR` or `PortfolioMAD` objects. For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-14, and “PortfolioMAD Object Workflow” on page 6-14.

`obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovarNumScenarios, NumAssets)` simulates multivariate normal asset return scenarios from mean and covariance of asset returns for `PortfolioCVaR` or `PortfolioMAD` objects using the optional input `NumScenarios`.

---

**Note** This function overwrites existing scenarios associated with `PortfolioCVaR` or `PortfolioMAD` objects, and also, possibly, `NumScenarios`.

If you want to use the function multiple times and you want to simulate identical scenarios each time the function is called, precede each function call with `rng(seed)` using a specified integer seed.

---

## Examples

### Simulate Multivariate Normal Asset Return Scenarios from Moments for a PortfolioCVaR Object

Given `PortfolioCVaR` object `p`, use the `simulateNormalScenariosByMoments` function to simulate multivariate normal asset return scenarios from moments.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
```

```
AssetMean = [.5]
AssetMean = 0.5000
AssetCovar = [.5]
AssetCovar = 0.5000
NumScenarios = 100
NumScenarios = 100

p = simulateNormalScenariosByMoments(p, AssetMean, AssetCovar, NumScenarios)

p =
  PortfolioCVaR with properties:

### **Simulate Multivariate Normal Asset Return Scenarios from Moments for a PortfolioMAD Object**

Given PortfolioMAD object `p`, use the `simulateNormalScenariosByMoments` function to simulate multivariate normal asset return scenarios from moments.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

AssetMean = [.5]
AssetMean = 0.5000

AssetCovar = [.5]
AssetCovar = 0.5000

NumScenarios = 100
NumScenarios = 100

p = simulateNormalScenariosByMoments(p, AssetMean, AssetCovar, NumScenarios)

p =
PortfolioMAD with properties:
    BuyCost: []
    SellCost: []
    RiskFreeRate: []
    Turnover: []
    BuyTurnover: []
    SellTurnover: []
    NumScenarios: 100
    Name: []
    NumAssets: 4
    AssetList: []

```

```
MaxNumAssets: []  
BoundType: [4x1 categorical]
```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using a `PortfolioCVaR` or `PortfolioMAD` object.

For more information on creating a `PortfolioCVaR` or `PortfolioMAD` object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **AssetMean** — Mean of asset returns

vector

Mean of asset returns, specified as a vector.

---

**Note** If `AssetMean` is a scalar and the number of assets is known, scalar expansion occurs. If the number of assets cannot be determined, this function assumes that `NumAssets = 1`.

---

Data Types: double

### **AssetCovar** — Covariance of asset returns

symmetric positive semidefinite matrix

Covariance of asset returns, specified as a symmetric positive semidefinite matrix.

---

### **Note**

- If `AssetCovar` is a scalar and the number of assets is known, a diagonal matrix is formed with the scalar value along the diagonals. If it is not possible to determine the number of assets, this method assumes that `NumAssets = 1`.
  - If `AssetCovar` is a vector, a diagonal matrix is formed with the vector along the diagonal.
  - If `AssetCovar` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.
- 

Data Types: double

### **NumScenarios** — Number of scenarios to simulate

positive integer

Number of scenarios to simulate, specified as a positive integer.

Data Types: double

**NumAssets — Number of assets**

scalar

Number of assets, specified as a scalar.

Data Types: double

**Output Arguments****obj — Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a `PortfolioCVaR` or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `PortfolioCVaR`
- `PortfolioMAD`

**Tips**

You can also use dot notation to simulate multivariate normal asset return scenarios from a mean and covariance of asset returns for a `PortfolioCVaR` or `PortfolioMAD` object.

```
obj = obj.simulateNormalScenariosByMoments(AssetMean, AssetCovar, NumScenarios, NumAssets);
```

## setfield

Set content of specific field

---

**Note** `setfield` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = setfield(tsobj,field,V)
```

```
newfts = setfield(tsobj,field,{dates},V)
```

### Description

`setfield` treats the contents of fields in a time series object (`tsobj`) as fields in a structure.

`newfts = setfield(tsobj,field,V)` sets the contents of the specified field to the value `V`. This is equivalent to the syntax `S.field = V`.

`newfts = setfield(tsobj,field,{dates},V)` sets the contents of the specified field for the specified dates. `dates` can be individual cells of date character vectors or a cell of a date character vector's range using the `::` operator, for example, `'03/01/99::03/31/99'`. Dates can contain time-of-day information.

### Examples

**Example 1.** Set the closing value for all days to 3890.

```
load dji30short
format bank
myfts1 = setfield(myfts1, 'Close', 3890)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/setfield (line 84)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
myfts1 =
    desc: DJI30MAR94.dat
    freq: Daily (1)

    'dates: (20)'    'Open: (20)'    'High: (20)'    'Low: (20)'    'Close: (20)'
    '04-Mar-1994'   [ 3830.90]     [ 3868.04]     [ 3800.50]     [ 3890.00]
    '07-Mar-1994'   [ 3851.72]     [ 3882.40]     [ 3824.71]     [ 3890.00]

    '16-Mar-1994'   [ 3851.03]     [ 3879.53]     [ 3819.94]     [ 3890.00]
    '17-Mar-1994'   [ 3853.62]     [ 3891.34]     [ 3821.66]     [ 3890.00]
    '18-Mar-1994'   [ 3865.42]     [ 3911.78]     [ 3838.65]     [ 3890.00]
    '21-Mar-1994'   [ 3878.38]     [ 3898.25]     [ 3838.65]     [ 3890.00]
    '22-Mar-1994'   [ 3865.71]     [ 3896.23]     [ 3840.66]     [ 3890.00]
    '23-Mar-1994'   [ 3868.88]     [ 3901.41]     [ 3839.80]     [ 3890.00]
    '24-Mar-1994'   [ 3849.88]     [ 3865.42]     [ 3792.58]     [ 3890.00]
```

```
'25-Mar-1994' [ 3827.13] [ 3826.85] [ 3774.73] [ 3890.00]
'28-Mar-1994' [ 3776.46] [ 3793.45] [ 3719.74] [ 3890.00]
'29-Mar-1994' [ 3757.17] [ 3771.86] [ 3689.23] [ 3890.00]
'30-Mar-1994' [ 3688.36] [ 3718.88] [ 3612.36] [ 3890.00]
'31-Mar-1994' [ 3639.71] [ 3673.10] [ 3544.12] [ 3890.00]
```

**Example 2.** Set values for specific times on specific days.

First create a financial time series containing time-of-day data.

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
                       times]);
myfts = fints(dates_times, [(1:4)'; nan; 6], {'Data1'}, 1, ...
             'My FINTS')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/display (line 66)

myfts =

```
desc: My FINTS
freq: Daily (1)
```

```
'dates: (6)'      'times: (6)'      'Data1: (6)'
'01-Jan-2001'    '11:00'          [          1]
'    "    '    '12:00'          [          2]
'02-Jan-2001'    '11:00'          [          3]
'    "    '    '12:00'          [          4]
'03-Jan-2001'    '11:00'          [         NaN]
'    "    '    '12:00'          [          6]
```

Now use `setfield` to replace the data in `myfts` with new data starting at 12:00 on January 1, 2001 and ending at 11:00 on January 3, 2001.

```
S = setfield(myfts, 'Data1', ...
             {'01-Jan-2001 12:00:03-Jan-2001 11:00'}, (102:105)')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/setfield (line 84)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/display (line 66)

S =

```
desc: My FINTS
freq: Daily (1)
```

```
'dates: (6)'      'times: (6)'      'Data1: (6)'
'01-Jan-2001'    '11:00'          [          1.00]
'    "    '    '12:00'          [         102.00]
'02-Jan-2001'    '11:00'          [         103.00]
'    "    '    '12:00'          [         104.00]
'03-Jan-2001'    '11:00'          [         105.00]
'    "    '    '12:00'          [           6.00]
```

# sharpe

Compute Sharpe ratio for one or more assets

## Syntax

```
sharpe(Asset)
```

```
sharpe(Asset,Cash)
```

```
Ratio = sharpe(Asset,Cash)
```

## Arguments

|       |                                                                                                                                                                                                                                                                                                                                                          |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Asset | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES observations of asset returns for NUMSERIES asset return series.                                                                                                                                                                                                                                          |
| Cash  | (Optional) Either a scalar return for a riskless asset or a vector of asset returns to be a proxy for a riskless asset. In either case, the return periodicity must be the same as the periodicity of Asset. For example, if Asset is monthly data, then Cash must be monthly returns. If no value is supplied, the default value for Cash returns is 0. |

## Description

Given NUMSERIES assets with NUMSAMPLES returns for each asset in a NUMSAMPLES-by-NUMSERIES matrix Asset and given either a scalar Cash asset return or a vector of Cash asset returns, the Sharpe ratio is computed for each asset.

The output is Ratio, a 1-by-NUMSERIES row vector of Sharpe ratios for each series in Asset. Any series in Asset with standard deviation of returns equal to 0 has a NaN value for its Sharpe ratio.

---

**Note** If Cash is a vector, Asset and Cash need not have the same number of returns but must have the same periodicity of returns. The classic Sharpe ratio assumes that Cash is riskless. In reality, a short-term cash rate is not necessarily riskless. NaN values in the data are ignored.

---

## Examples

See “Sharpe Ratio” on page 7-5.

## size

Number of dates and data series

---

**Note** `size` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
szfts = size(tsoobj,dim)
```

```
[numRows,numCols] = size(tsoobj)
```

### Arguments

|                     |                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsoobj</code> | Financial time series object.                                                                                                                                                                |
| <code>dim</code>    | (Optional) A scalar that specifies the following dimension:<br><br><code>dim = 1</code> returns number of dates (rows).<br><br><code>dim = 2</code> returns number of data series (columns). |

### Description

`szfts = size(tsoobj)` returns the number of dates (rows) and the number of data series (columns) in the financial time series object `tsoobj`. The result is returned in the vector `szfts`, whose first element is the number of dates and second is the number of data series.

`szfts = size(tsoobj,dim)` specifies the dimension you want to extract.

`numRows` returns a scalar representing the number of dates (rows).

`numCols` returns a scalar representing the number of data series (columns).

### See Also

`length` | `size`

## smoothts

Smooth data

---

**Note** `smoothts` is not recommended. Use `smoothdata` instead.

---

### Syntax

```
output = smoothts(input)
```

```
output = smoothts(input, 'b', wsize)
```

```
output = smoothts(input, 'g', wsize, stdev)
```

```
output = smoothts(input, 'e', n)
```

### Arguments

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>input</code>            | Financial time series object or a row-oriented matrix. In a row-oriented matrix, each row represents an individual set of observations.                                                                                                                                                                                                                                                                                                                                 |
| <code>'b', 'g', or 'e'</code> | Smoothing method (essentially the type of filter used). Can be Exponential (e), Gaussian (g), or Box (b). Default = b.                                                                                                                                                                                                                                                                                                                                                  |
| <code>wsize</code>            | Window size (scalar). Default = 5.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>stdev</code>            | Scalar that represents the standard deviation of the Gaussian window. Default = 0.65.                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>n</code>                | For Exponential method, specifies window size or exponential factor, depending upon value. <ul style="list-style-type: none"> <li>• <math>n &gt; 1</math> (window size) or period length</li> <li>• <math>n &lt; 1</math> and <math>&gt; 0</math> (exponential factor: alpha)</li> <li>• <math>n = 1</math> (either window size or alpha)</li> </ul> <p>If <code>n</code> is not supplied, the defaults are <code>wsize = 5</code> and <code>alpha = 0.3333</code>.</p> |

### Description

`smoothts` smooths the input data using the specified method.

`output = smoothts(input)` smooths the input data using the default Box method with window size, `wsize`, of 5.

`output = smoothts(input, 'b', wsize)` smooths the input data using the Box (simple, linear) method. `wsize` specifies the width of the box to be used.

`output = smoothts(input, 'g', wsize, stdev)` smooths the input data using the Gaussian window method.

`output = smoothts(input, 'e', n)` smooths the input data using the Exponential method. `n` can represent the window size (period length) or alpha. If  $n > 1$ , `n` represents the window size. If  $0 < n < 1$ , `n` represents alpha, where

$$\alpha = \frac{2}{wsize + 1}.$$

If `input` is a financial time series object, `output` is a financial time series object identical to `input` except for contents. If `input` is a row-oriented matrix, `output` is a row-oriented matrix of the same length.

## sortfts

Sort financial time series

---

**Note** `sortfts` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
sfts = sortfts(tsoobj)
sfts = sortfts(tsoobj, flag)
sfts = sortfts(tsoobj, seriesnames, flag)
[sfts, sidx] = sortfts(...)
```

### Arguments

|                          |                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsoobj</code>      | Financial time series object.                                                                                                        |
| <code>flag</code>        | (Optional) Sort order:<br><br><code>flag = 1</code> ; increasing order (default)<br><br><code>flag = -1</code> ; decreasing order    |
| <code>seriesnames</code> | (Optional) Character vector containing a data series name or cell array of character vectors containing a list of data series names. |

### Description

`sfts = sortfts(tsoobj)` sorts the financial time series object `tsoobj` in increasing order based only upon the `'dates'` vector if `tsoobj` does not contain time-of-day information. If the object includes time-of-day information, the sort is based upon a combination of the `'dates'` and `'times'` vectors. The `'times'` vector cannot be sorted individually.

`sfts = sortfts(tsoobj, flag)` sets the order of the sort. `flag = 1`: increasing date and time order. `flag = -1`: decreasing date and time order.

`sfts = sortfts(tsoobj, seriesnames, flag)` sorts the financial time series object `tsoobj` based upon the data series name(s) `seriesnames`. The `seriesnames` argument can be a single character vector containing a data series name or a cell array of character vectors containing a list of data series names. If the optional `flag` is set to `-1`, the sort is in decreasing order.

`[sfts, sidx] = sortfts(...)` also returns the index of the original object `tsoobj` sorted based on `'dates'` or specified data series name(s).

## spctkd

Slow stochastics

---

**Note** `spctkd` is not recommended. Use `stochosc` instead.

---

### Syntax

```
[spctk,spctd] = spctkd(fastpctk,fastpctd)
[spctk,spctd] = spctkd([fastpctk fastpctd])
[spctk,spctd] = spctkd(fastpctk,fastpctd,dperiods,dmmethod)
[spctk,spctd] = spctkd([fastpctk fastpctd], dperiods, dmmethod)
skdts = spctkd(tsobj)
skdts = spctkd(tsobj,dperiods,dmmethod)
skdts = spctkd(tsobj,dperiods,dmmethod,'ParameterName',ParameterValue, ...)
```

### Arguments

|                       |                                                                   |
|-----------------------|-------------------------------------------------------------------|
| <code>fastpctk</code> | Fast stochastic F%K (vector).                                     |
| <code>fastpctd</code> | Fast stochastic F%D (vector).                                     |
| <code>dperiods</code> | (Optional) %D periods. Default = 3.                               |
| <code>dmmethod</code> | (Optional) %D moving average method. Default = 'e' (exponential). |
| <code>tsobj</code>    | Financial time series object.                                     |

### Description

`[spctk,spctd] = spctkd(fastpctk,fastpctd)` calculates the slow stochastics S%K and S%D. `spctk` and `spctd` are column vectors representing the respective slow stochastics. The inputs must be single column-oriented vectors containing the fast stochastics F%K and F%D.

`[spctk,spctd] = spctkd([fastpctk fastpctd])` accepts a two-column matrix as input. The first column contains the fast stochastic F%K values, and the second contains the fast stochastic F%D values.

`[spctk,spctd] = spctkd(fastpctk,fastpctd,dperiods,dmmethod)` calculates the slow stochastics, S%K and S%D, using the value of `dperiods` to set the number of periods and `dmmethod` to indicate the moving average method. The inputs `fastpctk` and `fastpctd` must contain the fast stochastics, F%K and F%D, in column orientation. `spctk` and `spctd` are column vectors representing the respective slow stochastics.

Valid moving average methods for %D are exponential ('e'), triangular ('t'), and modified ('m'). See `tsmovav` for explanations of these methods.

`[spctk,spctd] = spctkd([fastpctk fastpctd],dperiods,dmmethod)` accepts a two-column matrix rather than two separate vectors. The first column contains the F%K values, and the second contains the F%D values.

`skdts = spctkd(tsoj)` calculates the slow stochastics, S%K and S%D. `tsoj` must contain the fast stochastics, F%K and F%D, in data series named `PercentK` and `PercentD`. The `skdts` output is a financial time series object with the same dates as `tsoj`. Within `tsoj` the two series `SlowPctK` and `SlowPctD` represent the respective slow stochastics.

`skdts = spctkd(tsoj,dperiods,dmmethod)` lets you specify the length and the method of the moving average used to calculate S%D values.

`skdts = spctkd(tsoj,dperiods,dmmethod,'ParameterName',ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- `KName`: F%K series name
- `DName`: F%D series name

Parameter values are the character vectors that represent the valid parameter names.

## Examples

### Calculate the Slow Stochastics

This example shows how to calculate the slow stochastics for Disney stock and plot the results.

```
load disney.mat
dis_FastStoch = fpctkd(dis);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
dis_SlowStoch = spctkd(dis_FastStoch);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
plot(dis_SlowStoch)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
title('Slow Stochastics for Disney')
```

## std

Standard deviation

---

**Note** `std` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
tsstd = std(tsobj)
```

```
tsstd = std(tsobj,flag)
```

### Arguments

|                    |                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsobj</code> | Financial time series object.                                                                                                                                                      |
| <code>flag</code>  | (Optional) Normalization factor:<br><br><code>flag = 1</code> normalizes by <code>n</code> (number of observations).<br><br><code>flag = 0</code> normalizes by <code>n-1</code> . |

### Description

`tsstd = std(tsobj)` computes the standard deviation of each data series in the financial time series object `tsobj` and returns the results in `tsstd`. The `tsstd` output is a structure with field `name(s)` identical to the data series `name(s)`.

`tsstd = std(tsobj,flag)` normalizes the data as indicated by `flag`.

## stochosc

Stochastic oscillator

---

**Note** `stochosc` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
percentKnD = stochosc(Data)
percentKnD = stochosc( ___, Name, Value)
```

### Description

`percentKnD = stochosc(Data)` calculates the stochastic oscillator.

`percentKnD = stochosc( ___, Name, Value)` adds optional name-value pair arguments.

### Input Arguments

#### Data — Data with high, low, open, close information

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, `Data` is an M-by-3 matrix of high, low, and closing prices stored in the corresponding columns, respectively. Timetables and tables with M rows must contain variables named 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

#### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `percentKnD = stochosc(TMW, 'NumPeriodsD', 10, 'NumPeriodsK', 3, 'Type', 'exponential')`

#### NumPeriodsK — Period difference for PercentK

10 (default) | positive integer

Period difference for `PercentK`, specified as the comma-separated pair consisting of 'NumPeriodsK' and a scalar positive integer.

Data Types: double

#### NumPeriodsD — Length of moving average in periods for PercentD

3 (default) | positive integer

Length of moving average in periods for PercentD, specified as the comma-separated pair consisting of 'NumPeriodsD' and a scalar positive integer.

Data Types: double

### Type — Moving average method for PercentD calculation

'e' (exponential) (default) | character vector with values 'exponential' or 'triangular'

Moving average method for PercentD calculation, specified as the comma-separated pair consisting of 'Type' and a character vector with a value of:

- 'exponential' - Exponential moving average is a weighted moving average. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10 period exponential moving average weights the most recent price by 18.18%.
- 'triangular' - Triangular moving average is a double-smoothing of the data. The first simple moving average is calculated and then a second simple moving average is calculated on the first moving average with the same window size.

Data Types: char

## Output Arguments

### percentKnD — PercentK and PercentD

matrix | table | timetable

PercentK and PercentD, returned with the same number of rows (M) and type (matrix, table, or timetable) as the input Data.

## Examples

### Calculate the Stochastic Oscillator for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
oscillator = stochosc(TMW,'NumPeriodsD',7,'NumPeriodsK',10,'Type','exponential');
plot(oscillator.Time,oscillator.FastPercentK,oscillator.Time,oscillator.FastPercentD)
title('Stochastic Oscillator for TMW')
```

## More About

### Stochastic Oscillator

The stochastic oscillator calculates the Fast PercentK (F%K), Fast PercentD (F%D), Slow PercentK (S%K), and Slow PercentD (S%D) from the series of high, low, and closing stock prices.

By default, the stochastic oscillator is based on 10-period difference for PercentK and a 3-period exponential moving average for PercentD.

## Topics

“Using Timetables in Finance”

“Convert Financial Time Series Objects `fints` to Timetables” on page 12-2

**Introduced before R2006a**

# subsasgn

Content assignment

---

**Note** `subsasgn` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
subsasgn
```

## Description

`subsasgn` assigns content to a component within a financial time series object. `subsasgn` supports integer indexing or date character vector indexing into the time series object with values assigned to the designated components. *Serial date numbers cannot be used as indices.* To use date character vector indexing, enclose the date character vector(s) in a pair of single quotation marks ' '.

You can use integer indexing on the object as in any other MATLAB matrix. It will return the appropriate entry(ies) from the object.

You must specify the component to which you want to assign values. An assigned value must be either a scalar or a column vector.

## Examples

Given a time series `myfts` with a default data series name of `series1`,

```
myfts.series1('07/01/98::07/03/98') = [1 2 3]';
```

assigns the values 1, 2, and 3 corresponding to the first three days of July, 1998.

```
myfts('07/01/98::07/05/98')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
```

```
ans =
```

```
desc: Data Assignment
freq: Daily (1)

'dates: (5)'    'series1: (5)'
'01-Jul-1998'  [          1]
'02-Jul-1998'  [          2]
'03-Jul-1998'  [          3]
'04-Jul-1998'  [    4561.2]
'05-Jul-1998'  [    5612.3]
```

When the financial time series object contains a time-of-day specification, you can assign data to a specific time on a specific day. For example, create a financial time series object called `timeday` containing both dates and times:

```

dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
times]);
timeday = fints(dates_times, (1:6)', {'Data1'}, 1, 'My first FINTS')

```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

| 'dates: (6)'  | 'times: (6)' | 'Data1: (6)' |
|---------------|--------------|--------------|
| '01-Jan-2001' | '11:00'      | [ 999]       |
| ' "           | '12:00'      | [ 2]         |
| '02-Jan-2001' | '11:00'      | [ 3]         |
| ' "           | '12:00'      | [ 4]         |
| '03-Jan-2001' | '11:00'      | [ 5]         |
| ' "           | '12:00'      | [ 6]         |

For value assignment using date character vectors, enclose the character vector in single quotation marks. If a date has multiple times, designating only the date and assigning a value results in every element of that date taking on the assigned value. For example, to assign the value 0.5 to all times-of-day on January 1, 2001, enter

```
timedata('01-Jan-2001') = 0.5
```

The result is

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/size (line 28)  
In help (line 53)

```

timedata =

  desc: My first FINTS
  freq: Daily (1)

  'dates: (6)'   'times: (6)'   'Data1: (6)'
  '01-Jan-2001' '11:00'       [ 0.5000]
  '    "    '    '12:00'       [ 0.5000]
  '02-Jan-2001' '11:00'       [ 3]
  '    "    '    '12:00'       [ 4]
  '03-Jan-2001' '11:00'       [ 5]
  '    "    '    '12:00'       [ 6]

```

To access the individual components of the financial time series object, use the structure syntax. For example, to assign a range of data to all the data items in the series `Data1`, you can use

```
timedata.Data1 = (0: .1 : .5)'
```

```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/size (line 28)
   In help (line 53)

```

```

timedata =

  desc: My first FINTS
  freq: Daily (1)

## Topics

“Financial Time Series Operations” on page 13-6

**Introduced before R2006a**

## subref

Subscripted reference

---

**Note** `subref` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

`subref`

### Description

`subref` implements indexing for a financial time series object. Integer indexing or date (and time) character vector indexing is allowed. *Serial date numbers cannot be used as indices.*

To use date character vector indexing, enclose the date character vector(s) in a pair of single quotation marks ' '.

You can use integer indexing on the object as in any other MATLAB matrix. It returns the appropriate entry(ies) from the object.

Additionally, `subref` lets you access the individual components of the object using the structure syntax.

### Examples

Create a time series named `myfts`:

```
myfts = fints((datenum('07/01/98'):datenum('07/01/98')+4)',...
[1234.56; 2345.61; 3456.12; 4561.23; 5612.34], [], 'Daily',...
'Data Reference')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints (line 165)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/display (line 66)
```

```
myfts =
```

```
desc: Data Reference
freq: Daily (1)
```

```
'dates: (5)'      'series1: (5)'
'01-Jul-1998'    [ 1.2346e+03]
'02-Jul-1998'    [ 2.3456e+03]
'03-Jul-1998'    [ 3.4561e+03]
'04-Jul-1998'    [ 4.5612e+03]
'05-Jul-1998'    [ 5.6123e+03]
```

Extract the data for the single day July 1, 1998:

```
myfts('07/01/98')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```
desc: Data Reference
freq: Daily (1)

'dates: (1)'    'series1: (1)'
'01-Jul-1998'  [ 1.2346e+03]
```

Now, extract the data for the range of dates July 1, 1998, through July 5, 1998:

```
myfts('07/01/98::07/03/98')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```
desc: Data Reference
freq: Daily (1)

'dates: (3)'    'series1: (3)'
'01-Jul-1998'  [ 1.2346e+03]
'02-Jul-1998'  [ 2.3456e+03]
'03-Jul-1998'  [ 3.4561e+03]
```

You can use the MATLAB structure syntax to access the individual components of a financial time series object. To get the description field of `myfts`, enter

```
myfts.desc
```

at the command line, which returns

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
```

```
ans =
```

```
'Data Reference'
```

Similarly

```
myfts.series1
```

returns

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```

desc: Data Reference
freq: Daily (1)

'dates: (5)'      'series1: (5)'
'01-Jul-1998'    [ 1.2346e+03]
'02-Jul-1998'    [ 2.3456e+03]
'03-Jul-1998'    [ 3.4561e+03]
'04-Jul-1998'    [ 4.5612e+03]
'05-Jul-1998'    [ 5.6123e+03]

```

The syntax for integer indexing is the same as for any other MATLAB matrix. Create a new financial time series object containing both dates and times:

```

dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
                      times]);
anewfts = fints(dates_times, (1:6), {'Data1'}, 1, 'Another FinTs')

```

```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)

```

```
anewfts =
```

```

desc: Another FinTs
freq: Daily (1)

'dates: (6)'      'times: (6)'      'Data1: (6)'
'01-Jan-2001'    '11:00'          [ 1]
'    "    '    '12:00'          [ 2]
'02-Jan-2001'    '11:00'          [ 3]
'    "    '    '12:00'          [ 4]
'03-Jan-2001'    '11:00'          [ 5]
'    "    '    '12:00'          [ 6]

```

Use integer indexing to extract the second and third data items from the object.

```
anewfts(2:3)
```

```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)

```

```
ans =
```

```

desc: Another FinTs
freq: Daily (1)

'dates: (2)'      'times: (2)'      'Data1: (2)'
'01-Jan-2001'    '12:00'          [ 2]
'02-Jan-2001'    '11:00'          [ 3]

```

For date character vector, enclose the indexing character vector in a pair of single quotation marks.

If there is one date with multiple times, indexing with only the date returns all the times for that specific date:

```
anewfts('01-Jan-2001')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```
desc: Another FinTs
freq: Daily (1)
```

```
'dates: (2)'    'times: (2)'    'Data1: (2)'
'01-Jan-2001'  '11:00'        [          1]
'    "    '    '12:00'        [          2]
```

To specify one specific date and time, index with that date and time:

```
anewfts('01-Jan-2001 12:00')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```
desc: Another FinTs
freq: Daily (1)
```

```
'dates: (1)'    'times: (1)'    'Data1: (1)'
'01-Jan-2001'  '12:00'        [          2]
```

To specify a range of dates and times, use the double colon (: :) operator:

```
anewfts('01-Jan-2001 12:00::03-Jan-2001 11:00')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```
desc: Another FinTs
freq: Daily (1)
```

```
'dates: (4)'    'times: (4)'    'Data1: (4)'
'01-Jan-2001'  '12:00'        [          2]
'02-Jan-2001'  '11:00'        [          3]
'    "    '    '12:00'        [          4]
'03-Jan-2001'  '11:00'        [          5]
```

To request all the dates, times, and data, use the :: operator without specifying any specific date or time:

```
anewfts('::')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/display (line 66)
```

```
ans =
```

```
desc: Another FinTs  
freq: Daily (1)
```

```
'dates: (6)'      'times: (6)'      'Data1: (6)'  
'01-Jan-2001'    '11:00'          [          1]  
'    "    '    '12:00'          [          2]  
'02-Jan-2001'    '11:00'          [          3]  
'    "    '    '12:00'          [          4]  
'03-Jan-2001'    '11:00'          [          5]  
'    "    '    '12:00'          [          6]
```

# targetreturn

Portfolio weight accuracy

## Syntax

```
return = targetreturn(Universe,Window,Offset,Weights)
```

## Arguments

|          |                                                                                                                                                                                                                                                                                                   |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Universe | Number of observations (NUMOBS) by number of assets plus one (NASSETS + 1) array containing total return data for a group of securities. Each row represents an observation. Column 1 contains MATLAB serial date numbers. The remaining columns contain the total return data for each security. |
| Window   | Number of data periods used to calculate frontier.                                                                                                                                                                                                                                                |
| Offset   | Increment in number of periods at which each frontier is generated.                                                                                                                                                                                                                               |
| Weights  | Number of assets (NASSETS) by number of curves (NCURVES) matrix of asset allocation weights needed to obtain the target rate of return.                                                                                                                                                           |

## Description

`return = targetreturn(Universe,Window,Offset,Weights)` computes target return values for each window of data and given portfolio weights. These values should match the input target return used with `selectreturn`.

## taxedrr

After-tax rate of return

### Syntax

Return = taxedrr(PreTaxReturn, TaxRate)

### Arguments

|              |                                                      |
|--------------|------------------------------------------------------|
| PreTaxReturn | Nominal rate of return. Enter as a decimal fraction. |
| TaxRate      | Tax rate. Enter as a decimal fraction.               |

### Description

Return = taxedrr(PreTaxReturn, TaxRate) calculates the after-tax rate of return.

### Examples

#### Calculate the After-Tax Rate of Return

This example shows how to calculate the after-tax rate of return, given an investment that has a 12% nominal rate of return and is taxed at a 30% rate.

```
Return = taxedrr(0.12, 0.30)
```

```
Return = 0.0840
```

# tbilldisc2yield

Convert Treasury bill discount to equivalent yield

## Syntax

```
[BEYield,MMYield] = tbilldisc2yield(Discount,Settle,Maturity)
```

## Description

[BEYield,MMYield] = tbilldisc2yield(Discount,Settle,Maturity) converts the discount rate on Treasury bills into their respective money-market or bond-equivalent yields.

## Examples

### Convert the Discount Rate on Treasury Bills

This example shows how to convert the discount rate on Treasury bills into their respective money-market or bond-equivalent yields, given a Treasury bill with the following characteristics.

```
Discount = 0.0497;  
Settle = '01-Oct-02';  
Maturity = '31-Mar-03';
```

```
[BEYield MMYield] = tbilldisc2yield(Discount, Settle, Maturity)
```

```
BEYield = 0.0517
```

```
MMYield = 0.0510
```

### Convert the Discount Rate on Treasury Bills Using datetime Inputs

This example shows how to use `datetime` inputs to convert the discount rate on Treasury bills into their respective money-market or bond-equivalent yields, given a Treasury bill with the following characteristics.

```
Discount = 0.0497;  
Settle = datetime('01-Oct-02','Locale','en_US');  
Maturity = datetime('31-Mar-03','Locale','en_US');  
[BEYield MMYield] = tbilldisc2yield(Discount, Settle, Maturity)
```

```
BEYield = 0.0517
```

```
MMYield = 0.0510
```

## Input Arguments

### **Discount — Discount rate of Treasury bills**

decimal

Discount rate of the Treasury bills, specified as a scalar or a NTBILLS-by-1 vector of decimal values. The discount rate basis is actual/360.

Data Types: double

### **Settle — Settlement date of Treasury bill**

serial date number | date character vector | datetime

Settlement date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays. **Settle** must be earlier than **Maturity**.

Data Types: double | char | datetime

### **Maturity — Maturity date of Treasury bill**

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### **BEYield — Bond equivalent yields of Treasury bills**

numeric

Bond equivalent yields of the Treasury bills, returned as a NTBILLS-by-1 vector. The bond-equivalent yield basis is actual/365.

### **MMYield — Money-market yields of Treasury bills**

numeric

Money-market yields of the Treasury bills, returned as a NTBILLS-by-1 vector. The money-market yield basis is actual/360.

"Treasury Bills Defined" on page 2-27

**Introduced before R2006a**

## tbillprice

Price Treasury bill

### Syntax

```
Price = tbillprice(Rate,Settle,Maturity)
Price = tbillprice( ____,Type)
```

### Description

Price = tbillprice(Rate,Settle,Maturity) computes the price of a Treasury bill given a yield or discount rate.

Price = tbillprice( \_\_\_\_,Type) adds an optional argument for Type.

### Examples

#### Compute the Price of a Treasury Bill Using the Bond-Equivalent Yield

Given a Treasury bill with the following characteristics, compute the price of the Treasury bill using the bond-equivalent yield (Type = 2) as input.

```
Rate = 0.045;
Settle = '01-Oct-02';
Maturity = '31-Mar-03';
```

```
Type = 2;
```

```
Price = tbillprice(Rate, Settle, Maturity, Type)
```

```
Price = 97.8172
```

#### Price a Portfolio of Treasury Bills

Use tbillprice to price a portfolio of Treasury bills.

```
Rate = [0.045; 0.046];
Settle = {'02-Jan-02'; '01-Mar-02'};
Maturity = {'30-June-02'; '30-June-02'};
Type = [2 3];
```

```
Price = tbillprice(Rate, Settle, Maturity, Type)
```

```
Price = 2×1
```

```
97.8408
98.4539
```

## Price a Portfolio of Treasury Bills Using datetime Input

Use `tbillprice` to price a portfolio of Treasury bills using `datetime` input.

```
Rate = [0.045; 0.046];
Type = [2 3];

Settle = datetime({'2002-01-02'; '2002-03-01'}, 'InputFormat', 'yyyy-MM-dd', 'Locale', 'en_US');
Maturity = datetime({'2002-06-30'; '2002-06-30'}, 'InputFormat', 'yyyy-MM-dd', 'Locale', 'en_US');
Price = tbillprice(Rate, Settle, Maturity, Type)

Price = 2×1

    97.8408
    98.4539
```

## Input Arguments

### Rate — Bond-equivalent yield, money-market yield, or discount rate

decimal

Bond-equivalent yield, money-market yield, or discount rate (defined by the input `Type`), specified as a scalar or a `NTBILLS`-by-1 vector of decimal values.

Data Types: `double`

### Settle — Settlement date of Treasury bill

serial date number | date character vector | `datetime`

Settlement date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-1 vector of serial date numbers, date character vectors, or `datetime` arrays.

Data Types: `double` | `char` | `datetime`

### Maturity — Maturity date of Treasury bill

serial date number | date character vector | `datetime`

Maturity date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-1 vector of serial date numbers, date character vectors, or `datetime` arrays.

Data Types: `double` | `char` | `datetime`

### Type — (Optional) Rate type

2 (default) | numeric with values 1 = money market, 2 = bond-equivalent, 3 = discount rate

Rate type (determines how to interpret values entered in `Rate`), specified as a numeric value of 1, 2, or 3 using a scalar or a `NTBILLS`-by-1 vector.

---

**Note** The bond-equivalent yield basis is actual/365. The money-market yield basis is actual/360. The discount rate basis is actual/360.

---

Data Types: double

## Output Arguments

### **Price — Treasury bill price for every \$100 face**

numeric

Treasury bill prices for every \$100 face, returned as a NTBILLS-by-1 vector.

# tbillrepo

Break-even discount of repurchase agreement

## Syntax

```
TBEDiscount = tbillrepo(RepoRate,InitialDiscount,PurchaseDate,SaleDate,
Maturity)
```

## Description

TBEDiscount = tbillrepo(RepoRate,InitialDiscount,PurchaseDate,SaleDate, Maturity) computes the true break-even discount of a repurchase agreement.

## Examples

### Compute the True Break-Even Discount

This example shows how to compute the true break-even discount of a Treasury bill repurchase agreement.

```
RepoRate = [0.045; 0.0475];
InitialDiscount = 0.0475;
PurchaseDate = '3-Jan-2002';
SaleDate = '3-Feb-2002';
Maturity = '3-Apr-2002';
```

```
TBEDiscount = tbillrepo(RepoRate, InitialDiscount,...
PurchaseDate, SaleDate, Maturity)
```

```
TBEDiscount = 2×1
```

```
0.0491
0.0478
```

### Compute the True Break-Even Discount Using datetime Inputs

This example shows how to use datetime inputs to compute the true break-even discount of a Treasury bill repurchase agreement.

```
RepoRate = [0.045; 0.0475];
InitialDiscount = 0.0475;
PurchaseDate = datetime('3-Jan-2002','Locale','en_US');
SaleDate = datetime('3-Feb-2002','Locale','en_US');
Maturity = datetime('3-Apr-2002','Locale','en_US');
TBEDiscount = tbillrepo(RepoRate, InitialDiscount,...
PurchaseDate, SaleDate, Maturity)
```

```
TBEDiscount = 2×1  
  
    0.0491  
    0.0478
```

## Input Arguments

### **RepoRate — Annualized, 360-day based repurchase rate**

decimal

Annualized, 360-day based repurchase rate, specified as a scalar of a NTBILLS-by-1 vector of decimal values.

Data Types: double

### **InitialDiscount — Discount on Treasury bill on day of purchase**

decimal

Discount on the Treasury bill on the day of purchase, specified as a scalar of a NTBILLS-by-1 vector of decimal values.

Data Types: double

### **PurchaseDate — Date Treasury bill is purchased**

serial date number | date character vector | datetime

Date the Treasury bill is purchased, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **SaleDate — Date Treasury bill repurchase term is due**

serial date number | date character vector | datetime

Date the Treasury bill repurchase term is due, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Maturity — Maturity date of Treasury bill**

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### **TBEDiscount — True break-even discount of repurchase agreement**

numeric

True break-even discount of a repurchase agreement, returned as a scalar or NTBILLS-by-1 vector.

## tbillval01

Value of one basis point

### Syntax

```
[Val01Disc,Val01MMY,Val01BEY] = tbillval01(Settle,Maturity)
```

### Description

[Val01Disc,Val01MMY,Val01BEY] = tbillval01(Settle,Maturity) calculates the value of one basis point of \$100 Treasury bill face value on the discount rate, money-market yield, or bond-equivalent yield.

### Examples

#### Compute the Value of One Basis Point

This example shows how to compute the value of one basis point, given a Treasury bill with the following settle and maturity dates.

```
Settle = '01-Mar-03';  
Maturity = '30-June-03';  
[Val01Disc, Val01MMY, Val01BEY] = tbillval01(Settle, Maturity)
```

```
Val01Disc = 0.0034
```

```
Val01MMY = 0.0034
```

```
Val01BEY = 0.0033
```

#### Compute the Value of One Basis Point Using datetime Inputs

This example shows how to use `datetime` inputs to compute the value of one basis point, given a Treasury bill with the following settle and maturity dates.

```
Settle = datetime(2003,3,1);  
Maturity = datetime(2003,6,30);  
[Val01Disc, Val01MMY, Val01BEY] = tbillval01(Settle, Maturity)
```

```
Val01Disc = 0.0034
```

```
Val01MMY = 0.0034
```

```
Val01BEY = 0.0033
```

## Input Arguments

### **Settle — Settlement date of Treasury bill**

serial date number | date character vector | datetime

Settlement date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays. **Settle** must be earlier than **Maturity**.

Data Types: double | char | datetime

### **Maturity — Maturity date of Treasury bill**

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### **Val01Disc — Value of one basis point of discount rate for every \$100 face**

numeric

Value of one basis point of discount rate for every \$100 face, returned as a NTBILLS-by-1 vector.

### **Val01MMY — Value of one basis point of money-market yield for every \$100 face**

numeric

Value of one basis point of money-market yield for every \$100 face, returned as a NTBILLS-by-1 vector.

### **Val01BEY — Value of one basis point of bond-equivalent yield for every \$100 face**

numeric

Value of one basis point of bond-equivalent yield for every \$100 face, returned as a NTBILLS-by-1 vector.

# tbillyield

Yield on Treasury bill

## Syntax

```
[MMYield,BEYield,Discount] = tbillyield(Price,Settle,Maturity)
```

## Description

[MMYield,BEYield,Discount] = tbillyield(Price,Settle,Maturity) computes the yield of US Treasury bills given Price, Settle, and Maturity.

## Examples

### Compute the Yield of U.S. Treasury Bills

This example shows how to compute the yield of U.S. Treasury bills, given a Treasury bill with the following characteristics.

```
Price = 98.75;  
Settle = '01-Oct-02';  
Maturity = '31-Mar-03';
```

```
[MMYield, BEYield, Discount] = tbillyield(Price, Settle,...  
Maturity)
```

```
MMYield = 0.0252
```

```
BEYield = 0.0255
```

```
Discount = 0.0249
```

### Compute the Yield of U.S. Treasury Bills Using datetime Inputs

This example shows how to use datetime inputs to compute the yield of U.S. Treasury bills, given a Treasury bill with the following characteristics.

```
Price = 98.75;  
Settle = datetime('01-Oct-2002','Locale','en_US');  
Maturity = datetime('31-Mar-2003','Locale','en_US');  
[MMYield, BEYield, Discount] = tbillyield(Price, Settle,Maturity)
```

```
MMYield = 0.0252
```

```
BEYield = 0.0255
```

```
Discount = 0.0249
```

## Input Arguments

### **Price — Price of Treasury bills for every \$100 face value**

numeric

Price of Treasury bills for every \$100 face value, specified as a scalar of a NTBILLS-by-1 vector of decimal values.

Data Types: double

### **Settle — Settlement date of Treasury bill**

serial date number | date character vector | datetime

Settlement date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays. **Settle** must be earlier than **Maturity**.

Data Types: double | char | datetime

### **Maturity — Maturity date of Treasury bill**

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### **MMYield — Money-market yields of Treasury bills**

numeric

Money-market yields of the Treasury bills, returned as a NTBILLS-by-1 vector.

### **BEYield — Bond equivalent yields of Treasury bills**

numeric

Bond equivalent yields of the Treasury bills, returned as a NTBILLS-by-1 vector.

### **Discount — Discount rates of Treasury bills**

numeric

Discount rates of the Treasury bills, returned as a NTBILLS-by-1 vector.

## tbillyield2disc

Convert Treasury bill yield to equivalent discount

### Syntax

```
Discount = tbillyield2disc(Yield,Settle,Maturity)
Discount = tbillyield2disc( ____,Type)
```

### Description

`Discount = tbillyield2disc(Yield,Settle,Maturity)` converts the yield on some Treasury bills into their respective discount rates.

`Discount = tbillyield2disc( ____,Type)` adds an optional argument for `Type`.

### Examples

#### Compute the Discount Rate on a Money-Market Basis

Given a Treasury bill with these characteristics, compute the discount rate.

```
Yield = 0.0497;
Settle = '01-Oct-02';
Maturity = '31-Mar-03';

Discount = tbillyield2disc(Yield,Settle,Maturity)

Discount = 0.0485
```

#### Compute the Discount Rate on a Money-Market Basis Using datetime Inputs

Given a Treasury bill with these characteristics, compute the discount rate using datetime inputs.

```
Yield = 0.0497;
Settle = datetime('01-Oct-2002','Locale','en_US');
Maturity = datetime('31-Mar-2003','Locale','en_US');

Discount = tbillyield2disc(Yield,Settle,Maturity)

Discount = 0.0485
```

### Input Arguments

#### Yield — Yield of Treasury bills

decimal

Yield of Treasury bills, specified as a scalar of a `NTBILLS`-by-1 vector of decimal values.

Data Types: double

### **Settle — Settlement date of Treasury bill**

serial date number | date character vector | datetime

Settlement date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Maturity — Maturity date of Treasury bill**

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Type — Yield type**

1 (default) | numeric with values 1 = money market, 2 = bond-equivalent

(Optional) Yield type (determines how to interpret values entered in Yield), specified as a numeric value of 1 or 2 using a scalar or a NTBILLS-by-1 vector.

---

**Note** The bond-equivalent yield basis is actual/365. The money-market yield basis is actual/360.

---

Data Types: double

## **Output Arguments**

### **Discount — Discount rates of Treasury bills**

numeric

Discount rates of the Treasury bills, returned as a NTBILLS-by-1 vector.

## **References**

## tbl2bond

Treasury bond parameters given Treasury bill parameters

### Syntax

```
[TBondMatrix,Settle] = tbl2bond(TBillMatrix)
```

### Description

[TBondMatrix,Settle] = tbl2bond(TBillMatrix) restates US Treasury bill market parameters in US Treasury bond form as zero-coupon bonds. This function makes Treasury bills directly comparable to Treasury bonds and notes.

### Examples

#### Restate U.S. Treasury Bill in U.S. Treasury Bond Form

This example shows how to restate U.S. Treasury bill market parameters in U.S. Treasury bond form, given published Treasury bill market parameters for December 22, 1997.

```
TBill = [datenum('jan 02 1998') 10 0.0526 0.0522 0.0530
         datenum('feb 05 1998') 44 0.0537 0.0533 0.0544
         datenum('mar 05 1998') 72 0.0529 0.0527 0.0540];
```

```
TBond = tbl2bond(TBill)
```

```
TBond = 3×5
105 ×
```

```
    0    7.2976    0.0010    0.0010    0.0000
    0    7.2979    0.0010    0.0010    0.0000
    0    7.2982    0.0010    0.0010    0.0000
```

#### Restate U.S. Treasury Bill in U.S. Treasury Bond Form Using datetime Input

This example shows how to use datetime input to restate U.S. Treasury bill market parameters in U.S. Treasury bond form, given published Treasury bill market parameters for December 22, 1997.

```
TBill = [datenum('jan 02 1998') 10 0.0526 0.0522 0.0530
         datenum('feb 05 1998') 44 0.0537 0.0533 0.0544
         datenum('mar 05 1998') 72 0.0529 0.0527 0.0540];
```

```
dates = datetime(TBill(:,1), 'ConvertFrom', 'datenum', 'Locale', 'en_US');
data = TBill(:,2:end);
t=[table(dates) array2table(data)];
[TBond, Settle] = tbl2bond(t)
```

| TBond=3x5 table |             |        |        |          |
|-----------------|-------------|--------|--------|----------|
| CouponRate      | Maturity    | Bid    | Asked  | AskYield |
| 0               | 02-Jan-1998 | 99.854 | 99.855 | 0.053    |
| 0               | 05-Feb-1998 | 99.344 | 99.349 | 0.0544   |
| 0               | 05-Mar-1998 | 98.942 | 98.946 | 0.054    |

Settle = 3x1 datetime  
 22-Dec-1997  
 22-Dec-1997  
 22-Dec-1997

## Input Arguments

### TBillMatrix — Treasury bill parameters

table | matrix

Treasury bill parameters, specified as a 5-column table or a N-by-5 matrix of bond information where the table columns or matrix columns contains:

- **Maturity** (Required) Maturity date of Treasury bills, specified as a serial date number when using a matrix. Use `datenum` to convert date character vectors to serial date numbers. If the input `TBillMatrix` is a table, the `Maturity` dates can be serial date numbers, date character vectors, or datetime arrays.
- **DaysMaturity** (Required) Days to maturity, specified as an integer. Days to maturity are quoted on a skip-day basis; the actual number of days from settlement to maturity is `DaysMaturity + 1`.
- **Bid** (Required) Bid bank-discount rate (the percentage discount from face value at which the bill could be bought, annualized on a simple-interest basis), specified as a decimal fraction.
- **Asked** (Required) Asked bank-discount rate, specified as a decimal fraction.
- **AskYield** (Required) Asked yield (the bond-equivalent yield from holding the bill to maturity, annualized on a simple-interest basis and assuming a 365-day year), specified as a decimal fraction.

Data Types: double | table

## Output Arguments

### TBondMatrix — Treasury bond parameters

table | matrix

Treasury bond parameters, returned as a table or matrix depending on the `TBillMatrix` input.

When `TBillMatrix` is a table, `TBondMatrix` is also a table, and the variable type for the `Maturity` dates in `TBondMatrix` (column 1) matches the variable type for `Maturity` in `TBillMatrix`. For example, if `Maturity` dates are datetime arrays in `TBillMatrix`, they will also be datetime arrays in `TBondMatrix`.

When `TBillMatrix` input is a N-by-5 matrix, then each row describes a Treasury bond.

The parameters or columns returned for `TBondMatrix` are:

- `CouponRate` (Column 1) Coupon rate, which is always 0 since the Treasury bills are, by definition, a zero coupon instrument.
- `Maturity` (Column 2) Maturity date for each bond in the portfolio as a serial date number. The format of the dates matches the format used for `Maturity` in `TBillMatrix` (serial date number, date character vector, or datetime array).
- `Bid` (Column 3) Bid price based on \$100 face value.
- `Asked` (Column 4) Asked price based on \$100 face value.
- `AskYield` (Column 5) Asked yield to maturity: the effective return from holding the bond to maturity, annualized on a compound-interest basis.

### **Settle — Settlement dates implied by maturity dates and number of days to maturity quote**

serial date number | datetime

Settlement dates implied by the maturity dates and the number of days to maturity quote, returned as a N-by-5 vector containing serial date numbers, by default. `Settle` is returned as a datetime array only if the input `TBillMatrix` is a table containing datetime arrays for `Maturity` in the first column.

## thirdwednesday

Find third Wednesday of month

### Syntax

```
[BeginDates,EndDates] = thirdwednesday(Month,Year)
[BeginDates,EndDates] = thirdwednesday( ____,outputType)
```

### Description

[BeginDates,EndDates] = thirdwednesday(Month,Year) computes the beginning and end period date for a LIBOR contract (third Wednesdays of delivery months).

[BeginDates,EndDates] = thirdwednesday( \_\_\_\_,outputType), using optional input arguments, computes the beginning and end period date for a LIBOR contract (third Wednesdays of delivery months).

The type of the outputs depends on the input `outputType`. If this variable is 'datenum', `BeginDates` and `EndDates` are serial date numbers. If `outputType` is 'datetime', then `BeginDates` and `EndDates` are datetime arrays. By default, `outputType` is set to 'datenum'.

### Examples

#### Determine the Third Wednesday for Given Months and Years

Find the third Wednesday dates for swaps commencing in the month of October in the years 2002, 2003, and 2004.

```
Months = [10; 10; 10];
Year = [2002; 2003; 2004];
[BeginDates, EndDates] = thirdwednesday(Months, Year);
datestr(BeginDates)
```

```
ans = 3x11 char array
    '16-Oct-2002'
    '15-Oct-2003'
    '20-Oct-2004'
```

```
datestr(EndDates)
```

```
ans = 3x11 char array
    '16-Jan-2003'
    '15-Jan-2004'
    '20-Jan-2005'
```

Find the third Wednesday dates for swaps commencing in the month of October in the years 2002, 2003, and 2004 using an `outputType` of 'datetime'.

```
Months = [10; 10; 10];
Year = [2002; 2003; 2004];
[BeginDates, EndDates] = thirdwednesday(Months, Year, 'datetime')
```

```
BeginDates = 3x1 datetime
    16-Oct-2002
    15-Oct-2003
    20-Oct-2004
```

```
EndDates = 3x1 datetime
    16-Jan-2003
    15-Jan-2004
    20-Jan-2005
```

## Input Arguments

### Month — Month of delivery for Eurodollar futures

integer from 1 through 12 | vector of integers from 1 through 12

Month of delivery for Eurodollar futures, specified as an N-by-1 vector of integers from 1 through 12.

Duplicate dates are returned when identical months and years are supplied.

Data Types: `single` | `double`

### Year — Delivery year for Eurodollar futures/Libor contracts corresponding to Month

four-digit nonnegative integer | vector of four-digit nonnegative integers

Delivery year for Eurodollar futures/Libor contracts corresponding to Month, specified as an N-by-1 vector of four-digit nonnegative integers.

Duplicate dates are returned when identical months and years are supplied.

Data Types: `single` | `double`

### outputType — Output date format

'datenum' (default) | character vector with values 'datenum' or 'datetime'

Output date format, specified as a character vector with values 'datenum' or 'datetime'. If outputType is 'datenum', then BeginDates and EndDates are serial date numbers. However, if outputType is 'datetime', then BeginDates and EndDates are datetime arrays.

Data Types: `char`

## Output Arguments

### BeginDates — Third Wednesday of given month and year

serial date number | date character vector

Third Wednesday of given month and year, returned as serial date numbers or date character vectors, or datetime arrays. This is also the beginning of the 3-month period contract.

The type of the outputs depends on the input `outputType`. If this variable is 'datenum', `BeginDates` and `EndDates` are serial date numbers. If `outputType` is 'datetime', then `BeginDates` and `EndDates` are datetime arrays. By default, `outputType` is set to 'datenum'.

**EndDates — End of three-month period contract for given month and year**

serial date number | date character vector

End of three-month period contract for given month and year, returned as serial date numbers or date character vectors, or datetime arrays.

The type of the outputs depends on the input `outputType`. If this variable is 'datenum', `BeginDates` and `EndDates` are serial date numbers. If `outputType` is 'datetime', then `BeginDates` and `EndDates` are datetime arrays. By default, `outputType` is set to 'datenum'.

# thirtytwo2dec

Thirty-second quotation to decimal

## Syntax

```
OutNumber = thirtytwo2dec(InNumber,InFraction)
```

## Description

`OutNumber = thirtytwo2dec(InNumber,InFraction)` changes the price quotation for a bond or bond future from a fraction with a denominator of 32 to a decimal.

## Examples

### Change the Price Quotation for a Bond or Bond Future From a Fraction

This example shows how to change the price quotation for a bond or bond future from a fraction with a denominator of 32 to a decimal, given two bonds that are quoted as 101-25 and 102-31.

```
InNumber = [101; 102];  
InFraction = [25; 31];
```

```
OutNumber = thirtytwo2dec(InNumber, InFraction)
```

```
OutNumber = 2×1
```

```
101.7813  
102.9688
```

## Input Arguments

### **InNumber** — Input number

integer

Input number, specified as a scalar or an N-by-1 vector of integers representing price without the fractional components.

Data Types: double

### **InFraction** — Fractional portions of each element in InNumber

numeric decimal fraction

Fractional portions of each element in `InNumber`, specified as a scalar or an N-by-1 vector of numeric decimal fractions.

Data Types: double

## **Output Arguments**

**OutNumber** — **Output number that represents sum of InNumber and InFraction**  
decimal

Output number that represents sum of InNumber and InFraction, returned as a decimal.

## **See Also**

dec2thirtytwo

**Introduced before R2006a**

# tick2ret

Convert price series to return series

## Syntax

```
[Returns,Intervals] = tick2ret(Data)
[Returns,Intervals] = tick2ret( ___,Name,Value)
```

## Description

[Returns,Intervals] = tick2ret(Data) computes asset returns for NUMOBS price observations of NASSETS assets.

[Returns,Intervals] = tick2ret( \_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Convert Price Series to Return Series

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock. Then convert a price series to a return series, given the first 10 periodic returns of TMW.

```
load SimulatedStock.mat
```

```
TMW_Close = TMW(1:10,'Close');
[Returns,Intervals] = tick2ret(TMW_Close)
```

```
Returns=9x1 timetable
      Time      Close

13-Sep-2012    0.0081628
14-Sep-2012   -0.00051245
17-Sep-2012   -0.02902
```

```
Intervals = 9x1 duration
24:00:00
24:00:00
24:00:00
72:00:00
24:00:00
24:00:00
24:00:00
```

```
24:00:00
72:00:00
```

### Convert Price Series to Return Series Using `datetime` Input

Use `datetime` input to convert a price series to a return series, given periodic returns of two stocks observed in the first, second, third, and fourth quarters.

```
TickSeries = [100 80
110 90
115 88
110 91];
```

```
TickTimes = datetime({'1/1/2015','1/7/2015','1/16/2015','1/28/2015'},'InputFormat','MM/dd/yyyy')
[Returns,Intervals] = tick2ret(TickSeries,'TickTimes',TickTimes)
```

```
Returns = 3x2
```

```
    0.1000    0.1250
    0.0455   -0.0222
   -0.0435    0.0341
```

```
Intervals = 3x1 duration
```

```
144:00:00
216:00:00
288:00:00
```

## Input Arguments

### Data — Data for asset prices

matrix | table | timetable

Data for asset prices, specified as a `NUMOBS``NASSETS` matrix, table, or timetable. Prices across a given row are assumed to occur at the same time for all columns, and each column is a price series of an individual asset.

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `[Returns,Intervals] = tick2ret(TickSeries,'TickTimes',TickTimes)`

### TickTimes — Observation times associated with prices

sequential observation times from 1,2,...`NUMOBS` assumed for all assets (default) | vector

Observation times associated with prices, specified as the comma-separated pair consisting of `'TickTimes'` and a `NUMOBS` element column vector of monotonically increasing observation times

associated with the prices in `Data`. Times are taken either as serial date numbers (day units), date strings, datetime arrays, or as decimal numbers in arbitrary units (for example, yearly).

---

**Note** If the input `Data` type is a timetable, the row times information in the timetable overwrites the `TickTimes` input.

---

Data Types: `double` | `datetime` | `string`

### Method — Method to convert asset prices to returns

'Simple' (default) | character vector with value of 'Simple' or 'Continuous' | string with value of "Simple" or "Continuous"

Method to convert asset prices to returns, specified as the comma-separated pair consisting of 'Method' and a string or character vector indicating the method to convert asset prices to returns.

If the method is 'Simple', then simple periodic returns at time  $t$  are computed as:

$$\text{Returns}(t) = \text{Data}(t)/\text{Data}(t-1) - 1.$$

If the method is 'Continuous', the continuous returns are computed as:

$$\text{Returns}(t) = \log(\text{Data}(t)/\text{Data}(t-1)).$$

Data Types: `char` | `string`

## Output Arguments

### Returns — Time series array of asset returns

`matrix` | `table` | `timetable`

Time series array of asset returns, returned as a `NUMOBS - 1`-by-`NASSETS` array of asset returns with the same type (`matrix`, `table`, or `timetable`) as the input `Data`. The first row contains the oldest returns and the last row contains the most recent. Returns across a given row are assumed to occur at the same time for all columns, and each column is a return series of an individual asset.

### Intervals — Interval times between successive prices

`vector`

Interval times between successive prices, returned as a `NUMOBS - 1` length column vector where  $\text{Intervals}(t) = \text{TickTimes}(t) - \text{TickTimes}(t - 1)$ .

## Extended Capabilities

### Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports input `Data` that is specified as a tall column vector, a tall table, or a tall timetable. For more information, see `tall` and "Tall Arrays" (MATLAB).

## tick2ret (fts)

Convert price series to return series for time series object

---

**Note** `tick2ret (fts)` is not recommended. Use `tick2ret` instead.

---

### Syntax

```
returnFts = tick2ret(priceFts)
```

```
returnFts = tick2ret(priceFts, 'PARAM1', VALUE1, 'PARAM2', VALUE2', ...)
```

### Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>priceFts</code> | Financial time series object of prices.                                                                                                                                                                                                                                                                                                                                              |
| <code>'PARAM1'</code> | (Optional) <i>Method</i> is a character vector indicating the method to convert asset returns to prices. The value must be defined as 'Simple' (default) or 'Continuous'. If <i>Method</i> is 'Simple', <code>tick2ret</code> uses simple periodic returns. If <i>Method</i> is 'Continuous', the function uses continuously compounded returns. Case is ignored for <i>Method</i> . |

### Description

`returnFts = tick2ret(priceFts, 'PARAM1', VALUE1, 'PARAM2', VALUE2', ...)` generates a financial time series object of returns.

---

**Note** The *i*'th return is quoted for the period `PriceSeries(i)` to `PriceSeries(i+1)` and is not normalized by the time increment between successive price observations.

---

If *Method* is unspecified or 'Simple', the prices are

$$\text{ReturnSeries}(i) = \text{PriceSeries}(i+1)/\text{PriceSeries}(i) - 1$$

If *Method* is 'Continuous', the prices are

$$\text{ReturnSeries}(i) = \log[\text{PriceSeries}(i+1)/\text{PriceSeries}(i)]$$

### Examples

#### Convert Price Series to Return Series for a `fints` Object

Compute the return series from the following price series:

```
PriceSeries = [100.0000 100.0000
110.0000 112.0000
```

```
115.5000 116.4800
109.7250 122.3040]
```

```
PriceSeries = 4x2
```

```
100.0000 100.0000
110.0000 112.0000
115.5000 116.4800
109.7250 122.3040
```

Use the following dates:

```
Dates = {'18-Dec-2000'
'18-Jun-2001'
'17-Sep-2001'
'18-Dec-2001'}
```

```
Dates = 4x1 cell
{'18-Dec-2000'}
{'18-Jun-2001'}
{'17-Sep-2001'}
{'18-Dec-2001'}
```

The fints object is:

```
p = fints(Dates, PriceSeries)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
p =
```

```
desc: (none)
freq: Unknown (0)

{'dates: (4)'} {'series1: (4)'} {'series2: (4)'}
{'18-Dec-2000'} {[ 100]} {[ 100]}
{'18-Jun-2001'} {[ 110]} {[ 112]}
{'17-Sep-2001'} {[ 115.5000]} {[ 116.4800]}
{'18-Dec-2001'} {[ 109.7250]} {[ 122.3040]}
```

returnFts is computed as:

```
tick2ret(p)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
ans =
```

```
desc: (none)
freq: Unknown (0)

{'dates: (3)'} {'series1: (3)'} {'series2: (3)'}
{'18-Jun-2001'} {[ 0.1000]} {[ 0.1200]}
{'17-Sep-2001'} {[ 0.0500]} {[ 0.0400]}
{'18-Dec-2001'} {[ -0.0500]} {[ 0.0500]}
```

Note that for  $n$  dates in the original time series, there are  $(n-1)$  dates returned for `returnFts` from `tick2ret`. The formula for the date output dates is described as: `RetDate(i) = PriceDate (i+1)`.

**See Also**

`portsim` | `ret2tick`

**Introduced before R2006a**

## time2date

Dates from time and frequency

### Syntax

```
Dates = time2date(Settle,TFactors)
Dates = time2date( ____,Compounding,Basis,EndMonthRule)
```

### Description

Dates = time2date(Settle,TFactors) computes Dates corresponding to compounded rate quotes between Settle and TFactors. time2date is the inverse of date2time.

Dates = time2date( \_\_\_\_,Compounding,Basis,EndMonthRule) computes Dates corresponding to compounded rate quotes between Settle and TFactors using optional input arguments for Compounding, Basis, and EndMonthRule. time2date is the inverse of date2time.

### Examples

#### Calculate Dates Using time2date

Show that date2time and time2date are the inverse of each other. First compute the time factors using date2time.

```
Settle = '1-Sep-2002';
Dates = datenum(['31-Aug-2005'; '28-Feb-2006'; '15-Jun-2006';
                '31-Dec-2006']);
Compounding = 2;
Basis = 0;
EndMonthRule = 1;
TFactors = date2time(Settle, Dates, Compounding, Basis,...
                    EndMonthRule)
```

```
TFactors = 4×1
```

```
5.9945
6.9945
7.5738
8.6576
```

Now use the calculated TFactors in time2date and compare the calculated dates with the original set.

```
Dates_calc = time2date(Settle, TFactors, Compounding, Basis,...
                    EndMonthRule)
```

```
Dates_calc = 4×1
```

```
732555
732736
```

```
732843
733042
```

```
datestr(Dates_calc)
```

```
ans = 4x11 char array
'31-Aug-2005'
'28-Feb-2006'
'15-Jun-2006'
'31-Dec-2006'
```

Show time2date support for datetime input for Settle.

```
Settle = '1-Sep-2002';
Dates = datenum(['31-Aug-2005'; '28-Feb-2006'; '15-Jun-2006';
                '31-Dec-2006']);
Compounding = 2;
Basis = 0;
EndMonthRule = 1;
TFactors = date2time(Settle, Dates, Compounding, Basis,...
                    EndMonthRule);
Dates_calc = time2date(datetime(Settle,'Locale','en_US'), TFactors,...
                    Compounding, Basis, EndMonthRule)

Dates_calc = 4x1 datetime
    31-Aug-2005
    28-Feb-2006
    15-Jun-2006
    31-Dec-2006
```

## Input Arguments

### Settle — Settlement date

serial date number | date character vector | datetime object

Settlement date, specified as a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### TFactors — Time factors

vector

Time factors, corresponding to the compounding value, specified as a vector. TFactors must be equal to or greater than zero.

Data Types: double

### Compounding — Rate at which input zero rates are compounded when annualized

2 (Semiannual compounding) (default) | scalar with numeric values of 0, 1, 2, 3, 4, 5, 6, 12, 365, -1

Rate at which input zero rates are compounded when annualized, specified as a scalar with numeric values of: 0, 1, 2, 3, 4, 5, 6, 12, 365, or -1. Allowed values are defined as:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

The optional **Compounding** argument determines the formula for the discount factors (**Disc**):

- **Compounding** = 1, 2, 3, 4, 6, 12
  - $\text{Disc} = (1 + Z/F)^{-T}$ , where  $F$  is the compounding frequency,  $Z$  is the zero rate, and  $T$  is the time in periodic units, for example,  $T = F$  is one year.
- **Compounding** = 365
  - $\text{Disc} = (1 + Z/F)^{-T}$ , where  $F$  is the number of days in the basis year and  $T$  is a number of days elapsed computed by basis.
- **Compounding** = -1
  - $\text{Disc} = \exp(-T*Z)$ , where  $T$  is time in years.

### **Basis — Day-count basis**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis, specified as an integer with a value of 0 through 13 or a N-by-1 vector of integers with values 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

### **EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [0, 1] or a using a N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

## **Output Arguments**

### **Dates — Dates corresponding to compounded rate quotes between `Settle` and `TFactors`**

serial date number | datetime array

Dates corresponding to compounded rate quotes between `Settle` and `TFactors`, returned as a scalar or a N-by-1 vector using serial date numbers or datetime arrays.

Data Types: `double` | `datetime`

## **See Also**

`cfamounts` | `cftimes` | `date2time` | `datetime`

## times

Financial time series multiplication

---

**Note** `times` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = tsubj_1 .* tsubj_2
```

```
newfts = tsubj .* array
```

```
newfts = array .* tsubj
```

### Arguments

|                               |                                                                                                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsubj_1, tsubj_2</code> | Pair of financial time series objects.                                                                                                                                                  |
| <code>array</code>            | A scalar value or array with the number of rows equal to the number of dates in <code>tsubj</code> and the number of columns equal to the number of data series in <code>tsubj</code> . |

### Description

The `times` method multiplies element by element the components of one financial time series object by the components of the other. You can also multiply the entire object by an array.

If an object is to be multiplied by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is multiplied by another object, follows the order of the first object.

`newfts = tsubj_1 .* tsubj_2` multiplies financial time series objects element by element.

`newfts = tsubj .* array` multiplies a financial time series object element by element by an array.

`newfts = array .* tsubj` and `newfts = array / tsubj` multiplies an array element by element by a financial time series object.

For financial time series objects, the `times` operation is identical to the `mtimes` operation.

# tmfactor

Time factors of arbitrary dates

## Syntax

```
TFactors = tmfactor(Settle,Maturity)
```

## Arguments

|          |                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Settle   | Settlement date. A vector of serial date numbers, date character vectors, or datetime arrays. <b>Settle</b> must be earlier than <b>Maturity</b> . |
| Maturity | Maturity date. A vector of serial date numbers, date character vectors, or datetime arrays.                                                        |

## Description

`TFactors = tmfactor(Settle,Maturity)` determines the time factors from a vector of Settlement dates to a vector of Maturity dates.

## Examples

Find the `TFactors` for `Settle` and `Maturity` dates.

```
TFactors = tmfactor('1-Jan-2015','1-Jan-2016')
```

```
TFactors =
```

```
2
```

Find the `TFactors` for `Settle` and `Maturity` dates using a datetime array.

```
TFactors = tmfactor(datetime('1-Jan-2015','Locale','en_US'),'1-Jan-2016')
```

```
TFactors =
```

```
2
```

## toannual

Convert to annual

---

**Note** `toannual` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = toannual(oldfts)
```

```
newfts = toannual(oldfts,'ParameterName',ParameterValue, ...)
```

### Arguments

|                     |                               |
|---------------------|-------------------------------|
| <code>oldfts</code> | Financial time series object. |
|---------------------|-------------------------------|

### Description

`newfts = toannual(oldfts)` converts a financial time series of any frequency to one of an annual frequency. The default end-of-year is the last business day of the December. `toannual` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as '00:00' for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `toannual` triggers the use of the defaults.

---

`newfts = toannual(oldfts,'ParameterName',ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name          | Parameter Value      | Description                                                                                                                                                                  |
|-------------------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>CalcMethod</code> | <code>CumSum</code>  | Returns the cumulative sum of the values within each year. Data for missing dates are given the value 0.                                                                     |
| <code>CalcMethod</code> | <code>Exact</code>   | Returns the exact value at the end-of-year date. No data manipulation occurs.                                                                                                |
| <code>CalcMethod</code> | <code>Nearest</code> | (Default) Returns the values located at the end-of-year dates. If there is missing data, <code>Nearest</code> returns the nearest data point preceding the end-of-year date. |
| <code>CalcMethod</code> | <code>SimpAvg</code> | Returns an averaged annual value that only takes into account dates with data (non- <code>NaN</code> ) within each year.                                                     |

| Parameter Name                                                                                                                    | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalcMethod                                                                                                                        | v21x            | This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-year value using a previous toannual algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.                                                                                                                                                    |
| <b>Note</b> If you set CalcMethod to v21x, settings for all the following parameter name/parameter value pairs are not supported. |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| BusDays                                                                                                                           | 0               | Returns a financial time series that ranges from (or between) the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).                                                                                                                                                                                                                                                                                                   |
| BusDays                                                                                                                           | 1               | (Default) Generates a monthly financial time series that ranges from the first date to the last date in oldfts (excludes NYSE nonbusiness days and holidays and weekends based on AltHolidays and Weekend). If an end-of-month date falls on a nonbusiness day or NYSE holiday, returns the last business day of the month.<br><br>NYSE market closures, holidays, and weekends are observed if AltHolidays and Weekend are not supplied or empty ( []). |
| DateFilter                                                                                                                        | Absolute        | (Default) Returns all annual dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.<br><br><b>Note</b> The default is to create a time series with every date at the specified periodicity, which is with DateFilter = Absolute. If you use DateFilter = Relative, the endpoint effects do not apply since only your data defines which dates appear in the output time series object.                           |
| DateFilter                                                                                                                        | Relative        | Returns only the annual dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.                                                                                                                                                                                                                                                                                                                                                        |
| ED                                                                                                                                | 0               | Annual period ends on the last day or last business day of the month.                                                                                                                                                                                                                                                                                                                                                                                    |
| ED                                                                                                                                | 1 - 31          | Specifies a particular annual day. Months that do not contain the specified day return the last day (or last business day) of the month (for example, ED = 31 does not exist for February.)                                                                                                                                                                                                                                                              |
| EM                                                                                                                                | 1 - 12          | (Default) The annual period ends on the last day (or last business day) of the specified month. All subsequent annual dates are calculated from this month. Default annual month is December (12).                                                                                                                                                                                                                                                       |

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EndPtTol       | [Begin, End]    | <p>Denotes the minimum number of days that constitute an odd annual period at the endpoints of the time series (before the first-time series date and after the last end-of-year date).</p> <p>Begin and End must be -1 or any positive integer greater than or equal to 0.</p> <p>A single value input for 'EndPtTol' is the same as specifying that single value for Begin and End.</p> <p>-1 Exclude odd annual period dates and data from calculations.</p> <p>0 (Default) Include odd annual period dates and data in calculations.</p> <p>n Number of days (any positive integer) that constitute an odd annual period. If there are insufficient days for a complete year, the endpoint data is ignored.</p> |

The following diagram is a general depiction of the factors involved in the determination of endpoints for this function.

|             |       |                                                                                                                                                                                                                                          |
|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TimeSpec    | First | Returns only the observation that occurs at the first (earliest) time for a specific date.                                                                                                                                               |
| TimeSpec    | Last  | (Default) Returns only the observation that occurs at the last (latest) time for a specific date.                                                                                                                                        |
| AltHolidays |       | Vector of dates specifying an alternate set of market closure dates.                                                                                                                                                                     |
| AltHolidays | -1    | Excludes all holidays.                                                                                                                                                                                                                   |
| Weekend     |       | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend = [1 0 0 0 0 0 1]. |

## Examples

## Transform Time Series Object from Weekly to Annual Values

This example shows how to transform a time series object from weekly to annual values.

Load the data from the file `predict_ret_data.mat` and use the `fints` function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see ["mat"](#)

x0 =

```
desc: Index
freq: Weekly (2)

# todayly

Convert to daily

---

**Note** `todayly` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = todayly(oldfts)
```

```
newfts = todayly(oldfts,'ParameterName',ParameterValue, ...)
```

## Arguments

|                     |                              |
|---------------------|------------------------------|
| <code>oldfts</code> | Financial time series object |
|---------------------|------------------------------|

## Description

`newfts = todayly(oldfts)` converts a financial time series of any frequency to a daily frequency. `todayly` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as '00:00' for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `todayly` trigger the use of the defaults.

---

`newfts = todayly(oldfts,'ParameterName',ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name                                                                                                                                               | Parameter Value    | Description                                                                                                                                                                |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>CalcMethod</code>                                                                                                                                      | <code>Exact</code> | Returns the value at specific dates/times. No data manipulation occurs.                                                                                                    |
| <code>CalcMethod</code>                                                                                                                                      | <code>v21x</code>  | This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns a five-day business week that starts on Monday and ends on Friday. |
| <b>Note</b> If you set <code>CalcMethod</code> to <code>v21x</code> , settings for all the following parameter name/parameter value pairs are not supported. |                    |                                                                                                                                                                            |
| <code>BusDays</code>                                                                                                                                         | <code>0</code>     | Generates a financial time series that ranges from (or between) the first date to the last date in <code>oldfts</code> (includes NYSE nonbusiness days and holidays).      |

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BusDays        | 1               | (Default) Generates a daily financial time series that ranges from the first date to the last date in <code>oldfts</code> (excludes NYSE nonbusiness days and holidays and weekends based on <code>AltHolidays</code> and <code>Weekend</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DateFilter     | Absolute        | <p>NYSE market closures, holidays, and weekends are observed if <code>AltHolidays</code> and <code>Weekend</code> are not supplied or empty (<code>[]</code>).</p> <p>(Default) Displays all daily dates between the start and end dates of <code>oldfts</code>. Some dates may be disregarded if <code>BusDays = 1</code>.</p> <hr/> <p><b>Note</b> The default is to create a time series with every date at the specified periodicity, which is with <code>DateFilter = Absolute</code>. If you use <code>DateFilter = Relative</code>, the endpoint effects do not apply since only your data defines which dates appear in the output time series object.</p> |
| DateFilter     | Relative        | Displays only dates that exist in <code>oldfts</code> . Some dates may be disregarded if <code>BusDays = 1</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| TimeSpec       | First           | Returns only the observation that occurs at the first (earliest) time for a specific date.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| TimeSpec       | Last            | (Default) Returns only the observation that occurs at the last (latest) time for a specific date.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| AltHolidays    |                 | Vector of dates specifying an alternate set of market closure dates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| AltHolidays    | -1              | Excludes all holidays.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Weekend        |                 | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then <code>Weekend = [1 0 0 0 0 0 1]</code> .                                                                                                                                                                                                                                                                                                                                                                                                             |

## Examples

### Transform Time Series Object from Weekly to Daily Values

Load the data from the file `predict_ret_data.mat` and use the `fints` function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
x0 =
    desc: Index
```

freq: Weekly (2)

```

{'dates: (53)'}      {'Metric: (53)'}
{'01-Jan-1999' }    {[      97.8872]}
{'08-Jan-1999' }    {[      97.0847]}

# today

Current date

## Syntax

```
Date = today
Date = today(outputType)
```

## Description

`Date = today` returns the current date as a serial date number.

`Date = today(outputType)` returns the current date using an optional `outputType`. The type of output is determined by an optional `outputType` variable input.

## Examples

### Return the Current Date

Use `today` to return the current date with the default serial date number.

```
Date = today
Date = 737850
```

Use the optional argument `outputType` to return a datetime array.

```
Date = today('datetime')
Date = datetime
      29-Feb-2020
```

## Input Arguments

### **outputType** — Type of output

'datenum' (default) | character vector with values 'datetime' or 'datenum'

Type of output, specified as a character vector with values 'datetime' or 'datenum'.

If `outputType` is 'datenum', then `Date` is a serial date number. If `outputType` is 'datetime', then `Date` is a datetime array. By default, `outputType` is 'datenum'.

Data Types: char

## Output Arguments

### **Date** — Current date

serial date number or datetime array

Current date, returned as a serial date number or datetime array, depending on the optional input argument `outputType`.

# todecimal

Fractional to decimal conversion

## Syntax

```
usddec = todecimal(quote,fracpart)
```

## Description

`usddec = todecimal(quote,fracpart)` returns the decimal equivalent, `usddec`, of a security whose price is normally quoted as a whole number and a fraction (`quote`). `fracpart` indicates the fractional base (denominator) with which the security is normally quoted (default = 32).

## Examples

In the *Wall Street Journal*, bond prices are quoted in fractional form based on a denominator of 32. For example, if you see the quoted price is 100:05 it means 100 5/32. To find the equivalent decimal value, enter

```
usddec = todecimal(100.05)
```

```
usddec =  
100.1563
```

```
usddec = todecimal(97.04, 16)
```

```
usddec =  
97.2500
```

---

**Note** The convention of using . (period) as a substitute for : (colon) in the input is adopted from Excel software.

## tomonthly

Convert to monthly

---

**Note** `tomonthly` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = tomonthly(oldfts)
```

```
newfts = tomonthly(oldfts, 'ParameterName', ParameterValue, ...)
```

### Arguments

|                     |                               |
|---------------------|-------------------------------|
| <code>oldfts</code> | Financial time series object. |
|---------------------|-------------------------------|

### Description

`newfts = tomonthly(oldfts)` converts a financial time series of any frequency to a monthly frequency. The default end-of-month day is the last business day of the month. `tomonthly` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as `00:00` for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `tomonthly` triggers the use of the defaults.

---

`newfts = tomonthly(oldfts, 'ParameterName', ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name | Parameter Value | Description                                                                                                                                                        |
|----------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalcMethod     | CumSum          | Returns the cumulative sum of the values within each month. Data for missing dates are given the value 0.                                                          |
|                | Exact           | Returns the exact value at the end-of-month date. No data manipulation occurs.                                                                                     |
|                | Nearest         | (Default) Returns the values located at the end-of-month date. If there is missing data, 'Nearest' returns the nearest data point preceding the end-of-month date. |
|                | SimpAvg         | Returns an averaged monthly value that only takes into account dates with data (non-NaN) within each month.                                                        |

| Parameter Name                                                                                                                    | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                   | v21x            | This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-month value using a previous tomonthly algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.                                                                                                                                                  |
| <b>Note</b> If you set CalcMethod to v21x, settings for all the following parameter name/parameter value pairs are not supported. |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| BusDays                                                                                                                           | 0               | Generates a monthly financial time series that ranges from the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).                                                                                                                                                                                                                                                                                                      |
|                                                                                                                                   | 1               | (Default) Generates a monthly financial time series that ranges from the first date to the last date in oldfts (excludes NYSE nonbusiness days and holidays and weekends based on AltHolidays and Weekend). If an end-of-month date falls on a nonbusiness day or NYSE holiday, returns the last business day of the month.<br><br>NYSE market closures, holidays, and weekends are observed if AltHolidays and Weekend are not supplied or empty ( []). |
| DateFilter                                                                                                                        | Absolute        | (Default) Returns all monthly dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.<br><br><b>Note</b> The default is to create a time series with every date at the specified periodicity, which is with DateFilter = Absolute. If you use DateFilter = Relative, the endpoint effects do not apply since only your data defines which dates appear in the output time series object.                          |
|                                                                                                                                   | Relative        | Returns only monthly dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.                                                                                                                                                                                                                                                                                                                                                           |
| ED                                                                                                                                | 0               | (Default) The end-of-month date is the last day (or last business day) of the month.                                                                                                                                                                                                                                                                                                                                                                     |
|                                                                                                                                   | 1 - 31          | Returns values on the specified end-of-month day. Months that do not contain the specified end-of-month day return the last day of the month instead (for example, ED = 31 does not exist for February).<br><br>If end-of-month falls on a NYSE non-business day or holiday, the previous business day is returned if BusDays = 1.                                                                                                                       |

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EndPtTol       | [Begin, End]    | <p>Denotes the minimum number of days that constitute an odd month at the end points of the time series (before the first whole period and after the last whole period).</p> <p>Begin and End must be -1 or any positive integer greater than or equal to 0.</p> <p>A single value input for EndPtTol is the same as specifying that single value for Begin and End.</p> <p>-1 Do not include odd month dates and data in calculations.</p> <p>0 (Default) Include all odd month dates and data in calculations.</p> <p>n Number of days that constitute an odd month. If the minimum number of days is not met, the odd month dates and data are ignored.</p> |

The following diagram is a general depiction of the factors involved in the determination of end points for this function.

|             |       |                                                                                                                                                                                                                                          |
|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TimeSpec    | First | Returns only the observation that occurs at the first (earliest) time for a specific date.                                                                                                                                               |
|             | Last  | (Default) Returns only the observation that occurs at the last (latest) time for a specific date.                                                                                                                                        |
| AltHolidays |       | Vector of dates specifying an alternate set of market closure dates.                                                                                                                                                                     |
|             | -1    | Excludes all holidays.                                                                                                                                                                                                                   |
| Weekend     |       | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend = [1 0 0 0 0 0 1]. |

## Examples

## Transform Time Series Object from Weekly to Monthly Values

This example shows how to transform a time series object from weekly to monthly values.

Load the data from the file `predict_ret_data.mat` and use the `fints` function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [<a href="mat](#)

```
x0 =
```

```
desc: Index
freq: Weekly (2)

# toquarterly

Convert to quarterly

---

**Note** `toquarterly` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = toquarterly(oldfts)
```

```
newfts = toquarterly(oldfts,'ParameterName',ParameterValue, ...)
```

## Arguments

|                     |                              |
|---------------------|------------------------------|
| <code>oldfts</code> | Financial time series object |
|---------------------|------------------------------|

## Description

`newfts = toquarterly(oldfts)` converts a financial time series of any frequency to a quarterly frequency. The default quarterly days are the last business day of March, June, September, and December. `toquarterly` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as `00:00` for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `toquarterly` triggers the use of the defaults.

---

`newfts = toquarterly(oldfts,'ParameterName',ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name | Parameter Value | Description                                                                                                                                                                       |
|----------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalcMethod     | CumSum          | Returns the cumulative sum of the values between each quarter. Data for missing dates are given the value 0.                                                                      |
|                | Exact           | Returns the exact value at the end-of-quarter date. No data manipulation occurs.                                                                                                  |
|                | Nearest         | (Default) Returns the values located at the end-of-quarter date. If there is missing data, <code>Nearest</code> returns the nearest data point preceding the end-of-quarter date. |
|                | SimpAvg         | Returns an averaged quarterly value that only takes into account dates with data (non- <code>NaN</code> ) within each quarter.                                                    |

| Parameter Name                                                                                                                                 | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                                | v21x            | This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-quarter value using a previous <code>toquarterly</code> algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.                                                                                                                                                                                              |
| <b>Note</b> If you set <code>CalcMethod</code> to v21x, settings for all the following parameter name/parameter value pairs are not supported. |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| BusDays                                                                                                                                        | 0               | Generates a financial time series that ranges from (or between) the first date to the last date in <code>oldfts</code> (includes NYSE nonbusiness days and holidays).                                                                                                                                                                                                                                                                                                                                                 |
|                                                                                                                                                | 1               | (Default) Generates a financial time series that ranges from the first date to the last date in <code>oldfts</code> (excludes NYSE nonbusiness days and holidays and weekends based on <code>AltHolidays</code> and <code>Weekend</code> ). If an end-of-quarter date falls on a nonbusiness day or NYSE holiday, returns the last business day of the quarter.<br><br>NYSE market closures, holidays, and weekends are observed if <code>AltHolidays</code> and <code>Weekend</code> are not supplied or empty ({}). |
| DateFilter                                                                                                                                     | Absolute        | (Default) Returns all quarterly dates between the start and end dates of <code>oldfts</code> . Some dates may be disregarded if <code>BusDays = 1</code> .                                                                                                                                                                                                                                                                                                                                                            |
|                                                                                                                                                | Relative        | <b>Note</b> The default is to create a time series with every date at the specified periodicity, which is with <code>DateFilter = Absolute</code> . If you use <code>DateFilter = Relative</code> , the endpoint effects do not apply since only your data defines which dates appear in the output time series object.                                                                                                                                                                                               |
| ED                                                                                                                                             | 0               | (Default) The end-of-quarter date is the last day (or last business day) of the quarter.                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                                                                                                                                                | 1 - 31          | Specifies a particular end-of-quarter day. Months that do not contain the specified end-of-quarter day return the last day of the quarter instead (for example, <code>ED = 31</code> does not exist for February).                                                                                                                                                                                                                                                                                                    |
| EM                                                                                                                                             | 1 - 12          | Last month of the first quarter. All subsequent quarterly dates are based on this month. The default end-of-first-quarter month is March (3).                                                                                                                                                                                                                                                                                                                                                                         |

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EndPtTol       | [Begin, End]    | <p>Denotes the minimum number of days that constitute an odd quarter at the endpoints of the time series (before the first whole period and after the last whole period).</p> <p>Begin and End must be -1 or any positive integer greater than or equal to 0.</p> <p>A single value input for EndPtTol is the same as specifying that single value for Begin and End.</p> <p>-1 Do not include odd quarter dates and data in calculations.</p> <p>0 (Default) Include all odd quarter dates and data in calculations.</p> <p>n Number of days (any positive integer) that constitute an odd quarter. If there are insufficient days for a complete quarter, the odd quarter dates and data are ignored.</p> |

The following diagram is a general depiction of the factors involved in the determination of endpoints for this function.

|             |       |                                                                                                                                                                                                                                          |
|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TimeSpec    | First | Returns only the observation that occurs at the first (earliest) time for a specific date.                                                                                                                                               |
|             | Last  | (Default) Returns only the observation that occurs at the last (latest) time for a specific date.                                                                                                                                        |
| AltHolidays |       | Vector of dates specifying an alternate set of market closure dates.                                                                                                                                                                     |
|             | -1    | Excludes all holidays.                                                                                                                                                                                                                   |
| Weekend     |       | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend = [1 0 0 0 0 0 1]. |

## Examples

## Transform Time Series Object from Weekly to Quarterly Values

This example shows how to transform a time series object from weekly to quarterly values.

Load the data from the file `predict_ret_data.mat` and use the `fints` function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
x0 =
```

```
desc: Index
freq: Weekly (2)
```

```

## toquoted

Decimal to fractional conversion

### Syntax

```
quote = toquoted(usddec,fracpart)
```

### Description

`quote = toquoted(usddec,fracpart)` returns the fractional equivalent, `quote`, of the decimal figure, `usddec`, based on the fractional base (denominator), `fracpart`. The fractional bases are the ones used for quoting equity prices in the United States (denominator 2, 4, 8, 16, or 32). If `fracpart` is not entered, the denominator 32 is assumed.

### Examples

A United States equity price in decimal form is 101.625. To convert this to fractional form in eighths of a dollar:

```
quote = toquoted(101.625, 8)
```

```
quote =  
    101.05
```

The answer is interpreted as 101 5/8.

---

**Note** The convention of using . (period) as a substitute for : (colon) in the output is adopted from Excel software.

# tosemi

Convert to semiannual

---

**Note** `tosemi` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to `Timetables`”.

---

## Syntax

```
newfts = tosemi(oldfts)
```

```
newfts = tosemi(oldfts,'ParameterName',ParameterValue, ...)
```

## Arguments

|                     |                               |
|---------------------|-------------------------------|
| <code>oldfts</code> | Financial time series object. |
|---------------------|-------------------------------|

## Description

`newfts = tosemi(oldfts)` converts a financial time series of any frequency to a semiannual frequency. The default semiannual days are the last business day of June and December. `tosemi` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as `00:00` for those days that did not previously exist in `oldfts`.

---

Empty (`[]`) passed as inputs for parameter pair values for `tosemi` triggers the use of the defaults.

---

`newfts = tosemi(oldfts,'ParameterName',ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name | Parameter Value | Description                                                                                                                                                                     |
|----------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalcMethod     | CumSum          | Returns the cumulative sum of the values within each semiannual period. Data for missing dates are given the value 0.                                                           |
|                | Exact           | Returns the exact value at the end-of-period date. No data manipulation occurs.                                                                                                 |
|                | Nearest         | (Default) Returns the values located at the end-of-period date. If there is missing data, <code>Nearest</code> returns the nearest data point preceding the end-of-period date. |
|                | SimpAvg         | Returns an averaged semiannual value that only takes into account dates with data (non- <code>NaN</code> ) within each semiannual period.                                       |

| Parameter Name                                                                                                                    | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------------------------------------------------------------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                   | v21x            | This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-period value using a previous tosemi algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.                                                                                                                                                |
| <b>Note</b> If you set CalcMethod to v21x, settings for all the following parameter name/parameter value pairs are not supported. |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| BusDays                                                                                                                           | 0               | Generates a financial time series that ranges from (or between) the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).                                                                                                                                                                                                                                                                                             |
|                                                                                                                                   | 1               | (Default) Generates a financial time series that ranges from the first date to the last date in oldfts (excludes NYSE nonbusiness days and holidays and weekends based on AltHolidays and Weekend). If an end-of-quarter date falls on a nonbusiness day or NYSE holiday, returns the last business day of the quarter.<br><br>NYSE market closures, holidays, and weekends are observed if AltHolidays and Weekend are not supplied or empty ( []). |
| DateFilter                                                                                                                        | Absolute        | (Default) Returns all semiannual dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.<br><br><b>Note</b> The default is to create a time series with every date at the specified periodicity, which is with DateFilter = Absolute. If you use DateFilter = Relative, the endpoint effects do not apply since only your data defines which dates appear in the output time series object.                   |
|                                                                                                                                   | Relative        | Returns only semiannual dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.                                                                                                                                                                                                                                                                                                                                                    |
| ED                                                                                                                                | 0               | (Default) The end-of-period date is the last day (or last business day) of the semiannual period.                                                                                                                                                                                                                                                                                                                                                    |
|                                                                                                                                   | 1 - 31          | Specifies a particular end-of-period day. Months that do not contain the specified end-of-period day return the last day of the semiannual period instead (for example, ED = 31 does not exist for February).                                                                                                                                                                                                                                        |
| EM                                                                                                                                | 1 - 12          | End month of the first semiannual period. All subsequent period dates are based on this month. The default end-of-period months are June (6) and December (12).                                                                                                                                                                                                                                                                                      |

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EndPtTol       | [Begin, End]    | <p>Denotes the minimum number of days that constitute an odd semiannual period at the endpoints of the time series (before the first whole period and after the last whole period).</p> <p>Begin and End must be -1 or any positive integer greater than or equal to 0.</p> <p>A single value input for EndPtTol is the same as specifying that single value for Begin and End.</p> <p>-1 Do not include odd period dates and data in calculations.</p> <p>0 (Default) Include all odd period dates and data in calculations.</p> <p>n Number of days (any positive integer) that constitute an odd period. If there are insufficient days for a complete semiannual period, the odd period dates and data are ignored.</p> |

The following diagram is a general depiction of the factors involved in the determination of endpoints for this function.

|             |       |                                                                                                                                                                                                                                          |
|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TimeSpec    | First | Returns only the observation that occurs at the first (earliest) time for a specific date.                                                                                                                                               |
|             | Last  | (Default) Returns only the observation that occurs at the last (latest) time for a specific date.                                                                                                                                        |
| AltHolidays |       | Vector of dates specifying an alternate set of market closure dates.                                                                                                                                                                     |
|             | -1    | Excludes all holidays.                                                                                                                                                                                                                   |
| Weekend     |       | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend = [1 0 0 0 0 0 1]. |

## Examples

## Transform Time Series Object from Weekly to Semiannual Values

This example shows how to transform a time series object from weekly to semiannual values.

Load the data from the file `predict_ret_data.mat` and then use the `fints` function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
x0 =
```

```
desc: Index
freq: Weekly (2)
```

```
{'dates: (53)'} {'Metric: (53)'}
{'01-Jan-1999'} {[ 97.8872]}
{'08-Jan-1999'} {[ 97.0847]}
{'15-Jan-1999'} {[ 109.6312]}
{'22-Jan-1999'} {[ 105.5743]}
{'29-Jan-1999'} {[ 108.4028]}
{'05-Feb-1999'} {[ 134.4882]}
{'12-Feb-1999'} {[ 117.5581]}
{'19-Feb-1999'} {[ 106.6683]}
{'26-Feb-1999'} {[ 118.2912]}
{'05-Mar-1999'} {[ 105.6835]}
{'12-Mar-1999'} {[ 128.5836]}
{'19-Mar-1999'} {[ 115.1746]}
{'26-Mar-1999'} {[ 131.2854]}
{'02-Apr-1999'} {[ 130.7116]}
{'09-Apr-1999'} {[ 123.1684]}
{'16-Apr-1999'} {[ 107.2975]}
{'23-Apr-1999'} {[ 91.5625]}
{'30-Apr-1999'} {[ 78.5738]}
{'07-May-1999'} {[ 65.2904]}
{'14-May-1999'} {[ 70.8581]}
{'21-May-1999'} {[ 72.4807]}
{'28-May-1999'} {[ 72.9190]}
{'04-Jun-1999'} {[ 64.3460]}
{'11-Jun-1999'} {[ 59.8743]}
{'18-Jun-1999'} {[ 55.0026]}
{'25-Jun-1999'} {[ 49.4032]}
{'02-Jul-1999'} {[ 49.9485]}
{'09-Jul-1999'} {[ 47.8061]}
{'16-Jul-1999'} {[ 61.0517]}
{'23-Jul-1999'} {[ 58.9313]}
{'30-Jul-1999'} {[ 53.9584]}
{'06-Aug-1999'} {[ 44.8472]}
{'13-Aug-1999'} {[ 45.0463]}
{'20-Aug-1999'} {[ 45.1088]}
{'27-Aug-1999'} {[ 56.4897]}
{'03-Sep-1999'} {[ 61.2449]}
{'10-Sep-1999'} {[ 58.1012]}
{'17-Sep-1999'} {[ 50.8974]}
{'24-Sep-1999'} {[ 46.5143]}
```

```

{'01-Oct-1999' } {[ 38.0806]}
{'08-Oct-1999' } {[ 33.6664]}
{'15-Oct-1999' } {[ 34.2992]}
{'22-Oct-1999' } {[ 33.4202]}
{'29-Oct-1999' } {[ 36.9287]}
{'05-Nov-1999' } {[ 35.1278]}
{'12-Nov-1999' } {[ 41.8128]}
{'19-Nov-1999' } {[ 35.8199]}
{'26-Nov-1999' } {[ 36.9495]}
{'03-Dec-1999' } {[ 36.2880]}
{'10-Dec-1999' } {[ 33.8457]}
{'17-Dec-1999' } {[ 33.3868]}
{'24-Dec-1999' } {[ 32.7737]}
{'31-Dec-1999' } {[ 28.5665]}

```

Use `tosemi` to obtain the semiannual aggregate for the `x0` times series.

```
x1 = tosemi(x0)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
x1 =
```

```

desc: TOSEMI: Index
freq: Semiannual (5)

{'dates: (2)'} {'Metric: (2)'}
{'30-Jun-1999'} {[ 49.4032]}
{'31-Dec-1999'} {[ 28.5665]}

```

## Introduced before R2006a

## totalreturnprice

Total return price time series

### Syntax

Return = totalreturnprice(Price,Action,Dividend)

### Description

Return = totalreturnprice(Price,Action,Dividend) generates a total return price time series given price data, action or split data, and dividend data. All input data is unadjusted.

### Examples

#### Compute Return Using datetime Input for Price and Action

Compute Return returned as a table using datetime input in tables for Price and Action.

```
act = [732313, 2; 732314 ,2];
div = [732313, 0.0800; 732314, 0.0800];
prc = [732313, 12; 732314, 13];

prcTableDateTime=table(datetime(prc(:,1),'ConvertFrom','datenum'),prc(:,2));
acttableString=table(datestr(act(:,1)),act(:,2));
divTableNum = array2table(div);
Return = totalreturnprice(prcTableDateTime,acttableString,divTableNum)
```

Return=2×2 table

| Date        | Return |
|-------------|--------|
| 01-Jan-2005 | 1      |
| 02-Jan-2005 | 1.0833 |

### Input Arguments

#### Price — Price of security

matrix | table

Price of security, specified as a table or an NUMOBS-by-2 matrix. If Price is a table, the dates can either be serial date numbers, date character vectors, or datetime arrays. If Price is an NUMOBS-by-2 matrix of price data, column 1 contains MATLAB serial date numbers and column 2 contains price values.

Data Types: double | table

#### Action — Action or split data

matrix | table

Action or split data, specified as a table or an NUMOBS-by-2 matrix. If Action is a table, the dates can either be serial date numbers, date character vectors, or datetime arrays. If Action is an NUMOBS-by-2 matrix of price data, column 1 contains MATLAB serial date numbers and column 2 contains split ratios.

Data Types: double | table

### **Dividend — Dividend payouts**

matrix | table

Dividend payouts, specified as a table or an NUMOBS-by-2 matrix. If Dividend is a table, the dates can either be serial date numbers, date character vectors, or datetime arrays. If Dividend is a NUMOBS-by-2 matrix of price data, column 1 contains MATLAB serial date numbers and column 2 contains dividend payouts.

Data Types: double | table

## **Output Arguments**

### **Return — Total return price time series**

matrix | table

Total return price time series, returned as a NUMOBS-by-2 matrix (if all inputs are matrices) or table (if any inputs are tables) of price data, where column 1 is dates and column 2 is total return price values. Dates in column 1 are in datetime format if any inputs specify dates in datetime format. Dates in column 1 are in date character vector format if no inputs specify dates in datetime format, but any of them use date character vector format. Otherwise, dates in column 1 are specified as serial date numbers.

## tweekly

Convert to weekly

---

**Note** `tweekly` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to `Timetables`”.

---

### Syntax

```
newfts = tweekly(oldfts)
```

```
newfts = tweekly(oldfts,'ParameterName',ParameterValue, ...)
```

### Arguments

|                     |                               |
|---------------------|-------------------------------|
| <code>oldfts</code> | Financial time series object. |
|---------------------|-------------------------------|

### Description

`newfts = tweekly(oldfts)` converts a financial time series of any frequency to a weekly frequency. The default weekly days are Fridays or the last business day of the week. `tweekly` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as `00:00` for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `tweekly` triggers the use of the defaults.

---

`newfts = tweekly(oldfts,'ParameterName',ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name | Parameter Value | Description                                                                                                                                                                  |
|----------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalcMethod     | CumSum          | Returns the cumulative sum of the values within each week. Data for missing dates are given the value <code>0</code> .                                                       |
|                | Exact           | Returns the exact value at the end-of-week dates. No data manipulation occurs.                                                                                               |
|                | Nearest         | (Default) Returns the values located at the end-of-week dates. If there is missing data, <code>Nearest</code> returns the nearest data point preceding the end-of-week date. |
|                | SimpAvg         | Returns an averaged weekly value that only takes into account dates with data (non- <code>NaN</code> ) within each week.                                                     |

| AltHolidays    |                 | Vector of dates specifying an alternate set of market closure dates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

The following diagram is a general depiction of the factors involved in the determination of endpoints for this function.

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                              |
|----------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | -1              | Excludes all holidays.                                                                                                                                                                                                                   |
| Weekend        |                 | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend = [1 0 0 0 0 0 1]. |

## Examples

### Transform Time Series Object from Quarterly to Weekly Values

This example shows how to transform a time series object from quarterly to weekly values.

Load the data from the file `predict_ret_data.mat` and use the `fints` function to create a time series object with a quarterly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'q', 'Index')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
x0 =
```

```
desc: Index
freq: Quarterly (4)

## tr2bonds

Term-structure parameters given Treasury bond parameters

### Syntax

```
[Bonds,Prices,Yields] = tr2bonds(TreasuryMatrix,Settle)
[Bonds,Prices,Yields] = tr2bonds( ___,Settle)
```

### Description

[Bonds,Prices,Yields] = tr2bonds(TreasuryMatrix,Settle) returns term-structure parameters (Bonds, Prices, and Yields) sorted by ascending maturity date, given Treasury bond parameters. The formats of the output matrix and vectors meet requirements for input to the zbtprice and zbtyield zero-curve bootstrapping functions.

[Bonds,Prices,Yields] = tr2bonds( \_\_\_,Settle) adds an optional argument for Settle.

### Examples

#### Return Term-Structure Parameters Given Treasury Bond Parameters

This example shows how to return term-structure parameters (bond information, prices, and yields) sorted by ascending maturity date, given Treasury bond market parameters for December 22, 1997.

```
Matrix =[0.0650 datenum('15-apr-1999') 101.03125 101.09375 0.0564
         0.05125 datenum('17-dec-1998') 99.4375 99.5 0.0563
         0.0625 datenum('30-jul-1998') 100.3125 100.375 0.0560
         0.06125 datenum('26-mar-1998') 100.09375 100.15625 0.0546];
```

```
[Bonds, Prices, Yields] = tr2bonds(Matrix)
```

```
Bonds = 4×6

## Return Term-Structure Parameters Given Treasury Bond Parameters Using datetime Input

This example shows how to use `datetime` input to return term-structure parameters (bond information, prices, and yields) sorted by ascending maturity date, given Treasury bond market parameters for December 22, 1997.

```
Matrix =[0.0650 datenum('15-apr-1999') 101.03125 101.09375 0.0564
         0.05125 datenum('17-dec-1998') 99.4375 99.5 0.0563
         0.0625 datenum('30-jul-1998') 100.3125 100.375 0.0560
         0.06125 datenum('26-mar-1998') 100.09375 100.15625 0.0546];
```

```
t=array2table(Matrix);
t.Matrix2=datetime(t{:,2},'ConvertFrom','datenum','Locale','en_US');
[Bonds, Prices, Yields] = tr2bonds(t,datetime('1-Jan-1997','Locale','en_US'))
```

Bonds=4×6 table

## Input Arguments

### TreasuryMatrix — Treasury bond parameters

table | matrix

Treasury bond parameters, specified as a 5-column table or a NumBonds-by-5 matrix of bond information where the table columns or matrix columns contains:

- **CouponRate** (Required) Coupon rate of the Treasury bond, specified as a decimal indicating the coupon rates for each bond in the portfolio.
- **Maturity** (Required) Maturity date of the Treasury bond, specified as a serial date number when using a matrix. Use `datenum` to convert date character vectors to serial date numbers. If the input `TreasuryMatrix` is a table, the **Maturity** dates can be serial date numbers, date character vectors, or datetime arrays.
- **Bid** (Required) Bid prices, specified using an integer-decimal form for each bond in the portfolio.
- **Asked** (Required) Asked prices, specified using an integer-decimal form for each bond in the portfolio.
- **AskYield** (Required) Quoted ask yield, specified using a decimal form for each bond in the portfolio.

Data Types: `double` | `table`

### **Settle — Settlement date of Treasury bond**

`serial date number` | `date character vector` | `datetime`

(Optional) Settlement date of the Treasury bond, specified as a scalar or a NINST-by-1 vector of serial date numbers, date character vectors, or datetime arrays. The **Settle** date must be before the **Maturity** date.

Data Types: `double` | `char` | `datetime`

## **Output Arguments**

### **Bonds — Coupon bond information**

`numeric`

Coupon bond information, returned as a table or matrix depending on the `TreasuryMatrix` input.

When `TreasuryMatrix` is a table, **Bonds** is also a table, and the variable type for the **Maturity** dates in **Bonds** (column 1) matches the variable type for **Maturity** in `TreasuryMatrix`.

When `TreasuryMatrix` input is a n-by-5 matrix, then each row describes a bond.

The parameters or columns returned for **Bonds** are:

- **Maturity** (Column 1) Maturity date for each bond in the portfolio as a serial date number. The format of the dates matches the format used for **Maturity** in `TreasuryMatrix` (serial date number, date character vector, or datetime array).
- **CouponRate** (Column 2) Coupon rate for each bond in the portfolio in decimal form.
- **Face** (Column 3, Optional) Face or par value for each bond in the portfolio. The default is 100.
- **Period** (Column 4, Optional) Number of coupon payments per year for each bond in the portfolio with allowed values: 1, 2, 3, 4, 6, and 12. The default is 2, unless you are dealing with zero coupons, then **Period** is 0 instead of 2.
- **Basis** (Column 5, Optional) Day-count basis for each bond in the portfolio with possible values:
  - 0 = actual/actual (default)
  - 1 = 30/360 (SIA)
  - 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252
- For more information, see “Basis” on page 2-18.
- `EndMonthRule` (Column 6, Optional) End-of-month rule flag for each bond in the portfolio. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on, meaning that a bond's coupon payment date is always the last actual day of the month. The default is 1.

### Prices — Bond prices

numeric

Bond prices, returned as a column vector containing the price of each bond in `Bonds`, respectively. The number of rows ( $n$ ) matches the number of rows in `Bonds`.

### Yields — Bond yields

numeric

Bond yields, returned as a column vector containing the yield to maturity of each bond in `Bonds`, respectively. The number of rows ( $n$ ) matches the number of rows in `Bonds`.

If the optional input argument `Settle` is used, `Yields` is computed as a semiannual yield to maturity. If the input `Settle` is not used, the quoted input yields are used.

### Introduced before R2006a

## transprob

Estimate transition probabilities from credit ratings data

### Syntax

```
[transMat,sampleTotals,idTotals] = transprob(data)
[transMat,sampleTotals,idTotals] = transprob( ___,Name,Value)
```

### Description

[transMat,sampleTotals,idTotals] = transprob(data) constructs a transition matrix from historical data of credit ratings.

[transMat,sampleTotals,idTotals] = transprob( \_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Construct a Transition Matrix From a Table of Historical Data of Credit Ratings

Using the historical credit rating table as input data from `Data_TransProb.mat` display the first ten rows and compute the transition matrix:

```
load Data_TransProb
data(1:10,:)
```

```
ans=10x3 table
      ID          Date          Rating
      ---          ---          ---
    {'00010283'} {'10-Nov-1984'} {'CCC'}
    {'00010283'} {'12-May-1986'} {'B'  }
    {'00010283'} {'29-Jun-1988'} {'CCC'}
    {'00010283'} {'12-Dec-1991'} {'D'  }
    {'00013326'} {'09-Feb-1985'} {'A'  }
    {'00013326'} {'24-Feb-1994'} {'AA' }
    {'00013326'} {'10-Nov-2000'} {'BBB'}
    {'00014413'} {'23-Dec-1982'} {'B'  }
    {'00014413'} {'20-Apr-1988'} {'BB' }
    {'00014413'} {'16-Jan-1998'} {'B'  }
```

```
% Estimate transition probabilities with default settings
transMat = transprob(data)
```

```
transMat = 8x8

    93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017

     0.1237    2.9003   92.2197    4.0756    0.5365    0.0661    0.0028    0.0753
```

```

0.0236    0.2312    5.0059    90.1846    3.7979    0.4733    0.0642    0.2193
0.0216    0.1134    0.6357    5.7960    88.9866    3.4497    0.2919    0.7050
0.0010    0.0062    0.1081    0.8697    7.3366    86.7215    2.5169    2.4399
0.0002    0.0011    0.0120    0.2582    1.4294    4.2898    81.2927    12.7167
      0          0          0          0          0          0          0    100.0000

```

Using the historical credit rating table input data from `Data_TransProb.mat`, compute the transition matrix using the cohort algorithm:

```

%Estimate transition probabilities with 'cohort' algorithm
transMatCoh = transprob(data,'algorithm','cohort')

```

```
transMatCoh = 8x8
```

```

93.1345    5.9335    0.7456    0.1553    0.0311         0         0         0
 1.7359   92.9198    4.5446    0.6046    0.1560         0         0    0.0390
 0.1268    2.9716   91.9913    4.3124    0.4711    0.0544         0    0.0725
 0.0210    0.3785    5.0683   89.7792    4.0379    0.4627    0.0421    0.2103
 0.0221    0.1105    0.6851    6.2320   88.3757    3.6464    0.2873    0.6409
      0          0    0.0761    0.7230    7.9909   86.1872    2.7397    2.2831
      0          0          0    0.3094    1.8561    4.5630   80.8971   12.3743
      0          0          0          0          0          0         0    100.0000

```

Using the historical credit rating data with ratings investment grade ('IG'), speculative grade ('SG'), and default ('D'), from `Data_TransProb.mat` display the first ten rows and compute the transition matrix:

```
dataIGSG(1:10,:)
```

```
ans=10x3 table
```

| ID           | Date            | Rating |
|--------------|-----------------|--------|
| {'00011253'} | {'04-Apr-1983'} | {'IG'} |
| {'00012751'} | {'17-Feb-1985'} | {'SG'} |
| {'00012751'} | {'19-May-1986'} | {'D' } |
| {'00014690'} | {'17-Jan-1983'} | {'IG'} |
| {'00012144'} | {'21-Nov-1984'} | {'IG'} |
| {'00012144'} | {'25-Mar-1992'} | {'SG'} |
| {'00012144'} | {'07-May-1994'} | {'IG'} |
| {'00012144'} | {'23-Jan-2000'} | {'SG'} |
| {'00012144'} | {'20-Aug-2001'} | {'IG'} |
| {'00012937'} | {'07-Feb-1984'} | {'IG'} |

```
transMatIGSG = transprob(dataIGSG,'labels',{'IG','SG','D'})
```

```
transMatIGSG = 3x3
```

```

98.6719    1.2020    0.1261
 3.5781   93.3318    3.0901
      0          0    100.0000

```

Using the historical credit rating data with numeric ratings for investment grade (1), speculative grade (2), and default (3), from `Data_TransProb.mat` display the first ten rows and compute the transition matrix:

```
dataIGSGnum(1:10,:)
ans=10x3 table
      ID          Date          Rating
  _____  _____  _____
 {'00011253'} {'04-Apr-1983'}      1
 {'00012751'} {'17-Feb-1985'}      2
 {'00012751'} {'19-May-1986'}      3
 {'00014690'} {'17-Jan-1983'}      1
 {'00012144'} {'21-Nov-1984'}      1
 {'00012144'} {'25-Mar-1992'}      2
 {'00012144'} {'07-May-1994'}      1
 {'00012144'} {'23-Jan-2000'}      2
 {'00012144'} {'20-Aug-2001'}      1
 {'00012937'} {'07-Feb-1984'}      1
```

```
transMatIGSGnum = transprob(dataIGSGnum,'labels',{1,2,3})
```

```
transMatIGSGnum = 3x3
```

```
98.6719    1.2020    0.1261
 3.5781    93.3318    3.0901
 0          0    100.0000
```

### Create a Transition Matrix Using a Cell Array for Historical Data of Credit Ratings

Using a MATLAB® table containing the historical credit rating cell array input data (dataCellFormat) from Data\_TransProb.mat, estimate the transition probabilities with default settings.

```
load Data_TransProb
transMat = transprob(dataCellFormat)
```

```
transMat = 8x8
```

```
93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017
 1.6166    93.1518    4.3632    0.6602    0.1626    0.0055    0.0004    0.0396
 0.1237    2.9003    92.2197    4.0756    0.5365    0.0661    0.0028    0.0753
 0.0236    0.2312    5.0059    90.1846    3.7979    0.4733    0.0642    0.2193
 0.0216    0.1134    0.6357    5.7960    88.9866    3.4497    0.2919    0.7050
 0.0010    0.0062    0.1081    0.8697    7.3366    86.7215    2.5169    2.4399
 0.0002    0.0011    0.0120    0.2582    1.4294    4.2898    81.2927    12.7167
 0          0          0          0          0          0          0    100.0000
```

Using the historical credit rating cell array input data (dataCellFormat), compute the transition matrix using the cohort algorithm:

```
%Estimate transition probabilities with 'cohort' algorithm
transMatCoh = transprob(dataCellFormat,'algorithm','cohort')
```

```
transMatCoh = 8x8
```

```

93.1345    5.9335    0.7456    0.1553    0.0311    0    0    0
1.7359    92.9198    4.5446    0.6046    0.1560    0    0    0.0390
0.1268    2.9716    91.9913    4.3124    0.4711    0.0544    0    0.0725
0.0210    0.3785    5.0683    89.7792    4.0379    0.4627    0.0421    0.2103
0.0221    0.1105    0.6851    6.2320    88.3757    3.6464    0.2873    0.6409
0    0    0.0761    0.7230    7.9909    86.1872    2.7397    2.2831
0    0    0    0.3094    1.8561    4.5630    80.8971    12.3743
0    0    0    0    0    0    0    100.0000

```

## Visualize Transitions Data for transprob

This example shows how to visualize credit rating transitions that are used as an input to the `transprob` function. The example also describes how the `transprob` function treats rating transitions when the company data starts after the start date of the analysis, or when the end date of the analysis is after the last transition observed.

### Sample Data

Set up fictitious sample data for illustration purposes.

```

data = {'ABC', '17-Feb-2015', 'AA';
        'ABC', '6-Jul-2017', 'A';
        'LMN', '12-Aug-2014', 'B';
        'LMN', '9-Nov-2015', 'CCC';
        'LMN', '7-Sep-2016', 'D';
        'XYZ', '14-May-2013', 'BB';
        'XYZ', '21-Jun-2016', 'BBB'};
data = cell2table(data, 'VariableNames', {'ID', 'Date', 'Rating'});
disp(data)

```

| ID      | Date            | Rating  |
|---------|-----------------|---------|
| {'ABC'} | {'17-Feb-2015'} | {'AA' } |
| {'ABC'} | {'6-Jul-2017' } | {'A' }  |
| {'LMN'} | {'12-Aug-2014'} | {'B' }  |
| {'LMN'} | {'9-Nov-2015' } | {'CCC'} |
| {'LMN'} | {'7-Sep-2016' } | {'D' }  |
| {'XYZ'} | {'14-May-2013'} | {'BB' } |
| {'XYZ'} | {'21-Jun-2016'} | {'BBB'} |

The `transprob` function understands that this panel-data format indicates the dates when a new rating is assigned to a given company. `transprob` assumes that such ratings remain unchanged, unless a subsequent row explicitly indicates a rating change. For example, for company 'ABC', `transprob` understands that the 'A' rating is unchanged for any date after '6-Jul-2017' (indefinitely).

### Compute Transition Matrix and Transition Counts

The `transprob` function returns a transition probability matrix as the primary output. There are also optional outputs that contain additional information for how many transitions occurred. For more information, see `transprob` for information on the optional outputs for both the 'cohort' and the 'duration' methods.

For illustration purposes, this example allows you to pick the `StartYear` (limited to 2014 or 2015 for this example) and the `EndYear` (2016 or 2017). This example also uses the `hDisplayTransitions` helper function (see the Local Functions on page 19-0 section) to format the transitions information for ease of reading.

```
StartYear = ;
EndYear = ;
startDate = datetime(StartYear,12,31,'Locale','en_US');
endDate = datetime(EndYear,12,31,'Locale','en_US');
RatingLabels = ["AAA","AA","A","BBB","BB","B","CCC","D"];

[tm,st,it] = transprob(data,'startDate',startDate,'endDate',endDate,'algorithm','cohort','labels
```

The transition probabilities of the `TransMat` output indicate the probability of migrating between ratings. The probabilities are expressed in %, that is, they are multiplied by 100.

```
hDisplayTransitions(tm,RatingLabels,"Transition Matrix")
```

Transition Matrix

|     | AAA | AA | A   | BBB | BB | B | CCC | D   |
|-----|-----|----|-----|-----|----|---|-----|-----|
|     | —   | —  | —   | —   | —  | — | —   | —   |
| AAA | 100 | 0  | 0   | 0   | 0  | 0 | 0   | 0   |
| AA  | 0   | 50 | 50  | 0   | 0  | 0 | 0   | 0   |
| A   | 0   | 0  | 100 | 0   | 0  | 0 | 0   | 0   |
| BBB | 0   | 0  | 0   | 100 | 0  | 0 | 0   | 0   |
| BB  | 0   | 0  | 0   | 50  | 50 | 0 | 0   | 0   |
| B   | 0   | 0  | 0   | 0   | 0  | 0 | 100 | 0   |
| CCC | 0   | 0  | 0   | 0   | 0  | 0 | 0   | 100 |
| D   | 0   | 0  | 0   | 0   | 0  | 0 | 0   | 100 |

The transition counts are stored in the `sampleTotals` optional output and indicate how many transitions occurred between ratings for the entire sample (that is, all companies).

```
hDisplayTransitions(st.totalsMat,RatingLabels,"Transition counts, all companies")
```

Transition counts, all companies

|     | AAA | AA | A | BBB | BB | B | CCC | D |
|-----|-----|----|---|-----|----|---|-----|---|
|     | —   | —  | — | —   | —  | — | —   | — |
| AAA | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| AA  | 0   | 1  | 1 | 0   | 0  | 0 | 0   | 0 |
| A   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| BBB | 0   | 0  | 0 | 1   | 0  | 0 | 0   | 0 |
| BB  | 0   | 0  | 0 | 1   | 1  | 0 | 0   | 0 |
| B   | 0   | 0  | 0 | 0   | 0  | 0 | 1   | 0 |
| CCC | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 1 |
| D   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 1 |

The third output of `transprob` is `idTotals` that contains information about transitions at an ID level, company by company (in the same order that the companies appear in the input data).

Select a company to display the transition counts and a corresponding visualization of the transitions. The `hPlotTransitions` helper function (see the Local Functions on page 19-0 section) shows the transitions history for a company.

```

CompanyID = ;
UniqueIDs = unique(data.ID, 'stable');
[~, CompanyIndex] = ismember(CompanyID, UniqueIDs);
hDisplayTransitions(it(CompanyIndex).totalsMat, RatingLabels, strcat("Transition counts, company ID: ABC

```

Transition counts, company ID: ABC

|     | AAA | AA | A | BBB | BB | B | CCC | D |
|-----|-----|----|---|-----|----|---|-----|---|
| AAA | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| AA  | 0   | 1  | 1 | 0   | 0  | 0 | 0   | 0 |
| A   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| BBB | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| BB  | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| B   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| CCC | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| D   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |

```

hPlotTransitions(CompanyID, startDate, endDate, data, RatingLabels)

```

To understand how `transprob` handles data when the first observed date is after the start date of the analysis, or whose last observed date occurs before the end date of the analysis, consider the following example. For company 'ABC' suppose that the analysis has a start date of 31-Dec-2014 and end date of 31-Dec-2017. There are only two transitions reported for this company for that analysis time window. The first observation for 'ABC' happened on 17-Feb-2015. So the 31-Dec-2015 snapshot is the first time the company is observed. By 31-Dec-2016, the company

remained in the original 'AA' rating. By 31-Dec-2017, a downgrade to 'A' is recorded. Consistent with this, the transition counts show one transition from 'AA' to 'AA' (from the end of 2015 to the end of 2016), and one transition from 'AA' to 'A' (from the end of 2016 to the end of 2017). The plot shows the last rating as a dotted red line to emphasize that the last rating in the data is extrapolated indefinitely into the future. There is no extrapolation into the past; the company's history is ignored until a company rating is known for an entire transition period (31-Dec-2015 through 31-Dec-2016 in the case of 'ABC').

### Compute Transition Matrix Containing NR (Not Rated) Rating

Consider a different sample data containing only a single company 'DEF'. The data contains transitions of company 'DEF' from 'A' to 'NR' rating and a subsequent transition from 'NR' to 'BBB'.

```
dataNR = {'DEF', '17-Mar-2011', 'A';
          'DEF', '24-Mar-2014', 'NR';
          'DEF', '26-Sep-2016', 'BBB'};
dataNR = cell2table(dataNR, 'VariableNames', {'ID', 'Date', 'Rating'});
disp(dataNR)
```

| ID      | Date            | Rating  |
|---------|-----------------|---------|
| {'DEF'} | {'17-Mar-2011'} | {'A' }  |
| {'DEF'} | {'24-Mar-2014'} | {'NR' } |
| {'DEF'} | {'26-Sep-2016'} | {'BBB'} |

transprob treats 'NR' as another rating. The transition matrix below shows the estimated probability of transitioning into and out of 'NR'.

```
StartYearNR = 2010;
EndYearNR = 2018;
startDateNR = datetime(StartYearNR,12,31,'Locale','en_US');
endDateNR = datetime(EndYearNR,12,31,'Locale','en_US');
CompanyID_NR = "DEF";
```

```
RatingLabelsNR = ["AAA", "AA", "A", "BBB", "BB", "B", "CCC", "D", "NR"];
```

```
[tmNR,~,itNR] = transprob(dataNR,'startDate',startDateNR,'endDate',endDateNR,'algorithm','cohort');
hDisplayTransitions(tmNR,RatingLabelsNR,"Transition Matrix")
```

Transition Matrix

|     | AAA | AA  | A      | BBB | BB  | B   | CCC | D   | NR     |
|-----|-----|-----|--------|-----|-----|-----|-----|-----|--------|
| AAA | 100 | 0   | 0      | 0   | 0   | 0   | 0   | 0   | 0      |
| AA  | 0   | 100 | 0      | 0   | 0   | 0   | 0   | 0   | 0      |
| A   | 0   | 0   | 66.667 | 0   | 0   | 0   | 0   | 0   | 33.333 |
| BBB | 0   | 0   | 0      | 100 | 0   | 0   | 0   | 0   | 0      |
| BB  | 0   | 0   | 0      | 0   | 100 | 0   | 0   | 0   | 0      |
| B   | 0   | 0   | 0      | 0   | 0   | 100 | 0   | 0   | 0      |
| CCC | 0   | 0   | 0      | 0   | 0   | 0   | 100 | 0   | 0      |
| D   | 0   | 0   | 0      | 0   | 0   | 0   | 0   | 100 | 0      |
| NR  | 0   | 0   | 0      | 50  | 0   | 0   | 0   | 0   | 50     |

Display the transition counts and corresponding visualization of the transitions.

```
hDisplayTransitions(itNR.totalsMat,RatingLabelsNR, strcat("Transition counts, company ID: ", CompanyIDNR))
```

```
Transition counts, company ID: DEF
```

|     | AAA | AA | A | BBB | BB | B | CCC | D | NR |
|-----|-----|----|---|-----|----|---|-----|---|----|
| AAA | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| AA  | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| A   | 0   | 0  | 2 | 0   | 0  | 0 | 0   | 0 | 1  |
| BBB | 0   | 0  | 0 | 2   | 0  | 0 | 0   | 0 | 0  |
| BB  | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| B   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| CCC | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| D   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| NR  | 0   | 0  | 0 | 1   | 0  | 0 | 0   | 0 | 1  |

```
hPlotTransitions(CompanyID_NR, startDateNR, endDateNR, dataNR, RatingLabelsNR)
```

To remove the 'NR' from the transition matrix, use the 'excludeLabels' name-value input argument in `transprob`. The list of labels to exclude may or may not be specified in the name-value pair argument `labels`. For example, both `RatingLabels` and `RatingLabelsNR` generate the same output from `transprob`.

```
[tmNR,stNR,itNR] = transprob(dataNR,'startDate',startDateNR,'endDate',endDateNR,'algorithm','coh...')
hDisplayTransitions(tmNR,RatingLabels,"Transition Matrix")
```

## Transition Matrix

|     | AAA | AA  | A   | BBB | BB  | B   | CCC | D   |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|
|     | —   | —   | —   | —   | —   | —   | —   | —   |

| D   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 100 |

Display the transition counts and corresponding visualization of the transitions.

```
hDisplayTransitions(itNR.totalsMat,RatingLabels,strcat("Transition counts, company ID: ",CompanyID))
```

Transition counts, company ID: DEF

|     | AAA | AA | A | BBB | BB | B | CCC | D |
|-----|-----|----|---|-----|----|---|-----|---|
|     | —   | —  | — | —   | —  | — | —   | — |
| AAA | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| AA  | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| A   | 0   | 0  | 2 | 0   | 0  | 0 | 0   | 0 |
| BBB | 0   | 0  | 0 | 2   | 0  | 0 | 0   | 0 |
| BB  | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| B   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| CCC | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| D   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |

```
hPlotTransitions(CompanyID_NR,startDateNR,endDateNR,dataNR,RatingLabels)
```

Consistent with the previous plot, the transition counts still show two transitions from 'A' to 'A' (from the end of 2012 to the end of 2014), and two transitions from 'BBB' to 'BBB' (from the end of 2017 to the end of 2019).

However, different from the previous plot, specifying 'NR' using the 'excludeLabels' name-value input argument of `transprob` removes any transitions into and out of the 'NR' rating.

end
hold off;

% Add lines to indicate the snapshot dates
% transprob uses 1 as the default for 'snapsPerYear', hardcoded here for simplicity
% The call to cfdates generates the exact same snapshot dates that transprob uses
snapsPerYear = 1;
snapDates = cfdates(startDate-1,endDate,snapsPerYear)';
yLimits = ylim;
for ii=1:length(snapDates)
    line([snapDates(ii) snapDates(ii)],yLimits,'Color','m')
end
title(strcat("Company ID: ",CompanyID))
end

```

## Input Arguments

### data — Credit migration data

table | cell array of character vectors | preprocessed data structure

Using `transprob` to estimate transition probabilities given credit ratings historical data (that is, credit migration data), the data input can be one of the following:

- An `nRecords-by-3` MATLAB table containing the historical credit ratings data of the form:

| ID         | Date          | Rating |
|------------|---------------|--------|
| '00010283' | '10-Nov-1984' | 'CCC'  |
| '00010283' | '12-May-1986' | 'B'    |
| '00010283' | '29-Jun-1988' | 'CCC'  |
| '00010283' | '12-Dec-1991' | 'D'    |
| '00013326' | '09-Feb-1985' | 'A'    |
| '00013326' | '24-Feb-1994' | 'AA'   |
| '00013326' | '10-Nov-2000' | 'BBB'  |
| '00014413' | '23-Dec-1982' | 'B'    |

where each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). Column 3 is the rating assigned to the corresponding ID on the corresponding date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency. When using a MATLAB table input, the names of the columns are irrelevant, but the ID, date and rating information are assumed to be in the first, second, and third columns, respectively. Also, when using a table input, the first and third columns can be categorical arrays, and the second can be a datetime array. The following summarizes the supported data types for table input:

| Data Input Type | ID (1st Column)                                                                                                                     | Date (2nd Column)                                                                                                                | Rating (3rd Column)                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Table           | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Categorical array</li> </ul> | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Datetime array</li> </ul> | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Categorical array</li> </ul> |

- An `nRecords-by-3` cell array of character vectors containing the historical credit ratings data of the form:

```
'00010283' '10-Nov-1984' 'CCC'
'00010283' '12-May-1986' 'B'
'00010283' '29-Jun-1988' 'CCC'
'00010283' '12-Dec-1991' 'D'
'00013326' '09-Feb-1985' 'A'
'00013326' '24-Feb-1994' 'AA'
'00013326' '10-Nov-2000' 'BBB'
'00014413' '23-Dec-1982' 'B'
```

where each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). Column 3 is the rating assigned to the corresponding ID on the corresponding date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency. IDs, dates, and ratings are stored in character vector format, but they can also be entered in numeric format. The following summarizes the supported data types for cell array input:

| Data Input Type | ID (1st Column)                                                                                       | Date (2nd Column)                                                                                     | Rating (3rd Column)                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| Cell            | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> |

- A preprocessed data structure obtained using `transprobprep`. This data structure contains the fields `'idStart'`, `'numericDates'`, `'numericRatings'`, and `'ratingsLabels'`.

Data Types: `table` | `cell` | `struct`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `transMat = transprob(data, 'algorithm', 'cohort')`

### `algorithm` — Estimation algorithm

`'duration'` (default) | character vector with values are `'duration'` or `'cohort'`

Estimation algorithm, specified as the comma-separated pair consisting of `'algorithm'` and a character vector with a value of `'duration'` or `'cohort'`.

Data Types: `char`

### `endDate` — End date of the estimation time window

latest date in `data` (default) | character vector | serial date number | datetime

End date of the estimation time window, specified as the comma-separated pair consisting of 'endDate' and a date character vector, serial date number, or datetime object. The endDate cannot be a date before the startDate.

Data Types: char | double | datetime

### Labels — Credit-rating scale

{'AAA', 'AA', 'A', 'BBB', 'BB', 'B', 'CCC', 'D'} (default) | cell array of character vectors

Credit-rating scale, specified as the comma-separated pair consisting of 'labels' and a nRatings-by-1, or 1-by-nRatings cell array of character vectors.

labels must be consistent with the ratings labels used in the third column of data. Use a cell array of numbers for numeric ratings, and a cell array for character vectors for categorical ratings.

---

**Note** When the input argument data is a preprocessed data structure obtained from a previous call to transproprep, this optional input for 'labels' is unused because the labels in the 'ratingsLabels' field of transproprep take priority.

---

Data Types: cell

### snapsPerYear — Number of credit-rating snapshots per year

1 (default) | numeric values are 1, 2, 3, 4, 6, or 12

Number of credit-rating snapshots per year to be considered for the estimation, specified as the comma-separated pair consisting of 'snapsPerYear' and a numeric value of 1, 2, 3, 4, 6, or 12.

---

**Note** This parameter is only used with the 'cohort' algorithm.

---

Data Types: double

### startDate — Start date of the estimation time window

earliest date in data (default) | character vector | serial date number | datetime

Start date of the estimation time window, specified as the comma-separated pair consisting of 'startDate' and a date character vector, serial date number, or datetime object.

Data Types: char | double | datetime

### transInterval — Length of the transition interval in years

1 (one year transition probability) (default) | numeric

Length of the transition interval, in years, specified as the comma-separated pair consisting of 'transInterval' and a numeric value.

Data Types: double

### excludeLabels — Label that is excluded from the transition probability computation

' ' (do not exclude any label) (default) | numeric | character vector | string

Label that is excluded from the transition probability computation, specified as the comma-separated pair consisting of 'excludeLabels' and a character vector, string, or numerical rating.

If multiple labels are to be excluded, 'excludeLabels' must be a cell array containing all of the labels for exclusion. The type of the labels given in 'excludeLabels' must be consistent with the data type specified in the labels input.

The list of labels to exclude may or may not be specified in labels.

Data Types: double | char | string

## Output Arguments

### transMat — Matrix of transition probabilities in percent

matrix

Matrix of transition probabilities in percent, returned as a nRatings-by-nRatings transition matrix.

### sampleTotals — Structure with sample totals

structure

Structure with sample totals, returned with fields:

- totalsVec — A vector of size 1-by-nRatings.
- totalsMat — A matrix of size nRatings-by-nRatings.
- algorithm — A character vector with values 'duration' or 'cohort'.

For the 'duration' algorithm, totalsMat(*i,j*) contains the total transitions observed out of rating *i* into rating *j* (all the diagonal elements are zero). The total time spent on rating *i* is stored in totalsVec(*i*). For example, if there are three rating categories, Investment Grade (IG), Speculative Grade (SG), and Default (D), and the following information:

|                  |         |         |         |
|------------------|---------|---------|---------|
| Total time spent | IG      | SG      | D       |
| in rating:       | 4859.09 | 1503.36 | 1162.05 |

|                |    |     |    |    |
|----------------|----|-----|----|----|
| Transitions    |    | IG  | SG | D  |
| out of (row)   | IG | 0   | 89 | 7  |
| into (column): | SG | 202 | 0  | 32 |
|                | D  | 0   | 0  | 0  |

Then

```
totals.totalsVec = [4859.09 1503.36 1162.05]
totals.totalsMat = [ 0 89 7
                   202 0 32
                   0 0 0]
totals.algorithm = 'duration'
```

For the 'cohort' algorithm, totalsMat(*i,j*) contains the total transitions observed from rating *i* to rating *j*, and totalsVec(*i*) is the initial count in rating *i*. For example, given the following information:

|               |      |      |      |
|---------------|------|------|------|
| Initial count | IG   | SG   | D    |
| in rating:    | 4808 | 1572 | 1145 |

|              |    |      |      |      |
|--------------|----|------|------|------|
| Transitions  |    | IG   | SG   | D    |
| from (row)   | IG | 4721 | 80   | 7    |
| to (column): | SG | 193  | 1347 | 32   |
|              | D  | 0    | 0    | 1145 |

Then

```
totals.totalsVec = [4808  1572  1145]
totals.totalsMat = [4721   80    7
                  193  1347   32
                   0    0  1145]
totals.algorithm = 'cohort'
```

### **idTotals — IDs totals**

struct array

IDs totals, returned as a struct array of size  $nIDs$ -by-1, where  $nIDs$  is the number of distinct IDs in column 1 of `data` when this is a table or cell array or, equivalently, equal to the length of the `idStart` field minus 1 when `data` is a preprocessed data structure from `transprobprep`. For each ID in the sample, `idTotals` contains one structure with the following fields:

- `totalsVec` — A sparse vector of size 1-by- $nRatings$ .
- `totalsMat` — A sparse matrix of size  $nRatings$ -by- $nRatings$ .
- `algorithm` — A character vector with values 'duration' or 'cohort'.

These fields contain the same information described for the output `sampleTotals`, but at an ID level. For example, for 'duration', `idTotals(k).totalsVec` contains the total time that the  $k$ -th company spent on each rating.

## **More About**

### **Cohort Estimation**

The cohort algorithm estimates the transition probabilities based on a sequence of snapshots of credit ratings at regularly spaced points in time.

If the credit rating of a company changes twice between two snapshot dates, the intermediate rating is overlooked and only the initial and final ratings influence the estimates.

### **Duration Estimation**

Unlike the cohort method, the duration algorithm estimates the transition probabilities based on the full credit ratings history, looking at the exact dates on which the credit rating migrations occur.

There is no concept of snapshots in this method, and all credit rating migrations influence the estimates, even when a company's rating changes twice within a short time.

## **Algorithms**

### **Cohort Estimation**

The algorithm first determines a sequence  $t_0, \dots, t_K$  of snapshot dates. The elapsed time, in years, between two consecutive snapshot dates  $t_{k-1}$  and  $t_k$  is equal to  $1 / ns$ , where  $ns$  is the number of snapshots per year. These  $K + 1$  dates determine  $K$  transition periods.

The algorithm computes  $N_i^n$ , the number of transition periods in which obligor  $n$  starts at rating  $i$ . These are added up over all obligors to get  $N_i$ , the number of obligors in the sample that start a period at rating  $i$ . The number periods in which obligor  $n$  starts at rating  $i$  and ends at rating  $j$ , or

migrates from  $i$  to  $j$ , denoted by  $N_{ij}^n$ , is also computed. These are also added up to get  $N_{ij}$ , the total number of migrations from  $i$  to  $j$  in the sample.

The estimate of the transition probability from  $i$  to  $j$  in one period, denoted by  $P_{ij}$ , is

$$P_{ij} = \frac{N_{ij}}{N_i}$$

These probabilities are arranged in a one-period transition matrix  $P_0$ , where the  $ij$  entry in  $P_0$  is  $P_{ij}$ .

If the number of snapshots per year  $ns$  is 4 (quarterly snapshots), the probabilities in  $P_0$  are 3-month (or 0.25-year) transition probabilities. You may, however, be interested in 1-year or 2-year transition probabilities. The latter time interval is called the transition interval,  $\Delta t$ , and it is used to convert  $P_0$  into the final transition matrix,  $P$ , according to the formula:

$$P = P_0^{ns * \Delta t}$$

For example, if  $ns = 4$  and  $\Delta t = 2$ ,  $P$  contains the two-year transition probabilities estimated from quarterly snapshots.

---

**Note** For the cohort algorithm, optional output arguments `idTotals` and `sampleTotals` from `transprob` contain the following information:

- `idTotals(n).totalsVec = (N_i^n) \forall i`
- `idTotals(n).totalsMat = (N_{i,j}^n) \forall ij`
- `idTotals(n).algorithm = 'cohort'`
- `sampleTotals.totalsVec = (N_i) \forall i`
- `sampleTotals.totalsMat = (N_{i,j}) \forall ij`
- `sampleTotals.algorithm = 'cohort'`

For efficiency, the vectors and matrices in `idTotals` are stored as sparse arrays.

---

When ratings must be excluded (see the `excludeLabels` name-value input argument), all transitions involving the excluded ratings are removed from the sample. For example, if the 'NR' rating must be excluded, any transitions into 'NR' and out of 'NR' are excluded from the sample. The total counts for all other ratings are adjusted accordingly. For more information, see "Visualize Transitions Data for `transprob`".

### Duration Estimation

The algorithm computes  $T_i^n$ , the total time that obligor  $n$  spends in rating  $i$  within the estimation time window. These quantities are added up over all obligors to get  $T_i$ , the total time spent in rating  $i$ , collectively, by all obligors in the sample. The algorithm also computes  $T_{ij}^n$ , the number times that obligor  $n$  migrates from rating  $i$  to rating  $j$ , with  $i$  not equal to  $j$ , within the estimation time window. And it also adds them up to get  $T_{ij}$ , the total number of migrations, by all obligors in the sample, from the rating  $i$  to  $j$ , with  $i$  not equal to  $j$ .

To estimate the transition probabilities, the duration algorithm first computes a generator matrix  $\Lambda$ . Each off-diagonal entry of this matrix is an estimate of the transition rate out of rating  $i$  into rating  $j$ , and is

$$\lambda_{ij} = \frac{T_{ij}}{T_i}, i \neq j$$

The diagonal entries are computed as:

$$\lambda_{ii} = - \sum_{j \neq i} \lambda_{ij}$$

With the generator matrix and the transition interval  $\Delta t$  (e.g.,  $\Delta t = 2$  corresponds to two-year transition probabilities), the transition matrix is obtained as  $P = \exp(\Delta t \Lambda)$ , where *exp* denotes matrix exponentiation (*expm* in MATLAB).

---

**Note** For the duration algorithm, optional output arguments `idTotals` and `sampleTotals` from `transprob` contain the following information:

- `idTotals(n).totalsVec = (T_i^n) \forall i`
- `idTotals(n).totalsMat = (T_{i,j}^n) \forall ij`
- `idTotals(n).algorithm = 'duration'`
- `sampleTotals.totalsVec = (T_i) \forall i`
- `sampleTotals.totalsMat = (T_{i,j}) \forall ij`
- `sampleTotals.algorithm = 'duration'`

For efficiency, the vectors and matrices in `idTotals` are stored as sparse arrays.

---

When ratings must be excluded (see the `excludeLabels` name-value input argument), all transitions involving the exclude ratings are removed from the sample. For example, if the 'NR' rating must be excluded, any transitions into 'NR' and out of 'NR' are excluded from the sample. The total time spent in 'NR' (or any other excluded rating) is also removed.

## transprobytotals

Estimate transition probabilities using totals structure input

### Syntax

```
[transMat,sampleTotals] = transprobytotals(totals)
[transMat,sampleTotals] = transprobytotals( ___,Name,Value)
```

### Description

[transMat,sampleTotals] = transprobytotals(totals) estimates transition probabilities using a totals structure input. transprobytotals is useful for removing outlier information, obtaining bootstrapped confidence intervals, or computing transition probability estimates for different periodicity parameters (1-year transitions, 2-year transitions, and so on) efficiently.

[transMat,sampleTotals] = transprobytotals( \_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Estimate Transition Probabilities Using a totals Structure Input

Use historical credit rating input data from Data\_TransProb.mat and transprob to generate input for transprobytotals:

```
load Data_TransProb
```

```
% Call TRANSPROB with three output arguments
```

```
[transMat, sampleTotals, idTotals] = transprob(data);
transMat
```

```
transMat = 8×8
```

```

93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017

```

## Input Arguments

### **totals** — Total transitions observed

structure | struct array

Total transitions observed, specified as a structure, or a struct array of length `nTotals`, with fields:

- `totalsVec` — A sparse vector of size 1-by-`nRatings1`.
- `totalsMat` — A sparse matrix of size `nRatings1`-by-`nRatings2` with `nRatings1` ≤ `nRatings2`.
- `algorithm` — A character vector with values 'duration' or 'cohort'.

For the 'duration' algorithm, `totalsMat(i,j)` contains the total transitions observed out of rating *i* into rating *j* (all the diagonal elements are 0). The total time spent on rating *i* is stored in `totalsVec(i)`. For example, you have three rating categories, Investment Grade (IG), Speculative Grade (SG), and Default (D), and the following information:

```

Total time spent   IG      SG      D
in rating:        4859.09  1503.36  1162.05

```

```

Transitions
out of (row)      IG      SG      D
into (column):   SG    202    0    32
                  D     0     0     0

```

Then:

```

totals.totalsVec = [4859.09 1503.36 1162.05]
totals.totalsMat = [ 0 89 7
                   202 0 32
                   0 0 0]
totals.algorithm = 'duration'

```

For the 'cohort' algorithm, `totalsMat(i,j)` contains the total transitions observed from rating  $i$  to rating  $j$ , and `totalsVec(i)` is the initial count in rating  $i$ . For example, given the following information:

|               |    |      |      |      |
|---------------|----|------|------|------|
| Initial count |    | IG   | SG   | D    |
| in rating:    |    | 4808 | 1572 | 1145 |
| Transitions   |    | IG   | SG   | D    |
| from (row)    | IG | 4721 | 80   | 7    |
| to (column):  | SG | 193  | 1347 | 32   |
|               | D  | 0    | 0    | 1145 |

Then:

```

totals.totalsVec = [4808 1572 1145]
totals.totalsMat = [4721 80 7
                   193 1347 32
                   0 0 1145]
totals.algorithm = 'cohort'

```

Common totals structures are the optional output arguments from `transprob`:

- `sampleTotals` — A single structure summarizing the totals information for the whole dataset.
- `idTotals` — A struct array with the totals information at the ID level.

Data Types: `struct` | `structure`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `transMat = transprobytotals(Totals1, 'transInterval', 5)`

### **snapsPerYear** — Number of credit-rating snapshots per year

1 (default) | numeric values are 1, 2, 3, 4, 6, or 12

Number of credit-rating snapshots per year to be considered for the estimation, specified as the comma-separated pair consisting of 'snapsPerYear' and a numeric value of 1, 2, 3, 4, 6, or 12.

---

**Note** This parameter is only used with the 'cohort' algorithm.

---

Data Types: `double`

### **transInterval** — Length of the transition interval in years

1 (one year transition probability) (default) | numeric

Length of the transition interval, in years, specified as the comma-separated pair consisting of 'transInterval' and a numeric value.

Data Types: double

## Output Arguments

### **transMat** — Matrix of transition probabilities in percent

matrix

Matrix of transition probabilities in percent, returned as a `nRatings1`-by-`nRatings2` transition matrix.

### **sampleTotals** — Structure with sample totals

structure

Structure with sample totals, returned with fields:

- `totalsVec` — A vector of size `1`-by-`nRatings1`.
- `totalsMat` — A matrix of size `nRatings1`-by-`nRatings2` with `nRatings1` ≤ `nRatings2`.
- `algorithm` — A character vector with values `'duration'` or `'cohort'`.

If `totals` is a struct array, `sampleTotals` contains the aggregated information. That is, `sampleTotals.totalsVec` is the sum of `totals(k).totalsVec` over all  $k$ , and similarly for `totalsMat`. When `totals` is itself a single structure, `sampleTotals` and `totals` are the same.

## More About

### Cohort Estimation

The cohort algorithm estimates the transition probabilities based on a sequence of snapshots of credit ratings at regularly spaced points in time.

If the credit rating of a company changes twice between two snapshot dates, the intermediate rating is overlooked and only the initial and final ratings influence the estimates.

### Duration Estimation

Unlike the cohort method, the duration algorithm estimates the transition probabilities based on the full credit ratings history, looking at the exact dates on which the credit rating migrations occur.

There is no concept of snapshots in this method, and all credit rating migrations influence the estimates, even when a company's rating changes twice within a short time.

# transprobfromthresholds

Convert from credit quality thresholds to transition probabilities

## Syntax

```
trans = transprobfromthresholds(thresh)
```

## Description

trans = transprobfromthresholds(thresh) transforms credit quality thresholds into transition probabilities

## Examples

### Transform Credit Quality Thresholds Into Transition Probabilities

Use historical credit rating input data from Data\_TransProb.mat, estimate transition probabilities with default settings.

```
load Data_TransProb
```

```
% Estimate transition probabilities with default settings
```

```
transMat = transprob(data)
```

```
transMat = 8x8
```

```

```

## Input Arguments

### thresh — Credit quality thresholds

matrix

Credit quality thresholds, specified as a M-by-N matrix of credit quality thresholds.

In each row, the first element must be `Inf` and the entries must satisfy the following monotonicity condition:

$$\text{thresh}(i,j) \geq \text{thresh}(i,j+1), \text{ for } 1 \leq j < N$$

The M-by-N input `thresh` and the M-by-N output `trans` are related as follows. The thresholds `thresh(i,j)` are critical values of a standard normal distribution  $z$ , such that:

$$\text{trans}(i,N) = P[z < \text{thresh}(i,N)],$$

$$\text{trans}(i,j) = P[z < \text{thresh}(i,j)] - P[z < \text{thresh}(i,j+1)], \text{ for } 1 \leq j < N$$

Any given row in the output matrix `trans` determines a probability distribution over a discrete set of  $N$  ratings 'R1', ..., 'RN', so that for any row  $i$  `trans(i,j)` is the probability of migrating into 'Rj'. `trans` can be a standard transition matrix, with  $M \leq N$ , in which case row  $i$  contains the transition probabilities for issuers with rating 'Ri'. But `trans` does not have to be a standard transition matrix. `trans` can contain individual transition probabilities for a set of M-specific issuers, with  $M > N$ .

For example, suppose that there are only  $N=3$  ratings, 'High', 'Low', and 'Default', with these credit quality thresholds:

|      | High | Low     | Default |
|------|------|---------|---------|
| High | Inf  | -2.0814 | -3.1214 |
| Low  | Inf  | 2.4044  | -1.7530 |

The matrix of transition probabilities is then:

|      | High  | Low   | Default |
|------|-------|-------|---------|
| High | 98.13 | 1.78  | 0.09    |
| Low  | 0.81  | 95.21 | 3.98    |

This means the probability of default for 'High' is equivalent to drawing a standard normal random number smaller than  $-3.1214$ , or 0.09%. The probability that a 'High' ends up the period with a

rating of 'Low' or lower is equivalent to drawing a standard normal random number smaller than  $-2.0814$ , or 1.87%. From here, the probability of ending with a 'Low' rating is:

$$P[z < -2.0814] - P[z < -3.1214] = 1.87\% - 0.09\% = 1.78\%$$

And the probability of ending with a 'High' rating is:

$$100\% - 1.87\% = 98.13\%$$

where 100% is the same as:

$$P[z < \text{Inf}]$$

Data Types: double

## Output Arguments

**trans** — Matrix of transition probabilities in percent  
matrix

Matrix of transition probabilities in percent, returned as a M-by-N matrix.

## transprobgrouptotals

Aggregate credit ratings information into fewer rating categories

### Syntax

```
totalsGrouped = transprobgrouptotals(totals,groupingEdges)
```

### Description

`totalsGrouped = transprobgrouptotals(totals,groupingEdges)` aggregates the credit ratings information stored in the `totals` input into fewer ratings categories, which are defined by the `groupingEdges` argument.

### Examples

#### Aggregate the Credit Ratings Information Stored in the totals Input

Use historical credit rating input data from `Data_TransProb.mat`. Load input data from file `Data_TransProb.mat`.

```
load Data_TransProb
```

```
% Call TRANSPROB with two output arguments
[transMat, sampleTotals] = transprob(data);
transMat
```

```
transMat = 8×8
```

```

```

## Input Arguments

### **totals** — Total transitions observed

structure | struct array

Total transitions observed, specified as a structure, or a struct array of length nTotals, with fields:

- **totalsVec** — A sparse vector of size 1-by-nRatings1.
- **totalsMat** — A sparse matrix of size nRatings1-by-nRatings2 with nRatings1 ≤ nRatings2.
- **algorithm** — A character vector with values 'duration' or 'cohort'.

For the 'duration' algorithm, **totalsMat**(*i,j*) contains the total transitions observed out of rating *i* into rating *j* (all the diagonal elements are 0). The total time spent on rating *i* is stored in **totalsVec**(*i*). For example, you have three rating categories, Investment Grade (IG), Speculative Grade (SG), and Default (D), and the following information:

| Total time spent | IG      | SG      | D       |
|------------------|---------|---------|---------|
| in rating:       | 4859.09 | 1503.36 | 1162.05 |

| Transitions    | IG | SG  | D  |    |
|----------------|----|-----|----|----|
| out of (row)   | IG | 0   | 89 | 7  |
| into (column): | SG | 202 | 0  | 32 |
|                | D  | 0   | 0  | 0  |

Then:

```
totals.totalsVec = [4859.09 1503.36 1162.05]
totals.totalsMat = [ 0 89 7
                   202 0 32
                   0 0 0]
totals.algorithm = 'duration'
```

For the 'cohort' algorithm, **totalsMat**(*i,j*) contains the total transitions observed from rating *i* to rating *j*, and **totalsVec**(*i*) is the initial count in rating *i*. For example, given the following information:

```

Initial count      IG      SG      D
in rating:        4808    1572    1145

Transitions        IG      SG      D
from (row)  IG  4721     80     7
to (column): SG   193    1347    32
                D     0       0    1145

```

Then:

```

totals.totalsVec = [4808    1572    1145]
totals.totalsMat = [4721     80     7
                   193    1347    32
                   0       0    1145]
totals.algorithm = 'cohort'

```

Common totals structures are the optional output arguments from `transprob`:

- `sampleTotals` — A single structure summarizing the totals information for the whole dataset.
- `idTotals` — A struct array with the totals information at the ID level.

Data Types: `struct` | `structure`

### **groupingEdges** — Indicator for grouping credit ratings into categories

numeric array

Indicator for grouping credit ratings into categories, specified as a numeric array.

This table illustrates how to group a list of whole ratings into investment grade (IG) and speculative grade (SG) categories. Eight ratings are in the original list. Ratings 1 to 4 are IG, ratings 5 to 7 are SG, and rating 8 is a category of its own. In this example, the array of grouping edges is `[4 7 8]`.

```

Original ratings: 'AAA' 'AA'  'A'  'BBB' | 'BB'  'B'  'CCC' | 'D'
Relative ordering: (1)  (2)  (3)  (4)  | (5) (6)  (7)  | (8)
Grouped ratings:           'IG'          |          'SG'          | 'D'
Grouping edges:                (4)  |                (7)  | (8)

```

In general, if `groupingEdges` has  $K$  elements  $\text{edge1} < \text{edge2} < \dots < \text{edgeK}$ , ratings 1 to  $\text{edge1}$  (inclusive) are grouped in the first category, ratings  $\text{edge1}+1$  to  $\text{edge2}$  in the second category, and so forth.

Regarding the last element,  $\text{edgeK}$ :

- If  $n\text{Ratings1}$  equals  $n\text{Ratings2}$ , then  $\text{edgeK}$  must equal  $n\text{Ratings1}$ . This leads to  $K$  groups, and  $n\text{RatingsGrouped1} = n\text{RatingsGrouped2} = K$ .
- If  $n\text{Ratings1} < n\text{Ratings2}$ , then either:
  - $\text{edgeK}$  equals  $n\text{Ratings1}$ , in which case ratings  $\text{edgeK}+1, \dots, n\text{Ratings2}$  are treated as categories of their own. This results in  $K+(n\text{Ratings2}-\text{edgeK})$  groups, with  $n\text{RatingsGrouped1} = K$  and  $n\text{RatingsGrouped2} = K + (n\text{Ratings2} - \text{edgeK})$ ; or
  - $\text{edgeK}$  equals  $n\text{Ratings2}$ , in which case there must be a  $j$ th edge element,  $\text{edgej}$ , such that  $\text{edgej}$  equals  $n\text{Ratings1}$ . This leads to  $K$  groups, and  $n\text{RatingsGrouped1} = j$  and  $n\text{RatingsGrouped2} = K$ .

Data Types: `double`

## Output Arguments

### **totalsGrouped — Aggregated information by categories**

structure | struct array

Aggregated information by categories, returned as a structure, or a struct array of length `nTotals`, with fields:

- `totalsVec` — A vector of size 1-by-`nRatingsGrouped1`.
- `totalsMat` — A matrix of size `nRatingsGrouped1`-by-`nRatingsGrouped2`.
- `algorithm` — A character vector, 'duration' or 'cohort'.

`nRatingsGrouped1` and `nRatingsGrouped2` are defined in the description of `groupingEdges`. Each structure contains aggregated information by categories, based on the information provided in the corresponding structure in `totals`, according to the grouping of ratings defined by `groupingEdges` and consistent with the `algorithm` choice.

Following the examples in the description of the `totals` input, suppose IG and SG are grouped into a single ND (Not-Defaulted) category, using the edges[2 3]. For the 'cohort' algorithm, the output is:

```
totalsGrouped.totalsVec = [6380  1145]
totalsGrouped.totalsMat = [6341   39
                          0   1145]
totalsGrouped.algorithm = 'cohort'
```

and for the 'duration' algorithm:

```
totalsGrouped.totalsVec = [6362.45  1162.05]
totalsGrouped.totalsMat = [0  39
                          0  0]
totalsGrouped.algorithm = 'duration'
```

## More About

### **Cohort Estimation**

The cohort algorithm estimates the transition probabilities based on a sequence of snapshots of credit ratings at regularly spaced points in time.

If the credit rating of a company changes twice between two snapshot dates, the intermediate rating is overlooked and only the initial and final ratings influence the estimates. For more information, see the Algorithms section of `transprob`.

### **Duration Estimation**

Unlike the cohort algorithm, the duration algorithm estimates the transition probabilities based on the full credit ratings history, looking at the exact dates on which the credit rating migrations occur.

There is no concept of snapshots in this method, and all credit rating migrations influence the estimates, even when a company's rating changes twice within a short time. For more information, see the Algorithms section of `transprob`.

## Introduced in R2011b

# transprobprep

Preprocess credit ratings data to estimate transition probabilities

## Syntax

```
[prepData] = transprobprep(data)
[prepData] = transprobprep( ___,Name,Value)
```

## Description

[prepData] = transprobprep(data) preprocesses credit ratings historical data (that is, credit migration data) for the subsequent estimation of transition probabilities.

[prepData] = transprobprep( \_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Aggregate the Credit Ratings Information Stored in the totals Input

Load input data from the file `Data_TransProb.mat` and display the first ten rows. In this example, the inputs are provided in character vector format.

```
load Data_TransProb
```

```
% Preprocess credit ratings data.
prepData = transprobprep(data)
```

```
prepData = struct with fields:
    idStart: [1506x1 double]
    numericDates: [4315x1 double]
    numericRatings: [4315x1 double]
    ratingsLabels: {'AAA' 'AA' 'A' 'BBB' 'BB' 'B' 'CCC' 'D'}
```

Estimate transition probabilities with the default settings.

```
transMat = transprob(prepData)
```

```
transMat = 8x8
```

```

## Input Arguments

### data — Historical data for credit ratings

table | cell array of character vectors

Historical input data for credit ratings, specified as one of the following:

- A MATLAB table of size nRecords-by-3 containing the credit ratings. Each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). The assigned credit rating corresponds to the associated ID on the associated date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency. When using a MATLAB table input, the names of the columns are irrelevant, but the ID, date and rating information are assumed to be in the first, second, and third columns, respectively. Also, when using a table input, the first and third columns can be categorical arrays, and the second can be a datetime array. Here is an example with all the information in table format:

| ID         | Date          | Rating |
|------------|---------------|--------|
| '00010283' | '10-Nov-1984' | 'CCC'  |
| '00010283' | '12-May-1986' | 'B'    |
| '00010283' | '29-Jun-1988' | 'CCC'  |
| '00010283' | '12-Dec-1991' | 'D'    |
| '00013326' | '09-Feb-1985' | 'A'    |
| '00013326' | '24-Feb-1994' | 'AA'   |

The following summarizes the supported data types for table input:

| Data Input Type | ID (1st Column)                                                                                                                     | Date (2nd Column)                                                                                                                | Rating (3rd Column)                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Table           | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Categorical array</li> </ul> | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Datetime array</li> </ul> | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Categorical array</li> </ul> |

- A cell array of size nRecords-by-3 containing the credit ratings. Each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). The assigned credit rating corresponds to the associated ID on the associated date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required but is recommended. IDs, dates, and ratings are stored in character vector format, but they can also be entered in numeric format. Here is an example with all the information in character vector format:

```
'00010283' '10-Nov-1984' 'CCC'
'00010283' '12-May-1986' 'B'
'00010283' '29-Jun-1988' 'CCC'
'00010283' '12-Dec-1991' 'D'
'00013326' '09-Feb-1985' 'A'
'00013326' '24-Feb-1994' 'AA'
```

The following summarizes the supported data types for cell array input:

| Data Input Type | ID (1st Column)                                                                                       | Date (2nd Column)                                                                                     | Rating (3rd Column)                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| Cell            | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> |

Data Types: `table` | `cell`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `prepData = transprobbprep(data, 'labels', {'AAA', 'AA', 'A', 'BBB', 'BB', 'B', 'CCC', 'F'})`

### Labels — Credit-rating scale

`{'AAA', 'AA', 'A', 'BBB', 'BB', 'B', 'CCC', 'D'}` (default) | cell array of character vectors

Credit-rating scale, specified as the comma-separated pair consisting of `'labels'` and a `nRatings`-by-1, or 1-by-`nRatings` cell array of character vectors.

`labels` must be consistent with the ratings labels used in the third column of `data`. Use a cell array of numbers for numeric ratings, and a cell array for character vectors for categorical ratings.

Data Types: `cell`

## Output Arguments

### `prepData` — Summary where credit ratings information corresponding to each company starts and ends

structure

Summary where the credit ratings information corresponding to each company starts and ends, returned as a structure with the following fields:

- `idStart` — Array of size  $(nIDs+1)$ -by-1, where `nIDs` is the number of distinct IDs in column 1 of `data`. This array summarizes where the credit ratings information corresponding to each company starts and ends. The dates and ratings corresponding to company `j` in `data` are stored from row `idStart(j)` to row `idStart(j+1)-1` of `numericDates` and `numericRatings`.
- `numericDates` — Array of size `nRecords`-by-1, containing the dates in column 2 of `data`, in numeric format.
- `numericRatings` — Array of size `nRecords`-by-1, containing the ratings in column 3 of `data`, mapped into numeric format.

- `ratingsLabels` — Cell array of size `1-by-nRatings`, containing the credit rating scale.

# transprobtothresholds

Convert from transition probabilities to credit quality thresholds

## Syntax

```
thresh = transprobtothresholds(trans)
```

## Description

`thresh = transprobtothresholds(trans)` transforms transition probabilities into credit quality thresholds.

## Examples

### Transform Transition Probabilities Into Credit Quality Thresholds

Use historical credit rating input data from `Data_TransProb.mat`. Load input data from file `Data_TransProb.mat`.

```
load Data_TransProb
```

```
% Estimate transition probabilities with default settings
```

```
transMat = transprob(data)
```

```
transMat = 8×8
```

```

```

## Input Arguments

### **trans** — Transition probabilities in percent

matrix

Transition probabilities in percent, specified as a M-by-N matrix. Entries cannot be negative and cannot exceed 100, and all rows must add up to 100.

Any given row in the M-by-N input matrix `trans` determines a probability distribution over a discrete set of N ratings. If the ratings are 'R1', . . . , 'RN', then for any row *i* `trans(i,j)` is the probability of migrating into 'Rj'. If `trans` is a standard transition matrix, then  $M \leq N$  and row *i* contains the transition probabilities for issuers with rating 'Ri'. But `trans` does not have to be a standard transition matrix. `trans` can contain individual transition probabilities for a set of M-specific issuers, with  $M > N$ .

The credit quality thresholds `thresh(i,j)` are critical values of a standard normal distribution *z*, such that:

$$\text{trans}(i,N) = P[z < \text{thresh}(i,N)],$$

$$\text{trans}(i,j) = P[z < \text{thresh}(i,j)] - P[z < \text{thresh}(i,j+1)], \text{ for } 1 \leq j < N$$

This implies that `thresh(i,1) = Inf`, for all *i*. For example, suppose that there are only  $N=3$  ratings, 'High', 'Low', and 'Default', with the following transition probabilities:

|      | High  | Low   | Default |
|------|-------|-------|---------|
| High | 98.13 | 1.78  | 0.09    |
| Low  | 0.81  | 95.21 | 3.98    |

The matrix of credit quality thresholds is:

|      | High | Low     | Default |
|------|------|---------|---------|
| High | Inf  | -2.0814 | -3.1214 |
| Low  | Inf  | 2.4044  | -1.7530 |

This means the probability of default for 'High' is equivalent to drawing a standard normal random number smaller than  $-3.1214$ , or 0.09%. The probability that a 'High' ends up the period with a rating of 'Low' or lower is equivalent to drawing a standard normal random number smaller than  $-2.0814$ , or 1.87%. From here, the probability of ending with a 'Low' rating is:

$$P[z < -2.0814] - P[z < -3.1214] = 1.87\% - 0.09\% = 1.78\%$$

And the probability of ending with a 'High' rating is:

$$100\% - 1.87\% = 98.13\%$$

where 100% is the same as:

$$P[z < \text{Inf}]$$

Data Types: double

## Output Arguments

### **thresh** — Credit quality thresholds

matrix

Credit quality thresholds, returned as a M-by-N matrix.

## tsaccel

Acceleration between times

---

**Note** `tsaccel` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a vector, matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
acceleration = tsaccel(Data)
acceleration = tsaccel( ___,Name,Value)
```

### Description

`acceleration = tsaccel(Data)` calculates the acceleration of a data series with time distance of  $n$  periods.

$n$  periods.

`acceleration = tsaccel( ___,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Calculate the Acceleration of a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
TMW.Volume = []; % remove VOLUME field
acceleration = tsaccel(TMW);
plot(acceleration.Time,acceleration.Variables)
legend('OPEN','HIGH','LOW','CLOSE')
title('Acceleration for TMW')
```

## Input Arguments

### Data — Data with high, low, open, close information

vector | matrix | table | timetable

Data with high, low, open, close information, specified as a vector, matrix, table, or timetable. For vector input, `Data` is a column vector of high, low, open, and closing prices stored in the corresponding columns. For matrix input, `Data` is an M-by-N column-oriented matrix of high, low, open, and closing prices stored in the corresponding columns. Timetables and tables with M rows must contain variables named 'High', 'Low', 'Open', and 'Close' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `acceleration = tsaccel(TMW, 'NumPeriods', 10, 'Datatype', 1)`

### NumPeriods — Period difference for acceleration

12 (default) | positive integer

Period difference for acceleration, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

**Datatype — Indicates if Data contains the data itself or the momentum of the data**

0 (Data contains the data itself) (default) | integer with values 0 or 1

Indicates if Data contains the data itself or the momentum of the data, specified as the comma-separated pair consisting of 'Datatype' and a scalar integer with a value of:

- 0 - Data contains the data itself.
- 1 - Data contains the momentum of the data.

Data Types: double

## Output Arguments

**acceleration — Acceleration series**

vector | matrix | table | timetable

Acceleration series, returned with the same number of rows (M) and columns (N) and the same type (vector, matrix, table, or timetable) as the input Data.

## More About

### Acceleration

Acceleration is defined as the difference of two momentum series separated by  $n$  periods.

Acceleration is the difference of the current momentum with the momentum  $n$  periods ago. By default, acceleration is based on 12-period difference.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
momentum = tsmom(Data)
momentum = tsmom( ___,Name,Value)
```

## Description

`momentum = tsmom(Data)` calculates the momentum of a data series with time distance of  $n$  periods.

`momentum = tsmom( ___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Momentum for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
TMW.Volume = []; % remove VOLUME field
momentum = tsmom(TMW);
plot(momentum.Time,momentum.Variables)
legend('OPEN','HIGH','LOW','CLOSE')
title('Acceleration for TMW')
```

## Input Arguments

### Data — Data with high, low, open, close information

vector | matrix | table | timetable

Data with high, low, open, close information, specified as a vector, matrix, table, or timetable. For vector input, `Data` is a column vector. For matrix input, `Data` is an M-by-N column oriented matrix. Timetables and tables with M rows can contain variables named 'High', 'Low', 'Open', and 'Close' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `momentum = tsmom(TMW, 'NumPeriods', 15)`

### NumPeriods — Period difference for momentum

12 (default) | positive integer

Period difference for momentum, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

## Output Arguments

### **momentum** — Momentum series

matrix | table | timetable

Momentum series, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## More About

### **Momentum Series**

Momentum series is the difference of the current data with the data  $n$  periods ago. By default, momentum is based on 12-period difference.

## tsmovavg

Moving average

---

**Note** `tsmovavg` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
output = tsmovavg(tsobj, 's', lag)
output = tsmovavg(vector, 's', lag, dim)

output = tsmovavg(tsobj, 'e', timeperiod)
output = tsmovavg(vector, 'e', timeperiod, dim)

output = tsmovavg(tsobj, 't', numperiod)
output = tsmovavg(vector, 't', numperiod, dim)

output = tsmovavg(tsobj, 'w', weights)
output = tsmovavg(vector, 'w', weights, dim)

output = tsmovavg(tsobj, 'm', numperiod)
output = tsmovavg(vector, 'm', numperiod, dim)
```

### Description

`tsmovavg` calculates the simple, exponential, triangular, weighted, and modified moving average of a vector or `fints` object of data. For information on working with financial time series (`fints` objects) data, see “Working with Financial Time Series Objects” on page 13-2.

`output = tsmovavg(tsobj, 's', lag)` returns the simple moving average by for financial time series object, `tsobj`. `lag` indicates the number of previous data points used with the current data point when calculating the moving average.

`output = tsmovavg(vector, 's', lag, dim)` returns the simple moving average for a vector. `lag` indicates the number of previous data points used with the current data point when calculating the moving average.

`output = tsmovavg(tsobj, 'e', timeperiod)` returns the exponential weighted moving average for financial time series object, `tsobj`. The exponential moving average is a weighted moving average, where `timeperiod` specifies the time period. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10-period exponential moving average weights the most recent price by 18.18%.  $\text{Exponential Percentage} = 2 / (\text{TIMEPER} + 1)$  or  $2 / (\text{WINDOW\_SIZE} + 1)$ .

`output = tsmovavg(vector, 'e', timeperiod, dim)` returns the exponential weighted moving average for a vector. The exponential moving average is a weighted moving average, where `timeperiod` specifies the time period. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10-period exponential moving average weights the most recent price by 18.18%.  $(2 / (\text{timeperiod} + 1))$ .

`output = tsmovavg(tsobj, 't', numperiod)` returns the triangular moving average for financial time series object, `tsobj`. The triangular moving average double-smooths the data. `tsmovavg` calculates the first simple moving average with window width of `ceil(numperiod + 1)/2`. Then it calculates a second simple moving average on the first moving average with the same window size.

`output = tsmovavg(vector, 't', numperiod, dim)` returns the triangular moving average for a vector. The triangular moving average double-smooths the data. `tsmovavg` calculates the first simple moving average with window width of `ceil(numperiod + 1)/2`. Then it calculates a second simple moving average on the first moving average with the same window size.

`output = tsmovavg(tsobj, 'w', weights)` returns the weighted moving average for the financial time series object, `tsobj`, by supplying weights for each element in the moving window. The length of the weight vector determines the size of the window. If larger weight factors are used for more recent prices and smaller factors for previous prices, the trend is more responsive to recent changes.

`output = tsmovavg(vector, 'w', weights, dim)` returns the weighted moving average for the vector by supplying weights for each element in the moving window. The length of the weight vector determines the size of the window. If larger weight factors are used for more recent prices and smaller factors for previous prices, the trend is more responsive to recent changes.

`output = tsmovavg(tsobj, 'm', numperiod)` returns the modified moving average for the financial time series object, `tsobj`. The modified moving average is similar to the simple moving average. Consider the argument `numperiod` to be the lag of the simple moving average. The first modified moving average is calculated like a simple moving average. Subsequent values are calculated by adding the new price and subtracting the last average from the resulting sum.

`output = tsmovavg(vector, 'm', numperiod, dim)` returns the modified moving average for the vector. The modified moving average is similar to the simple moving average. Consider the argument `numperiod` to be the lag of the simple moving average. The first modified moving average is calculated like a simple moving average. Subsequent values are calculated by adding the new price and subtracting the last average from the resulting sum.

## Examples

### Compute Five Forms of Moving Averages Using a Financial Time Series Object

Load the financial time series object, `dis` for Disney stock and look at the weekly data for this time series.

```
load disney.mat
weekly = toweekly(dis);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
dates = (weekly.dates);
price = fts2mat(weekly.CLOSE);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

Set the `|lag|` input argument for the window size for the moving average.

```
window_size = 12;
```

Calculate the simple moving average.

```
simple = tsmovavg(price, 's', window_size, 1);
```

Warning: TSMOVAVG will be removed in a future release. Use MOVAVG instead.

Calculate the exponential weighted moving average moving average.

```
exp = tsmovavg(price, 'e', window_size, 1);
```

Warning: TSMOVAVG will be removed in a future release. Use MOVAVG instead.

Calculate the triangular moving average moving average.

```
tri = tsmovavg(price, 't', window_size, 1);
```

Warning: TSMOVAVG will be removed in a future release. Use MOVAVG instead.

Calculate the weighted moving average moving average.

```
semi_gaussian = [0.026 0.045 0.071 0.1 0.12 0.138];  
semi_gaussian = [semi_gaussian fliplr(semi_gaussian)];  
weighted = tsmovavg(price, 'w', semi_gaussian, 1);
```

Warning: TSMOVAVG will be removed in a future release. Use MOVAVG instead.

Calculate the modified moving average moving average.

```
modif = tsmovavg(price, 'm', window_size, 1);
```

Warning: TSMOVAVG will be removed in a future release. Use MOVAVG instead.

Plot the results for the five moving average calculations for Disney stock.

```
plot(dates, price, ...  
     dates, simple, ...  
     dates, exp, ...  
     dates, tri, ...  
     dates, weighted, ...  
     dates, modif)  
datetick  
legend('Stock Price', 'Simple', 'Exponential', 'Triangular', 'Weighted', ...  
       'Modified', 'Location', 'NorthWest')  
title('Disney Weekly Price & Moving Averages')
```

## Input Arguments

### **tsobj** — Financial time series object

object

Financial time series object specified using a time series object created using `fints`.

### **'s'** — Indicator for simple moving average

character vector

`lag` is the parameter indicating the number of previous data points to be used in conjunction with the current data point when calculating the simple moving average.

### **lag** — Number of previous data points

nonnegative integer

Number of previous data points specified as a nonnegative integer. `lag` indicates the window size or number of periods of the moving average.

### **vector** — Set of observations

vector or matrix

Set of observations specified as a vector or matrix.

**dim — dimension to operate along**

positive integer with value 1 or 2

Dimension to operate along, specified as a positive integer with a value of 1 or 2. `dim` is an optional input argument, and if it is not included as an input, the default value 2 is assumed. The default of `dim = 2` indicates a row-oriented matrix, where each row is a variable and each column is an observation.

If `dim = 1`, the input is assumed to be a column vector or column-oriented matrix, where each column is a variable and each row an observation.

**'e' — Indicator for exponential moving average**

character vector

Exponential moving average is a weighted moving average, where `timeperiod` is the time period of the exponential moving average. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10 period exponential moving average weights the most recent price by 18.18%.

Exponential Percentage =  $2 / (\text{TIMEPER} + 1)$  or  $2 / (\text{WINDOW\_SIZE} + 1)$

**timeperiod — Length of time period**

nonnegative integer

Length of time period specified as a nonnegative integer.

**'t' — Indicator for triangular moving average**

character vector

Triangular moving average is a double-smoothing of the data. The first simple moving average is calculated with a window width of  $\text{ceil}(\text{numperiod} + 1) / 2$ . Then a second simple moving average is calculated on the first moving average with the same window size.

**'m' — Indicator for modified moving average**

character vector

The modified moving average is similar to the simple moving average. Consider the argument `numperiod` to be the lag of the simple moving average. The first modified moving average is calculated like a simple moving average. Subsequent values are calculated by adding the new price and subtracting the last average from the resulting sum.

**numperiod — Number of periods considered**

nonnegative integer

Number of periods considered specified as a nonnegative integer.

**'w' — Indicator for weighted moving average**

character vector

A weighted moving average is calculated with a weight vector, `weights`. The length of the weight vector determines the size of the window. If larger weight factors are used for more recent prices and smaller factors for previous prices, the trend is more responsive to recent changes.

**weights — Weights for each element in the moving window**

vector of weights

Weights for each element in the window specified as a vector of weights.

## Output Arguments

### **output** — Moving average calculation

vector or matrix

Moving average calculation returned as a vector or matrix. The output returned from `tsmovavg` is identical in format to the input.

## typprice

Typical price

---

**Note** `typprice` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
TypicalPrice = typprice(Data)
```

### Description

`TypicalPrice = typprice(Data)` calculates the typical prices from the series of high, low, and closing prices. The typical price is the average of the high, low, and closing prices for each period.

### Examples

#### Calculate the Typical Price for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
TypicalPrice = typprice(TMW);
plot(TypicalPrice.Time, TypicalPrice.TypicalPrice)
title('Typical Price for TMW')
```

## Input Arguments

### Data — Data for high, low, and closing prices

matrix | table | timetable

Data for high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-3 matrix of high, low, and closing prices stored in the corresponding columns. Timetables and tables with M rows must contain variables named 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### TypicalPrice — Typical price series

matrix | table | timetable

Typical price series, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

# uicalendar

Graphical calendar

## Syntax

```
uicalendar(Name, Value)
```

## Description

`uicalendar(Name, Value)` supports a customizable graphical calendar that interfaces with one or more `uicontrol`. `uicalendar` populates one or more `uicontrol` with user-selected dates.

## Examples

### Use uicalendar with an uicontrol

Create an `uicontrol`:

```
textH1 = uicontrol('style', 'edit', 'position', [10 10 100 20])
```

```
textH1 =
```

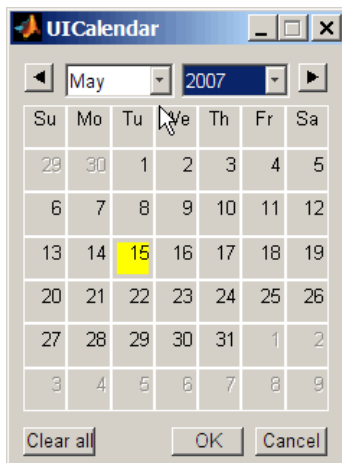

Uicontrol with properties:

```

        Style: 'edit'
        String: ''
    BackgroundColor: [0.9400 0.9400 0.9400]
        Callback: ''
        Value: 0
    Position: [10 10 100 20]
        Units: 'pixels'
```

Call `UICalendar`:

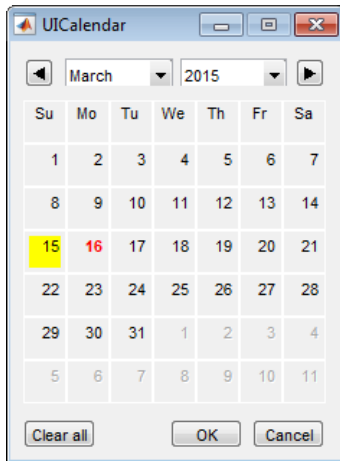

```
uicalendar('DestinationUI', {textH1, 'string'})
```

Select a date and click OK.

Alternatively, you can use datetime arrays for `InitDate` and `Holiday`.

```
uicalendar('InitDate',datetime('15-Mar-2015','Locale','en_US'),'Holiday',datetime('16-Mar-2015','Locale','en_US'))
```

Select a date and click OK. For more information on using `uicalendar` with an application, see “Example of Using UICalendar with an Application” on page 16-4.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `uicalendar('InitDate',datetime('15-Mar-2015','Locale','en_US'),'Holiday',datetime('16-Mar-2015','Locale','en_US'))`

### BusDays — Flag to indicate nonbusiness days

0 (Standard calendar without nonbusiness day indicators) (default) | numeric values of 0 or 1

Flag to indicate nonbusiness days, specified using numeric values of 0 or 1. The values are:

- 0 — (Default) Standard calendar without nonbusiness day indicators.
- 1 — Marks NYSE nonbusiness days in red.

Data Types: `logical`

### BusDaySelect — Flag to indicate whether business and nonbusiness days

1 (Allows selections of business and nonbusiness days) (default) | numeric values of 0 or 1

Flag to indicate whether business and nonbusiness days, specified using numeric values of 0 or 1. The values are:

- 0 — Only allow selection of business days. Nonbusiness days are determined from the following parameters:

- 'BusDays'
  - 'Holiday'
  - 'Weekend'
- 1 — (Default) Allows selections of business and nonbusiness days.

Data Types: logical

### **DateBoxColor — Color of date squares**

[date R G B]

Color of date squares, specified using [date R G B], where [R G B] is the color.

Data Types: double

### **DateStrColor — Color of numeric date number in the date square**

[date R G B]

Color of numeric date number in the date square, specified using [date R G B], where [R G B] is the color.

Data Types: double

### **DestinationUI — Destination object's handles**

'string' (default UI property populated with dates) (default) | values are H or {H, {Prop}}

Destination object's handles, specified with values H or {H, {Prop}}. The values are:

- H — Scalar or vector of the destination object's handles. The default UI property that is populated with the dates is a character vector.
- {H, {Prop}} — Cell array of handles and the destination object's UI properties. H must be a scalar or vector and Prop must be a single property character vector or a cell array of property character vectors.

Data Types: char | cell

### **Holiday — Holiday dates in calendar**

serial date numbers | datetime arrays

Holiday dates in calendar, specified using a scalar or vector of serial date numbers or datetime arrays. The corresponding date character vector of the holiday appears Red.

Data Types: double | datetime

### **InitDate — Initial start date when calendar is initialized**

TODAY (default) | serial date number | datetime array | date character vector

Initial start date when calendar is initialized, specified with date values using a serial date number, datetime array, or date character vector. The values are:

- Datenum — Numeric or datetime array date value specifying the initial start date when the calendar is initialized. The default date is TODAY.
- Datestr — Date character vector value specifying the initial start date when the calendar is initialized. Datestr must include a Year, Month, and Day (for example, 01-Jan-2006).

Data Types: `double` | `char` | `datetime`

### **InputDateFormat — Format of initial start date**

character vector

Format of initial start date (`InitDate`), specified using a character vector. `Seedatestr` for date format values.

Data Types: `double` | `datetime`

### **OutputDateFormat — Format of output date**

character vector

Format of output date, specified using a character vector. `Seedatestr` for date format values.

Data Types: `double` | `datetime`

### **OutputDateStyle — Style for output date**

0 (default) | numeric value of 0, 1, 2, or 3

Style for output date, specified using a value of 0, 1, 2, or 3. The values are:

- 0 — (Default) Returns a single date character vector or a cell array (row) of date character vectors. For example, `{'01-Jan-2001, 02-Jan-2001, ...'}`.
- 1 — Returns a single date character vector or a cell (column) array of date character vectors. For example, `{'01-Jan-2001; 02-Jan-2001; ...'}`.
- 2 — Returns a character vector representation of a row vector of datenums. For example, `'[732758, 732759, 732760, 732761]'`.
- 3 — Returns a character vector representation of a column vector of datenums. For example, `'[732758; 732759; 732760; 732761]'`.

Data Types: `double`

### **SelectionType — Flag for date selection**

1 (default) | numeric value of 0 or 1

Flag for date selection, specified with using a value of 0 or 1. The values are:

- 0 — Allows multiple date selections.
- 1 — (Default) Allows only a single date selection.

Data Types: `logical`

### **Weekend — Define weekend days**

1 (default) | numeric values of 1 through 7

Define weekend days, specified using a value of 1 through 7. Weekend days are marked in red. `DayOfWeek` can be a vector containing the following numeric values:

- 1 — Sunday
- 2 — Monday
- 3 — Tuesday

- 4 — Wednesday
- 5 — Thursday
- 6 — Friday
- 7 — Saturday

Also this value can be a vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days then `WEEKEND = [1 0 0 0 0 0 1]`.

Data Types: double

### **WindowState — Window figure properties**

Normal (default) | character vector with value of Normal or Modal

Window figure properties, specified with using a character vector with a value of Normal or Modal. The values are:

- Normal — (Default) Standard figure properties.
- Modal — Modal figures remain stacked above all normal figures and the MATLAB Command Window.

Data Types: char

## var

Variance

---

**Note** `var` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
y = var(X)
y = var(X,1)
y = var(X,W)
y = var(X,W,DIM)
```

### Arguments

|     |                                              |
|-----|----------------------------------------------|
| X   | Financial times series object.               |
| W   | Weight vector used in calculating variance.  |
| DIM | Dimension of X used in calculating variance. |

### Description

`var` supports financial time series objects based on the MATLAB `var` function. See `var`.

`y = var(X)`, if `X` is a financial time series object and returns the variance of each series.

`var` normalizes `y` by  $N - 1$  if  $N > 1$ , where  $N$  is the sample size. This is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples. For  $N = 1$ , `y` is normalized by  $N$ .

`y = var(X,1)` normalizes by  $N$  and produces the second moment of the sample about its mean. `var(X, 0)` is the same as `var(X)`.

`y = var(X,W)` computes the variance using the weight vector `W`. The length of `W` must equal the length of the dimension over which `var` operates, and its elements must be nonnegative. `var` normalizes `W` to sum to 1. Use a value of 0 for `W` to use the default normalization by  $N - 1$ , or use a value of 1 to use  $N$ .

`y = var(X,W,DIM)` takes the variance along the dimension `DIM` of `X`.

### Examples

The variance is the square of the standard deviation. Consider if

```
f = fints((today:today+1)', [4 -2 1; 9 5 7])
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints (line 165)  
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/display (line 66)
```

```
f =
```

```
  desc: (none)  
  freq: Unknown (0)
```

```
  'dates: (2)'   'series1: (2)'   'series2: (2)'   'series3: (2)'  
'02-Oct-2017' [          4] [          -2] [          1]  
'03-Oct-2017' [          9] [           5] [          7]
```

```
then
```

```
var(f, 0, 1)
```

```
is
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/var (line 49)  
[12.5 24.5 18.0]
```

```
and
```

```
var(f, 0, 2)
```

```
is
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/var (line 49)  
[9.0; 4.0]
```

## vertcat

Concatenate financial time series objects vertically

---

**Note** `vertcat` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
vertcat
```

### Description

`vertcat` implements vertical concatenation of financial time series objects. `vertcat` essentially adds data points to a time series object. Objects to be vertically concatenated must not have any duplicate dates and/or times or any overlapping dates and/or times. The description fields are concatenated as well. They are separated by `||`.

### Examples

Create two financial time series objects with daily frequencies:

```
myfts = fints((today:today+4)', (1:5)', 'DataSeries', 'd')
yourfts = fints((today+5:today+9)', (11:15)', 'DataSeries', 'd')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
myfts =
```

```
desc: (none)
freq: Daily (1)

'dates: (5)'      'DataSeries: (5)'
'02-Oct-2017'    [          1]
'03-Oct-2017'    [          2]
'04-Oct-2017'    [          3]
'05-Oct-2017'    [          4]
'06-Oct-2017'    [          5]
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
yourfts =
```

```
desc: (none)
freq: Daily (1)
```

```

'dates: (5)'      'DataSeries: (5)'
'07-Oct-2017'   [          11]
'08-Oct-2017'   [          12]
'09-Oct-2017'   [          13]
'10-Oct-2017'   [          14]
'11-Oct-2017'   [          15]

```

Use `vertcat` to concatenate them vertically:

```
newfts1 = [myfts; yourfts]
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/vertcat (line 35)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/display (line 66)
```

```
newfts1 =
```

```

desc:  ||
freq:  Daily (1)

'dates: (10)'      'DataSeries: (10)'
'11-Dec-2001'     [          1]
'12-Dec-2001'     [          2]
'13-Dec-2001'     [          3]
'14-Dec-2001'     [          4]
'15-Dec-2001'     [          5]
'16-Dec-2001'     [         11]
'17-Dec-2001'     [         12]
'18-Dec-2001'     [         13]
'19-Dec-2001'     [         14]
'20-Dec-2001'     [         15]

```

Create two financial time series objects with different frequencies:

```

myfts = fints((today:today+4)', (1:5)', 'DataSeries', 'd');
hisfts = fints((today+5:7:today+34)', (11:15)', 'DataSeries', ...
'w')

```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints (line 165)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints (line 165)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/display (line 66)
```

```
hisfts =
```

```

desc: (none)
freq: Weekly (2)

'dates: (5)'      'DataSeries: (5)'
'07-Oct-2017'   [          11]
'14-Oct-2017'   [          12]
'21-Oct-2017'   [          13]
'28-Oct-2017'   [          14]
'04-Nov-2017'   [          15]

```

Concatenate these two objects vertically:

```
newfts2 = [myfts; hisfts]
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/vertcat (line 35)  
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/display (line 66)
```

```
newfts2 =
```

```
desc:  ||  
freq:  Unknown (0)  
  
'dates: (10)'      'DataSeries: (10)'  
'11-Dec-2001'     [          1]  
'12-Dec-2001'     [          2]  
'13-Dec-2001'     [          3]  
'14-Dec-2001'     [          4]  
'15-Dec-2001'     [          5]  
'16-Dec-2001'     [         11]  
'23-Dec-2001'     [         12]  
'30-Dec-2001'     [         13]  
'06-Jan-2002'     [         14]  
'13-Jan-2002'     [         15]
```

If all frequency indicators are the same, the new object has the same frequency indicator. However, if one of the concatenated objects has a different `freq` from the other(s), the frequency of the resulting object is set to `Unknown (0)`. In these examples, `newfts1` has `Daily` frequency, while `newfts2` has `Unknown (0)` frequency.

“Financial Time Series Operations” on page 13-6

**Introduced before R2006a**

# volarea

Price and volume chart

---

**Note** volarea is updated to accept data input as a matrix, timetable, or table.

The syntax for volarea has changed. Previously, when using table input, the first column of dates could be serial date numbers, date character vectors, or datetime arrays, and you were required to have specific number of columns.

When using table input, the new syntax for volarea supports:

- No need for time information. If you want to pass in date information, use timetable input.
  - No requirement of specific number of columns. However, you must provide valid column names. volarea must contain a column named 'price' (case insensitive).
- 

## Syntax

```
volarea(Data)  
h = volarea(ax,Data)
```

## Description

volarea(Data) plots a chart from a series of price and traded volume of a security.

h = volarea(ax,Data) adds an optional argument for ax.

## Examples

### Plot Asset Date, Price, and Volume on a Single Axis for a Stock

Load the file SimulatedStock.mat, which provides a timetable (TMW) for financial data for TMW stock. This example shows how to plot asset date, price, and volume on a single axis, given asset TMW containing asset price and volume in most recent 21 days. Note that the variable name of asset price is be renamed to 'Price' (case insensitive).

```
load SimulatedStock.mat;  
TMW.Properties.VariableNames{'Close'} = 'Price';  
volarea(TMW(end-20:end,:))  
title('Price and Volume Chart for TMW')
```

## Input Arguments

### Data — Data for prices and traded volume

matrix | table | timetable

Data for prices and traded volume, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-2 matrix of prices and traded volume. Timetables and tables with M rows must contain variables named 'Price' and 'Volume' (case insensitive).

Data Types: double | table | timetable

### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The volarea plot is created in the axes specified by ax instead of in the current axes (ax = gca). The option ax can precede any of the input argument combinations.

Data Types: object

## Output Arguments

### h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

### **See Also**

`candle` | `highlow` | `kagi` | `linebreak` | `movavg` | `pointfig` | `table` | `timetable`

### **Topics**

“Using Timetables in Finance”

“Convert Financial Time Series Objects `fints` to Timetables” on page 12-2

**Introduced in R2008a**

## volroc

Volume rate of change

---

**Note** `volroc` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a vector, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
volumeChangeRate = volroc(Data)
volumeChangeRate = volroc( ___, Name, Value)
```

### Description

`volumeChangeRate = volroc(Data)` calculates the volume rate-of-change from a data series of volume traded. The volume rate-of-change is calculated between the current volume and the volume  $n$  periods ago. By default, the Volume rate of change is based on a 12-period difference.

`volumeChangeRate = volroc( ___, Name, Value)` adds optional name-value pair arguments.

### Examples

#### Calculate the Volume Rate of Change for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
volumeChangeRate = volroc(TMW);
plot(volumeChangeRate.Time, volumeChangeRate.VolumeChangeRate)
title('Volume Rate of Change for TMW')
```

## Input Arguments

### Data — Data for volume traded

vector | table | timetable

Data for volume traded, specified as a vector, table, or timetable. For vector input, `Data` is an M-by-1 column vector of volume traded. Timetables and tables with M rows must contain a variable named 'Volume' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `volumeChangeRate = volroc(TMW, 'NumPeriods', 18)`

### NumPeriods — Period difference for volumeChangeRate

12 (default) | positive integer

Period difference for `volumeChangeRate`, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

## Output Arguments

### **volumeChangeRate — Volume rate of change series**

vector | table | timetable

Volume rate of change series, returned with the same number of rows (M) and the same type (vector, table, or timetable) as the input Data.

# wclose

Weighted close

---

**Note** wclose has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

`WeightedClose = wclose(Data)`

## Description

`WeightedClose = wclose(Data)` calculates the weighted closing prices from the series of high, low, and closing prices. The weighted closing price is the average of twice the closing price plus the high and low prices.

## Examples

### Calculate the Weighted Closing Prices for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
WeightedClose = wclose(TMW);
plot(WeightedClose.Time,WeightedClose.WeightedClose)
title('Weighted Closing Prices for TMW')
```

## Input Arguments

### Data — Data for high, low, and closing prices

matrix | table | timetable

Data for high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-3 matrix of high, low, and closing prices stored in the corresponding columns. Timetables and tables with M rows must contain variables named 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### WeightedClose — Weighted closing price series

matrix | table | timetable

Weighted closing price series, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input **Data**.

“Convert Financial Time Series Objects fints to Timetables” on page 12-2

**Introduced before R2006a**

## weeknum

Week in year

### Syntax

```
[N] = weeknum(D)
[N] = weeknum( ____, W, E)
```

### Description

[N] = weeknum(D) returns the week in year. The weeknum function considers the week containing January 1 to be the first week of the year.

[N] = weeknum( \_\_\_\_, W, E) returns the week in year using the optional input arguments for W and E. The weeknum function considers the week containing January 1 to be the first week of the year.

### Examples

#### Determine the Week of the Year

Determine the week of the year using a serial date number.

```
N = weeknum(728647)
```

```
N = 52
```

Determine the week of the year using a character vector.

```
N = weeknum('19-Dec-1994')
```

```
N = 52
```

Determine the week of the year using a datetime array.

```
N = weeknum(datetime('19-Dec-1994','Locale','en_US'))
```

```
N = 52
```

The first week of the year must have at least four days in it. For example, January 8, 2004 was a Thursday. The European standard is used because the first week of the year is the first week longer than three days.

```
weeknum('08-jan-2004',1,1)
```

```
ans = 1
```

You can also use weeknum with datenum.

```
weeknum(datenum('01-Jan-2004'):datenum('08-Jan-2004'))
```

```
ans = 1×8
```

```
1 1 1 2 2 2 2 2
```

The default start day of the week is Sunday. Every day after, and including the first Sunday of the year (04-Jan-2004), returns 2 denoting the second week. In this case, the first of week of the year started before January 1, 2004. You can also use `weeknum` with `datenum` and specify a `D` value of 5 to indicate that the weeks start on Thursday.

```
weeknum(datenum('01-Jan-2004'):datenum('08-Jan-2004'),5)
```

```
ans = 1×8
```

```
1 1 1 1 1 1 1 2
```

The first week of the year that has four or more days, based on the specified start day, is considered week one (even if this is not the first week in the calendar). Any day falling in (or before) this week is given a week number of 1.

## Input Arguments

### D — Date to determine week in year

serial date number | data character vector | datetime array

Date to determine week in year, specified as a serial date number, date character vector, or datetime array.

Serial date numbers can be a matrix. Date character vectors can be specified as a one-dimensional cell array of character vectors. All the date character vectors must have the same format.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

Data Types: `single` | `double` | `char` | `datetime`

### W — Day a week begins

1 (default) | integer with value 1 through 7 | vector of integers with values 1 through 7

Day a week begins, specified as an integer or a vector of integers from 1 through 7.

- 1 — Sunday (default)
- 2 — Monday
- 3 — Tuesday
- 4 — Wednesday
- 5 — Thursday
- 6 — Friday
- 7 — Saturday

The `weeknum` function considers the week containing January 1 to be the first week of the year.

Data Types: `single` | `double`

### E — Flag indicates if week of year display is European standard

0 (default) | numeric with values 1 or 0

Flag indicates if week of year display is European standard, specified as 1 (to use the European standard) or 0 (not to use the European standard).

The European standard considers first week of year to be first week longer than three days, offset by the given week's start day.

Data Types: `logical`

## Output Arguments

### **N** — Week number of the year, given D

`numeric` | `column vector`

Week number of the year, given D, returned as a numeric value, given D, a serial date number, date character vector, or datetime array. If D is a one-dimensional cell array of character vectors, then `weeknum` returns a column vector of *M* week numbers, where *M* is the number of character vectors in D.

If the optional input arguments *W* and *E* are defined, the week of the year is in the European standard.

# weights2holdings

Portfolio values and weights into holdings

## Syntax

Holdings = weights2holdings(Values,Weights,Prices)

## Arguments

|         |                                                                                                                                                                                                               |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values  | Scalar or number of portfolios (NPORTS) vector containing portfolio values.                                                                                                                                   |
| Weights | NPORTS by number of assets (NASSETS) matrix with portfolio weights. The weights sum to the value of a Budget constraint, which is usually 1. (See holdings2weights for information about budget constraints.) |
| Prices  | NASSETS vector of prices.                                                                                                                                                                                     |

## Description

Holdings = weights2holdings(Values,Weights,Prices) converts portfolio values and weights into portfolio holdings.

Holdings is a NPORTS-by-NASSETS matrix containing the holdings of NPORTS portfolios that contain NASSETS assets.

---

**Note** This function does not create round-lot positions. Holdings are floating-point values.

---

## See Also

holdings2weights

## Topics

**Introduced before R2006a**

## willad

Williams Accumulation/Distribution line

---

**Note** `willad` has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
WADLine = willad(Data)
```

### Description

`WADLine = willad(Data)` calculates the Williams Accumulation/Distribution line from the series of high, low, and closing prices.

### Examples

#### Calculate the Williams Accumulation/Distribution Line for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
WADLine = willad(TMW);
plot(WADLine.Time,WADLine.WillAD)
title('Williams A/D Line for TMW')
```

## Input Arguments

### Data — Data for high, low, and closing prices

matrix | table | timetable

Data for high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, `Data` is an  $M$ -by-3 matrix of high, low, and closing prices stored in the corresponding columns. Timetables and tables with  $M$  rows must contain variables named 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### WADLine — Williams Accumulation/Distribution line

matrix | table | timetable

Williams Accumulation/Distribution line, returned with the same number of rows ( $M$ ) and the same type (matrix, table, or timetable) as the input `Data`.

# willpctr

Williams %R

---

**Note** willpctr has been partially removed and will no longer accept a `fints` object (`tsobj`) argument. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

## Syntax

```
PercentR = willpctr(Data)
PercentR = willpctr( ___,Name,Value)
```

## Description

`PercentR = willpctr(Data)` calculates the Williams PercentR (%R) values for a data series of with high, low, and closing prices.

`PercentR = willpctr( ___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Williams %R for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
PercentR = willpctr(TMW);
plot(PercentR.Time,PercentR.WillPercentR)
title('Williams %R for TMW')
```

## Input Arguments

### Data — Data with high, low, and close information

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-3 with high, low, and closing prices stored in the corresponding columns. Timetables and tables with `M` rows must contain variables named `'High'`, `'Low'`, and `'Close'` (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `PercentR = willpctr(TMW, 'NumPeriods', 15)`

### NumPeriods — Moving window for Williams PercentR

14 (default) | positive integer

Moving window for Williams PercentR, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar positive integer.

Data Types: double

## Output Arguments

### PercentR — Williams PercentR series

matrix | table | timetable

Williams PercentR series, returned with the same number of rows (**M**) and the same type (matrix, table, or timetable) as the input **Data**.

## More About

### Williams %R

Williams %R shows the current closing price in relation to the high and low of the past  $n$  days.

By default, Williams %R values are based on 14 periods.

## wrkdydif

Number of working days between dates

### Syntax

```
Days = wrkdydif(StartDate,EndDate,Holidays)
```

### Description

`Days = wrkdydif(StartDate,EndDate,Holidays)` returns the number of working days between dates `StartDate` and `EndDate` inclusive. `Holidays` is the number of holidays between the given dates, an integer.

### Examples

#### Determine the Number of Working Days Between a StartDate and EndDate

Determine `Days` using date character vectors for `StartDate` and `EndDate`.

```
Days = wrkdydif('9/1/2000', '9/11/2000', 1)
```

```
Days = 6
```

Determine `Days` using serial date numbers for `StartDate` and `EndDate`.

```
Days = wrkdydif(730730, 730740, 1)
```

```
Days = 6
```

Determine `Days` using a datetime array for `EndDate`.

```
Days = wrkdydif('9/1/2000', datetime('11-Sep-2000','Locale','en_US'), 1)
```

```
Days = 6
```

### Input Arguments

#### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

#### EndDate — End date

serial date number | date character vector | datetime object

End date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Holidays — Holidays between StartDate and EndDate**

vector of integers

Holidays between the StartDate and EndDate, specified as an N-by-1 or 1-by-N vector of integers.

Data Types: single | double

## **Output Arguments**

### **Days — Number of working days between dates StartDate and EndDate inclusive**

integer

Number of working days between dates StartDate and EndDate inclusive, returned an N-by-1 or 1-by-N vector of integers.

## x2mdate

Excel serial date number to MATLAB serial date number or datetime format

### Syntax

```
MATLABDate = x2mdate(ExcelDateNumber,Convention)
MATLABDate = x2mdate( ____,outputType)
```

### Description

`MATLABDate = x2mdate(ExcelDateNumber,Convention)` converts Excel serial date numbers to MATLAB serial date numbers or datetime format.

MATLAB date numbers start with 1 = January 1, 0000 A.D., hence there is a difference of 693960 relative to the 1900 date system, or 695422 relative to the 1904 date system. This function is useful with Spreadsheet Link software.

`MATLABDate = x2mdate( ____,outputType)` converts Excel serial date numbers to MATLAB serial date numbers or datetime format using an optional input argument for `outputType`.

The type of output is determined by an optional `outputType` input. If `outputType` is 'datenum', then `MATLABDate` is a serial date number. If `outputType` is 'datetime', then `MATLABDate` is a datetime array. By default, `outputType` is 'datenum'.

### Examples

#### Convert Excel Serial Date Numbers to MATLAB Dates

Given Excel® date numbers in the 1904 system, convert them to MATLAB® serial date numbers, and then to date character vectors.

```
ExDates = [35423 35788 36153];
MATLABDate = x2mdate(ExDates, 1)

MATLABDate = 1×3

    730845    731210    731575
```

```
datestr(MATLABDate)

ans = 3×11 char array
    '25-Dec-2000'
    '25-Dec-2001'
    '25-Dec-2002'
```

Alternatively, use the optional input `outputType` to specify 'datetime' to return datetime format.

```
ExDates = [35423 35788 36153];
MATLABDate = x2mdate(ExDates, 1,'datetime')
```

```
MATLABDate = 1x3 datetime
    25-Dec-2000    25-Dec-2001    25-Dec-2002
```

## Input Arguments

### ExcelDateNumber — Excel serial date number

serial date number

Excel serial date number, specified as a scalar or vector of Excel serial date numbers.

Data Types: `double`

### Convention — Flag for Excel date system

0 (Excel 1900 date system is in effect) (default) | numeric with value 0 or 1

Flag for Excel date system, specified as a scalar or vector as a numeric with a value 0 or 1. `Convention` must be either a scalar or else must be the same size as `ExcelDateNumber`.

When `Convention = 0` (default), the Excel 1900 date system is in effect. When `Convention = 1`, the Excel 1904 date system is used.

In the Excel 1900 date system, the Excel serial date number 1 corresponds to January 1, 1900 A.D. In the Excel 1904 date system, date number 0 is January 1, 1904 A.D.

Due to a software limitation in Excel software, the year 1900 is considered a leap year. As a result, all `DATEVALUE`'s reported by Excel software between Jan. 1, 1900 and Feb. 28, 1900 (inclusive) differs from the values reported by 1. For example:

- In Excel software, Jan. 1, 1900 = 1
- In MATLAB, Jan. 1, 1900 - 693960 (for 1900 date system) = 2

```
datenum('Jan 1, 1900') - 693960
```

```
ans =
```

```
2
```

Data Types: `logical`

### outputType — Output date format

'datenum' (default) | character vector with values 'datenum' or 'datetime'

Output date format, specified as a character vector with values 'datenum' or 'datetime'. The output `MATLABDate` is in serial date format if 'datenum' is specified or datetime format if 'datetime' is specified. By default the output is in serial date format.

Data Types: `char`

## Output Arguments

### MATLABDate — MATLAB date

serial date numbers | datetime format

MATLAB date, returned as serial date numbers or datetime format.

The type of output is determined by an optional `outputType` input argument. If `outputType` is `'datenum'`, then `MATLABDate` is a serial date number. If `outputType` is `'datetime'`, then `MATLABDate` is a datetime array. By default, `outputType` is `'datenum'`.

# xirr

Internal rate of return for nonperiodic cash flow

## Syntax

```
Return = xirr(CashFlow, CashFlowDates)
Return = xirr(CashFlow, CashFlowDates, Guess, MaxIterations, Basis)
```

## Description

`Return = xirr(CashFlow, CashFlowDates)` returns the internal rate of return for a schedule of nonperiodic cash flows.

`Return = xirr(CashFlow, CashFlowDates, Guess, MaxIterations, Basis)` returns the internal rate of return for a schedule of nonperiodic cash flows with optional inputs.

## Input Arguments

### CashFlow

A vector or matrix of cash flows. If `CashFlow` is a matrix, each column represents a separate stream of cash flows whose internal rate of return is calculated. The first cash flow of each stream is the initial investment, entered as a negative number.

### CashFlowDates

(Required) `CashFlowDates` is specified as serial date numbers, date character vectors, or datetime arrays. The size of the input date numbers for `CashFlowDates` must be the same size as `CashFlow`. Each column of `CashFlowDate` represents the dates of the corresponding column of `CashFlow`.

### Guess

The initial estimate of the internal rate of return. `Guess` is a scalar applied to all streams, or a vector the same length as the number of streams.

**Default:** 0.1 (10%)

### MaxIterations

The positive integer number of iterations used by Newton's method to solve the internal rate of return. `MaxIterations` is a scalar applied to all streams, or a vector the same length as the number of streams.

**Default:** 50

### Basis

Day-count basis of the instrument. A vector of integers.

- 0 = actual/actual (default)

- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

**Default:** 0

## Output Arguments

### Return

Vector of the annualized internal rate of return of each cash flow stream. A NaN indicates that a solution is not found.

## Examples

Find the internal rate of return for an investment of \$10,000 that returns the following nonperiodic cash flow. The original investment is the first cash flow and is a negative number.

| Cash Flow | Dates             |
|-----------|-------------------|
| (\$10000) | January 12, 2007  |
| \$2500    | February 14, 2008 |
| \$2000    | March 3, 2008     |
| \$3000    | June 14, 2008     |
| \$4000    | December 1, 2008  |

Calculate the internal rate of return for this nonperiodic cash flow:

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
CashFlowDates = ['01/12/2007'
                 '02/14/2008'
                 '03/03/2008'
                 '06/14/2008'
                 '12/01/2008'];
Return = xirr(CashFlow, CashFlowDates)
```

This returns:

Return =  
0.1006 (or 10.0644% per annum)

Alternatively, you can use `datetime` input to calculate the internal rate of return for this nonperiodic cash flow:

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
CashFlowDates = ['01/12/2007'
                 '02/14/2008'
                 '03/03/2008'
                 '06/14/2008'
                 '12/01/2008'];
CashFlowDates = datetime(CashFlowDates, 'Locale', 'en_US');
Return = xirr(CashFlow, CashFlowDates)
```

This returns:

Return =  
0.1006 (or 10.0644% per annum)

## year

Year of date

### Syntax

```
Year = year(Date)
Year = year( ____, F)
```

### Description

`Year = year(Date)` returns the year of date given a serial date number or a date character vector.

`Year = year( ____, F)` returns the year of date given a serial date number or a date character vector, `Date`, using format defined by the optional input `F`. `Date` can be a character array where each row corresponds to one date character vector, or a one-dimensional cell array of character vectors. All the character vectors in `Date` must have the same format `F`. `F` must designate a supported date format symbol. For more information on supported date formats, see `datestr`.

### Examples

#### Determine the Year of the Date for Various Dates

Find the year for `Date` using a serial date number.

```
Year = year(731798.776)
Year = 2003
```

Find the year for `Date` using a date character vector format.

```
Year = year('05-Aug-2003')
Year = 2003
```

Use the optional `F` argument to designate a country-specific date format for a given `Date`.

```
Year = year('1999/05/09', 'yyyy/dd/mm')
Year = 1999
```

### Input Arguments

#### Date — Date to determine year

serial date number | date character vector | cell array of date character vectors

Date to determine year, specified as a serial date number or date character vector.

`Date` can be an array of date character vectors, where each row corresponds to one date character vector, or a one-dimensional cell array of character vectors. All the character vectors in `Date` must

---

have the same format `F`. `F` must designate a supported date format symbol. For more information on supported date formats, see `datestr`

Data Types: `single` | `double` | `char` | `cell`

### **F — Date format symbol**

character vector designating date format

Date format symbol, specified as a character vector to designate the date format symbol for input argument `Date`. For more information on supported date character vector formats, see `datestr`. Note, formats with 'Q' are not accepted.

Data Types: `char`

## **Output Arguments**

### **Year — Numeric representation of the year**

nonnegative integer

Numeric representation of the year, returned as a nonnegative integer.

## **See Also**

`datevec` | `day` | `month` | `yeardays`

### **Topics**

“Handle and Convert Dates” on page 2-2

**Introduced before R2006a**

## yeardays

Number of days in year

### Syntax

```
Days = yeardays(Year)
Days = yeardays( ____,Basis)
```

### Description

Days = yeardays(Year) returns the number of days in the given Year.

Days = yeardays( \_\_\_\_,Basis) returns the number of days in the given Year, based on the optional argument Basis for day-count.

### Examples

#### Determine the Number of Days in a Given Year

Find the number of days in a given Year.

```
Days = yeardays(2000)
```

```
Days = 366
```

Find the number of days in a given Year using the optional argument Basis.

```
Days = yeardays(2000, 1)
```

```
Days = 360
```

### Input Arguments

#### Year — Year to determine days

4 digit integer

Data Types: single | double

#### Basis — Day-count basis

0 (actual/actual) (default) | vector of integers with values 0,1,2,3,4,5,6,7,8,9,10,11,12,13

Day-count basis, specified as a vector of integers with values 0,1,2,3,4,5,6,7,8,9,10,11,12,13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

## Output Arguments

### Days — Number of days in given Year

nonnegative integer

Number of days in given Year, returned as a nonnegative integer.

## See Also

`days360` | `days365` | `daysact` | `year` | `yearfrac`

## Topics

“Handle and Convert Dates” on page 2-2

**Introduced before R2006a**

## yearfrac

Fraction of year between dates

### Syntax

```
YearFraction = yearfrac(StartDate,EndDate,Basis)
```

### Description

`YearFraction = yearfrac(StartDate,EndDate,Basis)` returns a fraction, in years, based on the number of days between dates `StartDate` and `EndDate` using the given day-count `Basis`.

The number of days in a year (365 or 366) is equal to the number of days in the calendar year after the `StartDate`. If `EndDate` is earlier than `StartDate`, `YearFraction` is negative.

All specified arguments must be number of instruments (NUMINST-by-1) or (1-by-NUMINST) conforming vectors or scalar arguments.

### Examples

#### Compute yearfrac When the Calendar Year After the StartDate is Not a Leap Year

Given a `Basis` of 0 and a `Basis` of 1, compute `yearfrac`.

Define the `StartDate` and `EndDate` using a `Basis` of 0.

```
YearFraction = yearfrac('14 mar 01', '14 sep 01', 0)
```

```
YearFraction = 0.5041
```

Define the `StartDate` and `EndDate` using a `Basis` of 1.

```
YearFraction = yearfrac('14 mar 01', '14 sep 01', 1)
```

```
YearFraction = 0.5000
```

#### Compute yearfrac When the Calendar Year After the StartDate is a Leap Year

Given a `Basis` of 0, compute `yearfrac` when the calendar after `StartDate` is in a leap year.

Define the `StartDate` and `EndDate` using a `Basis` of 0.

```
yearFraction = yearfrac('14 mar 03', '14 sep 03', 0)
```

```
yearFraction = 0.5027
```

There are 184 days between March 14 and September 14, and the calendar year after the `StartDate` is a leap year, so `yearfrac` returns  $184/366 = 0.5027$ .

### Compute the Fraction of a Year Using an actual/actual Basis

To get the fraction of a year between '31-Jul-2015' and '30-Sep-2015' using the actual/actual basis:

```
yearfrac('31-Jul-2015', '30-Sep-2015', 0)*2
```

```
ans = 0.3333
```

For the actual/actual basis, the fraction of a year is calculated as:

(Actual Days between Start Date and End Date)/(Actual Days between Start Date and exactly one year after Start Date)

There are 61 days between 31-Jul-2015 and 30-Sep-2015. Since the next year is a leap year, there are 366 days between 31-Jul-2015 and 31-Jul-2016. So, there is 61/366 which is exactly 1/6. So given this, exactly 2/6 is the expected result for the fraction of the six-month period.

### Compute yearfrac When the Date Range Spans a Leap Year

Use a Basis of 12 to compute yearfrac when parts of the date range are in leap year and in a non-leap year. The output YearFraction is a fraction, in years, based on the number of days between the StartDate and EndDate.

```
YearFraction = yearfrac('1-Jan-2016', '30-Jan-2017', 12)
```

```
YearFraction = 1.0795
```

### Compute yearfrac When Specifying datetime Arrays

Given a Basis of 9, compute yearfrac when the StartDate and EndDate are specified using datetime arrays.

```
yearfrac(datetime('1-Jan-2000', 'Locale', 'en_US'), '1/1/2001', 9)
```

```
ans = 1.0167
```

## Input Arguments

#### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

#### EndDate — End date

serial date number | date character vector | datetime object

End date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `char` | `datetime`

### **Basis — Day-count basis for each set of dates**

0 (actual/actual) (default) | vector of numerics with values 0 through 13

Day-count basis for each set of dates, specified as an N-by-1 or 1-by-N vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `single` | `double`

## **Output Arguments**

### **YearFraction — Real numbers identifying interval, in years, between StartDate and EndDate**

vector

Real numbers identifying the interval, in years, between StartDate and EndDate, returned an N-by-1 or 1-by-N vector.

## **More About**

### **Difference Between yearfrac and date2time**

The difference between `yearfrac` and `date2time` is that `date2time` counts full periods as a whole integer, even if the number of actual days in the periods are different. `yearfrac` does not count full periods.

For example,

```
yearfrac('1/1/2000', '1/1/2001', 9)
```

```
ans =
```

```
1.0167
```

yearfrac for Basis 9 (ACT/360 ICMA) calculates  $366/360 = 1.0167$ . So, even if the dates have the same month and date, with a difference of 1 in the year, the returned value may not be exactly 1. On the other hand, date2time calculates one full year period:

```
date2time('1/1/2000', '1/1/2001', 1, 9)
```

```
ans =
```

```
1
```

## ylddisc

Yield of discounted security

### Syntax

```
Yield = ylddisc(Settle,Maturity,Face,Price)
Yield = ylddisc( ____,Basis)
```

### Description

Yield = ylddisc(Settle,Maturity,Face,Price) returns the yield of a discounted security.

Yield = ylddisc( \_\_\_\_,Basis) adds optional an argument for Basis.

### Examples

#### Find the Yield of a Discounted Security

This example shows how to find the yield of the following discounted security.

```
Settle = '10/14/2000';
Maturity = '03/17/2001';
Face = 100;
Price = 96.28;
Basis = 2;
```

```
Yield = ylddisc(Settle, Maturity, Face, Price, Basis)
```

```
Yield = 0.0903
```

#### Find the Yield of a Discounted Security Using datetime Inputs

This example shows how to use datetime inputs to find the yield of the following discounted security.

```
Settle = '10/14/2000';
Maturity = '03/17/2001';
Face = 100;
Price = 96.28;
Basis = 2;
```

```
Settle = datetime(Settle,'Locale','en_US');
Maturity = datetime(Maturity,'Locale','en_US');
```

```
Yield = ylddisc(Settle, Maturity, Face, Price, Basis)
```

```
Yield = 0.0903
```

## Input Arguments

### **Settle — Settlement date of security**

serial date number | date character vector | datetime

Settlement date of the security, specified as serial date numbers, date character vectors, or datetime arrays. The `Settle` date must be before the `Maturity` date.

Data Types: double | char | datetime

### **Maturity — Maturity date of security**

serial date number | date character vector | datetime

Maturity date of the security, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Face — Redemption value of security**

numeric

Redemption value (par value) of the security, specified as a numeric value.

Data Types: double

### **Price — Discount price of security**

numeric

Discount price of the security, specified as a numeric value.

Data Types: double

### **Basis — (Optional) Day-count basis**

0 (actual/actual) (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Day-count basis for the security, specified using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `double`

## **Output Arguments**

### **Yield — Yield of discounted security**

`numeric`

Yield of discounted security, returned as a numeric value.

# yldmat

Yield with interest at maturity

## Syntax

```
Yield = yldmat(Settle,Maturity,Issue,Face,Price,CouponRate)
Yield = yldmat( ____,Basis)
```

## Description

Yield = yldmat(Settle,Maturity,Issue,Face,Price,CouponRate) returns the yield of a security paying interest at maturity.

Yield = yldmat( \_\_\_\_,Basis) adds an optional argument for Basis.

## Examples

### Find the Yield of a Security Paying Interest at Maturity

This example shows how to find the yield of a security paying interest at maturity for the following.

```
Settle = '02/07/2000';
Maturity = '04/13/2000';
Issue = '10/11/1999';
Face = 100;
Price = 99.98;
CouponRate = 0.0608;
Basis = 1;

Yield = yldmat(Settle, Maturity, Issue, Face, Price, ...
CouponRate, Basis)

Yield = 0.0607
```

### Find the Yield of a Security Paying Interest at Maturity Using datetime Inputs

This example shows how to use datetime inputs find the yield of a security paying interest at maturity for the following:

```
Settle = '7-Feb-2000';
Maturity = '13-Apr-2000';
Issue = '11-Oct-1999';
Face = 100;
Price = 99.98;
CouponRate = 0.0608;
Basis = 1;

Settle = datetime(Settle,'Locale','en_US');
```

```
Maturity = datetime(Maturity, 'Locale', 'en_US');  
Issue = datetime(Issue, 'Locale', 'en_US');  
  
Yield = yldmat(Settle, Maturity, Issue, Face, Price, ...  
CouponRate, Basis)  
  
Yield = 0.0607
```

## Input Arguments

### **Settle** — Settlement date of security

serial date number | date character vector | datetime

Settlement date of the security, specified as serial date numbers, date character vectors, or datetime arrays. The **Settle** date must be before the **Maturity** date.

Data Types: double | char | datetime

### **Maturity** — Maturity date of security

serial date number | date character vector | datetime

Maturity date of the security, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Issue** — Issue date of security

serial date number | date character vector | datetime

Issue date of the security, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Face** — Redemption value of security

numeric

Redemption value (par value) of the security, specified as a numeric value.

Data Types: double

### **Price** — Price of security

numeric

Price of the security, specified as a numeric value.

Data Types: double

### **CouponRate** — Coupon rate of security

decimal fraction

Coupon rate of the security, specified as a decimal fraction.

Data Types: double

### **Basis** — Day-count basis

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

(Optional) Day-count basis for the security, specified using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: double

## Output Arguments

### **Yield — Yield of a security paying interest at maturity**

numeric

Yield of a security paying interest at maturity, returned as a numeric value.

## References

## yldtbill

Yield of Treasury bill

### Syntax

```
Yield = yldtbill(Settle,Maturity,Face,Price)
```

### Description

`Yield = yldtbill(Settle,Maturity,Face,Price)` returns the yield for a Treasury bill.

### Examples

#### Find the Yield for a Treasury Bill

This example shows how to return the yield for a Treasury bill, given the settlement date of a Treasury bill is February 10, 2000, the maturity date is August 6, 2000, the par value is \$1000, and the price is \$981.36.

```
Yield = yldtbill('2/10/2000', '8/6/2000', 1000, 981.36)
```

```
Yield = 0.0384
```

#### Find the Yield for a Treasury Bill Using datetime Inputs

This example shows how to use `datetime` inputs to return the yield for a Treasury bill, given the settlement date of a Treasury bill is February 10, 2000, the maturity date is August 6, 2000, the par value is \$1000, and the price is \$981.36.

```
Yield = yldtbill(datetime('10-Feb-2000','Locale','en_US'), datetime('6-Aug-2000','Locale','en_US
```

```
Yield = 0.0384
```

### Input Arguments

#### Settle — Settlement date of Treasury bill

serial date number | date character vector | datetime

Settlement date of the Treasury bill, specified as serial date numbers, date character vectors, or datetime arrays. The `Settle` date must be before the `Maturity` date.

Data Types: double | char | datetime

#### Maturity — Maturity date of Treasury bill

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `char` | `datetime`

### **Face — Redemption value of Treasury bill**

numeric

Redemption value (par value) of the Treasury bill, specified as a numeric value.

Data Types: `double`

### **Price — Price of Treasury bill**

numeric

Price of the Treasury bill, specified as a numeric value.

Data Types: `double`

## **Output Arguments**

### **Yield — Yield for Treasury bill**

numeric

Yield for Treasury bill, returned as a numeric value.

## zbtprice

Zero curve bootstrapping from coupon bond data given price

### Syntax

```
[ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle)
ZeroRates, CurveDates = zbtprice( ____, OutputCompounding)
```

### Description

[ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle) uses the bootstrap method to return a zero curve given a portfolio of coupon bonds and their prices.

A zero curve consists of the yields to maturity for a portfolio of theoretical zero-coupon bonds that are derived from the input `Bonds` portfolio. The bootstrap method that this function uses does *not* require alignment among the cash-flow dates of the bonds in the input portfolio. It uses theoretical par bond arbitrage and yield interpolation to derive all zero rates; specifically, the interest rates for cash flows are determined using linear interpolation. For best results, use a portfolio of at least 30 bonds evenly spaced across the investment horizon.

ZeroRates, CurveDates = zbtprice( \_\_\_\_, OutputCompounding) adds an optional argument for `OutputCompounding`.

### Examples

#### Compute a Zero Curve Given a Portfolio of Coupon Bonds and Their Prices

Given data and prices for 12 coupon bonds, two with the same maturity date, and given the common settlement date.

```
Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;
         datenum('7/1/2000') 0.06 100 2 0 0;
         datenum('7/1/2000') 0.09375 100 6 1 0;
         datenum('6/30/2001') 0.05125 100 1 3 1;
         datenum('4/15/2002') 0.07125 100 4 1 0;
         datenum('1/15/2000') 0.065 100 2 0 0;
         datenum('9/1/1999') 0.08 100 3 3 0;
         datenum('4/30/2001') 0.05875 100 2 0 0;
         datenum('11/15/1999') 0.07125 100 2 0 0;
         datenum('6/30/2000') 0.07 100 2 3 1;
         datenum('7/1/2001') 0.0525 100 2 3 0;
         datenum('4/30/2002') 0.07 100 2 0 0];

Prices = [99.375;
         99.875;
         105.75 ;
         96.875;
         103.625;
         101.125;
         103.125;
```

```

    99.375;
    101.0 ;
    101.25 ;
    96.375;
    102.75 ];

```

```
Settle = datenum('12/18/1997');
```

Set semiannual compounding for the zero curve.

```
OutputCompounding = 2;
```

Execute the function `zbtprice` which returns the zero curve at the maturity dates. Note the mean zero rate for the two bonds with the same maturity date.

```
[ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle,...
OutputCompounding)
```

```
ZeroRates = 11x1

## Input Arguments

### Bonds — Coupon bond information to generate zero curve

table | matrix

Coupon bond information to generate zero curve, specified as a 6-column table or a n-by-2 to n-by-6 matrix of bond information, where the table columns or matrix columns contains:

- **Maturity** (Column 1, Required) Maturity date of the bond, as a serial date number. Use `datenum` to convert date character vectors to serial date numbers. If the input **Bonds** is a table, the **Maturity** dates can be serial date numbers, date character vectors, or datetime arrays.
- **CouponRate** (Column 2, Required) Decimal fraction indicating the coupon rate of the bond.
- **Face** (Column 3, Optional) Redemption or face value of the bond. Default = 100.
- **Period** (Column 4, Optional) Coupons per year of the bond. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
- **Basis** (Column 5, Optional) Day-count basis of the bond. A vector of integers.
  - 0 = actual/actual (default)
  - 1 = 30/360 (SIA)
  - 2 = actual/360
  - 3 = actual/365
  - 4 = 30/360 (BMA)
  - 5 = 30/360 (ISDA)
  - 6 = 30/360 (European)
  - 7 = actual/365 (Japanese)
  - 8 = actual/actual (ICMA)
  - 9 = actual/360 (ICMA)
  - 10 = actual/365 (ICMA)
  - 11 = 30/360E (ICMA)
  - 12 = actual/365 (ISDA)
  - 13 = BUS/252
  - For more information, see “Basis” on page 2-18.
- **EndMonthRule** (Column 6, Optional) End-of-month rule. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month

:

---

### Note

- If `Bonds` is a table, the `Maturity` dates can be serial date numbers, date character vectors, or datetime arrays.
  - If `Bonds` is a matrix, is an n-by-2 to n-by-6 matrix where each row describes a bond, the first two columns (`Maturity` and `CouponRate`) are required. The remainder of the columns are optional but must be added in order. All rows in `Bonds` must have the same number of columns.
- 

Data Types: `double` | `table`

### **Prices — Clean price (price without accrued interest) of each bond in Bonds**

numeric

Clean price (price without accrued interest) of each bond in `Bonds`, specified as a N-by-1 column vector. The number of rows ( $n$ ) must match the number of rows in `Bonds`.

Data Types: `double`

### **Settle — Settlement date representing time zero in derivation of zero curve**

serial date number | date character vector | datetime

Settlement date representing time zero in derivation of zero curve, specified as serial date number, date character vector, or datetime array. `Settle` represents time zero for deriving the zero curve, and it is normally the common settlement date for all the bonds.

Data Types: `double` | `char` | `datetime`

### **OutputCompounding — Compounding frequency of output ZeroRates**

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

(Optional) Compounding frequency of output `ZeroRates`, specified using the allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: `double`

## **Output Arguments**

### **ZeroRates — Implied zero rates for each point along the investment horizon defined by maturity date**

decimal fractions

Implied zero rates for each point along the investment horizon defined by a maturity date, returned as a  $m$ -by-1 vector of decimal fractions where  $m$  is the number of bonds of unique maturity dates. In aggregate, the rates in `ZeroRates` constitute a zero curve.

If more than one bond has the same `Maturity` date, `zbtprice` returns the mean zero rate for that `Maturity`. Any rates before the first `Maturity` are assumed to be equal to the rate at the first `Maturity`, that is, the curve is assumed to be flat before the first `Maturity`.

### **CurveDates — Maturity dates that correspond to ZeroRates**

serial date number | date character vector | datetime

Maturity dates that correspond to the `ZeroRates`, returned as a  $m$ -by-1 vector of unique maturity dates, where  $m$  is the number of bonds of different maturity dates. These dates begin with the earliest `Maturity` date and end with the latest `Maturitydate` in the `Bonds` table or matrix.

If either inputs for `Bonds` or `Settle` have datetime values, then `CurveDates` is datetimes. Otherwise `CurveDates` is serial date numbers.

## zbtyield

Zero curve bootstrapping from coupon bond data given yield

### Syntax

```
[ZeroRates, CurveDates] = zbtyield(Bonds, YieldsSettle)
ZeroRates, CurveDates = zbtyield( ____, OutputCompounding)
```

### Description

[ZeroRates, CurveDates] = zbtyield(Bonds, YieldsSettle) uses the bootstrap method to return a zero curve given a portfolio of coupon bonds and their yields.

A zero curve consists of the yields to maturity for a portfolio of theoretical zero-coupon bonds that are derived from the input `Bonds` portfolio. The bootstrap method that this function uses does *not* require alignment among the cash-flow dates of the bonds in the input portfolio. It uses theoretical par bond arbitrage and yield interpolation to derive all zero rates; specifically, the interest rates for cash flows are determined using linear interpolation. For best results, use a portfolio of at least 30 bonds evenly spaced across the investment horizon.

`ZeroRates, CurveDates = zbtyield( ____, OutputCompounding)` adds an optional argument for `OutputCompounding`.

### Examples

#### Compute a Zero Curve Given a Portfolio of Coupon Bonds and Their Yields

Given data and yields to maturity for 12 coupon bonds, two with the same maturity date; and given the common settlement date.

```
Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;
          datenum('7/1/2000') 0.06 100 2 0 0;
          datenum('7/1/2000') 0.09375 100 6 1 0;
          datenum('6/30/2001') 0.05125 100 1 3 1;
          datenum('4/15/2002') 0.07125 100 4 1 0;
          datenum('1/15/2000') 0.065 100 2 0 0;
          datenum('9/1/1999') 0.08 100 3 3 0;
          datenum('4/30/2001') 0.05875 100 2 0 0;
          datenum('11/15/1999') 0.07125 100 2 0 0;
          datenum('6/30/2000') 0.07 100 2 3 1;
          datenum('7/1/2001') 0.0525 100 2 3 0;
          datenum('4/30/2002') 0.07 100 2 0 0];

Yields = [0.0616
          0.0605
          0.0687
          0.0612
          0.0615
          0.0591
          0.0603]
```

```

0.0608
0.0655
0.0646
0.0641
0.0627];

```

```
Settle = datenum('12/18/1997');
```

Set semiannual compounding for the zero curve.

```
OutputCompounding = 2;
```

Execute the function `zbyield` which returns the zero curve at the maturity dates. Note the mean zero rate for the two bonds with the same maturity date.

```
[ZeroRates, CurveDates] = zbyield(Bonds, Yields, Settle, ...
OutputCompounding)
```

```
ZeroRates = 11x1
```

## Input Arguments

### Bonds — Coupon bond information to generate zero curve

table | matrix

Coupon bond information to generate zero curve, specified as a 6-column table or a n-by-2 to n-by-6 matrix of bond information, where the table columns or matrix columns contains:

- **Maturity** (Column 1, Required) Maturity date of the bond, as a serial date number. Use `datenum` to convert date character vectors to serial date numbers. If the input `Bonds` is a table, the `Maturity` dates can be serial date numbers, date character vectors, or datetime arrays.
- **CouponRate** (Column 2, Required) Decimal fraction indicating the coupon rate of the bond.
- **Face** (Column 3, Optional) Redemption or face value of the bond. Default = 100.
- **Period** (Column 4, Optional) Coupons per year of the bond. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
- **Basis** (Column 5, Optional) Day-count basis of the bond. A vector of integers.
  - 0 = actual/actual (default)
  - 1 = 30/360 (SIA)
  - 2 = actual/360
  - 3 = actual/365
  - 4 = 30/360 (BMA)
  - 5 = 30/360 (ISDA)
  - 6 = 30/360 (European)
  - 7 = actual/365 (Japanese)
  - 8 = actual/actual (ICMA)
  - 9 = actual/360 (ICMA)
  - 10 = actual/365 (ICMA)
  - 11 = 30/360E (ICMA)
  - 12 = actual/365 (ISDA)
  - 13 = BUS/252
  - For more information, see “Basis” on page 2-18.
- **EndMonthRule** (Column 6, Optional) End-of-month rule. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month

:

---

**Note**

- If **Bonds** is a table, the **Maturity** dates can be serial date numbers, date character vectors, or datetime arrays.
  - If **Bonds** is a matrix, is an n-by-2 to n-by-6 matrix where each row describes a bond, the first two columns (**Maturity** and **CouponRate**) are required. The remainder of the columns are optional but must be added in order. All rows in **Bonds** must have the same number of columns.
- 

Data Types: double | table

**Yields — Yield to maturity of each bond in Bonds**

numeric

Yield to maturity of each bond in **Bonds**, specified as a N-by-1 column vector. The number of rows (*n*) must match the number of rows in **Bonds**.

---

**Note** Yield to maturity must be compounded semiannually.

---

Data Types: double

**Settle — Settlement date representing time zero in derivation of zero curve**

serial date number | date character vector | datetime

Settlement date representing time zero in derivation of zero curve, specified as serial date number, date character vector, or datetime array. **Settle** represents time zero for deriving the zero curve, and it is normally the common settlement date for all the bonds.

Data Types: double | char | datetime

**OutputCompounding — Compounding frequency of output ZeroRates**

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

(Optional) Compounding frequency of output **ZeroRates**, specified using the allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: double

## Output Arguments

### ZeroRates — Implied zero rates for each point along the investment horizon defined by maturity date

decimal fractions

Implied zero rates for each point along the investment horizon defined by a maturity date, returned as a  $m$ -by-1 vector of decimal fractions where  $m$  is the number of bonds with unique maturity dates. In aggregate, the rates in `ZeroRates` constitute a zero curve.

If more than one bond has the same `Maturity` date, `zbtyield` returns the mean zero rate for that `Maturity`. Any rates before the first `Maturity` are assumed to be equal to the rate at the first `Maturity`, that is, the curve is assumed to be flat before the first `Maturity`.

### CurveDates — Maturity dates that correspond to ZeroRates

serial date number | date character vector | datetime

Maturity dates that correspond to the `ZeroRates`, returned as a  $m$ -by-1 vector of unique maturity dates, where  $m$  is the number of bonds of different maturity dates. These dates begin with the earliest `Maturity` date and end with the latest `Maturitydate` in the `Bonds` table or matrix.

If either inputs for `Bonds` or `Settle` have `datetime` values, then `CurveDatesCurveDates` is `datetimes`. Otherwise `CurveDates` is serial date numbers.

**Introduced before R2006a**

# zero2disc

Discount curve given zero curve

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Compounding` and `Basis`.

---

## Syntax

```
[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle)
[DiscRates, CurveDates] = zero2disc( ____, Name, Value)
```

## Description

`[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle)` returns a discount curve given a zero curve and its maturity dates. If either inputs for `ZeroRates` or `CurveDates` is a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` is returned as a serial date number. The `DiscRates` output is the same for any of these input data types.

`[DiscRates, CurveDates] = zero2disc( ____, Name, Value)` adds optional name-value pair arguments

## Examples

### Compute a Discount Curve Given a Zero Curve and Maturity Dates

Given a zero curve over a set of maturity dates and a settlement date.

```
ZeroRates = [0.0464
             0.0509
             0.0524
             0.0525
             0.0531
             0.0525
             0.0530
             0.0531
             0.0549
             0.0536];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')
              datenum('25-Jun-2001')
              datenum('04-Sep-2001')
              datenum('12-Nov-2001')];
```

```
Settle = datenum('03-Nov-2000');
```

The zero curve is compounded daily on an actual/365 basis.

```
Compounding = 365;  
Basis = 3;
```

Execute the function `zero2disc` which returns the discount curve `DiscRates` at the maturity dates `CurveDates`.

```
[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, ...  
Settle, Compounding, Basis)
```

```
DiscRates = 10×1
```

```

## Input Arguments

### ZeroRates — Annualized zero rates

decimal fraction

Annualized zero rates, specified as a `NUMBONDS`-by-1 vector using decimal fractions. In aggregate, the zero rates constitute an implied zero curve for the investment horizon represented by `CurveDates`.

Data Types: `double`

### CurveDates — Maturity dates

serial date number | date character vector | datetime

Maturity dates that correspond to the input `ZeroRates`, specified as `NUMBONDS`-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `datetime` | `char`

### Settle — Common settlement date for ZeroRates

serial date number | date character vector | datetime

Common settlement date for `ZeroRates`, specified as serial date numbers, date character vectors, or datetime arrays. `Settle` is the settlement date for the bonds from which the zero curve was bootstrapped.

Data Types: `double` | `datetime` | `char`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle, 'Compounding', 4, 'Basis', 6)`

### Compounding — Rate at which input ZeroRates zero rates are compounded when annualized

2 (default) | numeric values: 0, 1, 2, 3, 4, 6, 12, 365, -1

Rate at which the input `ZeroRates` are compounded when annualized, specified as the comma-separated pair consisting of `'Compounding'` and allowed numeric values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

Data Types: `double`

**Basis — Day-count basis used for annualizing input ZeroRates**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis used for annualizing the input `ZeroRates`, specified as the comma-separated pair consisting of 'Basis' and allowed numeric values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

Data Types: `double`

**Output Arguments****DiscRates — Discount factors**

`decimal`

Discount factors, returned as a `NUMBONDS`-by-1 vector of decimal fractions. In aggregate, the discount factors constitute a discount curve for the investment horizon represented by `CurveDates`.

**CurveDates — Maturity dates that correspond to DiscRates**

`serial date number` | `date character vector` | `datetime`

Maturity dates that correspond to the `DiscRates`, returned as a `NUMBONDS`-by-1 vector of maturity dates that correspond to the discount factors. This vector is the same as the input vector `CurveDates`, but is sorted by ascending maturity.

If either inputs for `CurveDates` or `Settle` are a `datetime` array, `CurveDates` is returned as a `datetime` array. Otherwise, `CurveDates` is returned as a `serial date number`.

# zero2fwd

Forward curve given zero curve

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: `InputCompounding`, `InputBasis`, `OutputCompounding`, and `OutputBasis`.

---

## Syntax

```
[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle)
[ForwardRates, CurveDates] = zero2fwd( ___, Name, Value)
```

## Description

`[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle)` returns an implied forward rate curve given a zero curve and its maturity dates. If either input for `CurveDates` or `Settle` is a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` is returned as a serial date number. `ForwardRates` is the same for any of these input data types.

`[ForwardRates, CurveDates] = zero2fwd( ___, Name, Value)` adds optional name-value pair arguments

## Examples

### Compute an Implied Forward Rate Curve Given a Zero Curve and Maturity Dates

Given a zero curve over a set of maturity dates, a settlement date, and a compounding rate, compute the forward rate curve.

```
ZeroRates = [0.0458
             0.0502
             0.0518
             0.0519
             0.0524
             0.0519
             0.0523
             0.0525
             0.0541
             0.0529];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')
              datenum('25-Jun-2001')]
```

```

    datenum('04-Sep-2001')
    datenum('12-Nov-2001')];

```

```

Settle = datenum('03-Nov-2000');
InputCompounding = 1;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;

```

Execute the function `zero2fwd` to return the forward rate curve `ForwardRates` at the maturity dates `CurveDates`.

```

[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, ...
Settle, 'InputCompounding',1,'InputBasis',2,'OutputCompounding',1,'OutputBasis',2)

```

```

ForwardRates = 10×1

```

```

    0.0458
    0.0506
    0.0535
    0.0522
    0.0541

```

## Input Arguments

### ZeroRates — Annualized zero rates

decimal fraction

Annualized zero rates, specified as a `NUMBONDS`-by-1 vector using decimal fractions. In aggregate, the rates constitute an implied zero curve for the investment horizon represented by `CurveDates`. The first element pertains to forward rates from the settlement date to the first curve date.

Data Types: `double`

### CurveDates — Maturity dates

serial date number | date character vector | datetime

Maturity dates, specified as a `NUMBONDS`-by-1 vector using serial date numbers, date character vectors, or datetime arrays, that correspond to the `ZeroRates`.

Data Types: `double` | `datetime` | `char`

### Settle — Common settlement date for ZeroRates

serial date number | date character vector | datetime

Common settlement date for input `ZeroRates`, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `datetime` | `char`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle, 'InputCompounding', 3, 'InputBasis', 5, 'OutputCompounding', 4, 'OutputBasis', 5)`

### InputCompounding — Compounding frequency of input zero rates

2 (default) | numeric values: 0, 1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of input zero rates, specified as the comma-separated pair consisting of `'InputCompounding'` and allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

---

**Note** If `InputCompounding` is not specified, then `InputCompounding` is assigned the value specified for `OutputCompounding`. If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2 (semiannual) for both.

---

Data Types: double

**InputBasis — Day-count basis of input zero rates**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of input zero rates, specified as the comma-separated pair consisting of 'InputBasis' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If `InputBasis` is not specified, then `InputBasis` is assigned the value specified for `OutputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

**OutputCompounding — Compounding frequency of output forward rates**

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of output forward rates, specified as the comma-separated pair consisting of 'OutputCompounding' and allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year

- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

---

**Note** If `OutputCompounding` is not specified, then `OutputCompounding` is assigned the value specified for `InputCompounding`. If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2 (semiannual) for both.

---

Data Types: double

### **OutputBasis — Day-count basis of output forward rates**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of output forward rates, specified as the comma-separated pair consisting of 'OutputBasis' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If `OutputBasis` is not specified, then `OutputBasis` is assigned the value specified for `InputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

## **Output Arguments**

**ForwardRates — Forward curve for investment horizon represented by CurveDates**

numeric

Forward curve for the investment horizon represented by `CurveDates`, returned as a `NUMBONDS`-by-1 vector of decimal fractions. In aggregate, the rates in `ForwardRates` constitute a forward curve over the dates in `CurveDates`. `ForwardRates` are ordered by ascending maturity.

### **CurveDates — Maturity dates that correspond to ForwardRates**

serial date number | date character vector | datetime

Maturity dates that correspond to the `ForwardRates`, returned as a `NUMBONDS`-by-1 vector of maturity dates that correspond to the `ForwardRates`.

`ForwardRates` are expressed as serial date numbers (default) or datetimes (if `CurveDates` or `Settle` are datetime arrays), representing the maturity dates for each rate in `ForwardRates`. These dates are the same dates as those associated with the input `ZeroRates`, but are ordered by ascending maturity.

## zero2pyld

Par yield curve given zero curve

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: `InputCompounding`, `InputBasis`, `OutputCompounding`, and `OutputBasis`.

---

### Syntax

```
[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle)
[ParRates, CurveDates] = zero2pyld( ____, Name, Value)
```

### Description

`[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle)` returns a par yield curve given a zero curve and its maturity dates. If either input for `CurveDates` or `Settle` is a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` is returned as a serial date number. `ParRates` is the same for any of these input data types.

`[ParRates, CurveDates] = zero2pyld( ____, Name, Value)` adds optional name-value pair arguments

### Examples

#### Compute Par Yield Curve Given a Zero Curve and Maturity Dates

Given a zero curve over a set of maturity dates, a settlement date, and annual compounding for the input zero curve and monthly compounding for the output par rates, compute a par yield curve.

```
ZeroRates = [0.0457
             0.0487
             0.0506
             0.0507
             0.0505
             0.0504
             0.0506
             0.0516
             0.0539
             0.0530];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')
              datenum('25-Jun-2001')]
```

```

        datenum('04-Sep-2001')
        datenum('12-Nov-2001')]);

Settle = datenum('03-Nov-2000');
InputCompounding = 12;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;

[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates,...
Settle, 'InputCompounding',1,'InputBasis',1,'OutputCompounding',12,'OutputBasis',1)

### Compute Par Yield Curve Given a Zero Curve and Maturity Dates Using datetime Inputs

Given a zero curve over a set of maturity dates, a settlement date, and annual compounding for the input zero curve and monthly compounding for the output par rates, use `datetime` inputs to compute a par yield curve.

```

ZeroRates = [0.0457
0.0487
0.0506
0.0507
0.0505
0.0504
0.0506
0.0516
0.0539

```

```

0.0530];
CurveDates = [datenum('06-Nov-2000')
datenum('11-Dec-2000')
datenum('15-Jan-2001')
datenum('05-Feb-2001')
datenum('04-Mar-2001')
datenum('02-Apr-2001')
datenum('30-Apr-2001')
datenum('25-Jun-2001')
datenum('04-Sep-2001')
datenum('12-Nov-2001')];
Settle = datenum('03-Nov-2000');
InputCompounding = 12;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;

CurveDates = datetime(CurveDates, 'ConvertFrom', 'datenum', 'Locale', 'en_US');
Settle = datetime(Settle, 'ConvertFrom', 'datenum', 'Locale', 'en_US');
[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, ...
Settle, 'InputCompounding',12, 'InputBasis',2, 'OutputCompounding',1, 'OutputBasis',2)

ParRates = 10x1

    -0.0436
     0.0611
     0.0579
     0.0567
     0.0550
     0.0543
     0.0541
     0.0546
     0.0565
     0.0561

CurveDates = 10x1 datetime
    06-Nov-2000
    11-Dec-2000
    15-Jan-2001
    05-Feb-2001
    04-Mar-2001
    02-Apr-2001
    30-Apr-2001
    25-Jun-2001
    04-Sep-2001
    12-Nov-2001

```

### Demonstrate a Roundtrip From zero2pyld to pyld2zero

Given the following zero curve and its maturity dates, return the ParRates.

```

Settle = datenum('01-Feb-2013');

CurveDates = [datenum('01-Feb-2014')

```

```

    datenum('01-Feb-2015')
    datenum('01-Feb-2016')
    datenum('01-Feb-2018')
    datenum('01-Feb-2020')
    datenum('01-Feb-2023')
    datenum('01-Feb-2033')
    datenum('01-Feb-2043')];

OriginalZeroRates = [.11 0.30 0.64 1.44 2.07 2.61 3.29 3.55]'/100;

OutputCompounding = 1;
OutputBasis = 0;
InputCompounding = 1;
InputBasis = 0;

ParRates = zero2pyld(OriginalZeroRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)

ParRates = 8×1

    0.0011
    0.0030
    0.0064
    0.0142
    0.0202
    0.0251
    0.0310
    0.0331

```

For the ParRates, use the pyld2zero function to return the ZeroRatesOut and determine the roundtrip error.

```

ZeroRatesOut = pyld2zero(ParRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)

ZeroRatesOut = 8×1

    0.0011
    0.0030
    0.0064
    0.0144
    0.0207
    0.0261
    0.0329
    0.0355

```

```

max(abs(OriginalZeroRates - ZeroRatesOut)) % Roundtrip error

ans = 1.4919e-16

```

## Input Arguments

### ZeroRates — Annualized zero rates

decimal fraction

Annualized zero rates, specified as a `NUMBONDS`-by-1 vector using decimal fractions. In aggregate, the rates constitute an implied zero curve for the investment horizon represented by `CurveDates`.

Data Types: `double`

### CurveDates — Maturity dates

serial date number | date character vector | datetime

Maturity dates which correspond to the input `ZeroRates`, specified as a `NUMBONDS`-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `datetime` | `char`

### Settle — Common settlement date for ZeroRates

serial date number | date character vector | datetime

Common settlement date for input `ZeroRates`, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `datetime` | `char`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle, 'OutputCompounding', 3, 'OutputBasis', 5, 'InputCompounding', 4, 'InputBasis', 5)`

### OutputCompounding — Compounding frequency of output ParRates

2 (default) | numeric values: 0, 1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of output `ParRates`, specified as the comma-separated pair consisting of `'OutputCompounding'` and allowed values:

- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

## Note

- If `InputCompounding` is 1, 2, 3, 4, 6, or 12 and `OutputCompounding` is not specified, the value of `InputCompounding` is used.

- If `InputCompounding` is 0 (simple), -1 (continuous), or 365 (daily), a valid `OutputCompounding` value must also be specified.
  - If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2 (semiannual) for both.
- 

Data Types: double

### **OutputBasis — Day-count basis of output ParRates**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of output `ParRates`, specified as the comma-separated pair consisting of '`OutputBasis`' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If `OutputBasis` is not specified, then `OutputBasis` is assigned the value specified for `InputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

### **InputCompounding — Compounding frequency of input ZeroRates**

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of input `ZeroRates`, specified as the comma-separated pair consisting of '`InputCompounding`' and allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)

- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

---

**Note**

- If `InputCompounding` is set to 0 (simple), -1 (continuous), or 365 (daily), the `OutputCompounding` must also be specified using a valid value.
  - If `InputCompounding` is not specified, then `InputCompounding` is assigned the value specified for `OutputCompounding`.
  - If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2 (semiannual) for both.
- 

Data Types: double

**InputBasis — Day-count basis of input ZeroRates**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of the input `ZeroRates`, specified as the comma-separated pair consisting of '`InputBasis`' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-18.

---

**Note** If `InputBasis` is not specified, then `InputBasis` is assigned the value specified for `OutputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

## Output Arguments

### **ParRates — Par bond coupon rates**

numeric

Par bond coupon rates, returned as a NUMBONDS-by-1 numeric vector. ParRates are ordered by ascending maturity.

### **CurveDates — Maturity dates that correspond to ParRates**

serial date number | date character vector | datetime

Maturity dates that correspond to the ParRates, returned as a NUMBONDS-by-1 vector of maturity dates that correspond to each par rate contained in ParRates.

ParRates are expressed as serial date numbers (default) or datetimes (if CurveDates or Settle are datetime arrays). CurveDates are ordered by ascending maturity.

## compact

Create compact credit scorecard

### Syntax

```
csc = compact(sc)
```

### Description

`csc = compact(sc)` converts an existing `creditscorecard` object to a `compactCreditScorecard` object (`csc`).

---

**Note** To use this function, you must have a license for Risk Management Toolbox.

---

### Examples

#### Convert `creditscorecard` Object into `compactCreditScorecard` Object

Convert a `creditscorecard` object into a `compactCreditScorecard` object to use `displaypoints`, `score`, and `probdefault` from Risk Management Toolbox™ with the object.

First, create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData.mat
sc = creditscorecard(data)

sc =
  creditscorecard with properties:
      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x7 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: ''
      PredictorVars: {1x10 cell}
      Data: [1200x11 table]
```

Before creating a `compactCreditScorecard` object, you must use `autobinning` and `fitmodel` with the `creditscorecard` object.

```
sc = autobinning(sc);
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding `TmWBank`, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06

3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:

```
status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial
```

Estimated Coefficients:

|             | Estimate | SE       | tStat  | pValue     |
|-------------|----------|----------|--------|------------|
| (Intercept) | 0.70239  | 0.064001 | 10.975 | 5.0538e-28 |
| CustAge     | 0.60833  | 0.24932  | 2.44   | 0.014687   |
| ResStatus   | 1.377    | 0.65272  | 2.1097 | 0.034888   |
| EmpStatus   | 0.88565  | 0.293    | 3.0227 | 0.0025055  |
| CustIncome  | 0.70164  | 0.21844  | 3.2121 | 0.0013179  |
| TmWBank     | 1.1074   | 0.23271  | 4.7589 | 1.9464e-06 |
| OtherCC     | 1.0883   | 0.52912  | 2.0569 | 0.039696   |
| AMBalance   | 1.045    | 0.32214  | 3.2439 | 0.0011792  |

1200 observations, 1192 error degrees of freedom

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 89.7, p-value = 1.4e-16

Convert the `creditscorecard` object into a `compactCreditScorecard` object by using the `compact` function. To use `compact`, you must have a Risk Management Toolbox™ license.

```
csc = compact(sc)
```

```
csc =
```

```
compactCreditScorecard with properties:
```

```

    Description: ''
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    NumericPredictors: {'CustAge' 'CustIncome' 'TmWBank' 'AMBalance'}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    PredictorVars: {1x7 cell}
```

You can then use `displaypoints`, `score`, and `probdefault` from Risk Management Toolbox™ with the `compactCreditScorecard` object.

## Input Arguments

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object.

---

**Note** You must use a `creditscorecard` object (`sc`) for input that has been previously processed with `autobinning` and `fitmodel`, or `fitConstrainedModel`. Optionally, you can use `formatpoints` in addition to these functions.

---

## Output Arguments

### **csc** — Compact credit scorecard

`compactCreditScorecard` object

Compact credit scorecard, returned as a `compactCreditScorecard` object. You can then use `displaypoints`, `score`, and `probdefault` from the Risk Management Toolbox with this `csc` object.

## score

Compute credit scores for given data

### Syntax

```
Scores = score(sc)
```

```
Scores = score(sc, data)
```

```
[Scores,Points] = score(sc)
```

```
[Scores,Points] = score(sc,data)
```

### Description

`Scores = score(sc)` computes the credit scores for the `creditscorecard` object's training data. This data can be a "training" or a "live" dataset. If the `data` input argument is not explicitly provided, the `score` function determines scores for the existing `creditscorecard` object's data.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

`Scores = score(sc, data)` computes the credit scores for the given input data. This data can be a "training" or a "live" dataset.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

`[Scores,Points] = score(sc)` computes the credit scores and points for the given data. If the `data` input argument is not explicitly provided, the `score` function determines scores for the existing `creditscorecard` object's data.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

`[Scores,Points] = score(sc,data)` computes the credit scores and points for the given input data. This data can be a "training" or a "live" dataset.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

## Examples

### Obtain Scores for Training Data

This example shows how to use `score` to obtain scores for the training data.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:

```
status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial
```

Estimated Coefficients:

### Scores for Missing or Out-of-Range Data When Using the 'BinMissingData' Option

This example describes the assignment of points for missing data when the 'BinMissingData' option is set to `true`.

- Predictors that have missing data in the training set have an explicit bin for `<missing>` with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the `<missing>` bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values.

- Predictors with no missing data in the training set have no <missing> bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to NaN, and this leads to a score of NaN when running score. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in formatpoints to indicate how missing data should be treated for scoring purposes.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

ans=5×11 table

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | Oth |
|--------|---------|-------------|-------------|-----------|------------|---------|-----|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Ye  |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Ye  |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | N   |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Ye  |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Ye  |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

Number of rows: 1200

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

Number of missing values CustAge: 30

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

Number of missing values ResStatus: 40

Use `creditscorecard` with the name-value argument 'BinMissingData' set to true to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

creditscorecard with properties:

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Set a minimum value of zero for CustAge and CustIncome. With this, any negative age or income information becomes invalid or "out-of-range". For scoring purposes, out-of-range values are given the same points as missing values.

```
sc = modifybins(sc, 'CustAge', 'MinValue', 0);
sc = modifybins(sc, 'CustIncome', 'MinValue', 0);
```

Display and plot bin information for numeric data for 'CustAge' that includes missing data in a separate bin labelled <missing>.

```
[bi,cp] = bininfo(sc, 'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| { '[0,33)' }    | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |
| { '[33,37)' }   | 63   | 45  | 1.4    | -0.36795 | 0.012839   |
| { '[37,40)' }   | 72   | 47  | 1.5319 | -0.2779  | 0.0079824  |

| {'<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
plotbins(sc, 'ResStatus')
```

For the 'CustAge' and 'ResStatus' predictors, there is missing data (NaNs and <undefined>) in the training data, and the binning process estimates a WOE value of -0.15787 and 0.026469 respectively for missing data in these predictors, as shown above.

For EmpStatus and CustIncome there is no explicit bin for missing values because the training data has no missing values for these predictors.

```
bi = bininfo(sc, 'EmpStatus');
disp(bi)
```

| Bin | Good | Bad | Odds | WOE | InfoValue |
|-----|------|-----|------|-----|-----------|
|-----|------|-----|------|-----|-----------|

```

{'Unknown' } 396 239 1.6569 -0.19947 0.021715
{'Employed'} 407 158 2.5759 0.2418 0.026323
{'Totals' } 803 397 2.0227 NaN 0.048038

```

```

bi = bininfo(sc, 'CustIncome');
disp(bi)

```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the 'PointsOddsAndPDO' argument of `formatpoints`. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]);
PointsInfo = displaypoints(sc)
```

```
PointsInfo=38x3 table
    Predictors      Bin      Points
    _____  _____  _____
    {'CustAge' } {' [0,33) ' } 54.062
    {'CustAge' } {' [33,37) ' } 56.282
    {'CustAge' } {' [37,40) ' } 60.012
    {'CustAge' } {' [40,46) ' } 69.636
    {'CustAge' } {' [46,48) ' } 77.912
    {'CustAge' } {' [48,51) ' } 78.86
    {'CustAge' } {' [51,58) ' } 80.83
    {'CustAge' } {' [58,Inf]' } 96.76
    {'CustAge' } {' <missing>' } 64.984

    {'EmpStatus' } {' Unknown' } 58.807
    {'EmpStatus' } {' Employed' } 86.937
    {'EmpStatus' } {' <missing>' } NaN
    :
```

Notice that points for the <missing> bin for `CustAge` and `ResStatus` are explicitly shown (as 64.9836 and 74.1250, respectively). These points are computed from the WOE value for the <missing> bin, and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin. By default the points are set to `NaN` for missing data and they lead to a score of `NaN` when running `score`. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in `formatpoints` to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall 'MinValue' was earlier set to 0 for `CustAge` and `CustIncome`). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

```
tdata = dataMissing(11:18, mdl.PredictorNames); % Keep only the predictors retained in the model
% Set some missing values
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
```

```

tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)

```

| CustAge | ResStatus   | EmpStatus   | CustIncome | TmWBank | OtherCC | AMBalance |
|---------|-------------|-------------|------------|---------|---------|-----------|
| NaN     | Tenant      | Unknown     | 34000      | 44      | Yes     | 119.8     |
| 48      | <undefined> | Unknown     | 44000      | 14      | Yes     | 403.62    |
| 65      | Home Owner  | <undefined> | 48000      | 6       | No      | 111.88    |
| 44      | Other       | Unknown     | NaN        | 35      | No      | 436.41    |
| -100    | Other       | Employed    | 46000      | 16      | Yes     | 162.21    |
| 33      | House       | Employed    | 36000      | 36      | Yes     | 845.02    |
| 39      | Tenant      | Freelancer  | 34000      | 40      | Yes     | 756.26    |
| 24      | Home Owner  | Employed    | -1         | 19      | Yes     | 449.61    |

Score the new data and see how points are assigned for missing CustAge and ResStatus, because we have an explicit bin with points for <missing>. However, for EmpStatus and CustIncome the score function sets the points to NaN.

```

[Scores,Points] = score(sc,tdata);

### Score a New Dataset

This example shows how to use `score` to obtain scores for a new dataset (for example, a validation or a test dataset) using the optional `'data'` input in the `score` function.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

## Input Arguments

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **data** — Dataset to be scored

table

(Optional) Dataset to be scored, specified as a MATLAB table where each row corresponds to individual observations. The `data` must contain columns for each of the predictors in the `creditscorecard` object.

## Output Arguments

### **Scores** — Scores for each observation

vector

Scores for each observation, returned as a vector.

### Points — Points per predictor for each observation

table

Points per predictor for each observation, returned as a table.

## Algorithms

The score of an individual  $i$  is given by the formula

$$\text{Score}(i) = \text{Shift} + \text{Slope} * (b_0 + b_1 * \text{WOE}_1(i) + b_2 * \text{WOE}_2(i) + \dots + b_p * \text{WOE}_p(i))$$

where  $b_j$  is the coefficient of the  $j$ -th variable in the model, and  $\text{WOE}_j(i)$  is the Weight of Evidence (WOE) value for the  $i$ -th individual corresponding to the  $j$ -th model variable. **Shift** and **Slope** are scaling constants that can be controlled with `formatpoints`.

If the data for individual  $i$  is in the  $i$ -th row of a given dataset, to compute a score, the  $\text{data}(i,j)$  is binned using existing binning maps, and converted into a corresponding Weight of Evidence value  $\text{WOE}_j(i)$ . Using the model coefficients, the unscaled score is computed as

$$s = b_0 + b_1 * \text{WOE}_1(i) + \dots + b_p * \text{WOE}_p(i).$$

For simplicity, assume in the description above that the  $j$ -th variable in the model is the  $j$ -th column in the data input, although, in general, the order of variables in a given dataset does not have to match the order of variables in the model, and the dataset could have additional variables that are not used in the model.

The formatting options can be controlled using `formatpoints`.

## Introduced in R2014b

# formatpoints

Format scorecard points and scaling

## Syntax

```
sc = formatpoints(sc,Name,Value)
```

## Description

`sc = formatpoints(sc,Name,Value)` modifies the scorecard points and scaling using optional name-value pair arguments. For example, use optional name-value pair arguments to change the scaling of the scores or the rounding of the points.

## Examples

### Scale Points Using Points, Odds Levels, and PDO

This example shows how to use `formatpoints` to scale by providing the points, odds levels, and PDO (points to double the odds). By using `formatpoints` to scale, you can put points and scores in a desired range that is more meaningful for practical purposes. Technically, this involves a linear transformation from the unscaled to the scaled points by the `formatpoints` function.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

### Scale Points Using Worst and Best Scores

This example shows how to use `formatpoints` to scale by providing the **Worst** and **Best** score values. By using `formatpoints` to scale, you can put points and scores in a desired range that is more meaningful for practical purposes. Technically, this involves a linear transformation from the unscaled to the scaled points.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding `TmWBank`, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding `AMBBalance`, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding `EmpStatus`, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding `CustAge`, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding `ResStatus`, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding `OtherCC`, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

MinScore = -1.3100

MaxScore = 3.0726

## Round Points

This example shows how to use `formatpoints` to round points. Rounding is usually applied after scaling, otherwise, if the points for a particular predictor are all in a small range, rounding could cause the rounded points for different bins to be the same. Also, rounding all the points may slightly change the minimum and maximum total points.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

## Rounding and Default Probabilities

This example shows that rounding scorecard points can modify the original risk ranking of a credit scorecard. You can control rounding by using `formatpoints` with the optional name-value pair argument for `'Rounding'`.

Credit scores rank customers by risk. If higher scores are given to better, less risky customers, then higher scores must correspond to lower default probabilities. When you use the name-value pair argument for `'Rounding'`, depending on the value for `'Rounding'`, the rounding behavior is:

- When `'Rounding'` is set to `'None'` (default option), no rounding is applied to points or scores, and the risk ranking is completely consistent with the calibrated model.
- When `'Rounding'` is set to `'FinalScore'`, rounding is only applied to the final scores. In this case: a) Customers with different scores (different risk) may have the same rounded score. b) Customers with the same rounded score may have different default probabilities. c) Customer with higher rounded scores will always have lower default probability than customers with lower scores.
- When `'Rounding'` is set to `'AllPoints'`, rounding is applied to all points in the scorecard (all bins, all predictors). In this case: a) Customers with different scores (different risk) may have the same rounded score, or their ranking may even be reversed (the customer with the lower original score may have a higher rounded score). b) Customers with the same rounded score may have different default probabilities. c) Customer with higher rounded scores may in some cases have *higher* default probabilities than customers with lower scores.

## Create a creditcard

To demonstrate the rounding behavior, first create a `creditcard` object.

```
load CreditCardData
sc = creditcard(data, 'IDVar', 'CustID', 'ResponseVar', 'status');
sc = autobinning(sc);
sc = modifybins(sc, 'CustIncome', 'CutPoints', 20000:5000:60000);
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 1487.9719, Chi2Stat = 35.469392, PValue = 2.5909009e-09
2. Adding `TmWBank`, Deviance = 1465.7998, Chi2Stat = 22.172089, PValue = 2.4927133e-06
3. Adding `AMBALANCE`, Deviance = 1455.206, Chi2Stat = 10.593833, PValue = 0.0011346548
4. Adding `EmpStatus`, Deviance = 1446.3918, Chi2Stat = 8.8142314, PValue = 0.0029889009
5. Adding `CustAge`, Deviance = 1440.6825, Chi2Stat = 5.709236, PValue = 0.016875883
6. Adding `ResStatus`, Deviance = 1436.1363, Chi2Stat = 4.5462043, PValue = 0.032991806
7. Adding `OtherCC`, Deviance = 1431.9546, Chi2Stat = 4.1817827, PValue = 0.040860699

Generalized linear regression model:

```
status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial
```

Estimated Coefficients:

### Apply the 'Rounding' Options

Apply each of the three 'Rounding' options to the creditcard object.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]); % No Rounding
points1 = displaypoints(sc);
[S1,P1] = score(sc);
defProb1 = probdefault(sc);
```

```
sc = formatpoints(sc, 'Round', 'AllPoints'); % 'AllPoints' Rounding
points2 = displaypoints(sc);
[S2,P2] = score(sc);
defProb2 = probdefault(sc);
```

```
sc = formatpoints(sc, 'Round', 'FinalScore'); % 'FinalScore' Rounding
points3 = displaypoints(sc);
[S3,P3] = score(sc);
defProb3 = probdefault(sc);
```

### Compare the 'Rounding' Options

Visualize the default probabilities versus the scores.

```
figure
hold on
scatter(S1, defProb1, 'g*')
scatter(S2, defProb2, 'ro')
scatter(S3, defProb3, 'b+')
legend('No Rounding', 'AllPoints', 'FinalScore')
axis([388 394 0.695 0.705])
xlabel('Credit score')
ylabel('Default probability')
title('Default probabilities and Credit scores')
grid
```

Inspect the points and total scores for each 'Rounding' option, in table format.

```
ind = [208 363 694 886];
ProbDefault = defProb1(ind)
```

ProbDefault = 4x1

```
0.6997
0.6989
0.6982
0.6972
```

```
% ScoreNoRounding = S1(ind)
PointsNoRounding = P1(ind,:);
PointsNoRounding.Total = S1(ind)
```

```

The original `creditscorecard` model, without rounding, was calibrated to the data with a logistic regression. The ranking and probabilities have a statistical foundation.

Rounding, however, effectively modifies the `creditscorecard` model. When only the final score is rounded, this leads to some "ties" in rounded scores, but at least the risk ranking *across* scores is preserved (because if  $s1 \leq s2$ , then  $\text{round}(s1) \leq \text{round}(s2)$ ).

However, when you round all points, a score may gain extra points by chance. For example, in the second row in the table (row 363 of original data), the points for all predictors are rounded up by almost 0.5. The original score is 389.27. Rounding the final score makes it 389. However, rounding all points makes it 392, that is three points higher than rounding the final score.

### Scores for Missing or Out-of-Range Data

This example shows how to use `formatpoints` to score missing or out-of-range data. When data is scored, some observations can be either missing (NaN, or `undefined`) or out of range. You will need to decide whether or not points are assigned to these cases. Use the name-value pair argument `Missing` to do so.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Indicate that the minimum allowed value for 'CustAge' is zero. This makes any negative values for age invalid or out-of-range.

```
sc = modifybins(sc, 'CustAge', 'MinValue', 0);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

Suppose there are missing or out of range observations in the data that you want to score. Notice that by default, the points and score assigned to the missing value is NaN.

```
% Set up a data set with missing and out of range data for illustration purposes
```

```
newdata = data(1:5, :);
newdata.CustAge(1) = NaN; % missing
newdata.CustAge(2) = -100; % invalid
newdata.ResStatus(3) = '<undefined>'; % missing
newdata.ResStatus(4) = 'House'; % invalid
disp(newdata)
```

ans = 0.4790
```

### Scores for Missing or Out-of-Range Data When Using the 'BinMissingData' Option

This example describes the assignment of points for missing data when the 'BinMissingData' option is set to `true`.

- Predictors that have missing data in the training set have an explicit bin for `<missing>` with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the `<missing>` bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values.
- Predictors with no missing data in the training set have no `<missing>` bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to `NaN`, and this leads to a score of `NaN` when running `score`. For predictors that have no explicit `<missing>` bin, use the name-value argument 'Missing' in `formatpoints` to indicate how missing data should be treated for scoring purposes.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
    CustID  CustAge  TmAtAddress  ResStatus  EmpStatus  CustIncome  TmWBank  Other
    _____  _____  _____  _____  _____  _____  _____  _____
    1         53         62         <undefined>  Unknown    50000       55       Ye
    2         61         22         Home Owner   Employed    52000       25       Ye
    3         47         30         Tenant       Employed    37000       61       Ne
    4         NaN        75         Home Owner   Employed    53000       20       Ye
    5         68         56         Home Owner   Employed    53000       14       Ye
```

```
fprintf('Number of rows: %d\n',height(dataMissing))
Number of rows: 1200
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
Number of missing values CustAge: 30
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Set a minimum value of zero for `CustAge` and `CustIncome`. With this, any negative age or income information becomes invalid or "out-of-range". For scoring purposes, out-of-range values are given the same points as missing values.

```
sc = modifybins(sc,'CustAge','MinValue',0);
sc = modifybins(sc,'CustIncome','MinValue',0);
```

Display and plot bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
[bi,cp] = bininfo(sc,'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |

| { 'Totals' }    | 803  | 397 | 2.0227 | NaN      | 0.087112   |

```
plotbins(sc, 'CustAge')
```

Display and plot bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin            | Good | Bad | Odds   | WOE       | InfoValue  |
|----------------|------|-----|--------|-----------|------------|
| {'Tenant' }    | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Home Owner'} | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| {'Other' }     | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| {'<missing>' } | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }    | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
plotbins(sc, 'ResStatus')
```

For the 'CustAge' and 'ResStatus' predictors, there is missing data (NaNs and <undefined>) in the training data, and the binning process estimates a WOE value of  $-0.15787$  and  $0.026469$  respectively for missing data in these predictors, as shown above.

For EmpStatus and CustIncome there is no explicit bin for missing values because the training data has no missing values for these predictors.

```
bi = bininfo(sc, 'EmpStatus');
disp(bi)
```

| Bin           | Good | Bad | Odds   | WOE      | InfoValue |

```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

1200 observations, 1192 error degrees of freedom

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 88.5, p-value = 2.55e-16

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the `'PointsOddsAndPDO'` argument of `formatpoints`. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```

sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]);
PointsInfo = displaypoints(sc)

```

PointsInfo=38x3 table

| Predictors   | Bin          | Points |
|--------------|--------------|--------|
| {'CustAge' } | {'[0,33)'} } | 54.062 |

```

{'CustAge' } {'[33,37)' } 56.282
{'CustAge' } {'[37,40)' } 60.012
{'CustAge' } {'[40,46)' } 69.636
{'CustAge' } {'[46,48)' } 77.912
{'CustAge' } {'[48,51)' } 78.86
{'CustAge' } {'[51,58)' } 80.83
{'CustAge' } {'[58,Inf]' } 96.76
{'CustAge' } {'<missing>' } 64.984
{'ResStatus' } {'Tenant' } 62.138
{'ResStatus' } {'Home Owner' } 73.248
{'ResStatus' } {'Other' } 90.828
{'ResStatus' } {'<missing>' } 74.125
{'EmpStatus' } {'Unknown' } 58.807
{'EmpStatus' } {'Employed' } 86.937
{'EmpStatus' } {'<missing>' } NaN
:

```

Notice that points for the <missing> bin for CustAge and ResStatus are explicitly shown (as 64.9836 and 74.1250, respectively). These points are computed from the WOE value for the <missing> bin, and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin. By default the points are set to NaN for missing data and they lead to a score of NaN when running score. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in formatpoints to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall 'MinValue' was earlier set to 0 for CustAge and CustIncome). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

```

tdata = dataMissing(11:18,mdl.PredictorNames); % Keep only the predictors retained in the model
% Set some missing values
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)

```

| CustAge | ResStatus   | EmpStatus   | CustIncome | TmWBank | OtherCC | AMBance |
|---------|-------------|-------------|------------|---------|---------|---------|
| NaN     | Tenant      | Unknown     | 34000      | 44      | Yes     | 119.8   |
| 48      | <undefined> | Unknown     | 44000      | 14      | Yes     | 403.62  |
| 65      | Home Owner  | <undefined> | 48000      | 6       | No      | 111.88  |
| 44      | Other       | Unknown     | NaN        | 35      | No      | 436.41  |
| -100    | Other       | Employed    | 46000      | 16      | Yes     | 162.21  |
| 33      | House       | Employed    | 36000      | 36      | Yes     | 845.02  |

```

39    Tenant    Freelancer    34000    40    Yes    756.26
24    Home Owner    Employed    -1    19    Yes    449.61

```

Score the new data and see how points are assigned for missing `CustAge` and `ResStatus`, because we have an explicit bin with points for `<missing>`. However, for `EmpStatus` and `CustIncome` the score function sets the points to `NaN`.

```

[Scores,Points] = score(sc,tdata);
disp(Scores)

Use the name-value argument `'Missing'` in `formatpoints` to choose how to assign points to missing values for predictors that do not have an explicit `<missing>` bin. In this example, use the `'MinPoints'` option for the `'Missing'` argument. The minimum points for `EmpStatus` in the scorecard displayed above are `58.8072`, and for `CustIncome` the minimum points are `29.3753`.

```

sc = formatpoints(sc,'Missing','MinPoints');
[Scores,Points] = score(sc,tdata);

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `sc = formatpoints(sc, 'BasePoints', true, 'Round', 'AllPoints', 'WorstAndBestScores', [100, 700])`

---

**Note** `ShiftAndSlope`, `PointsOddsAndPDO`, and `WorstAndBestScores` are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (`BasePoints`, `Missing`, and `Round`) are not scaling methods and can be used together or with any one of the three scaling methods.

---

### BasePoints — Indicator for separating base points

false (default) | logical scalar

Indicator for separating base points, specified as the comma-separated pair consisting of `'BasePoints'` and a logical scalar. If `true`, the scorecard explicitly separates base points. If `false`, the base points are spread across all variables in the `creditscorecard` object.

Data Types: char

### Missing — Indicator for points assigned to missing or out-of-range information when scoring

NoScore (default) | character vector with values NoScore, ZeroWOE, MinPoints, and MaxPoints

Indicator for points assigned to missing or out-of-range information when scoring, specified as the comma-separated pair consisting of `'Missing'` and a character vector with a value for `NoScore`, `ZeroWOE`, `MinPoints`, or `MaxPoints`, where:

- `NoScore` — Missing and out-of-range data do not get points assigned and points are set to `NaN`. Also, the total score is set to `NaN`.
- `ZeroWOE` — Missing or out-of-range data get assigned a zero Weight-of-Evidence (WOE) value.
- `MinPoints` — Missing or out-of-range data get the minimum possible points for that predictor. This penalizes the score if higher scores are better.

- **MaxPoints** — Missing or out-of-range data get the maximum possible points for that predictor. This penalizes the score if lower scores are better.

---

**Note** When using the `creditscorecard` name-value argument `'BinMissingData'` with a value of `true`, missing data for numeric and categorical predictors is binned in a separate bin labeled `<missing>`. The `<missing>` bin only contains missing values for a predictor and does not contain invalid or out-of-range values for a predictor.

---

Data Types: `char`

### **Round — Indicator whether to round points or scores**

`'None'` (default) | character vector with values `'AllPoints'`, `'FinalScore'`

Indicator whether to round points or scores, specified as the comma-separated pair consisting of `'Round'` and a character vector with values `'AllPoints'`, `'FinalScore'` or `'None'`, where:

- `None` — No rounding is applied.
- `AllPoints` — Apply rounding to each predictor's points before adding up the total score.
- `FinalScore` — Round the final score only (rounding is applied after all points are added up).

For more information and an example of using the `'Round'` name-value pair argument, see “Rounding and Default Probabilities” on page 19-1598.

Data Types: `char`

### **ShiftAndSlope — Indicator for shift and slope scaling parameters**

`[0,1]` (default) | numeric array with two elements `[Shift,Slope]`

Indicator for shift and slope scaling parameters for the credit scorecard, specified as the comma-separated pair consisting of `'ShiftAndSlope'` and a numeric array with two elements `[Shift, Slope]`. `Slope` cannot be zero. The `ShiftAndSlope` values are used scale the scoring model.

---

**Note** `ShiftAndSlope`, `PointsOddsAndPDO`, and `WorstAndBestScores` are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (`BasePoints`, `Missing`, and `Round`) are not scaling methods and can be used together or with any one of the three scaling methods.

---

To remove a previous scaling and revert to unscaled scores, set `ShiftAndSlope` to `[0,1]`.

---

Data Types: `double`

### **PointsOddsAndPDO — Indicator for target points for given odds and double odds level**

numeric array with three elements `[Points,Odds,PDO]`

Indicator for target points (`Points`) for a given odds level (`Odds`) and the desired number of points to double the odds (`PDO`), specified as the comma-separated pair consisting of `'PointsOddsAndPDO'` and a numeric array with three elements `[Points,Odds,PDO]`. `Odds` must be a positive number. The `PointsOddsAndPDO` values are used to find scaling parameters for the scoring model.

---

**Note** The points to double the odds (`PDO`) may be positive or negative, depending on whether higher scores mean lower risk, or vice versa.

---

`ShiftAndSlope`, `PointsOddsAndPDO`, and `WorstAndBestScores` are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (`BasePoints`, `Missing`, and `Round`) are not scaling methods and can be used together or with any one of the three scaling methods.

To remove a previous scaling and revert to unscaled scores, set `ShiftAndSlope` to `[0, 1]`.

---

Data Types: `double`

### **WorstAndBestScores — Indicator for worst (highest risk) and best (lowest risk) scores in scorecard**

numeric array with two elements [`WorstScore`, `BestScore`]

Indicator for worst (highest risk) and best (lowest risk) scores in the scorecard, specified as the comma-separated pair consisting of '`WorstAndBestScores`' and a numeric array with two elements [`WorstScore`, `BestScore`]. `WorstScore` and `BestScore` must be different values. These `WorstAndBestScores` values are used to find scaling parameters for the scoring model.

---

**Note** `WorstScore` means the riskiest score, and its value could be lower or higher than the 'best' score. In other words, the 'minimum' score may be the 'worst' score or the 'best' score, depending on the desired scoring scale.

`ShiftAndSlope`, `PointsOddsAndPDO`, and `WorstAndBestScores` are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (`BasePoints`, `Missing`, and `Round`) are not scaling methods and can be used together or with any one of the three scaling methods.

To remove a previous scaling and revert to unscaled scores, set `ShiftAndSlope` to `[0, 1]`.

---

Data Types: `double`

## **Output Arguments**

### **sc — Credit scorecard model**

`creditscorecard` object

Credit scorecard model returned as an updated `creditscorecard` object. For more information on using the `creditscorecard` object, see `creditscorecard`.

## **Algorithms**

The score of an individual  $i$  is given by the formula

$$\text{Score}(i) = \text{Shift} + \text{Slope} * (b_0 + b_1 * \text{WOE}_1(i) + b_2 * \text{WOE}_2(i) + \dots + b_p * \text{WOE}_p(i))$$

where  $b_j$  is the coefficient of the  $j$ th variable in the model, and  $\text{WOE}_j(i)$  is the Weight of Evidence (WOE) value for the  $i$ th individual corresponding to the  $j$ th model variable. `Shift` and `Slope` are scaling constants further discussed below. The scaling constant can be controlled with `formatpoints`.

If the data for individual  $i$  is in the  $i$ -th row of a given dataset, to compute a score, the data( $i,j$ ) is binned using existing binning maps, and converted into a corresponding Weight of Evidence value  $WOE_j(i)$ . Using the model coefficients, the unscaled score is computed as

$$s = b_0 + b_1 * WOE_1(i) + \dots + b_p * WOE_p(i).$$

For simplicity, assume in the description above that the  $j$ -th variable in the model is the  $j$ -th column in the data input, although, in general, the order of variables in a given dataset does not have to match the order of variables in the model, and the dataset could have additional variables that are not used in the model.

The formatting options can be controlled using `formatpoints`. When the base points are reported separately (see the `formatpoints` parameter `BasePoints`), the base points are given by

$$\text{Base Points} = \text{Shift} + \text{Slope} * b_0,$$

and the points for the  $j$ -th predictor,  $i$ -th row are given by

$$\text{Points}_{ji} = \text{Slope} * (b_j * WOE_j(i)).$$

By default, the base points are not reported separately, in which case

$$\text{Points}_{ji} = (\text{Shift} + \text{Slope} * b_0) / p + \text{Slope} * (b_j * WOE_j(i)),$$

where  $p$  is the number of predictors in the scorecard model.

By default, no rounding is applied to the points by the score function (`Round` is `None`). If `Round` is set to `AllPoints` using `formatpoints`, then the points for individual  $i$  for variable  $j$  are given by

$$\text{points if rounding is 'AllPoints': round( Points}_{ji} )$$

and, if base points are reported separately, they are also rounded. This yields integer-valued points per predictor, hence also integer-valued scores. If `Round` is set to `FinalScore` using `formatpoints`, then the points per predictor are not rounded, and only the final score is rounded

$$\text{score if rounding is 'FinalScore': round(Score}(i)).$$

Regarding the scaling parameters, the `Shift` parameter, and the `Slope` parameter can be set directly with the `ShiftAndSlope` parameter of `formatpoints`. Alternatively, you can use the `formatpoints` parameter for `WorstAndBestScores`. In this case, the parameters `Shift` and `Slope` are found internally by solving the system

$$\begin{aligned} \text{Shift} + \text{Slope} * s_{\min} &= \text{WorstScore}, \\ \text{Shift} + \text{Slope} * s_{\max} &= \text{BestScore}, \end{aligned}$$

where `WorstScore` and `BestScore` are the first and second elements in the `formatpoints` parameter for `WorstAndBestScores` and `smin` and `smax` are the minimum and maximum possible unscaled scores:

$$\begin{aligned} s_{\min} &= b_0 + \min(b_1 * WOE_1) + \dots + \min(b_p * WOE_p), \\ s_{\max} &= b_0 + \max(b_1 * WOE_1) + \dots + \max(b_p * WOE_p). \end{aligned}$$

A third alternative to scale scores is the `PointsOddsAndPDO` parameter in `formatpoints`. In this case, assume that the unscaled score  $s$  gives the log-odds for a row, and the `Shift` and `Slope` parameters are found by solving the following system

$$\begin{aligned} \text{Points} &= \text{Shift} + \text{Slope} * \log(\text{Odds}) \\ \text{Points} + \text{PDO} &= \text{Shift} + \text{Slope} * \log(2 * \text{Odds}) \end{aligned}$$

where `Points`, `Odds`, and `PDO` ("points to double the odds") are the first, second, and third elements in the `PointsOddsAndPDO` parameter.

Whenever a given dataset has a missing or out-of-range value data ( $i,j$ ), the points for predictor  $j$ , for individual  $i$ , are set to `NaN` by default, which results in a missing score for that row (a `NaN` score). Using the `Missing` parameter for `formatpoints`, you can modify this behavior and set the corresponding Weight-of-Evidence (WOE) value to zero, or set the points to the minimum points, or the maximum points for that predictor.

## Introduced in R2014b

# displaypoints

Return points per predictor per bin

## Syntax

```
PointsInfo = displaypoints(sc)
[PointsInfo,MinScore,MaxScore] = displaypoints(sc)
[PointsInfo,MinScore,MaxScore] = displaypoints( ___,Name,Value)
```

## Description

`PointsInfo = displaypoints(sc)` returns a table of points for all bins of all predictor variables used in the `creditscorecard` object after a linear logistic regression model is fit using `fitmodel` to the Weight of Evidence data. The `PointsInfo` table displays information on the predictor name, bin labels, and the corresponding points per bin.

`[PointsInfo,MinScore,MaxScore] = displaypoints(sc)` returns a table of points for all bins of all predictor variables used in the `creditscorecard` object after a linear logistic regression model is fit (`fitmodel`) to the Weight of Evidence data. The `PointsInfo` table displays information on the predictor name, bin labels, and the corresponding points per bin and `displaypoints`. In addition, the optional `MinScore` and `MaxScore` values are returned.

`[PointsInfo,MinScore,MaxScore] = displaypoints( ___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Display Unscaled Points

This example shows how to use `displaypoints` after a model is fitted to compute the unscaled points per bin, for a given predictor in the `creditscorecard` model.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in the `creditscorecard` function to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding `TmWBank`, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06

3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

| {'EmpStatus' }  | {'Employed' }     | 0.31449   |
| {'EmpStatus' }  | {'<missing>' }    | NaN       |
| {'CustIncome' } | {'[-Inf,29000)' } | -0.45716  |
| :               |                   |           |

`displaypoints` always displays a '<missing>' bin for each predictor. The value of the '<missing>' bin comes from the initial `creditscorecard` object, and the '<missing>' bin is set to NaN whenever the scorecard model has no information on how to assign points to missing data.

To configure the points for the '<missing>' bin, you must use the initial `creditscorecard` object. For predictors that have missing values in the training set, the points for the '<missing>' bin are estimated from the data if the `'BinMissingData'` name-value pair argument is set to `true` using `creditscorecard`. When the `'BinMissingData'` parameter is set to `false`, or when the data contains no missing values in the training set, use the `'Missing'` name-value pair argument in `formatpoints` to indicate how to assign points to the missing data.

### Display Unscaled Points When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
```

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | OtherCC |
|--------|---------|-------------|-------------|-----------|------------|---------|---------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Yes     |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Yes     |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No      |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Yes     |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Yes     |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

| {'<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
plotbins(sc, 'ResStatus')
```

For the 'CustAge' and 'ResStatus' predictors, there is missing data (NaNs and <undefined>) in the training data, and the binning process estimates a WOE value of -0.15787 and 0.026469 respectively for missing data in these predictors, as shown above.

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit <missing> bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the <missing> bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

Display unscaled points for predictors retained in the fitting model (to scale points use `formatpoints`).

```
PointsInfo = displaypoints(sc)
```

PointsInfo=38×3 table

| Predictors     | Bin             | Points    |
|----------------|-----------------|-----------|
| {'CustAge' }   | {'[-Inf,33)' }  | -0.14173  |
| {'CustAge' }   | {'[33,37)' }    | -0.11095  |
| {'CustAge' }   | {'[37,40)' }    | -0.059244 |
| {'CustAge' }   | {'[40,46)' }    | 0.074167  |
| {'CustAge' }   | {'[46,48)' }    | 0.1889    |
| {'CustAge' }   | {'[48,51)' }    | 0.20204   |
| {'CustAge' }   | {'[51,58)' }    | 0.22935   |
| {'CustAge' }   | {'[58,Inf]' }   | 0.45019   |
| {'CustAge' }   | {'<missing>' }  | 0.0096749 |
| {'ResStatus' } | {'Tenant' }     | -0.029778 |
| {'ResStatus' } | {'Home Owner' } | 0.12425   |
| {'ResStatus' } | {'Other' }      | 0.36796   |
| {'ResStatus' } | {'<missing>' }  | 0.1364    |
| {'EmpStatus' } | {'Unknown' }    | -0.075948 |
| {'EmpStatus' } | {'Employed' }   | 0.31401   |
| {'EmpStatus' } | {'<missing>' }  | NaN       |
| :              |                 |           |

Notice that points for the <missing> bin for `CustAge` and `ResStatus` are explicitly shown. These points are computed from the WOE value for the <missing> bin and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin, and by default the points are set to NaN for missing data, and they lead to a score of NaN when running `score`. For predictors that have no explicit <missing> bin, use the name-value argument `'Missing'` in `formatpoints` to indicate how missing data should be treated for scoring purposes.

## Display Scaled Points

This example shows how to use `formatpoints` after a model is fitted to format scaled points, and then use `displaypoints` to display the scaled points per bin, for a given predictor in the `creditscorecard` model.

Points become scaled when a range is defined. Specifically, a linear transformation from the unscaled to the scaled points is necessary. This transformation is defined either by supplying a shift and slope or by specifying the worst and best scores possible. (For more information, see `formatpoints`.)

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in the `creditscorecard` function to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding `TmWBank`, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding `AMBalance`, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding `EmpStatus`, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding `CustAge`, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding `ResStatus`, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding `OtherCC`, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:

```
status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial
```

Estimated Coefficients:

|                         | Estimate | SE       | tStat  | pValue     |
|-------------------------|----------|----------|--------|------------|
| (Intercept)             | 0.70239  | 0.064001 | 10.975 | 5.0538e-28 |
| <code>CustAge</code>    | 0.60833  | 0.24932  | 2.44   | 0.014687   |
| <code>ResStatus</code>  | 1.377    | 0.65272  | 2.1097 | 0.034888   |

 Chi<sup>2</sup>-statistic vs. constant model: 89.7, p-value = 1.4e-16

Use the `formatpoints` function to scale providing the 'Worst' and 'Best' score values. The range provided below is a common score range.

```
sc = formatpoints(sc, 'WorstAndBestScores', [300 850]);
```

Display the points information again to verify that the points are now scaled and also display the scaled minimum and maximum scores.

```
[PointsInfo, MinScore, MaxScore] = displaypoints(sc)
```

PointsInfo=37×3 table

| Predictors      | Bin                | Points |
|-----------------|--------------------|--------|
| {'CustAge' }    | {'[-Inf,33) ' }    | 46.396 |
| {'CustAge' }    | {'[33,37) ' }      | 48.727 |
| {'CustAge' }    | {'[37,40) ' }      | 58.772 |
| {'CustAge' }    | {'[40,46) ' }      | 72.167 |
| {'CustAge' }    | {'[46,48) ' }      | 93.256 |
| {'CustAge' }    | {'[48,58) ' }      | 95.256 |
| {'CustAge' }    | {'[58,Inf] ' }     | 126.46 |
| {'CustAge' }    | {'<missing>' }     | NaN    |
| {'ResStatus' }  | {'Tenant' }        | 62.421 |
| {'ResStatus' }  | {'Home Owner' }    | 82.276 |
| {'ResStatus' }  | {'Other' }         | 113.58 |
| {'ResStatus' }  | {'<missing>' }     | NaN    |
| {'EmpStatus' }  | {'Unknown' }       | 56.765 |
| {'EmpStatus' }  | {'Employed' }      | 105.81 |
| {'EmpStatus' }  | {'<missing>' }     | NaN    |
| {'CustIncome' } | {'[-Inf,29000) ' } | 8.9706 |
|                 | :                  |        |

```
MinScore = 300
```

```
MaxScore = 850.0000
```

Notice that, as expected, the values of `MinScore` and `MaxScore` correspond to the worst and best possible scores.

### Separate the Base Points From the Total Points

This example shows how to use `displaypoints` after a model is fitted to separate the base points from the rest of the points assigned to each predictor variable. The name-value pair argument `'BasePoints'` in the `formatpoints` function is a boolean that serves this purpose. By default, the base points are spread across all variables in the scorecard.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in the `creditscorecard` function to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

### Display Points After Modifying Bin Labels

This example shows how to use `displaypoints` after a model is fitted and the `modifybins` function is used to provide user-defined bin labels for a numeric predictor.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in the `creditscorecard` function to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding `TmWBank`, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding `AMBBalance`, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding `EmpStatus`, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding `CustAge`, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding `ResStatus`, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding `OtherCC`, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:

```
status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial
```

Estimated Coefficients:

| Estimate | SE | tStat | pValue |
|----------|----|-------|--------|
|----------|----|-------|--------|

|             |         |          |        |            |
|-------------|---------|----------|--------|------------|
| (Intercept) | 0.70239 | 0.064001 | 10.975 | 5.0538e-28 |
| CustAge     | 0.60833 | 0.24932  | 2.44   | 0.014687   |
| ResStatus   | 1.377   | 0.65272  | 2.1097 | 0.034888   |
| EmpStatus   | 0.88565 | 0.293    | 3.0227 | 0.0025055  |
| CustIncome  | 0.70164 | 0.21844  | 3.2121 | 0.0013179  |

| OtherCC     | 1.0883  | 0.52912  | 2.0569 | 0.039696   |
| AMBalance   | 1.045   | 0.32214  | 3.2439 | 0.0011792  |

1200 observations, 1192 error degrees of freedom  
 Dispersion: 1  
 Chi<sup>2</sup>-statistic vs. constant model: 89.7, p-value = 1.4e-16

Use the `displaypoints` function to display point information.

```
[PointsInfo,MinScore,MaxScore] = displaypoints(sc)
```

PointsInfo=37×3 table

| Predictors      | Bin                | Points    |
|-----------------|--------------------|-----------|
| {'CustAge' }    | {'[-Inf,33) ' }    | -0.15894  |
| {'CustAge' }    | {'[33,37) ' }      | -0.14036  |
| {'CustAge' }    | {'[37,40) ' }      | -0.060323 |
| {'CustAge' }    | {'[40,46) ' }      | 0.046408  |
| {'CustAge' }    | {'[46,48) ' }      | 0.21445   |
| {'CustAge' }    | {'[48,58) ' }      | 0.23039   |
| {'CustAge' }    | {'[58,Inf] ' }     | 0.479     |
| {'CustAge' }    | {'<missing>' }     | NaN       |
| {'ResStatus' }  | {'Tenant' }        | -0.031252 |
| {'ResStatus' }  | {'Home Owner' }    | 0.12696   |
| {'ResStatus' }  | {'Other' }         | 0.37641   |
| {'ResStatus' }  | {'<missing>' }     | NaN       |
| {'EmpStatus' }  | {'Unknown' }       | -0.076317 |
| {'EmpStatus' }  | {'Employed' }      | 0.31449   |
| {'EmpStatus' }  | {'<missing>' }     | NaN       |
| {'CustIncome' } | {'[-Inf,29000) ' } | -0.45716  |
| :               |                    |           |

MinScore = -1.3100

MaxScore = 3.0726

Use the `modifybins` function to specify user-defined bin labels for 'CustAge' so that the bin ranges are described in natural language.

```
labels = {'Up to 32', '33 to 36', '37 to 39', '40 to 45', '46 to 47', '48 to 57', 'At least 58'};
sc = modifybins(sc, 'CustAge', 'BinLabels', labels);
```

Rerun `displaypoints` to verify the updated bin labels.

```
[PointsInfo,MinScore,MaxScore] = displaypoints(sc)
```

PointsInfo=37×3 table

| Predictors | Bin | Points |
|------------|-----|--------|
|------------|-----|--------|

```

{'CustAge' } {'Up to 32' } -0.15894
{'CustAge' } {'33 to 36' } -0.14036
{'CustAge' } {'37 to 39' } -0.060323
{'CustAge' } {'40 to 45' } 0.046408
{'CustAge' } {'46 to 47' } 0.21445
{'CustAge' } {'48 to 57' } 0.23039
{'CustAge' } {'At least 58' } 0.479
{'CustAge' } {'<missing>' } NaN
{'ResStatus' } {'Tenant' } -0.031252
{'ResStatus' } {'Home Owner' } 0.12696
{'ResStatus' } {'Other' } 0.37641
{'ResStatus' } {'<missing>' } NaN
{'EmpStatus' } {'Unknown' } -0.076317
{'EmpStatus' } {'Employed' } 0.31449
{'EmpStatus' } {'<missing>' } NaN
{'CustIncome' } {'[-Inf,29000)' } -0.45716
:

```

```
MinScore = -1.3100
```

```
MaxScore = 3.0726
```

### Compute the Predictor Weights

This example shows how to use a credit scorecard to compute the weights of the predictors. The weights of the predictors are determined from the range of points of each predictor, divided by the total range of points for the scorecard. The points for the scorecard not only take into consideration the betas, but also implicitly the binning of the predictor values and the corresponding weights of evidence.

Create a scorecard.

```

load CreditCardData.mat
sc = creditscorecard(data, 'IDVar', 'CustID');
sc = autobinning(sc);
sc = fitmodel(sc);

```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:

```

status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial

```

Estimated Coefficients:

| Estimate | SE | tStat | pValue |
|----------|----|-------|--------|
|----------|----|-------|--------|

|             |         |          |        |            |
|-------------|---------|----------|--------|------------|
| (Intercept) | 0.70239 | 0.064001 | 10.975 | 5.0538e-28 |
| CustAge     | 0.60833 | 0.24932  | 2.44   | 0.014687   |
| ResStatus   | 1.377   | 0.65272  | 2.1097 | 0.034888   |
| EmpStatus   | 0.88565 | 0.293    | 3.0227 | 0.0025055  |
| CustIncome  | 0.70164 | 0.21844  | 3.2121 | 0.0013179  |
| TmWBank     | 1.1074  | 0.23271  | 4.7589 | 1.9464e-06 |
| OtherCC     | 1.0883  | 0.52912  | 2.0569 | 0.039696   |
| AMBalance   | 1.045   | 0.32214  | 3.2439 | 0.0011792  |

1200 observations, 1192 error degrees of freedom  
 Dispersion: 1  
 Chi<sup>2</sup>-statistic vs. constant model: 89.7, p-value = 1.4e-16

Compute scorecard points and the MinPts and MaxPts scores.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]);
[PointsTable, MinPts, MaxPts] = displaypoints(sc);
PtsRange = MaxPts - MinPts;
disp(PointsTable(1:10, :));
```

| Predictors     | Bin             | Points |
|----------------|-----------------|--------|
| {'CustAge' }   | {'[-Inf, 33)' } | 52.821 |
| {'CustAge' }   | {'[33, 37)' }   | 54.161 |
| {'CustAge' }   | {'[37, 40)' }   | 59.934 |
| {'CustAge' }   | {'[40, 46)' }   | 67.633 |
| {'CustAge' }   | {'[46, 48)' }   | 79.755 |
| {'CustAge' }   | {'[48, 58)' }   | 80.905 |
| {'CustAge' }   | {'[58, Inf)' }  | 98.838 |
| {'CustAge' }   | {'<missing>' }  | NaN    |
| {'ResStatus' } | {'Tenant' }     | 62.031 |
| {'ResStatus' } | {'Home Owner' } | 73.444 |

```
fprintf('Min points: %g, Max points: %g\n', MinPts, MaxPts);
```

Min points: 355.505, Max points: 671.64

Compute the predictor weights.

```
Predictor = unique(PointsTable.Predictors, 'stable');
NumPred = length(Predictor);
Weight = zeros(NumPred, 1);
for ii=1:NumPred
    Ind = cellfun(@(x) strcmpi(Predictor{ii}, x), PointsTable.Predictors);
    MaxPtsPred = max(PointsTable.Points(Ind));
    MinPtsPred = min(PointsTable.Points(Ind));
    Weight(ii) = 100*(MaxPtsPred - MinPtsPred)/PtsRange;
end
```

```
PredictorWeights = table(Predictor, Weight);
PredictorWeights(end+1, :) = PredictorWeights(end, :);
PredictorWeights.Predictor{end} = 'Total';
PredictorWeights.Weight(end) = sum(Weight);
disp(PredictorWeights)
```

| Predictor | Weight |
|-----------|--------|
|-----------|--------|

```

{'CustAge'   }    14.556
{'ResStatus'}    9.302
{'EmpStatus'}   8.9174
{'CustIncome'} 20.401
{'TmWBank'   }  25.884
{'OtherCC'   }   7.9885
{'AMBalance' }  12.951
{'Total'     }   100

```

The weights are defined as the range of points for the predictor divided by the range of points for the scorecard.

### Display Points for creditcorecard Object That Contains Missing Data

To create a `creditscorecard` object using the `CreditCardData.mat` file, load the data (using a dataset from Refaat 2011). Using the `dataMissing` dataset, set the `'BinMissingData'` indicator to `true`.

```
load CreditCardData.mat
sc = creditscorecard(dataMissing, 'BinMissingData', true);
```

Use autobin角度 with the `creditscorecard` object.

```
sc = autobin角度(sc);
```

The binning map or rules for categorical data are summarized in a "category grouping" table, returned as an optional output. By default, each category is placed in a separate bin. Here is the information for the predictor `ResStatus`.

```
[bi, cg] = bininfo(sc, 'ResStatus')
```

```
bi=5x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'Tenant'   }    296    161    1.8385  -0.095463    0.0035249
{'Home Owner'}  352    171    2.0585   0.017549    0.00013382
{'Other'    }    128     52    2.4615   0.19637     0.0055808
{'<missing>'}  27     13    2.0769   0.026469    2.3248e-05
{'Totals'   }    803    397    2.0227      NaN     0.0092627
```

```
cg=3x2 table
      Category      BinNumber
-----
{'Tenant'   }          1
{'Home Owner'}        2
{'Other'    }          3
```

To group categories `'Tenant'` and `'Other'`, modify the category grouping table `cg`, so the bin number for `'Other'` is the same as the bin number for `'Tenant'`. Then use `modifybins` to update the `creditscorecard` object.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'Catg', cg);
```

Display the updated bin information using `bininfo`. Note that the bin labels has been updated and that the bin membership information is contained in the category grouping `cg`.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

```
bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'Group1'  }    296    161    1.8385  -0.095463  0.0035249
{'Group2'  }    480    223    2.1525   0.062196  0.0022419
{'<missing>}     27     13    2.0769   0.026469  2.3248e-05
{'Totals'  }    803    397    2.0227         NaN    0.00579
```

```
cg=3x2 table
      Category      BinNumber
-----
{'Tenant'    }          1
{'Home Owner'}          2
{'Other'     }          2
```

Use `formatpoints` with the 'Missing' name-value pair argument to indicate that missing data is assigned 'maxpoints'.

```
sc = formatpoints(sc, 'BasePoints', true, 'Missing', 'maxpoints', 'WorstAndBest', [300 800]);
```

Use `fitmodel` to fit the model.

```
sc = fitmodel(sc, 'VariableSelection', 'fullmodel', 'Display', 'Off');
```

Then use `displaypoints` with the `creditscorecard` object to return a table of points for all bins of all predictor variables used in the `compactCreditScorecard` object. By setting the `displaypoints` name-value pair argument for 'ShowCategoricalMembers' to true, all the members contained in each individual group are displayed.

```
[PointsInfo,MinScore,MaxScore] = displaypoints(sc, 'ShowCategoricalMembers', true)
```

```
PointsInfo=51x3 table
      Predictors      Bin      Points
-----
{'BasePoints' } {'BasePoints'}    535.25
{'CustID'     } {'[-Inf,121)'}    12.085
{'CustID'     } {'[121,241)'}     5.4738
{'CustID'     } {'[241,1081)'}   -1.4061
{'CustID'     } {'[1081,Inf]'}   -7.2217
{'CustID'     } {'<missing>'}    12.085
{'CustAge'    } {'[-Inf,33)'}   -25.973
{'CustAge'    } {'[33,37)'}     -22.67
{'CustAge'    } {'[37,40)'}     -17.122
{'CustAge'    } {'[40,46)'}     -2.8071
{'CustAge'    } {'[46,48)'}      9.5034
```

```

{'CustAge' } {' [48,51)' } 10.913
{'CustAge' } {' [51,58)' } 13.844
{'CustAge' } {' [58,Inf]' } 37.541
{'CustAge' } {' <missing>' } -9.7271
{'TmAtAddress' } {' [-Inf,23)' } -9.3683
:

```

```
MinScore = 300
```

```
MaxScore = 800.0000
```

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[PointsInfo,MinScore,MaxScore] = displaypoints(sc, 'ShowCategoricalMembers',true)`

### ShowCategoricalMembers — Indicator for how to display bins labels of categories that were grouped together

false (default) | true or false

Indicator for how to display bins labels of categories that were grouped together, specified as the comma-separated pair consisting of `'ShowCategoricalMembers'` and a logical scalar with a value of true or false.

By default, when `'ShowCategoricalMembers'` is false, bin labels are displayed as `Group1`, `Group2`, ..., `Groupn`, or if the bin labels were modified in `creditscorecard`, then the user-defined bin label names are displayed.

If `'ShowCategoricalMembers'` is true, all the members contained in each individual group are displayed.

Data Types: logical

## Output Arguments

### PointsInfo — One row per bin, per predictor, with the corresponding points

table

One row per bin, per predictor, with the corresponding points, returned as a table. For example:

| Predictors  | Bin         | Points        |
|-------------|-------------|---------------|
| Predictor_1 | Bin_11      | Points_11     |
| Predictor_1 | Bin_12      | Points_12     |
| Predictor_1 | Bin_13      | Points_13     |
|             | ...         | ...           |
| Predictor_1 | '<missing>' | NaN (Default) |
| Predictor_2 | Bin_21      | Points_21     |
| Predictor_2 | Bin_22      | Points_22     |
| Predictor_2 | Bin_23      | Points_23     |
|             | ...         | ...           |
| Predictor_2 | '<missing>' | NaN (Default) |
| Predictor_j | Bin_ji      | Points_ji     |
|             | ...         | ...           |
| Predictor_j | '<missing>' | NaN (Default) |

`displaypoints` always displays a '<missing>' bin for each predictor. The value of the '<missing>' bin comes from the initial `creditscorecard` object, and the '<missing>' bin is set to NaN whenever the scorecard model has no information on how to assign points to missing data.

To configure the points for the '<missing>' bin, you must use the initial `creditscorecard` object. For predictors that have missing values in the training set, the points for the '<missing>' bin are estimated from the data if the `'BinMissingData'` name-value pair argument for is set to `true` using `creditscorecard`. When the `'BinMissingData'` parameter is set to `false`, or when the data contains no missing values in the training set, use the `'Missing'` name-value pair argument in `formatpoints` to indicate how to assign points to the missing data.

Another option is to use `fillmissing` to specify replacement "fill" values for predictors with a NaN or `<undefined>` value. If you use `fillmissing`, then the `displaypoints` '<missing>' row has the same points as the bin associated with the fill value.

When base points are reported separately (see `formatpoints`), the first row of the returned `PointsInfo` table contains the base points.

### **MinScore — Minimum possible total score**

scalar

Minimum possible total score, returned as a scalar.

---

**Note** Minimum score is the lowest possible total score in the mathematical sense, independently of whether a low score means high risk or low risk.

---

### **MaxScore — Maximum possible total score**

scalar

Maximum possible total score, returned as a scalar.

---

**Note** Maximum score is the highest possible total score in the mathematical sense, independently of whether a high score means high risk or low risk.

---

## Algorithms

The points for predictor  $j$  and bin  $i$  are, by default, given by

$$\text{Points}_{ji} = (\text{Shift} + \text{Slope} * b_0) / p + \text{Slope} * (b_j * \text{WOE}_j(i))$$

where  $b_j$  is the model coefficient of predictor  $j$ ,  $p$  is the number of predictors in the model, and  $\text{WOE}_j(i)$  is the Weight of Evidence (WOE) value for the  $i$ -th bin corresponding to the  $j$ -th model predictor. `Shift` and `Slope` are scaling constants.

When the base points are reported separately (see the `formatpoints` name-value pair argument `BasePoints`), the base points are given by

$$\text{Base Points} = \text{Shift} + \text{Slope} * b_0,$$

and the points for the  $j$ -th predictor,  $i$ -th row are given by

$$\text{Points}_{ji} = \text{Slope} * (b_j * \text{WOE}_j(i)).$$

By default, the base points are not reported separately.

The minimum and maximum scores are:

$$\begin{aligned} \text{MinScore} &= \text{Shift} + \text{Slope} * b_0 + \min(\text{Slope} * b_1 * \text{WOE}_1) + \dots + \min(\text{Slope} * b_p * \text{WOE}_p), \\ \text{MaxScore} &= \text{Shift} + \text{Slope} * b_0 + \max(\text{Slope} * b_1 * \text{WOE}_1) + \dots + \max(\text{Slope} * b_p * \text{WOE}_p). \end{aligned}$$

Use `formatpoints` to control the way points are scaled, rounded, and whether the base points are reported separately. See `formatpoints` for more information on format parameters and for details and formulas on these formatting options.

## Introduced in R2014b

# fitmodel

Fit logistic regression model to Weight of Evidence (WOE) data

## Syntax

```
sc = fitmodel(sc)

[sc,mdl] = fitmodel(sc)
[sc,mdl] = fitmodel( ____,Name,Value)
```

## Description

`sc = fitmodel(sc)` fits a logistic regression model to the Weight of Evidence (WOE) data and stores the model predictor names and corresponding coefficients in the `creditscorecard` object.

`fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic or manual binning process. The response variable is mapped so that "Good" is 1, and "Bad" is 0. This implies that higher (unscaled) scores correspond to better (less risky) individuals (smaller probability of default).

Alternatively, you can use `setmodel` to provide names of the predictors that you want in the logistic regression model, along with their corresponding coefficients.

`[sc,mdl] = fitmodel(sc)` fits a logistic regression model to the Weight of Evidence (WOE) data and stores the model predictor names and corresponding coefficients in the `creditscorecard` object. `fitmodel` returns an updated `creditscorecard` object and a `GeneralizedLinearModel` object containing the fitted model.

`fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic or manual binning process. The response variable is mapped so that "Good" is 1, and "Bad" is 0. This implies that higher (unscaled) scores correspond to better (less risky) individuals (smaller probability of default).

Alternatively, you can use `setmodel` to provide names of the predictors that you want in the logistic regression model, along with their corresponding coefficients.

`[sc,mdl] = fitmodel( ____,Name,Value)` fits a logistic regression model to the Weight of Evidence (WOE) data using optional name-value pair arguments and stores the model predictor names and corresponding coefficients in the `creditscorecard` object. Using name-value pair arguments, you can select which Generalized Linear Model to fit the data. `fitmodel` returns an updated `creditscorecard` object and a `GeneralizedLinearModel` object containing the fitted model.

## Examples

### Fit a Stepwise Logistic Model

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```

load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
  creditscorecard with properties:

      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x11 table]

```

Perform automatic binning.

```

sc = autobinning(sc)

sc =
  creditscorecard with properties:

      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x11 table]

```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default).

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

```

Generalized linear regression model:
  status ~ [Linear formula with 8 terms in 7 predictors]
  Distribution = Binomial

```

```

Estimated Coefficients:
      Estimate      SE      tStat      pValue

```

|             |         |          |        |            |

1200 observations, 1192 error degrees of freedom  
 Dispersion: 1  
 Chi<sup>2</sup>-statistic vs. constant model: 89.7, p-value = 1.4e-16

### Fit a Stepwise Logistic Model For a creditcorecard Object Containing Weights

Use the CreditCardData.mat file to load the data (dataWeights) that contains a column (RowWeights) for the weights (using a dataset from Refaat 2011).

load CreditCardData

Create a creditcorecard object using the optional name-value pair argument for 'WeightsVar'.

```
sc = creditcorecard(dataWeights, 'IDVar', 'CustID', 'WeightsVar', 'RowWeights')
```

```
sc =
  creditcorecard with properties:
      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: 'RowWeights'
      VarNames: {1x12 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x12 table]
```

Perform automatic binning.

```
sc = autobinning(sc)
```

```
sc =
  creditcorecard with properties:
      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: 'RowWeights'
      VarNames: {1x12 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
```

```
IDVar: 'CustID'
PredictorVars: {1x9 cell}
Data: [1200x12 table]
```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). When the optional name-value pair argument `'WeightsVar'` is used to specify observation (sample) weights, the `mdl` output uses the weighted counts with `stepwiseglm` and `fitglm`.

```
[sc,mdl] = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 764.3187, Chi2Stat = 15.81927, PValue = 6.968927e-05
2. Adding `TmWBank`, Deviance = 751.0215, Chi2Stat = 13.29726, PValue = 0.0002657942
3. Adding `AMBalance`, Deviance = 743.7581, Chi2Stat = 7.263384, PValue = 0.007037455

Generalized linear regression model:

```
logit(status) ~ 1 + CustIncome + TmWBank + AMBalance
Distribution = Binomial
```

Estimated Coefficients:

|                         | Estimate | SE       | tStat  | pValue     |
|-------------------------|----------|----------|--------|------------|
| (Intercept)             | 0.70642  | 0.088702 | 7.964  | 1.6653e-15 |
| <code>CustIncome</code> | 1.0268   | 0.25758  | 3.9862 | 6.7132e-05 |
| <code>TmWBank</code>    | 1.0973   | 0.31294  | 3.5063 | 0.0004543  |
| <code>AMBalance</code>  | 1.0039   | 0.37576  | 2.6717 | 0.0075464  |

1200 observations, 1196 error degrees of freedom

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 36.4, p-value = 6.22e-08

### Fit a Logistic Model with All Predictors

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
```

```
sc = creditscorecard(data, 'IDVar', 'CustID')
```

```
sc =
```

```
creditscorecard with properties:
```

```
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
```

```
PredictorVars: {1x9 cell}
Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc, 'Algorithm', 'EqualFrequency')
```

```
sc =
creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. Set the `VariableSelection` name-value pair argument to `FullModel` to specify that all predictors must be included in the fitted logistic regression model.

```
sc = fitmodel(sc, 'VariableSelection', 'FullModel');
```

```
Generalized linear regression model:
status ~ [Linear formula with 10 terms in 9 predictors]
Distribution = Binomial
```

Estimated Coefficients:

|             | Estimate | SE       | tStat   | pValue    |
|-------------|----------|----------|---------|-----------|
| (Intercept) | 0.70262  | 0.063862 | 11.002  | 3.734e-28 |
| CustAge     | 0.57683  | 0.27064  | 2.1313  | 0.033062  |
| TmAtAddress | 1.0653   | 0.55233  | 1.9287  | 0.053762  |
| ResStatus   | 1.4189   | 0.65162  | 2.1775  | 0.029441  |
| EmpStatus   | 0.89916  | 0.29217  | 3.0776  | 0.002087  |
| CustIncome  | 0.77506  | 0.21942  | 3.5323  | 0.0004119 |
| TmWBank     | 1.0826   | 0.26583  | 4.0727  | 4.648e-05 |
| OtherCC     | 1.1354   | 0.52827  | 2.1493  | 0.031612  |
| AMBalance   | 0.99315  | 0.32642  | 3.0425  | 0.0023459 |
| UtilRate    | 0.16723  | 0.55745  | 0.29999 | 0.76419   |

1200 observations, 1190 error degrees of freedom

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 85.6, p-value = 1.25e-14

### Fit a Stepwise Logistic Model When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
```

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | Other |
|--------|---------|-------------|-------------|-----------|------------|---------|-------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Yes   |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Yes   |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No    |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Yes   |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Yes   |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Display and plot bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
[bi,cp] = bininfo(sc,'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| {'[-Inf,33)'} } | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |
| {'[33,37)'} }   | 63   | 45  | 1.4    | -0.36795 | 0.012839   |
| {'[37,40)'} }   | 72   | 47  | 1.5319 | -0.2779  | 0.0079824  |
| {'[40,46)'} }   | 172  | 89  | 1.9326 | -0.04556 | 0.0004549  |
| {'[46,48)'} }   | 59   | 25  | 2.36   | 0.15424  | 0.0016199  |
| {'[48,51)'} }   | 99   | 41  | 2.4146 | 0.17713  | 0.0035449  |
| {'[51,58)'} }   | 157  | 62  | 2.5323 | 0.22469  | 0.0088407  |
| {'[58,Inf]'} }  | 93   | 25  | 3.72   | 0.60931  | 0.032198   |
| {'<missing>'} } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN      | 0.087112   |

```
plotbins(sc, 'CustAge')
```

Display and plot bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue  |
|-----------------|------|-----|--------|-----------|------------|
| {'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| {'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |

```

{'<missing>' }    27    13    2.0769    0.026469    2.3248e-05
{'Totals'     }   803   397    2.0227         NaN    0.0092627

```

```
plotbins(sc, 'ResStatus')
```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation. For example, a missing value for customer age (`CustAge`) is replaced with `-0.15787` which is the WOE value for the `<missing>` bin for the `CustAge` predictor. However, when `'BinMissingData'` is false, a missing value for `CustAge` remains as missing (`NaN`) when applying the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 88.5, p-value = 2.55e-16

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[sc, mdl] = fitmodel(sc, 'VariableSelection', 'FullModel')`

### PredictorVars — Predictor variables for fitting creditscorecard object

all predictors in the `creditscorecard` object (default) | cell array of character vectors

Predictor variables for fitting the `creditscorecard` object, specified as the comma-separated pair consisting of `'PredictorVars'` and a cell array of character vectors. When provided, the `creditscorecard` object property `PredictorsVars` is updated. Note that the order of predictors in the original dataset is enforced, regardless of the order in which `'PredictorVars'` is provided. When not provided, the predictors used to create the `creditscorecard` object (by using `creditscorecard`) are used.

Data Types: cell

### VariableSelection — Variable selection method to fit logistic regression model

'Stepwise' (default) | character vector with values 'Stepwise', 'FullModel'

The variable selection method to fit the logistic regression model, specified as the comma-separated pair consisting of `'VariableSelection'` and a character vector with values `'Stepwise'` or `'FullModel'`:

- **Stepwise** — Uses a stepwise selection method which calls the Statistics and Machine Learning Toolbox function `stepwiseglm`. Only variables in `PredictorVars` can potentially become part of the model and uses the `StartingModel` name-value pair argument to select the starting model.
- **FullModel** — Fits a model with all predictor variables in the `PredictorVars` name-value pair argument and calls `fitglm`.

---

**Note** Only variables in the `PredictorVars` property of the `creditscorecard` object can potentially become part of the logistic regression model and only linear terms are included in this model with no interactions or any other higher-order terms.

The response variable is mapped so that “Good” is 1 and “Bad” is 0.

---

Data Types: char

### **StartingModel — Initial model for Stepwise variable selection**

'Constant' (default) | character vector with values 'Constant', 'Linear'

Initial model for the `Stepwise` variable selection method, specified as the comma-separated pair consisting of `StartingModel` and a character vector with values 'Constant' or 'Linear'. This option determines the initial model (constant or linear) that the Statistics and Machine Learning Toolbox function `stepwiseglm` starts with.

- **Constant** — Starts the stepwise method with an empty (constant only) model.
- **Linear** — Starts the stepwise method from a full (all predictors in) model.

---

**Note** `StartingModel` is used only for the `Stepwise` option of `VariableSelection` and has no effect for the `FullModel` option of `VariableSelection`.

---

Data Types: char

### **Display — Indicator to display model information at command line**

'On' (default) | character vector with values 'On', 'Off'

Indicator to display model information at command line, specified as the comma-separated pair consisting of `Display` and a character vector with value 'On' or 'Off'.

Data Types: char

## **Output Arguments**

### **sc — Credit scorecard model**

`creditscorecard` object

Credit scorecard model, returned as an updated `creditscorecard` object. The `creditscorecard` object contains information about the model predictors and coefficients used to fit the WOE data. For more information on using the `creditscorecard` object, see `creditscorecard`.

### **mdl — Fitted logistic model**

`GeneralizedLinearModel` object

Fitted logistic model, returned as an object of type `GeneralizedLinearModel` containing the fitted model. For more information on a `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

---

**Note** When creating the `creditscorecard` object with `creditscorecard`, if the optional name-value pair argument `WeightsVar` was used to specify observation (sample) weights, then `mdl` uses the weighted counts with `stepwiseglm` and `fitglm`.

---

## More About

### Using `fitmodel` with Weights

When observation weights are provided in the credit scorecard data, the weights are used to calibrate the model coefficients.

The underlying Statistics and Machine Learning Toolbox functionality for `stepwiseglm` and `fitglm` supports observation weights. The weights also affect the logistic model through the WOE values. The WOE transformation is applied to all predictors before fitting the logistic model. The observation weights directly impact the WOE values. For more information, see “Using `bininfo` with Weights” on page 19-1732 and “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

Therefore, the credit scorecard points and final score depend on the observation weights through both the logistic model coefficients and the WOE values.

### Models

A logistic regression model is used in the `creditscorecard` object.

For the model, the probability of being “Bad” is defined as:  $\text{ProbBad} = \exp(-s) / (1 + \exp(-s))$ .

# fitConstrainedModel

Fit logistic regression model to Weight of Evidence (WOE) data subject to constraints on model coefficients

## Syntax

```
[sc,mdl] = fitConstrainedModel(sc)
[sc,mdl] = fitConstrainedModel( ___,Name,Value)
```

## Description

`[sc,mdl] = fitConstrainedModel(sc)` fits a logistic regression model to the Weight of Evidence (WOE) data subject to equality, inequality, or bound constraints on the model coefficients. `fitConstrainedModel` stores the model predictor names and corresponding coefficients in an updated `creditscorecard` object `sc` and returns the `GeneralizedLinearModel` object `mdl` which contains the fitted model.

`[sc,mdl] = fitConstrainedModel( ___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Credit Scorecards with Constrained Logistic Regression Coefficients

To compute scores for a `creditscorecard` object with constraints for equality, inequality, or bounds on the coefficients of the logistic regression model, use `fitConstrainedModel`. Unlike `fitmodel`, `fitConstrainedModel` solves for both the unconstrained and constrained problem. The current solver used to minimize an objective function for `fitConstrainedModel` is `fmincon`, from the Optimization Toolbox™.

This example has three main sections. First, `fitConstrainedModel` is used to solve for the coefficients in the unconstrained model. Then, `fitConstrainedModel` demonstrates how to use several types of constraints. Finally, `fitConstrainedModel` uses bootstrapping for the significance analysis to determine which predictors to reject from the model.

#### Create the `creditscorecard` Object and Bin data

```
load CreditCardData.mat
sc = creditscorecard(data, 'IDVar', 'CustID');
sc = autobinning(sc);
```

#### Unconstrained Model Using `fitConstrainedModel`

Solve for the unconstrained coefficients using `fitConstrainedModel` with default values for the input parameters. `fitConstrainedModel` uses the internal optimization solver `fmincon` from the Optimization Toolbox™. If you do not set any constraints, `fmincon` treats the model as an unconstrained optimization problem. The default parameters for the `LowerBound` and `UpperBound` are `-Inf` and `+Inf`, respectively. For the equality and inequality constraints, the default is an empty numeric array.

```
[sc1,mdl1] = fitConstrainedModel(sc);
coeff1 = mdl1.Coefficients.Estimate;
disp(mdl1.Coefficients);
```

|             | Estimate  |
|-------------|-----------|
| (Intercept) | 0.70246   |
| CustAge     | 0.6057    |
| TmAtAddress | 1.0381    |
| ResStatus   | 1.3794    |
| EmpStatus   | 0.89648   |
| CustIncome  | 0.70179   |
| TmWBank     | 1.1132    |
| OtherCC     | 1.0598    |
| AMBalance   | 1.0572    |
| UtilRate    | -0.047597 |

Unlike `fitmodel` which gives  $p$ -values, when using `fitConstrainedModel`, you must use bootstrapping to find out which predictors are rejected from the model, when subject to constraints. This is illustrated in the "Significance Bootstrapping" section.

### Using `fitmodel` to Compare the Results and Calibrate the Model

`fitmodel` fits a logistic regression model to the Weight-of-Evidence (WOE) data and there are no constraints. You can compare the results from the "Unconstrained Model Using `fitConstrainedModel`" section with those of `fitmodel` to verify that the model is well calibrated.

Now, solve the unconstrained problem by using `fitmodel`. Note that `fitmodel` and `fitConstrainedModel` use different solvers. While `fitConstrainedModel` uses `fmincon`, `fitmodel` uses `stepwiseglm` by default. To include all predictors from the start, set the 'VariableSelection' name-value pair argument of `fitmodel` to 'fullmodel'.

```
[sc2,mdl2] = fitmodel(sc,'VariableSelection','fullmodel','Display','off');
coeff2 = mdl2.Coefficients.Estimate;
disp(mdl2.Coefficients);
```

|             | Estimate  | SE       | tStat     | pValue     |
|-------------|-----------|----------|-----------|------------|
| (Intercept) | 0.70246   | 0.064039 | 10.969    | 5.3719e-28 |
| CustAge     | 0.6057    | 0.24934  | 2.4292    | 0.015131   |
| TmAtAddress | 1.0381    | 0.94042  | 1.1039    | 0.26963    |
| ResStatus   | 1.3794    | 0.6526   | 2.1137    | 0.034538   |
| EmpStatus   | 0.89648   | 0.29339  | 3.0556    | 0.0022458  |
| CustIncome  | 0.70179   | 0.21866  | 3.2095    | 0.0013295  |
| TmWBank     | 1.1132    | 0.23346  | 4.7683    | 1.8579e-06 |
| OtherCC     | 1.0598    | 0.53005  | 1.9994    | 0.045568   |
| AMBalance   | 1.0572    | 0.36601  | 2.8884    | 0.0038718  |
| UtilRate    | -0.047597 | 0.61133  | -0.077858 | 0.93794    |

```
figure
plot(coeff1,'*')
hold on
plot(coeff2,'s')
xticklabels(mdl1.Coefficients.Properties.RowNames)
xtickangle(45)
ylabel('Model Coefficients')
```

```

title('Unconstrained Model Coefficients')
legend({'Calculated by fitConstrainedModel with defaults', 'Calculated by fimodel'}, 'Location', 'best',
grid on

```

As both the tables and the plot show, the model coefficients match. You can be confident that this implementation of `fitConstrainedModel` is well calibrated.

### Constrained Model

In the constrained model approach, you solve for the values of the coefficients  $b_i$  of the logistic model, subject to constraints. The supported constraints are bound, equality, or inequality. The coefficients maximize the likelihood-of-default function defined, for observation  $i$ , as:

$$L_i = p(\text{Default}_i)^{y_i} \times (1 - p(\text{Default}_i))^{1 - y_i}$$

where:

- $p(\text{Default}_i) = \frac{1}{1 + e^{-b \cdot x_i}}$
- $\mathbf{b} = [b_1 \ b_2 \ \dots \ b_K]$  is an unknown model coefficient
- $\mathbf{x}_i = [x_{i1} \ x_{i2} \ \dots \ x_{iK}]$  is the predictor values at observation  $i$
- $y_i$  is the response value; a value of 1 represents default and a value of 0 represents non-default

This formula is for non-weighted data. When observation  $i$  has weight  $w_i$ , it means that there are  $w_i$  as many observations  $i$ . Therefore, the probability that default occurs at observation  $i$  is the product of the probabilities of default:

$$p_i = p(\text{Default}_i)^{y_i} * p(\text{Default}_i)^{y_i} * \dots * p(\text{Default}_i)^{y_i} = p(\text{Default}_i)^{w_i * y_i}$$

$w_i$  times

Likewise, the probability of non-default for weighted observation  $i$  is:

$$\hat{p}_i = p(\sim\text{Default}_i)^{1 - y_i} * p(\sim\text{Default}_i)^{1 - y_i} * \dots * p(\sim\text{Default}_i)^{1 - y_i} = (1 - p(\text{Default}_i))^{w_i * (1 - y_i)}$$

$w_i$  times

For weighted data, if there is default at a given observation  $i$  whose weight is  $w_i$ , it is as if there was a  $w_i$  count of that one observation, and all of them either all default, or all non-default.  $w_i$  may or may not be an integer.

Therefore, for the weighted data, the likelihood-of-default function for observation  $i$  in the first equation becomes

$$L_i = p(\text{Default}_i)^{w_i * y_i} \times (1 - p(\text{Default}_i))^{w_i * (1 - y_i)}$$

By assumption, all defaults are independent events, so the objective function is

$$L = L_1 \times L_2 \times \dots \times L_N$$

or, in more convenient logarithmic terms:

$$\log(L) = \sum_{i=1}^N w_i * [y_i \log(p(\text{Default}_i)) + (1 - y_i) \log(1 - p(\text{Default}_i))]$$

### Apply Constraints on the Coefficients

After calibrating the unconstrained model as described in the "Unconstrained Model Using fitConstrainedModel" section, you can solve for the model coefficients subject to constraints. You can choose lower and upper bounds such that  $0 \leq b_i \leq 1, \forall i = 1 \dots K$ , except for the intercept. Also, since the customer age and customer income are somewhat correlated, you can also use additional constraints on their coefficients, for example,  $|b_{CusAge} - b_{CustIncome}| < 0.1$ . The coefficients corresponding to the predictors 'CustAge' and 'CustIncome' in this example are  $b_2$  and  $b_6$ , respectively.

```
K = length(sc.PredictorVars);
lb = [-Inf;zeros(K,1)];
ub = [Inf;ones(K,1)];
AIneq = [0 -1 0 0 0 1 0 0 0 0;0 -1 0 0 0 -1 0 0 0 0];
bIneq = [0.05;0.05];
Options = optimoptions('fmincon','SpecifyObjectiveGradient',true,'Display','off');
[sc3,mdl] = fitConstrainedModel(sc,'AInequality',AIneq,'bInequality',bIneq,...
    'LowerBound',lb,'UpperBound',ub,'Options',Options);
```

```
figure
plot(coeff1,'*','MarkerSize',8)
hold on
plot(mdl.Coefficients.Estimate,','MarkerSize',12)
line(xlim,[0 0],'color','k','linestyle',':')
```

```

line(xlim,[1 1], 'color', 'k', 'linestyle', ':')
text(1.1, 0.1, 'Lower bound')
text(1.1, 1.1, 'Upper bound')
grid on

xticklabels mdl.Coefficients.Properties.RowNames
xtickangle(45)
ylabel('Model Coefficients')
title('Comparison Between Unconstrained and Constrained Solutions')
legend({'Unconstrained', 'Constrained'}, 'Location', 'best')

```

### Significance Bootstrapping

For the unconstrained problem, standard formulas are available for computing  $p$ -values, which you use to evaluate which coefficients are significant and which are to be rejected. However, for the constrained problem, standard formulas are not available, and the derivation of formulas for significance analysis is complicated. A practical alternative is to perform significance analysis through *bootstrapping*.

In the bootstrapping approach, when using `fitConstrainedModel`, you set the name-value argument `'Bootstrap'` to `true` and chose a value for the name-value argument `'BootstrapIter'`. Bootstrapping means that  $N$  iter samples (with replacement) from the original observations are selected. In each iteration, `fitConstrainedModel` solves for the same constrained problem as the "Constrained Model" section. `fitConstrainedModel` obtains several values (solutions) for each coefficient  $b_i$  and you can plot these as a boxplot or histogram. Using the

boxplot or histogram, you can examine the median values to evaluate whether the coefficients are away from zero and how much the coefficients deviate from their means.

```
lb = [-Inf;zeros(K,1)];
ub = [Inf;ones(K,1)];
AIneq = [0 -1 0 0 0 1 0 0 0 0;0 1 0 0 0 -1 0 0 0 0];
bIneq = [0.05;0.05];
c0 = zeros(K,1);
NIter = 100;
Options = optimoptions('fmincon','SpecifyObjectiveGradient',true,'Display','off');
rng('default')

[sc,mdl] = fitConstrainedModel(sc,'AInequality',AIneq,'bInequality',bIneq,...
    'LowerBound',lb,'UpperBound',ub,'Bootstrap',true,'BootstrapIter',NIter,'Options',Options);

figure
boxplot(mdl.Bootstrap.Matrix,mdl.Coefficients.Properties.RowNames)
hold on
line(xlim,[0 0],'color','k','linestyle',':')
line(xlim,[1 1],'color','k','linestyle',':')
title('Bootstrapping with N = 100 Iterations')
ylabel('Model Coefficients')
xtickangle(45)
```

The solid red lines in the boxplot indicate that the median values and the bottom and top edges are for the 25<sup>th</sup> and 75<sup>th</sup> percentiles. The "whiskers" are the minimum and maximum values, not

including outliers. The dotted lines represent the lower and upper bound constraints on the coefficients. In this example, the coefficients cannot be negative, by construction.

To help decide which predictors to keep in the model, assess the proportion of times each coefficient is zero.

```
Tol = 1e-6;
figure
bar(100*sum mdl.Bootstrap.Matrix<= Tol)/NIter)
ylabel('% of Zeros')
title('Percentage of Zeros Over Bootstrap Iterations')
xticklabels mdl.Coefficients.Properties.RowNames)
xtickangle(45)
grid on
```

Based on the plot, you can reject 'UtilRate' since it has the highest number of zero values. You can also decide to reject 'TmAAddress' since it shows a peak, albeit small.

### Set the Corresponding Coefficients to Zero

To set the corresponding coefficients to zero, set their upper bound to zero and solve the model again using the original data set.

```
ub(3) = 0;
ub(end) = 0;
[sc,mdl] = fitConstrainedModel(sc, 'AInequality', AIneq, 'bInequality', bIneq, 'LowerBound', lb, 'UpperBound', ub);
Ind = (abs(mdl.Coefficients.Estimate) <= Tol);
```

```

ModelCoeff = mdl.Coefficients.Estimate(~Ind);
ModelPreds = mdl.Coefficients.Properties.RowNames(~Ind)';

figure
hold on
plot(ModelCoeff, '.', 'MarkerSize', 12)
ylim([0.2 1.2])
ylabel('Model Coefficients')
xticklabels(ModelPreds)
xtickangle(45)
title('Selected Model Coefficients After Bootstrapping')
grid on

```

### Set Constrained Coefficients Back Into the creditscorecard

Now that you have solved for the constrained coefficients, use `setmodel` to set the model's coefficients and predictors. Then you can compute the (unscaled) points.

```

ModelPreds = ModelPreds(2:end);
sc = setmodel(sc, ModelPreds, ModelCoeff);
p = displaypoints(sc);

```

```
disp(p)
```

| Predictors    | Bin              | Points   |

| { 'AMBalance' }  | { '<missing>' }         | } | NaN       |

Using the unscaled points, you can follow the remainder of the “Credit Scorecard Modeling Workflow” on page 8-51 to compute scores and probabilities of default and to validate the model.

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[sc,mdl] = fitConstrainedModel(sc,'LowerBound',2,'UpperBound',100)`

**PredictorVars — Predictor variables for fitting creditscorecard object**

all predictors in the `creditscorecard` object (default) | cell array of character vectors

Predictor variables for fitting the `creditscorecard` object, specified as the comma-separated pair consisting of 'PredictorVars' and a cell array of character vectors. If you provide predictor variables, then the function updates the `creditscorecard` object property `PredictorsVars`. The order of predictors in the original dataset is enforced, regardless of the order in which 'PredictorVars' is provided. When not provided, the predictors used to create the `creditscorecard` object (by using `creditscorecard`) are used.

Data Types: cell

**LowerBound — Lower bound**

-Inf (default) | scalar | vector

Lower bound, specified as the comma-separated pair consisting of 'LowerBound' and a scalar or a real vector of length  $N+1$ , where  $N$  is the number of model coefficients in the `creditscorecard` object.

Data Types: double

**UpperBound — Upper bound**

Inf (default) | scalar | vector

Upper bound, specified as the comma-separated pair consisting of 'UpperBound' and a scalar or a real vector of length  $N+1$ , where  $N$  is the number of model coefficients in the `creditscorecard` object.

Data Types: double

**AInequality — Matrix of linear inequality constraints**

[] (default) | matrix

Matrix of linear inequality constraints, specified as the comma-separated pair consisting of 'AInequality' and a real  $M$ -by- $N+1$  matrix, where  $M$  is the number of constraints and  $N$  is the number of model coefficients in the `creditscorecard` object.

Data Types: double

**bInequality — Vector of linear inequality constraints**

[] (default) | vector

Vector of linear inequality constraints, specified as the comma-separated pair consisting of 'bInequality' and a real  $M$ -by-1 vector, where  $M$  is the number of constraints.

Data Types: double

**AEquality — Matrix of linear equality constraints**

[] (default) | matrix

Matrix of linear equality constraints, specified as the comma-separated pair consisting of 'AEquality' and a real  $M$ -by- $N+1$  matrix, where  $M$  is the number of constraints and  $N$  is the number of model coefficients in the `creditscorecard` object.

Data Types: double

**bEquality — Vector of linear equality constraints**

[] (default) | vector

Vector of linear equality constraints, specified as the comma-separated pair consisting of 'bEquality' and a real M-by-1 vector, where M is the number of constraints.

Data Types: double

### **Bootstrap — Indicator that bootstrapping defines the solution accuracy**

false (default) | logical with a value of true or false

Indicator that bootstrapping defines the solution accuracy, specified as the comma-separated pair consisting of 'Bootstrap' and a logical with a value of true or false.

Data Types: logical

### **BootstrapIter — Number of bootstrapping iterations**

100 (default) | positive integer

Number of bootstrapping iterations, specified as the comma-separated pair consisting of 'BootstrapIter' and a positive integer.

Data Types: double

### **Options — optimoptions object**

optimoptions('fmincon','SpecifiedObjectiveGradient',true,'Display','off')  
(default) | object

optimoptions object, specified as the comma-separated pair consisting of 'Options' and an optimoptions object. You can create the object by using optimoptions from Optimization Toolbox.

Data Types: object

## **Output Arguments**

### **sc — Credit scorecard model**

creditscorecard object

Credit scorecard model, returned as an updated creditscorecard object. The creditscorecard object contains information about the model predictors and coefficients that fit the WOE data. For more information on using the creditscorecard object, see creditscorecard.

### **mdl — Fitted logistic model**

GeneralizedLinearModel object

Fitted logistic model, returned as a GeneralizedLinearModel object containing the fitted model. For more information on a GeneralizedLinearModel object, see GeneralizedLinearModel.

---

**Note** If you specify the optional `WeightsVar` argument when creating a `creditscorecard` object, then `mdl` uses the weighted counts with `stepwiseglm` and `fitglm`.

---

The `mdl` structure has the following fields:

- `Coefficients` is a table in which the `RowNames` property contains the names of the model coefficients and has a single column, 'Estimate', containing the solution.
- `Bootstrap` exists when 'Bootstrap' is set to true, and has two fields:

- CI contains the 95% confidence interval for the solution.
- `Matrix` an NIter-by-N matrix of coefficients, where NIter is the number of bootstrap iterations and N is the number of model coefficients.
- `Solver` has three fields:
  - `Options` additional information on the algorithm and solution.
  - `ExitFlag` contains an integer that codes the reason why the solver stopped. For more information, see `fmincon`.
  - `Output` is a structure with additional information on the optimization process.

## More About

### Model Coefficients

When you use `fitConstrainedModel` to solve for the model coefficients, the function solves for the same number of parameters as predictor variables you specify, plus one additional coefficient for the intercept.

The first coefficient corresponds to the intercept. If you provide predictor variables using the 'PredictorVars' optional input argument, then `fitConstrainedModel` updates the `creditscorecard` object property `PredictorsVars`. The order of predictors in the original dataset is enforced, regardless of the order in which 'PredictorVars' is provided. When not provided, the predictors used to create the `creditscorecard` object (by using `creditscorecard`) are used.

### Calibration

The constrained model is first calibrated such that, when unconstrained, the solution is identical, within a certain tolerance, to the solution given by `fitmodel`, with the 'fullmodel' choice for the name-value argument 'VariableSelection'.

As an exercise, you can test the calibration by leaving all name-value parameters of `fitConstrainedModel` to their default values. The solutions are identical to within a  $10^{-6}$  to  $10^{-5}$  tolerance.

### Calibration with Weights and Missing Data

If the credit scorecard data contains observation weights, the `fitConstrainedModel` function uses the weights to calibrate the model coefficients.

For credit scorecard data with no missing data and no weights, the likelihood function for observation  $i$  is

$$L_i = p(\text{Default}_i) \times \left( \frac{1}{1 + e^{-bx_i}} \right)$$

where:

- $b = [b_1 \ b_2 \dots \ b_K]$  is for unknown model coefficients
- $x_i = [x_{i1} \ x_{i2} \dots \ x_{iK}]$  is the predictor values at observation  $i$

- $y_i$  is the response value of 1 (the default) or a value of 0.

When observation  $i$  has weight  $w_i$ , it means that there are  $w_i$  observations. Because of the independence of defaults between observations, the probability that there is default at observation  $i$  is the product of the probabilities of default

$$p_i = p(\text{Default}_i) * p(\text{Default}_i) * \dots * p(\text{Default}_i) = p(\text{Default}_i)^{w_i \text{ times}}$$

Likewise, the probability of non-default for weighted observation  $i$  is

$$\hat{p}_i = p(\sim) * p(\sim) * \dots * p(\sim) = (1 - p(\text{Default}_i))^{w_i \text{ times}}$$

For weighted data, if there is default at a given observation  $i$  whose weight is  $w_i$ , it is as if there was  $w_i$  defaults of that one observation, and all of them either all default, or all non-default.  $w_i$  may or may not be an integer. Therefore, the likelihood function for observation  $i$  becomes

$$L_i = p(\text{Default}_i)^{w_i * y_i} \times (1 - p(\text{Default}_i))^{w_i * (1 - y_i)}$$

Likewise, for data with missing observations (NaN, <undefined>, or “Missing”), the model is calibrated by comparing the unconstrained case with results given by `fitglm`. Where the data contains missing observations, the WOE input matrix has NaN values. The NaN values do not pose any issue for `fitglm` (unconstrained), or `fmincon` (constrained). The only edge case is if all observations of a given predictor are missing, in which case, that predictor is discarded from the model.

## Bootstrapping

Bootstrapping is a method for estimating the accuracy of the solution obtained after iterating the objective function `NIter` times.

When 'Bootstrap' is set to `true`, the `fitConstrainedModel` function performs sampling with replacement of the WOE values and is passed to the objective function. At the end of the iterative process, the solutions are stored in a `NIter`-by-`N+1` matrix, where `N` is the number of model coefficients.

The 95% confidence interval (CI) returned in the output structure `mdl.Bootstrap` contains the values of the coefficients at the 25th and 97.5th percentiles.

## Models

A logistic regression model is used in the `creditscorecard` object.

For the model, the probability of being “Bad” is given by  $\text{ProbBad} = \exp(-s) / (1 + \exp(-s))$ .

# setmodel

Set model predictors and coefficients

## Syntax

```
sc = setmodel(sc,ModelPredictors,ModelCoefficients)
```

## Description

`sc = setmodel(sc,ModelPredictors,ModelCoefficients)` sets the predictors and coefficients of a linear logistic regression model fitted outside the `creditscorecard` object and returns an updated `creditscorecard` object. The predictors and coefficients are used for the computation of scorecard points. Use `setmodel` in lieu of `fitmodel`, which fits a linear logistic regression model, because `setmodel` offers increased flexibility. For example, when a model fitted with `fitmodel` needs to be modified, you can use `setmodel`. For more information, see “Workflows for Using `setmodel`” on page 19-1668.

---

**Note** When using `setmodel`, the following assumptions apply:

- The model coefficients correspond to a linear logistic regression model (where only linear terms are included in the model and there are no interactions or any other higher-order terms).
  - The model was previously fitted using Weight of Evidence (WOE) data with the response mapped so that ‘Good’ is 1 and ‘Bad’ is 0.
- 

## Examples

### Modify a GLM Model Fitted with `fitmodel`

This example shows how to use `setmodel` to make modifications to a logistic regression model initially fitted using the `fitmodel` function, and then set the new logistic regression model predictors and coefficients back into the `creditscorecard` object.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
    creditscorecard with properties:

        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: ''
        VarNames: {1x11 cell}
        NumericPredictors: {1x6 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
```

```

BinMissingData: 0
IDVar: 'CustID'
PredictorVars: {1x9 cell}
Data: [1200x11 table]

```

Perform automatic binning.

```
sc = autobinning(sc);
```

The standard workflow is to use the `fitmodel` function to fit a logistic regression model using a stepwise method. However, `fitmodel` only supports limited options regarding the stepwise procedure. You can use the optional `mdl` output argument from `fitmodel` to get a copy of the fitted `GeneralizedLinearModel` object, to later modify.

```
[sc,mdl] = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06

Dispersion: 1

Chi^2-statistic vs. constant model: 89.7, p-value = 1.4e-16

Suppose you want to include, or "force," the predictor 'UtilRate' in the logistic regression model, even though the stepwise method did not include it in the fitted model. You can add 'UtilRate' to the logistic regression model using the `GeneralizedLinearModel` object `mdl` directly.

```
mdl = mdl.addTerms('UtilRate')
```

```
mdl =
```

Generalized linear regression model:

```

status ~ [Linear formula with 9 terms in 8 predictors]
Distribution = Binomial

```

Estimated Coefficients:

### Fit a Logistic Regression Model Outside of the `creditscorecard` Object

This example shows how to use `setmodel` to fit a logistic regression model directly, without using the `fitmodel` function, and then set the new model predictors and coefficients back into the `creditscorecard` object. This approach gives more flexibility regarding options to control the stepwise procedure. This example fits a logistic regression model with a nondefault value for the `'PEnter'` parameter, the criterion to admit a new predictor in the logistic regression model during the stepwise procedure.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```

load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]

```

Perform automatic binning.

```
sc = autobinning(sc);
```

The logistic regression model needs to be fit with Weight of Evidence (WOE) data. The WOE transformation is a special case of binning, since the data first needs to be binned, and then the binned information is mapped to the corresponding WOE values. This transformation is done using the `bindata` function. `bindata` has an argument that prepares the data for the model fitting step. By setting the `bindata` name-value pair argument for `'OutputType'` to `WOEModelInput`:

- All predictors are converted to WOE values.
- The output contains only predictors and response (no `'IDVar'` or any unused variables).
- Predictors with infinite or undefined (NaN) WOE values are discarded.
- The response values are mapped so that "Good" is 1 and "Bad" is 0 (this implies that higher unscaled scores correspond to better, less risky customers).

```
bd = bindata(sc, 'OutputType', 'WOEModelInput');
```

For example, the first ten rows in the original data for the variables `'CustAge'`, `'ResStatus'`, `'CustIncome'`, and `'status'` (response variable) look like this:

```
data(1:10, {'CustAge' 'ResStatus' 'CustIncome' 'status'})
```

```
ans=10x4 table
```

| CustAge | ResStatus  | CustIncome | status |
|---------|------------|------------|--------|
| 53      | Tenant     | 50000      | 0      |
| 61      | Home Owner | 52000      | 0      |
| 47      | Tenant     | 37000      | 0      |
| 50      | Home Owner | 53000      | 0      |
| 68      | Home Owner | 53000      | 0      |
| 65      | Home Owner | 48000      | 0      |
| 34      | Home Owner | 32000      | 1      |
| 50      | Other      | 51000      | 0      |
| 50      | Tenant     | 52000      | 1      |
| 49      | Home Owner | 53000      | 1      |

Here is how the same ten rows look after calling `bindata` with the name-value pair argument `'OutputType'` set to `WOEModelInput`:

```
bd(1:10, {'CustAge' 'ResStatus' 'CustIncome' 'status'})
```

```
ans=10x4 table
```

| CustAge  | ResStatus | CustIncome | status |
|----------|-----------|------------|--------|
| 0.21378  | -0.095564 | 0.47972    | 1      |
| 0.62245  | 0.019329  | 0.47972    | 1      |
| 0.18758  | -0.095564 | -0.026696  | 1      |
| 0.21378  | 0.019329  | 0.47972    | 1      |
| 0.62245  | 0.019329  | 0.47972    | 1      |
| 0.62245  | 0.019329  | 0.47972    | 1      |
| 0.62245  | 0.019329  | 0.47972    | 1      |
| -0.39568 | 0.019329  | -0.29217   | 0      |
| 0.21378  | 0.20049   | 0.47972    | 1      |
| 0.21378  | -0.095564 | 0.47972    | 0      |
| 0.21378  | 0.019329  | 0.47972    | 0      |

Fit a logistic linear regression model using a stepwise method with the Statistics and Machine Learning Toolbox™ function `stepwiseglm`, but use a nondefault value for the `'PEnter'` and `'PRemove'` optional arguments. The predictors `'ResStatus'` and `'OtherCC'` would normally be included in the logistic linear regression model using default options for the stepwise procedure.

```
mdl = stepwiseglm(bd,'constant','Distribution','binomial',...
'Upper','linear','PEnter',0.025,'PRemove',0.05)
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

## Input Arguments

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **ModelPredictors** — Predictor names included in fitted model

cell array of character vectors with predictor values

```
{'PredictorName1','PredictorName2',...}
```

Predictor names included in the fitted model, specified as a cell array of character vectors as `{'PredictorName1','PredictorName2',...}`. The predictor names must match predictor variable names in the `creditscorecard` object.

---

**Note** Do not include a character vector for the constant term in `ModelPredictors`, `setmodel` internally handles the '(Intercept)' term based on the number of model coefficients (see `ModelCoefficients`).

---

Data Types: `cell`

### **ModelCoefficients** — Model coefficients corresponding to model predictors

numeric array with values `[coeff1,coeff2,...]`

Model coefficients corresponding to the model predictors, specified as a numeric array of model coefficients, `[coeff1,coeff2,...]`. If  $N$  is the number of predictor names provided in `ModelPredictors`, the size of `ModelCoefficients` can be  $N$  or  $N+1$ . If `ModelCoefficients` has  $N+1$  elements, then the first coefficient is used as the '(Intercept)' of the fitted model. Otherwise, the '(Intercept)' is set to 0.

Data Types: `double`

## **Output Arguments**

### **sc** — Credit scorecard model

`creditscorecard` object

Credit scorecard model, returned as an updated `creditscorecard` object. The `creditscorecard` object contains information about the model predictors and coefficients of the fitted model. For more information on using the `creditscorecard` object, see `creditscorecard`.

## **More About**

### **Workflows for Using `setmodel`**

When using `setmodel`, there are two possible workflows to set the final model predictors and model coefficients into a `creditscorecard` object.

The first workflow is:

- Use `fitmodel` to get the optional output argument `mdl`. This is a `GeneralizedLinearModel` object and you can add and remove terms, or modify the parameters of the stepwise procedure. Only linear terms can be in the model (no interactions or any other higher-order terms).
- Once the `GeneralizedLinearModel` object is satisfactory, set the final model predictors and model coefficients into the `creditscorecard` object using the `setmodel` input arguments for `ModelPredictors` and `ModelCoefficients`.

An alternate workflow is:

- Obtain the Weight of Evidence (WOE) data using `bindata`. Use the '`WOEModelInput`' option for the '`OutputType`' name-value pair argument in `bindata` to ensure that:
  - The predictors data is transformed to WOE.
  - Only predictors whose bins have finite WOE values are included.
  - The response variable is placed in the last column.
  - The response variable is mapped ("Good" is 1 and "Bad" is 0).
- Use the data from the previous step to fit a linear logistic regression model (only linear terms in the model, no interactions, or any other higher-order terms). See, for example, `stepwiseglm`.
- Once the `GeneralizedLinearModel` object is satisfactory, set the final model predictors and model coefficients into the `creditscorecard` object using the `setmodel` input arguments for `ModelPredictors` and `ModelCoefficients`.

## Introduced in R2014b

## bindata

Binned predictor variables

### Syntax

```
bdata = bindata(sc)
bdata = bindata(sc,data)
bdata = bindata(sc,Name,Value)
```

### Description

`bdata = bindata(sc)` binned predictor variables returned as a table. This is a table of the same size as the data input, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

`bdata = bindata(sc,data)` returns a table of binned predictor variables. `bindata` returns a table of the same size as the `creditscorecard` data, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

`bdata = bindata(sc,Name,Value)` binned predictor variables returned as a table using optional name-value pair arguments. This is a table of the same size as the data input, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

### Examples

#### Bin `creditscorecard` Data as Bin Numbers, Categories, or WOE Values

This example shows how to use the `bindata` function to simply bin or discretize data.

Suppose bin ranges of

- '0 to 30'
- '31 to 50'
- '51 and up'

are determined for the age variable (via manual or automatic binning). If a data point with age 41 is given, binning this data point means placing it in the bin for 41 years old, which is the second bin, or the '31 to 50' bin. Binning is then the mapping from the original data, into discrete groups or bins. In this example, you can say that a 41-year old is mapped into bin number 2, or that it is binned into the '31 to 50' category. If you know the Weight of Evidence (WOE) value for each of the three bins, you could also replace the data point 41 with the WOE value corresponding to the second bin. `bindata` supports the three binning formats just mentioned:

- Bin number (where the `'OutputType'` name-value pair argument is set to `'BinNumber'`); this is the default option, and in this case, 41 is mapped to bin 2.

- Categorical (where the 'OutputType' name-value pair argument is set to 'Categorical'); in this case, 41 is mapped to the '31 to 50' bin.
- WOE value (where the 'OutputType' name-value pair argument is set to 'WOE'); in this case, 41 is mapped to the WOE value of bin number 2.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument to indicate that 'CustID' contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
    creditscorecard with properties:

        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: ''
        VarNames: {1x11 cell}
        NumericPredictors: {1x6 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
        BinMissingData: 0
        IDVar: 'CustID'
        PredictorVars: {1x9 cell}
        Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc);
```

Show the bin information for 'CustAge'.

```
bininfo(sc, 'CustAge')
```

```
ans=8x6 table

### Bin Additional "Test" Data

This example shows how to use the `bindata` function's optional input for the data to bin. If not provided, `bindata` bins the `creditscorecard` training data. However, if a different dataset needs to be binned, for example, some "test" data, this can be passed into `bindata` as an optional input.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
  creditscorecard with properties:

      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc);
```

Show the bin information for 'CustAge'.

```
bininfo(sc, 'CustAge')
```

```
ans=8x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
      ---          ---    ---    ---      ---      ---
      {' [-Inf,33) ' }    70    53    1.3208   -0.42622   0.019746
      {' [33,37) ' }    64    47    1.3617   -0.39568   0.015308
      {' [37,40) ' }    73    47    1.5532   -0.26411   0.0072573
      {' [40,46) ' }   174    94    1.8511   -0.088658   0.001781
      {' [46,48) ' }    61    25     2.44    0.18758   0.0024372
      {' [48,58) ' }   263   105    2.5048    0.21378   0.013476
      {' [58,Inf] ' }    98    26    3.7692    0.62245    0.0352
      {' Totals ' }   803   397    2.0227      NaN    0.095205
```

For the purpose of illustration, take a few rows from the original data as "test" data and display the first 10 age values in the test data.

```
tdata = data(101:110, :);
tdata(1:10, 'CustAge')
```

```
ans=10x1 table

### Bin Additional "Test" Data When Using the 'BinMissingData' Option

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data with missing values. The variables `CustAge` and `ResStatus` have missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
```

```

CustID    CustAge    TmAtAddress    ResStatus    EmpStatus    CustIncome    TmWBank    Oth
-----
 1         53         62            <undefined>    Unknown      50000         55         Ye
 2         61         22            Home Owner    Employed     52000         25         Ye
 3         47         30            Tenant        Employed     37000         61         No
 4         NaN         75            Home Owner    Employed     53000         20         Ye
 5         68         56            Home Owner    Employed     53000         14         Ye

```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing, 'IDVar', 'CustID', 'BinMissingData', true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]

```

Display and plot bin information for numeric data for 'CustAge' that includes missing data in a separate bin labelled <missing>.

```

[bi,cp] = bininfo(sc,'CustAge');
disp(bi)

```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |

| {'Totals' }     | 803  | 397 | 2.0227 | NaN      | 0.087112   |

```

plotbins(sc,'CustAge')

```

Display and plot bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue  |
|-----------------|------|-----|--------|-----------|------------|
| {'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| {'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| {'<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
plotbins(sc, 'ResStatus')
```

For the 'CustAge' and 'ResStatus' predictors, there is missing data (NaNs and <undefined>) in the training data, and the binning process estimates a WOE value of -0.15787 and 0.026469 respectively for missing data in these predictors, as shown above.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data.

```
tdata = dataMissing(11:14,:);
tdata.CustAge(1) = NaN;
tdata.TmAtAddress(2) = NaN;
tdata.ResStatus(3) = '<undefined>';
tdata.EmpStatus(4) = '<undefined>';
disp(tdata)
```

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus   | CustIncome | TmWBank | 0 |
|--------|---------|-------------|-------------|-------------|------------|---------|---|
| 11     | NaN     | 24          | Tenant      | Unknown     | 34000      | 44      |   |
| 12     | 48      | NaN         | Other       | Unknown     | 44000      | 14      |   |
| 13     | 65      | 63          | <undefined> | Unknown     | 48000      | 6       |   |
| 14     | 44      | 75          | Other       | <undefined> | 41000      | 35      |   |

Convert the test data to WOE values. To do this, set the bindata name-value pair argument for 'OutputType' to 'WOE', passing the test data tdata as an optional input.

```
bdata = bindata(sc,tdata,'OutputType','WOE');
disp(bdata)
```

| CustID | CustAge  | TmAtAddress | ResStatus | EmpStatus | CustIncome | TmWBank  | Other     |
|--------|----------|-------------|-----------|-----------|------------|----------|-----------|
| 11     | -0.15787 | 0.02263     | -0.095463 | -0.19947  | -0.06843   | -0.12109 | 0.095463  |
| 12     | 0.17713  | NaN         | 0.19637   | -0.19947  | 0.20579    | -0.13107 | 0.095463  |
| 13     | 0.60931  | 0.02263     | 0.026469  | -0.19947  | 0.47972    | -0.25547 | -0.095463 |
| 14     | -0.04556 | 0.02263     | 0.19637   | NaN       | -0.011271  | -0.12109 | -0.095463 |

For the 'CustAge' and 'ResStatus' predictors, because there is missing data in the training data, the missing values in the test data get mapped to the WOE value estimated for the <missing> bin. Therefore, a missing value for 'CustAge' is replaced with -0.15787, and a missing value for 'ResStatus' is replaced with 0.026469.

For 'TmAtAddress' and 'EmpStatus', the training data has no missing values, therefore there is no bin for missing data, and there is no way to estimate a WOE value for missing data. Therefore, for these predictors, the WOE transformation leaves missing values as missing (that is, sets a WOE value of NaN).

These rules apply when 'OutputType' is set to 'WOE' or 'WOEModelInput'. The rationale is that if a data-based WOE value exists for missing data, it should be used for the WOE transformation and for subsequent steps (for example, fitting a logistic model or scoring).

On the other hand, when 'OutputType' is set to 'BinNumber' or 'Categorical', bindata leaves missing values as missing, since this allows you to subsequently treat the missing data as you see fit.

For example, when 'OutputType' is set to 'BinNumber', missing values are set to NaN:

```
bdata = bindata(sc,tdata,'OutputType','BinNumber');
disp(bdata)
```

| CustID | CustAge | TmAtAddress | ResStatus | EmpStatus | CustIncome | TmWBank | Other |
|--------|---------|-------------|-----------|-----------|------------|---------|-------|
| 11     | NaN     | 2           | 1         | 1         | 3          | 3       | 2     |
| 12     | 6       | NaN         | 3         | 1         | 6          | 2       | 2     |
| 13     | 8       | 2           | NaN       | 1         | 7          | 1       | 1     |
| 14     | 4       | 2           | 3         | NaN       | 5          | 3       | 1     |

And when 'OutputType' is set to 'Categorical', missing values are set to '<undefined>':

```
bdata = bindata(sc,tdata,'OutputType','Categorical');
disp(bdata)
```

| CustID | CustAge     | TmAtAddress | ResStatus   | EmpStatus   | CustIncome    | TmWBank    | Other      |
|--------|-------------|-------------|-------------|-------------|---------------|------------|------------|
| 11     | <undefined> | [23,83)     | Tenant      | Unknown     | [33000,35000) | [23,45)    | [23,45)    |
| 12     | [48,51)     | <undefined> | Other       | Unknown     | [42000,47000) | [12,23)    | [12,23)    |
| 13     | [58,Inf]    | [23,83)     | <undefined> | Unknown     | [47000,Inf]   | [-Inf,Inf) | [-Inf,Inf) |
| 14     | [40,46)     | [23,83)     | Other       | <undefined> | [40000,42000) | [23,45)    | [23,45)    |

### Apply a Weight of Evidence (WOE) Transformation to Data

bindata supports the following types of WOE transformation:

- When the 'OutputType' name-value argument is set to 'WOE', `bindata` simply applies the WOE transformation to all predictors and keeps the rest of the variables in the original data in place and unchanged.
- When the 'OutputType' name-value pair argument is set to 'WOEModelInput', `bindata` returns a table that can be used directly as an input for fitting a logistic regression model for the scorecard. In this case, `bindata`:
  - Applies WOE transformation to all predictors.
  - Returns predictor variables, but no IDVar or unused variables are included in the output.
  - Includes the mapped response variable as the last column.
  - The `fitmodel` function calls `bindata` internally using the 'WOEModelInput' option to fit the logistic regression model for the `creditscorecard` model.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument to indicate that 'CustID' contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
    creditscorecard with properties:

        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: ''
        VarNames: {1x11 cell}
        NumericPredictors: {1x6 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
        BinMissingData: 0
        IDVar: 'CustID'
        PredictorVars: {1x9 cell}
        Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc);
```

Show the bin information for 'CustAge'.

```
bininfo(sc, 'CustAge')
```

```
ans=8x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
      _____  _____  _____  _____  _____  _____
      {'[-Inf,33)'}      70      53      1.3208      -0.42622      0.019746
      {'[33,37)'}      64      47      1.3617      -0.39568      0.015308
      {'[37,40)'}      73      47      1.5532      -0.26411      0.0072573
      {'[40,46)'}      174      94      1.8511      -0.088658      0.001781
      {'[46,48)'}      61      25      2.44      0.18758      0.0024372
      {'[48,58)'}      263      105      2.5048      0.21378      0.013476
      {'[58,Inf]'}      98      26      3.7692      0.62245      0.0352
      {'Totals'}      803      397      2.0227      NaN      0.095205
```

These are the first 10 age values in the original data, used to create the `creditscorecard` object.

```
data(1:10, 'CustAge')
```

```
ans=10x1 table
```

```
  CustAge
```

```
-----
    53
    61

    50
    68
    65
    34
    50
    50
    49
```

Convert the test data to WOE values. To do this, set the `bindata` name-value pair argument for `'OutputType'` to `'WOE'`.

```
bdata = bindata(sc, 'OutputType', 'WOE');
```

These are the first 10 binned ages, in WOE format. The ages are mapped to the WOE values displayed internally by `bininfo`.

```
bdata(1:10, 'CustAge')
```

```
ans=10x1 table
```

```
  CustAge
```

```
-----
 0.21378
 0.62245
 0.18758
 0.21378
 0.62245
 0.62245
-0.39568
 0.21378
 0.21378
 0.21378
```

These are the first 10 binned ages, in WOE format. The ages are mapped to the WOE values displayed internally by `bininfo`.

```
bdata(1:10, 'CustAge')
```

```
ans=10x1 table
```

```
  CustAge
```

```
-----
 0.21378
 0.62245
 0.18758
 0.21378
```

```

0.62245
0.62245
-0.39568
0.21378
0.21378
0.21378

```

The size of the original data and the size of `bdata` output are the same because `bindata` leaves unused variables (such as `'IDVar'`) unchanged and in place.

```
whos data bdata
```

| Name  | Size    | Bytes  | Class | Attributes |
|-------|---------|--------|-------|------------|
| bdata | 1200x11 | 108988 | table |            |
| data  | 1200x11 | 84604  | table |            |

The response values are the same in the original data and in the binned data because, by default, `bindata` does not modify response values.

```
disp([data.status(1:10) bdata.status(1:10)])
```

```

0      0
0      0
0      0
0      0
0      0
0      0
1      1
0      0
1      1
1      1

```

When fitting a logistic regression model with WOE data, set the `'OutputType'` name-value pair argument to `'WOEModelInput'`.

```
bdata = bindata(sc, 'OutputType', 'WOEModelInput');
```

The binned predictor data is the same as when the `'OutputType'` name-value pair argument is set to `'WOE'`.

```
bdata(1:10, 'CustAge')
```

```
ans=10x1 table
    CustAge
```

```

-----
0.21378
0.62245
0.18758
0.21378
0.62245
0.62245
-0.39568
0.21378
0.21378
0.21378

```

However, the size of the original data and the size of `bdata` output are different. This is because `bindata` removes unused variables (such as `'IDVar'`).

```
whos data bdata
```

| Name  | Size    | Bytes | Class | Attributes |
|-------|---------|-------|-------|------------|
| bdata | 1200x10 | 99168 | table |            |
| data  | 1200x11 | 84604 | table |            |

The response values are also modified in this case and are mapped so that "Good" is 1 and "Bad" is 0.

```
disp([data.status(1:10) bdata.status(1:10)])
```

```

0     1
0     1
0     1
0     1
0     1
0     1
1     0
0     1
1     0
1     0

```

## Input Arguments

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **data** — Data to bin given the rules set in creditscorecard object

table

Data to bin given the rules set in the `creditscorecard` object, specified using a table. By default, `data` is set to the `creditscorecard` object's raw data.

Before creating a `creditscorecard` object, perform a data preparation task to have an appropriately structured data as input to a `creditscorecard` object.

Data Types: `table`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `bdata = bindata(sc, 'OutputType', 'WOE', 'ResponseFormat', 'Mapped')`

### **OutputType** — Output format

'BinNumber' (default) | character vector with values 'BinNumber', 'Categorical', 'WOE'

Output format, specified as the comma-separated pair consisting of `'OutputType'` and a character vector with the following values:

- `BinNumber` — Returns the bin numbers corresponding to each observation.
- `Categorical` — Returns the bin label corresponding to each observation.
- `WOE` — Returns the Weight of Evidence (WOE) corresponding to each observation.
- `WOEModelInput` — Use this option when fitting a model. This option:
  - Returns the Weight of Evidence (WOE) corresponding to each observation.
  - Returns predictor variables, but no `IDVar` or unused variables are included in the output.
  - Discards any predictors whose bins have `Inf` or `NaN` WOE values.
  - Includes the mapped response variable as the last column.

---

**Note** When the `bindata` name-value pair argument `'OutputType'` is set to `'WOEModelInput'`, the `bdata` output only contains the columns corresponding to predictors whose bins do not have `Inf` or `NaN` Weight of Evidence (WOE) values, and `bdata` includes the mapped response as the last column.

Missing data (if any) are included in the `bdata` output as missing data as well, and do not influence the rules to discard predictors when `'OutputType'` is set to `'WOEModelInput'`.

---

Data Types: `char`

### ResponseFormat — Response values format

`'RawData'` (default) | character vector with values `'RawData'`, `'Mapped'`

Response values format, specified as the comma-separated pair consisting of `'ResponseFormat'` and a character vector with the following values:

- `RawData` — The response variable is copied unchanged into the `bdata` output.
- `Mapped` — The response values are modified (if necessary) so that "Good" is mapped to 1, and "Bad" is mapped to 0.

Data Types: `char`

## Output Arguments

### `bdata` — Binned predictor variables

table

Binned predictor variables, returned as a table. This is a table of the same size (see exception in the following Note) as the data input, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

---

**Note** When the `bindata` name-value pair argument `'OutputType'` is set to `'WOEModelInput'`, the `bdata` output only contains the columns corresponding to predictors whose bins do not have `Inf` or `NaN` Weight of Evidence (WOE) values, and `bdata` includes the mapped response as the last column.

Missing data (if any) are included in the `bdata` output as missing data as well, and do not influence the rules to discard predictors when `'OutputType'` is set to `'WOEModelInput'`.

## Introduced in R2014b

## plotbins

Plot histogram counts for predictor variables

### Syntax

```
plotbins(sc,PredictorName)
hFigure = plotbins(sc,PredictorName)
hFigure = plotbins( ___,Name,Value)
```

### Description

`plotbins(sc,PredictorName)` plots histogram counts for given predictor variables. When a predictor's bins are modified using `modifybins` or `autobinning`, rerun `plotbins` to update the figure to reflect the change.

`hFigure = plotbins(sc,PredictorName)` returns a handle to the figure. `plotbins` plots histogram counts for given predictor variables. When a predictor's bins are modified using `modifybins` or `autobinning`, rerun `plotbins` to update the figure to reflect the change.

`hFigure = plotbins( ___,Name,Value)` returns a handle to the figure. `plotbins` plots histogram counts for given predictor variables using optional name-value pair arguments. When a predictor's bins are modified using `modifybins` or `autobinning`, rerun `plotbins` to update the figure to reflect the change.

### Examples

#### Plot a Histogram for Bin Information

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the `PredictorName` input argument for `CustIncome` using the defaults for the algorithm `Monotone`.

```
sc = autobinning(sc, 'CustIncome')
```

```
sc =
  creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: ''
```

```
PredictorVars: {1x10 cell}
Data: [1200x11 table]
```

Use `bininfo` to display the autobinned data.

```
[bi, cp] = bininfo(sc, 'CustIncome')
```

```
bi=8x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
      -----
{' [-Inf,29000) ' }    53     58    0.91379   -0.79457    0.06364
{' [29000,33000) ' }    74     49    1.5102   -0.29217    0.0091366
{' [33000,35000) ' }    68     36    1.8889   -0.06843    0.00041042
{' [35000,40000) ' }   193     98    1.9694  -0.026696    0.00017359
{' [40000,42000) ' }    68     34     2      -0.011271    1.0819e-05
{' [42000,47000) ' }   164     66    2.4848    0.20579    0.0078175
{' [47000,Inf] ' }    183     56    3.2679    0.47972    0.041657
{' Totals ' }        803    397    2.0227      NaN    0.12285
```

```
cp = 6x1
```

```
29000
33000
35000
40000
42000
47000
```

Manually remove the second cut point (the boundary between the second and third bins) to merge bins two and three. Use the `modifybins` function to update the scorecard and then display updated bin information.

```
cp(2) = [];
sc = modifybins(sc, 'CustIncome', 'CutPoints', cp);
bi = bininfo(sc, 'CustIncome')
```

```
bi=7x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
      -----
{' [-Inf,29000) ' }    53     58    0.91379   -0.79457    0.06364
{' [29000,35000) ' }   142     85    1.6706   -0.19124    0.0071274
{' [35000,40000) ' }   193     98    1.9694  -0.026696    0.00017359
{' [40000,42000) ' }    68     34     2      -0.011271    1.0819e-05
{' [42000,47000) ' }   164     66    2.4848    0.20579    0.0078175
{' [47000,Inf] ' }    183     56    3.2679    0.47972    0.041657
{' Totals ' }        803    397    2.0227      NaN    0.12043
```

Plot the histogram count for updated bin information for the PredictorName called `CustIncome`.

```
plotbins(sc, 'CustIncome')
xtickangle(30)
legend('Location', 'north')
```

### Plot a Histogram for Bin Information Using Name-Value Pair Arguments

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the `PredictorName` input argument for `CustIncome` using the defaults for the algorithm `Monotone`.

```
sc = autobinning(sc, 'CustIncome')
```

```
sc =
  creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: ''
    PredictorVars: {1x10 cell}
```

Data: [1200x11 table]

Use `bininfo` to display the autobinned data.

```
[bi, cp] = bininfo(sc, 'CustIncome')
```

```
bi=8x6 table
```

| Bin                 | Good | Bad | Odds    | WOE       | InfoValue  |
|---------------------|------|-----|---------|-----------|------------|
| {'[-Inf,29000)'} }  | 53   | 58  | 0.91379 | -0.79457  | 0.06364    |
| {'[29000,33000)'} } | 74   | 49  | 1.5102  | -0.29217  | 0.0091366  |
| {'[33000,35000)'} } | 68   | 36  | 1.8889  | -0.06843  | 0.00041042 |
| {'[35000,40000)'} } | 193  | 98  | 1.9694  | -0.026696 | 0.00017359 |
| {'[40000,42000)'} } | 68   | 34  | 2       | -0.011271 | 1.0819e-05 |

```
cp = 6x1
```

```
29000
33000
35000
40000
42000
47000
```

Plot the bin information for `CustIncome` without the Weight of Evidence (WOE) line and without a legend by setting the `'WOE'` and `'Legend'` name-value arguments to `'Off'`. Also, set the `'BinText'` name-value pair argument to `'PercentRows'` to show as text over the plot bars for the proportion of "Good" and "Bad" within each bin, that is, the probability of "Good" and "Bad" within each bin.

```
plotbins(sc, 'CustIncome', 'WOE', 'Off', 'Legend', 'Off', 'BinText', 'PercentRows')
xtickangle(30)
```

### Plot Bin Information When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

ans=5×11 table

|   | CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | Other |
|---|--------|---------|-------------|-------------|-----------|------------|---------|-------|
| 1 |        | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Ye    |
| 2 |        | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Ye    |
| 3 |        | 47      | 30          | Tenant      | Employed  | 37000      | 61      | Ne    |
| 4 |        | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Ye    |
| 5 |        | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Ye    |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

Number of rows: 1200

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

Number of missing values CustAge: 30

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

Number of missing values ResStatus: 40

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

creditscorecard with properties:

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Display and plot bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
[bi,cp] = bininfo(sc,'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| {'[-Inf,33)'} } | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |

| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
plotbins(sc, 'ResStatus')
```

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### PredictorName — Name of one or more predictors to plot

character vector with predictor name | cell array of character vectors with predictor names

Name of one or more predictors to plot, specified using a character vector or cell array of character vectors containing one or more names of the predictors.

Data Types: `char` | `cell`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `plotbins(sc,PredictorName,'BinText','Count','WOE','On')`

**BinText — Information to display on top of plotted bin counts**

'None' (default) | character vector with values 'None', 'Count', 'PercentRows', 'PercentCols', 'PercentTotal'

Information to display on top of plotted bin counts, specified as the comma-separated pair consisting of 'BinText' and a character vector with values:

- **None** — No text is displayed on top of the bins.
- **Count** — For each bin, displays the count for “Good” and “Bad.”
- **PercentRows** — For each bin, displays the count for “Good” and “Bad” as a percentage of the number of observations in the bin.
- **PercentCols** — For each bin, displays the count for “Good” and “Bad” as a percentage of the total “Good” and total “Bad” in the entire sample.
- **PercentTotal** — For each bin, displays the count for “Good” and “Bad” as a percentage of the total number of observations in the entire sample.

Data Types: char

**WOE — Indicator for Weight of Evidence (WOE)**

'On' (default) | character vector with values 'On', 'Off'

Indicator for Weight of Evidence (WOE) line, specified as the comma-separated pair consisting of 'WOE' and a character vector with values On or Off. When set to On, the WOE line is plotted on top of the histogram.

Data Types: char

**Legend — Indicator for legend on plot**

'On' (default) | character vector with values 'On', 'Off'

Indicator for legend on the plot, specified as the comma-separated pair consisting of 'Legend' and a character vector with values On or Off.

Data Types: char

**Output Arguments****hFigure — Figure handle for histogram plot for predictor variables**

figure object

Figure handle for histogram plot for predictor variables, returned as figure object or array of figure objects if more than one PredictorName is specified as an input.

## modifybins

Modify predictor's bins

### Syntax

```
sc = modifybins(sc, PredictorName, Name, Value)
```

### Description

`sc = modifybins(sc, PredictorName, Name, Value)` manually modifies predictor bins for numeric predictors or categorical predictors using optional name-value pair arguments. For numeric predictors, minimum value, maximum value, and cut points can be specified. For categorical predictors, category groupings can be specified. Bin labels can be specified for both types of predictors.

### Examples

#### Modify Predictor Bins for Numeric Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The predictor `CustIncome` is numeric. By default, each value of a predictor is placed in a separate bin.

```
bi = bininfo(sc, 'CustIncome')
```

```
bi=46x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
      ---      ---      ---      ---      ---      ---
      {'18000'}      2      3      0.66667      -1.1099      0.0056227
      {'19000'}      1      2      0.5      -1.3976      0.0053002

      {'24000'}      5      5      1      -0.70442      0.0044856
      {'25000'}      4      9      0.44444      -1.5153      0.026805
      {'26000'}      4      11      0.36364      -1.716      0.038999
      {'27000'}      6      6      1      -0.70442      0.0053827
      {'28000'}      13      11      1.1818      -0.53736      0.0061896
      {'29000'}      11      10      1.1      -0.60911      0.0069988
      {'30000'}      18      16      1.125      -0.58664      0.010493
      {'31000'}      24      8      3      0.39419      0.0038382
      {'32000'}      21      15      1.4      -0.36795      0.0042797
      {'33000'}      35      19      1.8421      -0.093509      0.00039951
```

Use `modifybins` to set a minimum value of 0, and cut points every 10000, from 20000 to 60000. Display updated bin information, including cut points.

```
sc = modifybins(sc, 'CustIncome', 'MinValue', 0, 'CutPoints', 20000:10000:60000);
[bi, cp] = bininfo(sc, 'CustIncome')
```

bi=7x6 table

| Bin                 | Good | Bad | Odds    | WOE       | InfoValue |
|---------------------|------|-----|---------|-----------|-----------|
| { '[0,20000)' }     | 3    | 5   | 0.6     | -1.2152   | 0.010765  |
| { '[20000,30000)' } | 61   | 63  | 0.96825 | -0.73668  | 0.060942  |
| { '[30000,40000)' } | 324  | 173 | 1.8728  | -0.076967 | 0.0024846 |
| { '[40000,50000)' } | 304  | 123 | 2.4715  | 0.20042   | 0.013781  |
| { '[50000,60000)' } | 103  | 32  | 3.2188  | 0.46457   | 0.022144  |
| { '[60000,Inf]' }   | 8    | 1   | 8       | 1.375     | 0.010235  |
| { 'Totals' }        | 803  | 397 | 2.0227  | NaN       | 0.12035   |

cp = 5x1

```
20000
30000
40000
50000
60000
```

The first and last bins contain very few points. To merge the first bin into the second one, remove the first cut point. Similarly, to merge the last bin into the second-to-last one, remove the last cut point. Then use `modifybins` to update the scorecard, and display updated bin information.

```
cp(1)=[];
cp(end)=[];
sc = modifybins(sc, 'CustIncome', 'CutPoints', cp);
bi = bininfo(sc, 'CustIncome')
```

bi=5x6 table

| Bin                 | Good | Bad | Odds    | WOE       | InfoValue |
|---------------------|------|-----|---------|-----------|-----------|
| { '[0,30000)' }     | 64   | 68  | 0.94118 | -0.76504  | 0.070065  |
| { '[30000,40000)' } | 324  | 173 | 1.8728  | -0.076967 | 0.0024846 |
| { '[40000,50000)' } | 304  | 123 | 2.4715  | 0.20042   | 0.013781  |
| { '[50000,Inf]' }   | 111  | 33  | 3.3636  | 0.5086    | 0.028028  |
| { 'Totals' }        | 803  | 397 | 2.0227  | NaN       | 0.11436   |

### Modify Predictor Bins for Categorical Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The binning map or rules for categorical data are summarized in a "category grouping" table, returned as an optional output. By default, each category is placed in a separate bin. Here is the information for the predictor ResStatus.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

```
bi=4x6 table
      Bin          Good    Bad    Odds    WOE    InfoValue
-----
{'Home Owner'}    365    177    2.0621    0.019329    0.0001682
{'Tenant'        }    307    167    1.8383   -0.095564    0.0036638
{'Other'         }    131     53    2.4717     0.20049    0.0059418
{'Totals'        }    803    397    2.0227         NaN    0.0097738
```

```
cg=3x2 table
      Category    BinNumber
-----
{'Home Owner'}    1
{'Tenant'        }    2
{'Other'         }    3
```

To group categories 'Tenant' and 'Other', modify the category grouping table cg, so the bin number for 'Other' is the same as the bin number for 'Tenant'. Then use `modifybins` to update the scorecard.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
```

Display the updated bin information. Note that the bin labels has been updated and that the bin membership information is contained in the category grouping cg.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

```
bi=3x6 table
      Bin          Good    Bad    Odds    WOE    InfoValue
-----
{'Group1'}        365    177    2.0621    0.019329    0.0001682
{'Group2'}        438    220    1.9909   -0.015827    0.00013772
{'Totals'}        803    397    2.0227         NaN    0.00030592
```

```
cg=3x2 table
      Category    BinNumber
-----
{'Home Owner'}    1
{'Tenant'        }    2
{'Other'         }    2
```

## Merge Bins for Numerical and Categorical Predictors

Create a `creditscorecard` object (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID', 'GoodLabel', 0);
```

For the numerical predictor `CustAge`, use the `modifybins` function to set the following cut points:

```
cp = [25 37 49 65];
sc = modifybins(sc, 'CustAge', 'CutPoints', cp, 'MinValue', 0, 'MaxValue', 75);
bininfo(sc, 'CustAge')
```

```
ans=6x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
      _____  _____  _____  _____  _____  _____
{'[0,25)'}      9         8         1.125     -0.58664    0.0052464
{'[25,37)'}    125        92         1.3587    -0.39789    0.030268
{'[37,49)'}    340       183         1.8579    -0.084959   0.0031898
{'[49,65)'}    298       108         2.7593     0.31054    0.030765
{'[65,75]'}     31         6         5.1667     0.93781    0.022031
{'Totals' }    803       397         2.0227      NaN         0.0915
```

Use the `modifybins` function to merge the 2nd and 3rd bins.

```
sc = modifybins(sc, 'CustAge', 'CutPoints', cp([1 3 4]));
bininfo(sc, 'CustAge')
```

```
ans=5x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
      _____  _____  _____  _____  _____  _____
{'[0,25)'}      9         8         1.125     -0.58664    0.0052464
{'[25,49)'}    465       275         1.6909    -0.17915    0.020355
{'[49,65)'}    298       108         2.7593     0.31054    0.030765
{'[65,75]'}     31         6         5.1667     0.93781    0.022031
{'Totals' }    803       397         2.0227      NaN         0.078397
```

Display bin information for the categorical predictor `ResStatus`.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

```
      Bin      Good      Bad      Odds      WOE      InfoValue
      _____  _____  _____  _____  _____  _____
{'Home Owner'}  365       177         2.0621     0.019329   0.0001682
{'Tenant' }     307       167         1.8383    -0.095564   0.0036638
{'Other' }      131        53         2.4717     0.20049    0.0059418
{'Totals' }     803       397         2.0227      NaN         0.0097738
```

Use the `modifybins` function to merge categories 2 and 3.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
bininfo(sc, 'ResStatus')
```

```
ans=3x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'Group1'}  365      177      2.0621      0.019329      0.0001682
{'Group2'}  438      220      1.9909     -0.015827      0.00013772
{'Totals'}  803      397      2.0227           NaN      0.00030592
```

### Split Bins for Numerical and Categorical Predictors

Create a creditcard object (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditcard(data, 'IDVar', 'CustID', 'GoodLabel', 0)

sc =
  creditcard with properties:
      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x11 table]
```

For the numerical predictor `TmAtAddress`, use the `modifybins` function to set the following cut points:

```
cp = [30 80 120];
sc = modifybins(sc, 'TmAtAddress', 'CutPoints', cp, 'MinValue', 0, 'MaxValue', 210);
bininfo(sc, 'TmAtAddress')
```

```
ans=5x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'[0,30]'}  }  330      154      2.1429      0.057722      0.0013305
{'[30,80]'} }  379      201      1.8856     -0.070187      0.0024086
{'[80,120]'} }   78       36      2.1667      0.068771      0.00044396
{'[120,210]'} }   16        6      2.6667      0.27641      0.0013301
{'Totals'}  }  803      397      2.0227           NaN      0.0055131
```

Use the `modifybins` function to split the 2nd bin.

```
sc = modifybins(sc, 'TmAtAddress', 'CutPoints', [cp(1) 50 cp(2:end)]);
bininfo(sc, 'TmAtAddress')
```

```
ans=6x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'[0,30)'}    }    330     154    2.1429    0.057722    0.0013305
{'[30,50)'}    }    211     104    2.0288    0.0030488    2.4387e-06
{'[50,80)'}    }    168      97     1.732    -0.15517     0.005449
{'[80,120)'}   }     78      36    2.1667    0.068771    0.00044396
{'[120,210]'}  }     16       6    2.6667    0.27641     0.0013301
{'Totals' }    803     397    2.0227      NaN     0.0085559
```

Display bin information for the categorical predictor ResStatus.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

```
bi=4x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'Home Owner'}  }    365     177    2.0621    0.019329    0.0001682
{'Tenant' }     }    307     167    1.8383   -0.095564    0.0036638
{'Other' }      }    131      53    2.4717    0.20049     0.0059418
{'Totals' }    }    803     397    2.0227      NaN     0.0097738
```

```
cg=3x2 table
      Category      BinNumber
-----
{'Home Owner'}    }           1
{'Tenant' }       }           2
{'Other' }        }           3
```

Use the modifybins function to merge categories 2 and 3.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
bininfo(sc, 'ResStatus')
```

```
ans=3x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'Group1'}    }    365     177    2.0621    0.019329    0.0001682
{'Group2'}    }    438     220    1.9909   -0.015827    0.00013772
{'Totals' }   }    803     397    2.0227      NaN     0.00030592
```

Use the modifybins function to split bin 2 and put Other under bin 3.

```
cg.BinNumber(3) = 3;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
[bi,cg] = bininfo(sc, 'ResStatus')
```

```

bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'Home Owner'}    365    177    2.0621    0.019329    0.0001682
{'Tenant'        }    307    167    1.8383   -0.095564    0.0036638
{'Other'         }    131     53    2.4717     0.20049    0.0059418
{'Totals'        }    803    397    2.0227         NaN    0.0097738

```

```

cg=3x2 table
      Category      BinNumber
-----
{'Home Owner'}    1
{'Tenant'        }    2
{'Other'         }    3

```

### Modify Bin Labels

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```

load CreditCardData
sc = creditscorecard(data);

```

Use `modifybins` to reset the minimum value and create three bins for the predictor `CustIncome` and display updated bin information.

```

sc = modifybins(sc, 'CustIncome', 'MinValue', 0, 'CutPoints', [30000 50000]);
bi = bininfo(sc, 'CustIncome')

```

```

bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'[0,30000)'}    64     68    0.94118   -0.76504    0.070065
{'[30000,50000)'} 628    296    2.1216    0.047762    0.0017421
{'[50000,Inf]'}  111     33    3.3636     0.5086     0.028028
{'Totals'        }    803    397    2.0227         NaN    0.099836

```

Modify the bin labels and display updated bin information.

```

NewLabels = {'Up to 30k', '30k to 50k', '50k and more'};
sc = modifybins(sc, 'CustIncome', 'BinLabels', NewLabels);
bi = bininfo(sc, 'CustIncome')

```

```

bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'Up to 30k'    }    64     68    0.94118   -0.76504    0.070065
{'30k to 50k'  }    628    296    2.1216    0.047762    0.0017421
{'50k and more'} 111     33    3.3636     0.5086     0.028028

```

```
{'Totals' } 803 397 2.0227 NaN 0.099836
```

Bin labels should be the last bin-modification step. As in this example, user-defined bin labels often contain information about the cut points, minimum, or maximum values for numeric data, or information about category groupings for categorical data. To prevent situations where user-defined labels and cut points are inconsistent (and labels are misleading), the `creditscorecard` object overrides user-defined labels every time the bins are modified using `modifybins`.

To illustrate `modifybins` overriding user-defined labels every time the bins are modified, reset the first cut point to 31000 and display updated bin information. Note that the bin labels are reset to their default format and accurately reflect the change in the cut points.

```
sc = modifybins(sc, 'CustIncome', 'CutPoints', [31000 50000]);
bi = bininfo(sc, 'CustIncome')
```

bi=4x6 table

| Bin                 | Good | Bad | Odds    | WOE      | InfoValue |
|---------------------|------|-----|---------|----------|-----------|
| { '[0,31000)' }     | 82   | 84  | 0.97619 | -0.72852 | 0.079751  |
| { '[31000,50000)' } | 610  | 280 | 2.1786  | 0.074251 | 0.0040364 |
| { '[50000,Inf]' }   | 111  | 33  | 3.3636  | 0.5086   | 0.028028  |
| { 'Totals' }        | 803  | 397 | 2.0227  | NaN      | 0.11182   |

### Modify Bin Information When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

ans=5x11 table

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | Other |
|--------|---------|-------------|-------------|-----------|------------|---------|-------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Ye    |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Ye    |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | Ne    |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Ye    |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Ye    |

```
fprintf('Number of rows: %d\n',height(dataMissing))
Number of rows: 1200
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
Number of missing values CustAge: 30
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

Number of missing values ResStatus: 40

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing data in a separate bin.

```
sc = creditscorecard(dataMissing, 'IDVar', 'CustID', 'BinMissingData', true);
sc = autobinining(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Display bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
[bi,cp] = bininfo(sc, 'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| {'[-Inf,33)'} } | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |
| {'[33,37)'} }   | 63   | 45  | 1.4    | -0.36795 | 0.012839   |
| {'[37,40)'} }   | 72   | 47  | 1.5319 | -0.2779  | 0.0079824  |
| {'[40,46)'} }   | 172  | 89  | 1.9326 | -0.04556 | 0.0004549  |
| {'[46,48)'} }   | 59   | 25  | 2.36   | 0.15424  | 0.0016199  |
| {'[48,51)'} }   | 99   | 41  | 2.4146 | 0.17713  | 0.0035449  |
| {'[51,58)'} }   | 157  | 62  | 2.5323 | 0.22469  | 0.0088407  |
| {'[58,Inf]'} }  | 93   | 25  | 3.72   | 0.60931  | 0.032198   |
| {'<missing>'} } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN      | 0.087112   |

```
plotbins(sc, 'CustAge')
```

For the numeric predictor CustAge, remove cut points 48 and 51 and then use modifybins to define a 'MinValue' of 0 to manually change the binning and notice that this does not affect the data in the <missing> bin and the <missing> bin remains at the end.

```

cp(cp==48) = [];
cp(cp==51) = [];
sc = modifybins(sc, 'CustAge', 'CutPoints', cp, 'MinValue', 0);
bi = bininfo(sc, 'CustAge');
disp(bi)
    
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| { '[0,33)' }    | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |
| { '[33,37)' }   | 63   | 45  | 1.4    | -0.36795 | 0.012839   |
| { '[37,40)' }   | 72   | 47  | 1.5319 | -0.2779  | 0.0079824  |
| { '[40,46)' }   | 172  | 89  | 1.9326 | -0.04556 | 0.0004549  |
| { '[46,58)' }   | 315  | 128 | 2.4609 | 0.19612  | 0.013701   |
| { '[58,Inf)' }  | 93   | 25  | 3.72   | 0.60931  | 0.032198   |
| { '<missing>' } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| { 'Totals' }    | 803  | 397 | 2.0227 | NaN      | 0.086808   |

```

plotbins(sc, 'CustAge')
    
```

Display bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue  |
|-----------------|------|-----|--------|-----------|------------|
| {'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| {'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| {'<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
plotbins(sc, 'ResStatus')
```

For the categorical predictor ResStatus, use modifybins to manually merge 'HomeOwner' and 'Other' into a single group by assigning the same bin number to these categories. Notice that this does not affect the data in the <missing> bin and the <missing> bin remains at the end.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
[bi, cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin            | Good | Bad | Odds   | WOE       | InfoValue  |
|----------------|------|-----|--------|-----------|------------|
| {'Group1' }    | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Group2' }    | 480  | 223 | 2.1525 | 0.062196  | 0.0022419  |
| {'<missing>' } | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }    | 803  | 397 | 2.0227 | NaN       | 0.00579    |

```
disp(cg)
```

| Category        | BinNumber |
|-----------------|-----------|
| {'Tenant' }     | 1         |
| {'Home Owner' } | 2         |
| {'Other' }      | 2         |

## Input Arguments

### **sc — Credit scorecard model**

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **PredictorName — Name of predictor**

character vector

Name of predictor, specified as a character vector containing the name of the predictor. `PredictorName` is case-sensitive.

Data Types: `char`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `sc = modifybins(sc, PredictorName, 'MinValue', 10, 'CutPoints', [23, 44, 66, 88])`

### **MinValue — Minimum acceptable value (numeric predictors only)**

-Inf (default) | numeric

Minimum acceptable value, specified as the comma-separated pair consisting of `'MinValue'` and a numeric value (for numeric predictors only). Values below this number are considered out of range.

Data Types: `double`

### **MaxValue — Maximum acceptable value (numeric predictors only)**

Inf (default) | numeric

Maximum acceptable value, specified as the comma-separated pair consisting of `'MaxValue'` and a numeric value (for numeric predictors only). Values above this number are considered out of range.

Data Types: `double`

### **CutPoints — Split points between bins**

each observed value of the predictor is placed in a separate bin (default) | nondecreasing numeric array

Split points between bins, specified as the comma-separated pair consisting of `'CutPoints'` and a nondecreasing numeric array. If there are `NumBins` bins, there are  $n = \text{NumBins} - 1$  cut points so that  $C_1, C_2, \dots, C_n$  describe the bin boundaries with the following convention:

- The first bin includes any values  $\geq \text{MinValue}$ , but  $< C_1$ .
- The second bin includes any values  $\geq C_1$ , but  $< C_2$ .
- The last bin includes any values  $\geq C_n$ , and  $\leq \text{MaxValue}$ .

---

**Note** Cut points do not include `MinValue` or `MaxValue`.

---

By default, cut points are defined so that each observed value of the predictor is placed in a separate bin. If the sorted observed values are  $V_1, \dots, V_M$ , the default cut points are  $V_2, \dots, V_M$ , which define  $M$  bins.

Data Types: double

### **CatGrouping** — Table with two columns named **Category** and **BinNumber**

each category is placed in a separate bin (default) | table with two columns named **Category** and **BinNumber**

Table with two columns named **Category** and **BinNumber**, specified as the comma-separated pair consisting of '**CatGrouping**' and a table, where the first column contains an exhaustive list of categories for the predictor, and the second column contains the bin number to which each category belongs.

By default, each category is placed in a separate bin. If the observed categories are '**Cat1**' ..., '**CatM**', the default category grouping is as follows.

| <b>Category</b> | <b>BinNumber</b> |
|-----------------|------------------|
| 'Cat1'          | 1                |
| 'Cat2'          | 2                |
| ...             | ...              |
| 'CatM'          | $M$              |

Data Types: double

### **BinLabels** — Bin labels for each bin

automatically generated bin labels depending on the predictor's type (default) | cell array of character vectors

Bin labels for each bin, specified as the comma-separated pair consisting of '**BinLabels**' and a cell array of character vectors with bin label names.

---

**Note** '**BinLabels**' does not support a value of <missing>.

---

Bin labels are used to tag the bins in different object functions such as `bininfo`, `plotbins`, and `displaypoints`. A `creditscorecard` object automatically sets default bins whenever bins are modified. The default format for bin labels depends on the predictor's type.

The format for **BinLabels** is:

- Numeric data — Before any manual or automatic modification of the predictor bins, there is a bin for each observed predictor value by default. In that case, the bin labels simply show the predictor values. Once the predictor bins have been modified, there are nondefault values for `MinValue` or `MaxValue`, or nondefault cut points  $C_1, C_2, \dots, C_n$ . In that case, the bin labels are:
  - Bin 1 label: '`[MinValue, C1]`'
  - Bin 2 label: '`[C1, C2]`'
  - Last bin label: '`[Cn, MaxValue]`'

For example, if there are three bins, `MinValue` is 0 and `MaxValue` is 40, and cut point 1 is 20 and cut point 2 is 30, then the corresponding three bin labels are:

```
' [0,20) '  
' [20,30) '  
' [30,40] '
```

- **Categorical data** — For categorical data, before any modification of the predictor bins, there is one bin per category. In that case, the bin labels simply show the predictor categories. Once the bins have been modified, the labels are set to 'Group1', 'Group2', and so on, for bin 1, bin 2, and so on, respectively. For example, suppose that we have the following category grouping

| Category | BinNumber |
|----------|-----------|
| 'Cat1'   | 1         |
| 'Cat2'   | 2         |
| 'Cat3'   | 2         |

Bin 1 contains 'Cat1' only and its bin label is set to 'Group1'. Bin 2 contains 'Cat2' and 'Cat3' and its bin label is set to 'Group2'.

---

**Tip** Using `BinLabels` should be the last step (if needed) in modifying bins. `BinLabels` definitions are overridden each time that the bins are modified using the `modifybins` or `autobinning` functions.

---

Data Types: cell

## Output Arguments

**sc** — Credit scorecard model  
`creditscorecard` object

Credit scorecard model, returned as an updated `creditscorecard` object. For more information on using the `creditscorecard` object, see `creditscorecard`.

## modifypredictor

Set properties of credit scorecard predictors

### Syntax

```
sc = modifypredictor(sc,PredictorName)
sc = modifypredictor( ___,Name,Value)
```

### Description

`sc = modifypredictor(sc,PredictorName)` sets the properties of the credit scorecard predictors.

`sc = modifypredictor( ___,Name,Value)` sets the properties of the credit scorecard predictors using optional name-value pair arguments.

### Examples

#### Modify a Predictor to Change the Predictor Type from Numeric to Categorical

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). In practice, categorical data many times is represented with numeric values. To show the case where categorical data is given as numeric data, the data for the variable 'ResStatus' is intentionally converted to numeric values.

```
load CreditCardData
data.ResStatus = double(data.ResStatus);
sc = creditscorecard(data, 'IDVar', 'CustID')
```

```
sc =
  creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
    CategoricalPredictors: {'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

```
[T,Stats] = predictorinfo(sc, 'ResStatus')
```

```
T=1x4 table
```

| PredictorType | LatestBinning | LatestFillMissingType | LatestFillMissing |
|---------------|---------------|-----------------------|-------------------|
|---------------|---------------|-----------------------|-------------------|

```
ResStatus      {'Numeric'}      {'Original Data'}      {'Original'}      {0x0 double}
```

```
Stats=4x1 table
      Value
-----
Min      1
Max      3
Mean     1.7017
Std      0.71833
```

Note that 'ResStatus' appears as part of the NumericPredictors property. Assume that you want 'ResStatus' to be treated as categorical data. For example, you may want to allow automatic binning algorithms to reorder the categories. Use modifypredictor to change the 'PredictorType' of the PredictorName 'ResStatus' from numeric to categorical.

```
sc = modifypredictor(sc, 'ResStatus', 'PredictorType', 'Categorical')
```

```
sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

```
[T,Stats] = predictorinfo(sc, 'ResStatus')
```

```
T=1x5 table
      PredictorType      Ordinal      LatestBinning      LatestFillMissingType      Late
-----
ResStatus      {'Categorical'}      false      {'Original Data'}      {'Original'}
```

```
Stats=3x1 table
      Count
-----
C1      542
C2      474
C3      184
```

Notice that 'ResStatus' now appears as part of the 'Categorical' predictors.

## Input Arguments

### **sc — Credit scorecard model**

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **PredictorName — Predictor name**

character vector | cell array of character vectors

Predictor name, specified using a character vector or cell array of character vectors containing the names of the credit scorecard predictors. `PredictorName` is case-sensitive.

Data Types: `char` | `cell`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `sc = modifypredictor(sc, {'CustAge', 'CustIncome'}, 'PredictorType', 'Categorical', 'Ordinal', true)`

### **PredictorType — Predictor type that one or more predictors are converted to**

' ' no conversion occurs (default) | character vector with values 'Numeric', 'Categorical'

Predictor type that one or more predictors are converted to, specified as the comma-separated pair consisting of 'PredictorType' and a character vector. Possible values are:

- ' ' — No conversion occurs.
- 'Numeric' — The predictor data specified by `PredictorName` is converted to numeric.
- 'Categorical' — The predictor data specified by `PredictorName` is converted to categorical.

Data Types: `char`

### **Ordinal — Indicator for whether predictors being converted to categorical are ordinal**

false (default) | logical with values true, false

Indicator for whether predictors being converted to categorical or existing categorical predictors are treated as ordinal data, specified as the comma-separated pair consisting of 'Ordinal' and a logical with values `true` or `false`.

---

**Note** This optional input parameter is only used for predictors of type 'Categorical'.

---

Data Types: `logical`

## Output Arguments

### **sc — Credit scorecard model**

creditscorecard object

Credit scorecard model, returned as an updated `creditscorecard` object.

**See Also**

`bininfo` | `creditscorecard` | `modifybins` | `predictorinfo`

**Introduced in R2015b**

## predictorinfo

Summary of credit scorecard predictor properties

### Syntax

```
[T,Stats] = predictorinfo(sc,PredictorName)
```

### Description

[T,Stats] = predictorinfo(sc,PredictorName) returns a summary of credit scorecard predictor properties and some basic predictor statistics.

### Examples

#### Obtain Information for a Specified PredictorName

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
  creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Obtain the predictor statistics for the PredictorName of CustAge.

```
[T,Stats] = predictorinfo(sc, 'CustAge')
```

T=1×4 table

|         | PredictorType | LatestBinning     | LatestFillMissingType | LatestFillMissingV |
|---------|---------------|-------------------|-----------------------|--------------------|
| CustAge | {'Numeric'}   | {'Original Data'} | {'Original'}          | {0×0 double}       |

Stats=4×1 table

Value

```

Min      21
Max      74
Mean    45.174
Std     9.8302

```

Obtain the predictor statistics for the PredictorName of ResStatus.

```
[T,Stats] = predictorinfo(sc, 'ResStatus')
```

T=1×5 table

|           | PredictorType   | Ordinal | LatestBinning     | LatestFillMissingType | LatestFillMissingValue |
|-----------|-----------------|---------|-------------------|-----------------------|------------------------|
| ResStatus | {'Categorical'} | false   | {'Original Data'} | {'Original'}          | {}                     |

Stats=3×1 table

|            | Count |
|------------|-------|
| Home Owner | 542   |
| Tenant     | 474   |
| Other      | 184   |

### Obtain Information for a Specified PredictorName After Using fillmissing

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```

load CreditCardData
sc = creditscorecard(dataMissing, 'BinMissingData', true, 'IDVar', 'CustID');
sc = autobinning(sc);

```

Use `fillmissing` to replace missing values for the `CustAge` predictor with a value of 38.

```
sc = fillmissing(sc, 'CustAge', 'constant', 38);
```

Obtain the predictor statistics for the PredictorName of CustAge.

```
[T,Stats] = predictorinfo(sc, 'CustAge')
```

T=1×4 table

|         | PredictorType | LatestBinning            | LatestFillMissingType | LatestFillMissingValue |
|---------|---------------|--------------------------|-----------------------|------------------------|
| CustAge | {'Numeric'}   | {'Automatic / Monotone'} | {'Constant'}          | {38}                   |

Stats=4×1 table

|     | Value |
|-----|-------|
| Min | 21    |
| Max | 74    |

```
Mean    44.932
Std     9.7436
```

Use `fillmissing` to replace missing values for the `ResStatus` predictor with a mode value.

```
sc = fillmissing(sc, 'ResStatus', 'mode');
```

Obtain the predictor statistics for the `PredictorName` of `ResStatus`.

```
[T,Stats] = predictorinfo(sc, 'ResStatus')
```

`T=1×5 table`

|           | PredictorType   | Ordinal | LatestBinning            | LatestFillMissingType |
|-----------|-----------------|---------|--------------------------|-----------------------|
| ResStatus | {'Categorical'} | false   | {'Automatic / Monotone'} | {'Mode'}              |

`Stats=3×1 table`

|            | Count |
|------------|-------|
| Tenant     | 457   |
| Home Owner | 563   |
| Other      | 180   |

## Input Arguments

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **PredictorName** — Predictor name

character vector

Predictor name, specified using a character vector containing the names of the credit scorecard predictor of interest. `PredictorName` is case-sensitive.

Data Types: `char`

## Output Arguments

### **T** — Summary information for specified predictor

table

Summary information for specified predictor, returned as table with the following columns:

- `'PredictorType'` — `'Numeric'` or `'Categorical'`.
- `'Ordinal'` — For categorical predictors, a boolean indicating whether it is ordinal.
- `'LatestBinning'` — Character vector indicating the last applied algorithm for the input argument `PredictorName`. The values are:

- 'Original Data' — When no binning is applied to the predictor.
- 'Automatic / BinningName' — Where 'BinningName' is one of the following: Monotone, Equal Width, or Equal Frequency.
- 'Manual' — After each call of `modifybins`, where either 'CutPoints', 'CatGrouping', 'MinValue', or 'MaxValue' are modified.
- 'LatestFillMissingType' — If `fillmissing` has been applied to the predictor, the value of the `Statistics` argument for `fillmissing` is displayed. If the predictor does not have any missing data, then the fill type is 'Original'.
- 'LatestFillMissingValue' — If `fillmissing` has been applied to the predictor, the fill value is displayed. If the predictor does not have any missing data, then the fill value is [ ].

The predictor's name is used as a row name in the table that is returned.

### Stats — Summary statistics for the input PredictorName

table

Summary statistics for the input `PredictorName`, returned as a table. The corresponding value is stored in the 'Value' column.

The table's row names indicate the relevant statistics for numeric predictors:

- 'Min' — Minimum value in the sample.
- 'Max' — Maximum value in the sample.
- 'Mean' — Mean value in the sample.
- 'Std' — Standard deviation of the sample.

---

**Note** For data types other than 'double' or 'single', numeric precision may be lost for the standard deviation. Data types other than 'double' or 'single' are cast as 'double' before computing the standard deviation.

---

For categorical predictors, the row names contain the names of the categories, with corresponding total count in the 'Count' column.

### See Also

`bininfo` | `creditscorecard` | `fillmissing` | `modifybins` | `modifypredictor`

**Introduced in R2015b**

## bininfo

Return predictor's bin information

### Syntax

```
bi = bininfo(sc,PredictorName)
```

```
bi = bininfo( ___,Name,Value)
```

```
[bi,bm] = bininfo(sc,PredictorName,Name,Value)
```

```
[bi,bm,mv] = bininfo(sc,PredictorName,Name,Value)
```

### Description

`bi = bininfo(sc,PredictorName)` returns information at bin level, such as frequencies of "Good," "Bad," and bin statistics for the predictor specified in `PredictorName`.

`bi = bininfo( ___,Name,Value)` adds optional name-value arguments.

`[bi,bm] = bininfo(sc,PredictorName,Name,Value)` adds optional name-value arguments. `bininfo` also optionally returns the binning map (`bm`) or bin rules in the form of a vector of cut points for numeric predictors, or a table of category groupings for categorical predictors.

`[bi,bm,mv] = bininfo(sc,PredictorName,Name,Value)` returns information at bin level, such as frequencies of "Good," "Bad," and bin statistics for the predictor specified in `PredictorName` using optional name-value pair arguments. `bininfo` optionally returns the binning map or bin rules in the form of a vector of cut points for numeric predictors, or a table of category groupings for categorical predictors. In addition, optional name-value pair arguments `mv` returns a numeric array containing the minimum and maximum values, as set (or defined) by the user. The `mv` output argument is set to an empty array for categorical predictors.

### Examples

#### Display Bin Information Using Default Options

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Display bin information for the categorical predictor `ResStatus`.

```
bi = bininfo(sc,'ResStatus')
```

```
bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'Home Owner'}    365    177    2.0621    0.019329    0.0001682
```

```

{'Tenant'   }   307   167   1.8383   -0.095564   0.0036638
{'Other'    }   131    53   2.4717    0.20049   0.0059418
{'Totals'   }   803   397   2.0227         NaN   0.0097738

```

### Display Bin Information For a creditcard Object Containing Weights

Use the CreditCardData.mat file to load the data (dataWeights) that contains a column (RowWeights) for the weights (using a dataset from Refaat 2011).

load CreditCardData

Create a creditcard object using the optional name-value pair argument for 'WeightsVar'.

```
sc = creditcard(dataWeights, 'WeightsVar', 'RowWeights')
```

```

sc =
    creditcard with properties:
        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: 'RowWeights'
        VarNames: {1x12 cell}
        NumericPredictors: {1x7 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
        BinMissingData: 0
        IDVar: ''
        PredictorVars: {1x10 cell}
        Data: [1200x12 table]

```

Display bin information for the numerical predictor 'CustIncome'. When the optional name-value pair argument 'WeightsVar' is used to specify observation (sample) weights, the bi table contains weighted counts.

```
bi = bininfo(sc, 'CustIncome');
bi(1:10,:)
```

```
ans=10x6 table
    Bin      Good      Bad      Odds      WOE      InfoValue
    _____  _____  _____  _____  _____  _____
    {'18000'}  0.94515    1.496    0.63179    -1.1667    0.0059198
    {'19000'}  0.47588    0.80569    0.59065    -1.2341    0.0034716
    {'20000'}  2.1671     1.4636    1.4806    -0.31509    0.00061392
    {'21000'}  3.2522     0.88064    3.693     0.59889    0.0021303
    {'22000'}  1.5438     1.2714    1.2142    -0.51346    0.0012913
    {'23000'}  1.787      2.7529    0.64913    -1.1397    0.010509
    {'24000'}  3.4111     2.2538    1.5135    -0.29311    0.00082663
    {'25000'}  2.2333     6.1383    0.36383    -1.7186    0.042642
    {'26000'}  2.1246     4.4754    0.47474    -1.4525    0.024526
    {'27000'}  3.1058     3.528     0.88032    -0.83501    0.0082144

```

### Display Bin Information Using Name-Value Arguments

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Display customized bin information for the categorical predictor `ResStatus`, keeping only the `WOE` column. The Weight-of-Evidence (WOE) is defined bin by bin, but there is no concept of "total WOE", therefore the last element in the `'Totals'` row is set to `NaN`.

```
bi = bininfo(sc, 'ResStatus', 'Statistics', 'WOE');
disp(bi)
```

| Bin             | Good | Bad | WOE       |
|-----------------|------|-----|-----------|
| {'Home Owner' } | 365  | 177 | 0.019329  |
| {'Tenant' }     | 307  | 167 | -0.095564 |
| {'Other' }      | 131  | 53  | 0.20049   |
| {'Totals' }     | 803  | 397 | NaN       |

Display customized bin information for the categorical predictor `ResStatus`, keeping only the `Odds` and `WOE` columns, without the `Totals` row.

```
bi = bininfo(sc, 'ResStatus', 'Statistics', {'Odds', 'WOE'}, 'Totals', 'Off');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       |
|-----------------|------|-----|--------|-----------|
| {'Home Owner' } | 365  | 177 | 2.0621 | 0.019329  |
| {'Tenant' }     | 307  | 167 | 1.8383 | -0.095564 |
| {'Other' }      | 131  | 53  | 2.4717 | 0.20049   |

Display information value, entropy, Gini, and chi square statistics. For more information on these statistics, see "Statistics for a Credit Scorecard" on page 19-1730.

For information value, entropy and Gini, the value reported at a bin level is the contribution of the bin to the total value. The total information value, entropy, and Gini measures are in the `'Totals'` row.

For chi square, if there are  $N$  bins, the first  $N-1$  values in the `'Chi2'` column report pairwise chi square statistics for contiguous bins. For example, this pairwise measure is also used by the `'Merge'` algorithm in `autobinning` to determine if two contiguous bins should be merged. In this example, the first value in the `'Chi2'` column (1.0331) is the chi square statistic of bins 1 and 2 (`'Home Owner'` and `'Tenant'`), and the second value in the column (2.5103) is the chi square statistic of bins 2 and 3 (`'Tenant'` and `'Other'`). There are no more pairwise chi square values to compute in this example, so the third element of the `'Chi2'` column is set to `NaN`. The chi square value reported in the `'Totals'` row is the chi square statistic computed over all bins.

```
bi = bininfo(sc, 'ResStatus', 'Statistics', {'InfoValue', 'Entropy', 'Gini', 'Chi2'});
disp(bi)
```

| Bin | Good | Bad | InfoValue | Entropy | Gini | Chi2 |
|-----|------|-----|-----------|---------|------|------|
|-----|------|-----|-----------|---------|------|------|

```

{'Home Owner'} 365 177 0.0001682 0.91138 0.43984 1.0331
{'Tenant' }    307 167 0.0036638 0.93612 0.45638 2.5103
{'Other' }     131 53 0.0059418 0.86618 0.41015 NaN
{'Totals' }    803 397 0.0097738 0.91422 0.44182 2.5549

```

## Display Bin Information and Binning Map for Categorical Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The binning map or rules for categorical data are summarized in a "category grouping" table, returned as an optional output. By default, each category is placed in a separate bin. Here is the information for the predictor `ResStatus`.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

```
bi=4x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'Home Owner'} 365      177      2.0621      0.019329      0.0001682
{'Tenant' }    307      167      1.8383     -0.095564      0.0036638
{'Other' }     131      53      2.4717      0.20049       0.0059418
{'Totals' }    803      397      2.0227      NaN           0.0097738
```

```
cg=3x2 table
      Category      BinNumber
-----
{'Home Owner'}      1
{'Tenant' }         2
{'Other' }          3
```

To group categories `Tenant` and `Other`, modify the category grouping table `cg` so that the bin number for `Other` is the same as the bin number for `Tenant`. Then use the `modifybins` function to update the scorecard.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
```

Display the updated bin information. The bin labels have been updated and that the bin membership information is contained in the category grouping `cg`.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

```
bi=3x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----

### Display Bin Information and Binning Map for Numeric Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```

load CreditCardData
sc = creditscorecard(data);

```

The predictor `CustIncome` is numeric. By default, each value of the predictor is placed in a separate bin.

```

bi = bininfo(sc, 'CustIncome')

```

```

bi=46x6 table
  Bin      Good      Bad      Odds      WOE      InfoValue

35000
40000
42000
47000
```

```
mv = 1x2
```

```
0 Inf
```

Note, it is recommended to avoid having bins with frequencies of zero because they lead to infinite or undefined (NaN) statistics. Use the `modifybins` or `autobinning` functions to modify bins.

### Display Bin Information for Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
```

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | OtherCC |
|--------|---------|-------------|-------------|-----------|------------|---------|---------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Yes     |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Yes     |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No      |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Yes     |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Yes     |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
```

```
PredictorVars: {1x9 cell}
Data: [1200x11 table]
```

Display bin information for numeric data for 'CustAge' that includes missing data in a separate bin labelled <missing>.

```
bi = bininfo(sc, 'CustAge');
disp(bi)
```

```
plotbins(sc, 'CustAge')
```

Display bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue  |
|-----------------|------|-----|--------|-----------|------------|
| {'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| {'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| {'<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
disp(cg)
```

| Category        | BinNumber |
|-----------------|-----------|
| {'Tenant' }     | 1         |
| {'Home Owner' } | 2         |
| {'Other' }      | 3         |

Note that the category grouping table does not include <missing> because this is a reserved bin and users cannot interact directly with the <missing> bin.

```
plotbins(sc, 'ResStatus')
```

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### PredictorName — Predictor name

character vector

Predictor name, specified using a character vector containing the name of the predictor. `PredictorName` is case-sensitive.

Data Types: char

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `bi = bininfo(sc, PredictorName, 'Statistics', 'WOE', 'Totals', 'On')`

### Statistics — List of statistics to include for bin information

{'Odds', 'WOE', 'InfoValue'} (default) | character vector with values 'Odds', 'WOE', 'InfoValue', 'Entropy', 'Gini', 'Chi2' | cell array of character vectors with values 'Odds', 'WOE', 'InfoValue', 'Entropy', 'Gini', 'Chi2'

List of statistics to include in the bin information, specified as the comma-separated pair consisting of 'Statistics' and a character vector or a cell array of character vectors. For more information, see "Statistics for a Credit Scorecard" on page 19-1730. Possible values are:

- 'Odds' — Odds information is the ratio of "Goods" over "Bads."
- 'WOE' — Weight of Evidence. The WOE Statistic measures the deviation between the distribution of "Goods" and "Bads."
- 'InfoValue' — Information value. Closely tied to the WOE, it is a statistic used to determine how strong a predictor is to use in the fitting model. It measures how strong the deviation is between the distributions of "Goods" and "Bads." However, bins with only "Good" or only "Bad" observations do lead to an infinite Information Value. Consider modifying the bins in those cases by using `modifybins` or `autobinning`.
- 'Entropy' — Entropy is a measure of unpredictability contained in the bins. The more the number of "Goods" and "Bads" differ within the bins, the lower the entropy.
- 'Gini' — Measure of statistical dispersion or inequality within a sample of data.
- 'Chi2' — Measure of statistical difference and independence between groups.

---

**Note** Avoid having bins with frequencies of zero because they lead to infinite or undefined (NaN) statistics. Use `modifybins` or `autobinning` to modify bins.

---

Data Types: char | cell

**Totals — Indicator to include row of totals at bottom information table**

'On' (default) | character vector with values 'On', 'Off'

Indicator to include a row of totals at the bottom of the information table, specified as the comma-separated pair consisting of 'Totals' and a character vector with values On or Off.

Data Types: char

**Output Arguments****bi — Bin information**

table

Bin information, returned as a table. The bin information table contains one row per bin and a row of totals. The columns contain bin descriptions, frequencies of “Good” and “Bad,” and bin statistics. Avoid having bins with frequencies of zero because they lead to infinite or undefined (NaN) statistics. Use `modifybins` or `autobinning` to modify bins.

---

**Note** When creating the `creditscorecard` object with `creditscorecard`, if the optional name-value pair argument `WeightsVar` was used to specify observation (sample) weights, then the `bi` table contains weighted counts.

---

**bm — Binning map or rules**

vector of cut points for numeric predictors | table of category groupings for categorical predictors

Binning map or rules, returned as a vector of cut points for numeric predictors, or a table of category groupings for categorical predictors. For more information, see `modifybins`.

**mv — Binning minimum and maximum values**

numeric array

Binning minimum and maximum values (as set or defined by the user), returned as a numeric array. The `mv` output argument is set to an empty array for categorical predictors.

**More About****Statistics for a Credit Scorecard**

Weight of Evidence (WOE) is a measure of the difference of the distribution of “Goods” and “Bads” within a bin.

Suppose the predictor's data takes on  $M$  possible values  $b_1, \dots, b_M$ . For binned data,  $M$  is a small number. The response takes on two values, “Good” and “Bad.” The frequency table of the data is given by:

|     | Good | Bad | Total |
|-----|------|-----|-------|
| b1: | n11  | n12 | n1    |
| b2: | n21  | n22 | n2    |
| bM: | nM1  | nM2 | nM    |

|        | Good  | Bad  | Total  |
|--------|-------|------|--------|
| Total: | nGood | nBad | nTotal |

The Weight of Evidence (WOE) is defined for each data value  $b_i$  as

$$\text{WOE}(i) = \log((n_{i1}/n_{\text{Good}})/(n_{i2}/n_{\text{Bad}})).$$

If you define

$$p_{\text{Good}}(i) = n_{i1}/n_{\text{Good}}, \quad p_{\text{Bad}}(i) = n_{i2}/n_{\text{Bad}}$$

then  $p_{\text{Good}}(i)$  is the proportion of “Good” observations that take on the value  $b_i$ , and similarly for  $p_{\text{Bad}}(i)$ . In other words,  $p_{\text{Good}}(i)$  gives the distribution of good observations over the  $M$  observed values of the predictor, and similarly for  $p_{\text{Bad}}(i)$ . With this, an equivalent formula for the WOE is

$$\text{WOE}(i) = \log(p_{\text{Good}}(i)/p_{\text{Bad}}(i)).$$

Using the same frequency table, the odds for row  $i$  are defined as

$$\text{Odds}(i) = n_{i1} / n_{i2},$$

and the odds for the sample are defined as

$$\text{Odds}_{\text{Total}} = n_{\text{Good}} / n_{\text{Bad}}.$$

For each row  $i$ , you can also compute its contribution to the total Information Value, given by

$$\text{InfoValue}(i) = (p_{\text{Good}}(i) - p_{\text{Bad}}(i)) * \text{WOE}(i),$$

and the total Information Value is simply the sum of all the  $\text{InfoValue}(i)$  terms. (A nansum is returned to discard contributions from rows with no observations at all.)

Likewise, for each row  $i$ , we can compute its contribution to the total Entropy, given by

$$\text{Entropy}(i) = -1/\log(2)*(n_{i1}/n_i*\log(n_{i1}/n_i)+n_{i2}/n_i*\log(n_{i2}/n_i)),$$

and the total Entropy is simply the weighted sum of the row entropies,

$$\text{Entropy} = \sum(n_i/n_{\text{Total}} * \text{Entropy}(i)), \quad i = 1..M.$$

Chi2 is computed pairwise for each pair of bins and measures the statistical difference between two groups when splitting or merging bins and is defined as:

$$\text{Chi2} = \sum(\sum((A_{ij} - E_{ij})^2/E_{ij}, j=1..k), i=m,m+1).$$

For more information on splitting and merging bins, see Split on page 19-1754 and Merge on page 19-1757.

Gini ratio is a measure of the parent node, that is, of the given bins/categories prior to splitting or merging. The Gini ratio is defined as:

$$\text{Gr} = 1 - G_{\text{hat}}/G_p$$

$G_{\text{hat}}$  is the weighted Gini measure for the current split or merge:

$$G_{\text{hat}} = \sum((n_j/N) * G_j, j=1..m).$$

For more information on splitting and merging bins, see Split on page 19-1754 and Merge on page 19-1757.

### Using bininfo with Weights

When observation weights are defined using the optional `WeightsVar` argument when creating a `creditscorecard` object, instead of counting the rows that are good or bad in each bin, the `bininfo` function accumulates the weight of the rows that are good or bad in each bin.

The “frequencies” reported are no longer the basic “count” of rows, but the “cumulative weight” of the rows that are good or bad and fall in a particular bin. Once these “weighted frequencies” are known, all other relevant statistics (`Good`, `Bad`, `Odds`, `WOE`, and `InfoValue`) are computed with the usual formulas. For more information, see “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

### Introduced in R2014b

# autobinning

Perform automatic binning of given predictors

## Syntax

```
sc = autobinning(sc)
sc = autobinning(sc,PredictorNames)
sc = autobinning( ___,Name,Value)
```

## Description

`sc = autobinning(sc)` performs automatic binning of all predictors.

Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the `creditscorecard` object. To apply the binning rules to the `creditscorecard` object data, or to a new dataset, use `bindata`.

`sc = autobinning(sc,PredictorNames)` performs automatic binning of the predictors given in `PredictorNames`.

Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the `creditscorecard` object. To apply the binning rules to the `creditscorecard` object data, or to a new dataset, use `bindata`.

`sc = autobinning( ___,Name,Value)` performs automatic binning of the predictors given in `PredictorNames` using optional name-value pair arguments. See the name-value argument `Algorithm` for a description of the supported binning algorithms.

Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the `creditscorecard` object. To apply the binning rules to the `creditscorecard` object data, or to a new dataset, use `bindata`.

## Examples

### Perform Automatic Binning Using the Defaults

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning using the default options. By default, `autobinning` bins all predictors and uses the `Monotone` algorithm.

```
sc = autobinning(sc);
```

Use `bininfo` to display the binned data for the predictor `CustAge`.

```
bi = bininfo(sc, 'CustAge')
```

| bi=8x6 table<br>Bin | Good | Bad | Odds   | WOE       | InfoValue |

| {'[-Inf,33)'} }     | 70   | 53  | 1.3208 | -0.42622  | 0.019746  |
| {'[33,37)'} }       | 64   | 47  | 1.3617 | -0.39568  | 0.015308  |
| {'[37,40)'} }       | 73   | 47  | 1.5532 | -0.26411  | 0.0072573 |
| {'[40,46)'} }       | 174  | 94  | 1.8511 | -0.088658 | 0.001781  |
| {'[46,48)'} }       | 61   | 25  | 2.44   | 0.18758   | 0.0024372 |
| {'[48,58)'} }       | 263  | 105 | 2.5048 | 0.21378   | 0.013476  |
| {'[58,Inf]'} }      | 98   | 26  | 3.7692 | 0.62245   | 0.0352    |
| {'Totals' }         | 803  | 397 | 2.0227 | NaN       | 0.095205  |

Use `plotbins` to display the histogram and WOE curve for the predictor `CustAge`.

```
plotbins(sc, 'CustAge')
```

### Perform Automatic Binning with a Named Predictor Using the Defaults

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the predictor `CustIncome` using the default options. By default, `autobinning` uses the Monotone algorithm.

```
sc = autobinning(sc, 'CustIncome');
```

Use `bininfo` to display the binned data.

```
bi = bininfo(sc, 'CustIncome')
```

```
bi=8x6 table
```

| Bin                  | Good | Bad | Odds    | WOE       | InfoValue  |
|----------------------|------|-----|---------|-----------|------------|
| {' [-Inf,29000) ' }  | 53   | 58  | 0.91379 | -0.79457  | 0.06364    |
| {' [29000,33000) ' } | 74   | 49  | 1.5102  | -0.29217  | 0.0091366  |
| {' [33000,35000) ' } | 68   | 36  | 1.8889  | -0.06843  | 0.00041042 |
| {' [35000,40000) ' } | 193  | 98  | 1.9694  | -0.026696 | 0.00017359 |
| {' [40000,42000) ' } | 68   | 34  | 2       | -0.011271 | 1.0819e-05 |
| {' [42000,47000) ' } | 164  | 66  | 2.4848  | 0.20579   | 0.0078175  |
| {' [47000,Inf] ' }   | 183  | 56  | 3.2679  | 0.47972   | 0.041657   |
| {' Totals ' }        | 803  | 397 | 2.0227  | NaN       | 0.12285    |

### Perform Automatic Binning Using Two Name-Value Pair Arguments

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the predictor `CustIncome` using the Monotone algorithm with the initial number of bins set to 20. This example explicitly sets both the `Algorithm` and the `AlgorithmOptions` name-value arguments.

```
AlgoOptions = {'InitialNumBins',20};
sc = autobinning(sc, 'CustIncome', 'Algorithm', 'Monotone', 'AlgorithmOptions', ...
    AlgoOptions);
```

Use `bininfo` to display the binned data. Here, the cut points, which delimit the bins, are also displayed.

```
[bi,cp] = bininfo(sc, 'CustIncome')
```

```
bi=11x6 table
```

| Bin                  | Good | Bad | Odds    | WOE       | InfoValue  |
|----------------------|------|-----|---------|-----------|------------|
| {' [-Inf,19000) ' }  | 2    | 3   | 0.66667 | -1.1099   | 0.0056227  |
| {' [19000,29000) ' } | 51   | 55  | 0.92727 | -0.77993  | 0.058516   |
| {' [29000,31000) ' } | 29   | 26  | 1.1154  | -0.59522  | 0.017486   |
| {' [31000,34000) ' } | 80   | 42  | 1.9048  | -0.060061 | 0.0003704  |
| {' [34000,35000) ' } | 33   | 17  | 1.9412  | -0.041124 | 7.095e-05  |
| {' [35000,40000) ' } | 193  | 98  | 1.9694  | -0.026696 | 0.00017359 |
| {' [40000,42000) ' } | 68   | 34  | 2       | -0.011271 | 1.0819e-05 |
| {' [42000,43000) ' } | 39   | 16  | 2.4375  | 0.18655   | 0.001542   |

```

{'[43000,47000)'} 125    50    2.5    0.21187    0.0062972
{'[47000,Inf]'}  183    56    3.2679  0.47972    0.041657
{'Totals'}       803   397    2.0227    NaN        0.13175

```

```
cp = 9×1
```

```

19000
29000
31000
34000
35000
40000
42000
43000
47000

```

### Perform Automatic Binning Using Multiple Name-Value Pair Arguments

This example shows how to use the autobinning default Monotone algorithm and the `AlgorithmOptions` name-value pair arguments associated with the Monotone algorithm. The `AlgorithmOptions` for the Monotone algorithm are three name-value pair parameters: 'InitialNumBins', 'Trend', and 'SortCategories'. 'InitialNumBins' and 'Trend' are applicable for numeric predictors and 'Trend' and 'SortCategories' are applicable for categorical predictors.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning for the numeric predictor `CustIncome` using the Monotone algorithm with 20 bins. This example explicitly sets both the `Algorithm` argument and the `AlgorithmOptions` name-value arguments for 'InitialNumBins' and 'Trend'.

```
AlgoOptions = {'InitialNumBins',20,'Trend','Increasing'};

sc = autobinning(sc,'CustIncome','Algorithm','Monotone',...
    'AlgorithmOptions',AlgoOptions);
```

Use `bininfo` to display the binned data.

```
bi = bininfo(sc,'CustIncome')
```

```
bi=11×6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'[-Inf,19000)'}    2     3    0.66667   -1.1099   0.0056227

## Perform Automatic Binning for Multiple Predictors

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning for the predictor `CustIncome` and `CustAge` using the default Monotone algorithm with `AlgorithmOptions` for `InitialNumBins` and `Trend`.

```
AlgoOptions = {'InitialNumBins',20,'Trend','Increasing'};
sc = autobinning(sc,{'CustAge','CustIncome'},'Algorithm','Monotone',...
    'AlgorithmOptions',AlgoOptions);
```

Use `bininfo` to display the binned data.

```
bi1 = bininfo(sc, 'CustIncome')
```

```
bi1=11x6 table
      Bin          Good    Bad    Odds    WOE    InfoValue
-----
{ '[-Inf,19000)' }      2      3    0.66667    -1.1099    0.0056227
{ '[19000,29000)' }    51     55    0.92727    -0.77993    0.058516
{ '[29000,31000)' }    29     26    1.1154    -0.59522    0.017486
{ '[31000,34000)' }    80     42    1.9048    -0.060061   0.0003704

```

### Perform Automatic Binning for a Categorical Predictor Using the Defaults

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the predictor that is a categorical predictor called `ResStatus` using the default options. By default, `autobinning` uses the Monotone algorithm.

```
sc = autobinning(sc, 'ResStatus');
```

Use `bininfo` to display the binned data.

```
bi = bininfo(sc, 'ResStatus')
```

```
bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'Tenant'   } 307    167    1.8383  -0.095564  0.0036638
{'Home Owner'} 365    177    2.0621   0.019329  0.0001682
{'Other'    } 131     53    2.4717   0.20049   0.0059418
{'Totals'   } 803    397    2.0227      NaN   0.0097738
```

### Perform Automatic Binning for a Categorical Predictor Using Name-Value Pair Arguments

This example shows how to modify the data (for this example only) to illustrate binning categorical predictors using the Monotone algorithm.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
```

Add two new categories and updating the response variable.

```
newdata = data;
rng('default'); %for reproducibility
Predictor = 'ResStatus';
Status     = newdata.status;
NumObs     = length(newdata.(Predictor));
Ind1 = randi(NumObs,100,1);
Ind2 = randi(NumObs,100,1);
newdata.(Predictor)(Ind1) = 'Subtenant';
newdata.(Predictor)(Ind2) = 'Coowner';
```

```
Status(Ind1) = randi(2,100,1)-1;
Status(Ind2) = randi(2,100,1)-1;
```

```
newdata.status = Status;
```

Update the `creditscorecard` object using the `newdata` and plot the bins for a later comparison.

```
scnew = creditscorecard(newdata, 'IDVar', 'CustID');
[bi, cg] = bininfo(scnew, Predictor)
```

`bi=6×6 table`

| Bin             | Good | Bad | Odds   | WOE      | InfoValue |
|-----------------|------|-----|--------|----------|-----------|
| {'Home Owner' } | 308  | 154 | 2      | 0.092373 | 0.0032392 |
| {'Tenant' }     | 264  | 136 | 1.9412 | 0.06252  | 0.0012907 |
| {'Other' }      | 109  | 49  | 2.2245 | 0.19875  | 0.0050386 |
| {'Subtenant' }  | 42   | 42  | 1      | -0.60077 | 0.026813  |
| {'CoOwner' }    | 52   | 44  | 1.1818 | -0.43372 | 0.015802  |
| {'Totals' }     | 775  | 425 | 1.8235 | NaN      | 0.052183  |

`cg=5×2 table`

| Category        | BinNumber |
|-----------------|-----------|
| {'Home Owner' } | 1         |
| {'Tenant' }     | 2         |
| {'Other' }      | 3         |
| {'Subtenant' }  | 4         |
| {'CoOwner' }    | 5         |

```
plotbins(scnew, Predictor)
```

Perform automatic binning for the categorical Predictor using the default Monotone algorithm with the AlgorithmOptions name-value pair arguments for 'SortCategories' and 'Trend'.

```
AlgoOptions = {'SortCategories','Goods','Trend','Increasing'};
```

```
scnew = autobinning(scnew,Predictor,'Algorithm','Monotone',...  
    'AlgorithmOptions',AlgoOptions);
```

Use bininfo to display the bin information. The second output parameter 'cg' captures the bin membership, which is the bin number that each group belongs to.

```
[bi,cg] = bininfo(scnew,Predictor)
```

```
bi=4x6 table
```

| Bin        | Good | Bad | Odds   | WOE      | InfoValue |
|------------|------|-----|--------|----------|-----------|
| {'Group1'} | 42   | 42  | 1      | -0.60077 | 0.026813  |
| {'Group2'} | 52   | 44  | 1.1818 | -0.43372 | 0.015802  |
| {'Group3'} | 681  | 339 | 2.0088 | 0.096788 | 0.0078459 |
| {'Totals'} | 775  | 425 | 1.8235 | NaN      | 0.05046   |

```
cg=5x2 table
```

| Category       | BinNumber |
|----------------|-----------|
| {'Subtenant' } | 1         |

```
{'CoOwner' } 2
{'Other' } 3
{'Tenant' } 3
{'Home Owner' } 3
```

Plot bins and compare with the histogram plotted pre-binning.

```
plotbins(scnew, Predictor)
```

### Perform Automatic Binning When Using Missing Data

Create a creditcard object using the CreditCardData.mat file to load the dataMissing with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

ans=5x11 table

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | Other |
|--------|---------|-------------|-------------|-----------|------------|---------|-------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Ye    |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Ye    |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No    |

|   |     |    |            |          |       |    |
|---|-----|----|------------|----------|-------|----|
| 4 | NaN | 75 | Home Owner | Employed | 53000 | 20 |
| 5 | 68  | 56 | Home Owner | Employed | 53000 | 14 |

```
fprintf('Number of rows: %d\n',height(dataMissing))
Number of rows: 1200
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
Number of missing values CustAge: 30
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric and categorical data in a separate bin.

```
sc = creditscorecard(dataMissing,'BinMissingData',true);
disp(sc)
```

creditscorecard with properties:

```
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: ''
    PredictorVars: {1x10 cell}
    Data: [1200x11 table]
```

Perform automatic binning using the Merge algorithm.

```
sc = autobinning(sc,'Algorithm','Merge');
```

Display bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>` and this is the last bin. No matter what binning algorithm is used in `autobinning`, the algorithm operates on the non-missing data and the bin for the `<missing>` numeric values for a predictor is always the last bin.

```
[bi,cp] = bininfo(sc,'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds    | WOE      | InfoValue  |
|-----------------|------|-----|---------|----------|------------|
| {'[-Inf,32)'} } | 56   | 39  | 1.4359  | -0.34263 | 0.0097643  |
| {'[32,33)'} }   | 13   | 13  | 1       | -0.70442 | 0.011663   |

| {'[34,65)'} }   | 677  | 317 | 2.1356  | 0.054351 | 0.002424   |
| {'[65,Inf]'} }  | 29   | 6   | 4.8333  | 0.87112  | 0.018295   |
| {'<missing>'} } | 19   | 11  | 1.7273  | -0.15787 | 0.00063885 |
| {'Totals' } }   | 803  | 397 | 2.0227  | NaN      | 0.057718   |

```
plotbins(sc,'CustAge')
```

Display bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing> and this is the last bin. No matter what binning algorithm is used in autobinning, the algorithm operates on the non-missing data and the bin for the <missing> categorical values for a predictor is always the last bin.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin            | Good | Bad | Odds   | WOE       | InfoValue  |
|----------------|------|-----|--------|-----------|------------|
| {'Group1' }    | 648  | 332 | 1.9518 | -0.035663 | 0.0010449  |
| {'Group2' }    | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| {'<missing>' } | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }    | 803  | 397 | 2.0227 | NaN       | 0.0066489  |

```
plotbins(sc, 'ResStatus')
```

### Perform Automatic Binning Using the Split Algorithm

This example demonstrates using the 'Split' algorithm with categorical and numeric predictors. Load the `CreditCardData.mat` dataset and modify so that it contains four categories for the predictor 'ResStatus' to demonstrate how the split algorithm works.

```
load CreditCardData.mat
x = data.ResStatus;
Ind = find(x == 'Tenant');
Nx = length(Ind);
x(Ind(1:floor(Nx/3))) = 'Subletter';
data.ResStatus = x;
```

Create a `creditscorecard` and use `bininfo` to display the 'Statistics'.

```
sc = creditscorecard(data, 'IDVar', 'CustID');
[bin, cg1] = bininfo(sc, 'ResStatus', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bin)
```

| Bin            | Good | Bad | Odds   | WOE      | InfoValue |
|----------------|------|-----|--------|----------|-----------|
| {'Home Owner'} | 365  | 177 | 2.0621 | 0.019329 | 0.0001682 |
| {'Tenant' }    | 204  | 112 | 1.8214 | -0.1048  | 0.0029415 |
| {'Other' }     | 131  | 53  | 2.4717 | 0.20049  | 0.0059418 |

```

{'Subletter' } 103    55    1.8727   -0.077023   0.00079103
{'Totals'    } 803    397    2.0227           NaN    0.0098426

```

```
disp(cg1)
```

```

      Category      BinNumber
-----
{'Home Owner' }          1
{'Tenant'     }          2
{'Other'      }          3
{'Subletter'  }          4

```

### Using the Split Algorithm with a Categorical Predictor

Apply presorting to the 'ResStatus' category using the default sorting by 'Odds' and specify the 'Split' algorithm.

```

sc = autobinning(sc, 'ResStatus', 'Algorithm', 'split', 'AlgorithmOptions', ...
    {'Measure', 'gini', 'SortCategories', 'odds', 'Tolerance', 1e-4});
[bi2, cg2] = bininfo(sc, 'ResStatus', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi2)

```

```

      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'Group1' } 307      167      1.8383   -0.095564   0.0036638
{'Group2' } 365      177      2.0621    0.019329   0.0001682
{'Group3' } 131       53      2.4717    0.20049    0.0059418
{'Totals' } 803      397      2.0227           NaN    0.0097738

```

```
disp(cg2)
```

```

      Category      BinNumber
-----
{'Tenant'     }          1
{'Subletter'  }          1
{'Home Owner' }          2
{'Other'      }          3

```

### Using the Split Algorithm with a Numeric Predictor

To demonstrate a split for the numeric predictor, 'TmAtAddress', first use autobinning with the default 'Monotone' algorithm.

```

sc = autobinning(sc, 'TmAtAddress');
bi3 = bininfo(sc, 'TmAtAddress', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi3)

```

```

      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'[-Inf,23)' } 239      129      1.8527   -0.087767   0.0023963
{'[23,83)'   } 480      232      2.069    0.02263    0.00030269
{'[83,Inf]'   }  84       36      2.3333    0.14288    0.00199
{'Totals'    } 803      397      2.0227           NaN    0.004689

```

Then use autobinning with the 'Split' algorithm.

```
sc = autobinning(sc, 'TmAtAddress', 'Algorithm', 'Split');
bi4 = bininfo(sc, 'TmAtAddress', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi4)
```

| Bin            | Good | Bad | Odds    | WOE       | InfoValue  |
|----------------|------|-----|---------|-----------|------------|
| {'[-Inf,4)'} } | 20   | 12  | 1.6667  | -0.19359  | 0.0010299  |
| {'[4,5)'} }    | 4    | 7   | 0.57143 | -1.264    | 0.015991   |
| {'[5,23)'} }   | 215  | 110 | 1.9545  | -0.034261 | 0.00031973 |
| {'[23,33)'} }  | 130  | 39  | 3.3333  | 0.49955   | 0.0318     |
| {'[33,Inf]'} } | 434  | 229 | 1.8952  | -0.065096 | 0.0023664  |
| {'Totals' }    | 803  | 397 | 2.0227  | NaN       | 0.051507   |

### Perform Automatic Binning Using the Merge Algorithm

Load the `CreditCardData.mat` dataset. This example demonstrates using the 'Merge' algorithm with categorical and numeric predictors.

```
load CreditCardData.mat
```

### Using the Merge Algorithm with a Categorical Predictor

To merge a categorical predictor, create a `creditscorecard` using default sorting by 'Odds' and then use `bininfo` on the categorical predictor 'ResStatus'.

```
sc = creditscorecard(data, 'IDVar', 'CustID');
[bi1, cg1] = bininfo(sc, 'ResStatus', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi1);
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue |
|-----------------|------|-----|--------|-----------|-----------|
| {'Home Owner' } | 365  | 177 | 2.0621 | 0.019329  | 0.0001682 |
| {'Tenant' }     | 307  | 167 | 1.8383 | -0.095564 | 0.0036638 |
| {'Other' }      | 131  | 53  | 2.4717 | 0.20049   | 0.0059418 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0097738 |

```
disp(cg1);
```

| Category        | BinNumber |
|-----------------|-----------|
| {'Home Owner' } | 1         |
| {'Tenant' }     | 2         |
| {'Other' }      | 3         |

Use `autobinning` and specify the 'Merge' algorithm.

```
sc = autobinning(sc, 'ResStatus', 'Algorithm', 'Merge');
[bi2, cg2] = bininfo(sc, 'ResStatus', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi2)
```

| Bin         | Good | Bad | Odds   | WOE       | InfoValue |
|-------------|------|-----|--------|-----------|-----------|
| {'Group1' } | 672  | 344 | 1.9535 | -0.034802 | 0.0010314 |

```

{'Group2'}    131    53    2.4717    0.20049    0.0059418
{'Totals'}    803    397    2.0227    NaN        0.0069732

```

```
disp(cg2)
```

```

      Category      BinNumber
-----
{'Tenant'   }          1
{'Home Owner'}        1
{'Other'    }          2

```

### Using the Merge Algorithm with a Numeric Predictor

To demonstrate a merge for the numeric predictor, 'TmAtAddress', first use autobinning with the default 'Monotone' algorithm.

```

sc = autobinning(sc, 'TmAtAddress');
bi3 = bininfo(sc, 'TmAtAddress', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi3)

```

```

      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'[-Inf,23)'}  239      129      1.8527    -0.087767    0.0023963
{'[23,83)'}   480      232      2.069     0.02263     0.00030269
{'[83,Inf]'}   84       36      2.3333     0.14288     0.00199
{'Totals'}    803      397      2.0227     NaN         0.004689

```

Then use autobinning with the 'Merge' algorithm.

```

sc = autobinning(sc, 'TmAtAddress', 'Algorithm', 'Merge');
bi4 = bininfo(sc, 'TmAtAddress', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi4)

```

```

      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'[-Inf,28)'}  303      152      1.9934    -0.014566    8.0646e-05
{'[28,30)'}    27       2       13.5      1.8983      0.054264
{'[30,98)'}   428      216      1.9815    -0.020574    0.00022794
{'[98,106)'}   11       13      0.84615   -0.87147     0.016599
{'[106,Inf]'}  34       14      2.4286     0.18288     0.0012942
{'Totals'}    803      397      2.0227     NaN         0.072466

```

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a creditscorecard object. Use creditscorecard to create a creditscorecard object.

### PredictorNames — Predictor or predictors names to automatically bin

character vector | cell array of character vectors

Predictor or predictors names to automatically bin, specified as a character vector or a cell array of character vectors containing the name of the predictor or predictors. PredictorNames are case-

sensitive and when no `PredictorNames` are defined, all predictors in the `PredictorVars` property of the `creditscorecard` object are binned.

Data Types: `char` | `cell`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `sc = autobinning(sc,'Algorithm','EqualFrequency')`

### Algorithm — Algorithm selection

'Monotone' (default) | character vector with values 'Monotone', 'Split', 'Merge', 'EqualFrequency', 'EqualWidth'

Algorithm selection, specified as the comma-separated pair consisting of 'Algorithm' and a character vector indicating which algorithm to use. The same algorithm is used for all predictors in `PredictorNames`. Possible values are:

- 'Monotone' — (default) Monotone Adjacent Pooling Algorithm (MAPA), also known as Maximum Likelihood Monotone Coarse Classifier (MLMCC). Supervised optimal binning algorithm that aims to find bins with a monotone Weight-Of-Evidence (WOE) trend. This algorithm assumes that only neighboring attributes can be grouped. Thus, for categorical predictors, categories are sorted before applying the algorithm (see 'SortCategories' option for `AlgorithmOptions`). For more information, see “Monotone” on page 19-1752.
- 'Split' — Supervised binning algorithm, where a measure is used to split the data into bins. The measures supported by 'Split' are `gini`, `chi2`, `infovalue`, and `entropy`. The resulting split must be such that the gain in the information function is maximized. For more information on these measures, see `AlgorithmOptions` and “Split” on page 19-1754.
- 'Merge' — Supervised automatic binning algorithm, where a measure is used to merge bins into buckets. The measures supported by 'Merge' are `chi2`, `gini`, `infovalue`, and `entropy`. The resulting merging must be such that any pair of adjacent bins is statistically different from each other, according to the chosen measure. For more information on these measures, see `AlgorithmOptions` and “Merge” on page 19-1757.
- 'EqualFrequency' — Unsupervised algorithm that divides the data into a predetermined number of bins that contain approximately the same number of observations. This algorithm is also known as “equal height” or “equal depth.” For categorical predictors, categories are sorted before applying the algorithm (see 'SortCategories' option for `AlgorithmOptions`). For more information, see “Equal Frequency” on page 19-1759.
- 'EqualWidth' — Unsupervised algorithm that divides the range of values in the domain of the predictor variable into a predetermined number of bins of “equal width.” For numeric data, the width is measured as the distance between bin edges. For categorical data, width is measured as the number of categories within a bin. For categorical predictors, categories are sorted before applying the algorithm (see 'SortCategories' option for `AlgorithmOptions`). For more information, see “Equal Width” on page 19-1760.

Data Types: `char`

### AlgorithmOptions — Algorithm options for selected Algorithm

{'InitialNumBins',10,'Trend','Auto','SortCategories','Odds'} for Monotone (default) | cell array with {'OptionName','OptionValue'} for Algorithm options

Algorithm options for the selected Algorithm, specified as the comma-separated pair consisting of 'AlgorithmOptions' and a cell array. Possible values are:

- For Monotone algorithm:
  - {'InitialNumBins', *n*} — Initial number (*n*) of bins (default is 10). 'InitialNumBins' must be an integer > 2. Used for numeric predictors only.
  - {'Trend', 'TrendOption'} — Determines whether the Weight-Of-Evidence (WOE) monotonic trend is expected to be increasing or decreasing. The values for 'TrendOption' are:
    - 'Auto' — (Default) Automatically determines if the WOE trend is increasing or decreasing.
    - 'Increasing' — Look for an increasing WOE trend.
    - 'Decreasing' — Look for a decreasing WOE trend.

The value of the optional input parameter 'Trend' does not necessarily reflect that of the resulting WOE curve. The parameter 'Trend' tells the algorithm to “look for” an increasing or decreasing trend, but the outcome may not show the desired trend. For example, the algorithm cannot find a decreasing trend when the data actually has an increasing WOE trend. For more information on the 'Trend' option, see “Monotone” on page 19-1752.

- {'SortCategories', 'SortOption'} — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
  - 'Odds' — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
  - 'Goods' — The categories are sorted by order of increasing values of “Good.”
  - 'Bads' — The categories are sorted by order of increasing values of “Bad.”
  - 'Totals' — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
  - 'None' — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from bininfo.)

For more information, see Sort Categories on page 19-1760

- For Split algorithm:
  - {'InitialNumBins', *n*} — Specifies an integer that determines the number ( $n > 0$ ) of bins that the predictor is initially binned into before splitting. Valid for numeric predictors only. Default is 50.
  - {'Measure', *MeasureName*} — Specifies the measure where '*MeasureName*' is one of the following: 'Gini' (default), 'Chi2', 'InfoValue', or 'Entropy'.
  - {'MinBad', *n*} — Specifies the minimum number *n* ( $n \geq 0$ ) of Bads per bin. The default value is 1, to avoid pure bins.
  - {'MaxBad', *n*} — Specifies the maximum number *n* ( $n \geq 0$ ) of Bads per bin. The default value is Inf.
  - {'MinGood', *n*} — Specifies the minimum number *n* ( $n \geq 0$ ) of Goods per bin. The default value is 1, to avoid pure bins.
  - {'MaxGood', *n*} — Specifies the maximum number *n* ( $n \geq 0$ ) of Goods per bin. The default value is Inf.

- `{'MinCount',  $n$ }` — Specifies the minimum number  $n$  ( $n \geq 0$ ) of observations per bin. The default value is 1, to avoid empty bins.
- `{'MaxCount',  $n$ }` — Specifies the maximum number  $n$  ( $n \geq 0$ ) of observations per bin. The default value is Inf.
- `{'MaxNumBins',  $n$ }` — Specifies the maximum number  $n$  ( $n \geq 2$ ) of bins resulting from the splitting. The default value is 5.
- `{'Tolerance',  $Tol$ }` — Specifies the minimum gain ( $>0$ ) in the information function, during the iteration scheme, to select the cut-point that maximizes the gain. The default is  $1e-4$ .
- `{'Significance',  $n$ }` — Significance level threshold for the chi-square statistic, above which splitting happens. Values are in the interval  $[0, 1]$ . Default is 0.9 (90% significance level).
- `{'SortCategories', 'SortOption'}` — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
  - 'Goods' — The categories are sorted by order of increasing values of "Good."
  - 'Bads' — The categories are sorted by order of increasing values of "Bad."
  - 'Odds' — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of "Good" to "Bad" observations, for the given category.
  - 'Totals' — The categories are sorted by order of increasing values of total number of observations ("Good" plus "Bad").
  - 'None' — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

For more information, see Sort Categories on page 19-1760

- For Merge algorithm:
  - `{'InitialNumBins',  $n$ }` — Specifies an integer that determines the number ( $n > 0$ ) of bins that the predictor is initially binned into before merging. Valid for numeric predictors only. Default is 50.
  - `{'Measure',  $MeasureName$ }` — Specifies the measure where ' $MeasureName$ ' is one of the following: 'Chi2' (default), 'Gini', 'InfoValue', or 'Entropy'.
  - `{'MinNumBins',  $n$ }` — Specifies the minimum number  $n$  ( $n \geq 2$ ) of bins that result from merging. The default value is 2.
  - `{'MaxNumBins',  $n$ }` — Specifies the maximum number  $n$  ( $n \geq 2$ ) of bins that result from merging. The default value is 5.
  - `{'Tolerance',  $n$ }` — Specifies the minimum threshold below which merging happens for the information value and entropy statistics. Valid values are in the interval  $(0, 1)$ . Default is  $1e-3$ .
  - `{'Significance',  $n$ }` — Significance level threshold for the chi-square statistic, below which merging happens. Values are in the interval  $[0, 1]$ . Default is 0.9 (90% significance level).
  - `{'SortCategories', 'SortOption'}` — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
    - 'Goods' — The categories are sorted by order of increasing values of "Good."
    - 'Bads' — The categories are sorted by order of increasing values of "Bad."

- 'Odds' — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
- 'Totals' — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
- 'None' — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

For more information, see Sort Categories on page 19-1760

- For EqualFrequency algorithm:
  - {'NumBins',  $n$ } — Specifies the desired number ( $n$ ) of bins. The default is {'NumBins', 5} and the number of bins must be a positive number.
  - {'SortCategories', 'SortOption'} — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
    - 'Odds' — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
    - 'Goods' — The categories are sorted by order of increasing values of “Good.”
    - 'Bads' — The categories are sorted by order of increasing values of “Bad.”
    - 'Totals' — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
    - 'None' — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

For more information, see Sort Categories on page 19-1760

- For EqualWidth algorithm:
  - {'NumBins',  $n$ } — Specifies the desired number ( $n$ ) of bins. The default is {'NumBins', 5} and the number of bins must be a positive number.
  - {'SortCategories', 'SortOption'} — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
    - 'Odds' — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
    - 'Goods' — The categories are sorted by order of increasing values of “Good.”
    - 'Bads' — The categories are sorted by order of increasing values of “Bad.”
    - 'Totals' — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
    - 'None' — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

For more information, see Sort Categories on page 19-1760

```
Example: sc =
autobinning(sc, 'CustAge', 'Algorithm', 'Monotone', 'AlgorithmOptions',
{'Trend', 'Increasing'})
```

Data Types: cell

### **Display** — Indicator to display information on status of the binning process at command line

'Off' (default) | character vector with values 'On', 'Off'

Indicator to display the information on status of the binning process at command line, specified as the comma-separated pair consisting of 'Display' and a character vector with a value of 'On' or 'Off'.

Data Types: char

## **Output Arguments**

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, returned as an updated `creditscorecard` object containing the automatically determined binning maps or rules (cut points or category groupings) for one or more predictors. For more information on using the `creditscorecard` object, see `creditscorecard`.

---

**Note** If you have previously used the `modifybins` function to manually modify bins, these changes are lost when running `autobinning` because all the data is automatically binned based on internal `autobinning` rules.

---

## **More About**

### **Monotone**

The 'Monotone' algorithm is an implementation of the Monotone Adjacent Pooling Algorithm (MAPA), also known as Maximum Likelihood Monotone Coarse Classifier (MLMCC); see Anderson or Thomas in the "References" on page 19-1761.

### **Preprocessing**

During the preprocessing phase, preprocessing of numeric predictors consists in applying equal frequency binning, with the number of bins determined by the 'InitialNumBins' parameter (the default is 10 bins). The preprocessing of categorical predictors consists in sorting the categories according to the 'SortCategories' criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the "Sort Categories" on page 19-1760 definition or the description of `AlgorithmOptions` option for 'SortCategories' for more information.

### **Main Algorithm**

The following example illustrates how the 'Monotone' algorithm arrives at cut points for numeric data.

| Bin                      | Good | Bad | Iteration1 | Iteration2 | Iteration3 | Iteration4 |
|--------------------------|------|-----|------------|------------|------------|------------|
| ' [-<br>Inf, 33000)<br>' | 127  | 107 | 0.543      |            |            |            |
| ' [33000, 38<br>000) '   | 194  | 90  | 0.620      | 0.683      |            |            |
| ' [38000, 42<br>000) '   | 135  | 78  | 0.624      | 0.662      |            |            |
| ' [42000, 47<br>000) '   | 164  | 66  | 0.645      | 0.678      | 0.713      |            |
| ' [47000, In<br>f] '     | 183  | 56  | 0.669      | 0.700      | 0.740      | 0.766      |

Initially, the numeric data is preprocessed with an equal frequency binning. In this example, for simplicity, only the five initial bins are used. The first column indicates the equal frequency bin ranges, and the second and third columns have the “Good” and “Bad” counts per bin. (The number of observations is 1,200, so a perfect equal frequency binning would result in five bins with 240 observations each. In this case, the observations per bin do not match 240 exactly. This is a common situation when the data has repeated values.)

Monotone finds break points based on the cumulative proportion of “Good” observations. In the 'Iteration1' column, the first value (0.543) is the number of “Good” observations in the first bin (127), divided by the total number of observations in the bin (127+107). The second value (0.620) is the number of “Good” observations in bins 1 and 2, divided by the total number of observations in bins 1 and 2. And so forth. The first cut point is set where the minimum of this cumulative ratio is found, which is in the first bin in this example. This is the end of iteration 1.

Starting from the second bin (the first bin after the location of the minimum value in the previous iteration), cumulative proportions of “Good” observations are computed again. The second cut point is set where the minimum of this cumulative ratio is found. In this case, it happens to be in bin number 3, therefore bins 2 and 3 are merged.

The algorithm proceeds the same way for two more iterations. In this particular example, in the end it only merges bins 2 and 3. The final binning has four bins with cut points at 33,000, 42,000, and 47,000.

For categorical data, the only difference is that the preprocessing step consists in reordering the categories. Consider the following categorical data:

| Bin          | Good | Bad | Odds  |
|--------------|------|-----|-------|
| 'Home Owner' | 365  | 177 | 2.062 |
| 'Tenant'     | 307  | 167 | 1.838 |
| 'Other'      | 131  | 53  | 2.474 |

The preprocessing step, by default, sorts the categories by 'Odds'. (See the “Sort Categories” on page 19-1760 definition or the description of `AlgorithmOptions` option for 'SortCategories' for more information.) Then, it applies the same steps described above, shown in the following table:

| Bin          | Good | Bad | Odds  | Iteration1 | Iteration2 | Iteration3 |
|--------------|------|-----|-------|------------|------------|------------|
| 'Tenant'     | 307  | 167 | 1.838 | 0.648      |            |            |
| 'Home Owner' | 365  | 177 | 2.062 | 0.661      | 0.673      |            |
| 'Other'      | 131  | 53  | 2.472 | 0.669      | 0.683      | 0.712      |

In this case, the Monotone algorithm would not merge any categories. The only difference, compared with the data before the application of the algorithm, is that the categories are now sorted by 'Odds'.

In both the numeric and categorical examples above, the implicit 'Trend' choice is 'Increasing'. (See the description of `AlgorithmOptions` option for the 'Monotone' 'Trend' option.) If you set the trend to 'Decreasing', the algorithm looks for the maximum (instead of the minimum) cumulative ratios to determine the cut points. In that case, at iteration 1, the maximum would be in the last bin, which would imply that all bins should be merged into a single bin. Binning into a single bin is a total loss of information and has no practical use. Therefore, when the chosen trend leads to a single bin, the Monotone implementation rejects it, and the algorithm returns the bins found after the preprocessing step. This state is the initial equal frequency binning for numeric data and the sorted categories for categorical data. The implementation of the Monotone algorithm by default uses a heuristic to identify the trend ('Auto' option for 'Trend').

## Split

Split is a supervised automatic binning algorithm, where a measure is used to split the data into buckets. The supported measures are `gini`, `chi2`, `infovalue`, and `entropy`.

Internally, the split algorithm proceeds as follows:

- 1 All categories are merged into a single bin.
- 2 At the first iteration, all potential cutpoint indices are tested to see which one results in the maximum increase in the information function (Gini, InfoValue, Entropy, or Chi2). That cutpoint is then selected, and the bin is split.
- 3 The same procedure is reiterated for the next sub-bins.
- 4 The algorithm stops when the maximum number of bins is reached or when the splitting does not result in any additional change in the information change function.

The following table for a categorical predictor summarizes the values of the change function at each iteration. In this example, 'Gini' is the measure of choice, such that the goal is to see a decrease of the Gini measure at each iteration.

| Iteration<br>0 Bin<br>Number | Member       | Gini | Iteration<br>1 Bin<br>Number | Member       | Gini    | Iteration<br>2 Bin<br>Number | Member       | Gini    |
|------------------------------|--------------|------|------------------------------|--------------|---------|------------------------------|--------------|---------|
| 1                            | 'Tenant'     |      | 1                            | 'Tenant'     |         | 1                            | 'Tenant'     | 0.45638 |
| 1                            | 'Subletter'  |      | 1                            | 'Subletter'  | 0.44789 | 1                            | 'Subletter'  |         |
| 1                            | 'Home Owner' |      | 1                            | 'Home Owner' |         | 2                            | 'Home Owner' | 0.43984 |
| 1                            | 'Other'      |      | 2                            | 'Other'      | 0.41015 | 3                            | 'Other'      | 0.41015 |

| Iteration<br>0 Bin<br>Number | Member | Gini     | Iteration<br>1 Bin<br>Number | Member | Gini     | Iteration<br>2 Bin<br>Number | Member | Gini     |
|------------------------------|--------|----------|------------------------------|--------|----------|------------------------------|--------|----------|
| Total Gini                   |        | 0.442765 |                              |        | 0.442102 |                              |        | 0.441822 |
| Relative<br>Change           |        | 0        |                              |        | 0.001498 |                              |        | 0.002128 |

The relative change at iteration  $i$  is with respect to the Gini measure of the entire bins at iteration  $i-1$ . The final result corresponds to that from the last iteration which, in this example, is iteration 2.

The following table for a numeric predictor summarizes the values of the change function at each iteration. In this example, 'Gini' is the measure of choice, such that the goal is to see a decrease of the Gini measure at each iteration. Since most numeric predictors in datasets contain many bins, there is a preprocessing step where the data is pre-binned into 50 equal-frequency bins. This makes the pool of valid cutpoints to choose from for splitting smaller and more manageable.

| Iteration<br>0 Bin<br>Number | Member | Gini     | Iteration<br>1 Bin<br>Number | Gini     | Iteration<br>2 Bin<br>Number | Gini     | Iteration<br>3 Bin<br>Number | Gini     |
|------------------------------|--------|----------|------------------------------|----------|------------------------------|----------|------------------------------|----------|
| 1                            | '21'   |          | ' [-<br>Inf, 47]<br>'        | 0.473897 | ' [-<br>Inf, 47]<br>'        | 0.473897 | ' [-<br>Inf, 35]<br>'        | 0.494941 |
| 1                            | '22'   |          | ' [47, In<br>f] '            | 0.385238 | ' [47, 61<br>] '             | 0.407072 | ' [35,<br>47] '              | 0.463201 |
| 1                            | '23'   |          |                              |          | ' [61, In<br>f] '            | 0.208795 | ' [47,<br>61] '              | 0.407072 |
| 1                            | '74'   |          |                              | 0        |                              |          | ' [61, In<br>f] '            | 0.208795 |
| Total Gini                   |        | 0.442765 |                              | 0.435035 |                              | 0.432048 |                              | 0.430511 |
| Relative<br>Change           |        | 0        |                              | 0.01746  |                              | 0.006867 |                              | 0.0356   |

The resulting split must be such that the information function (content) increases. As such, the best split is the one that results in the maximum information gain. The information functions supported are:

- Gini: Each split results in an increase in the Gini Ratio, defined as:

$$G_r = 1 - G_{\hat{}}/G_p$$

$G_p$  is the Gini measure of the parent node, that is, of the given bins/categories prior to splitting.  
 $G_{\hat{}}$  is the weighted Gini measure for the current split:

$$G_{\hat{}} = \text{Sum}((n_j/N) * \text{Gini}(j), j=1..m)$$

where

$n_j$  is the total number of observations in the  $j$ th bin.

$N$  is the total number of observations in the dataset.

$m$  is the number of splits for the given variable.

$Gini(j)$  is the Gini measure for the  $j$ th bin.

The Gini measure for the split/node  $j$  is:

$$Gini(j) = 1 - (G_j^2 + B_j^2) / (n_j)^2$$

where  $G_j, B_j$  = Number of Goods and Bads for bin  $j$ .

- **InfoValue:** The information value for each split results in an increase in the total information. The split that is retained is the one which results in the maximum gain, within the acceptable gain tolerance. The Information Value (IV) for a given observation  $j$  is defined as:

$$IV = \sum (pG_i - pB_i) * \log(pG_i/pB_i), i=1..n$$

where

$pG_i$  is the distribution of Goods at observation  $i$ , that is  $Goods(i)/Total\_Goods$ .

$pB_i$  is the distribution of Bads at observation  $i$ , that is  $Bads(i)/Total\_Bads$ .

$n$  is the total number of bins.

- **Entropy:** Each split results in a decrease in entropy variance defined as:

$$E = -\sum(n_i * E_i, i=1..n)$$

where

$n_i$  is the total count for bin  $i$ , that is  $(n_i = G_i + B_i)$ .

$E_i$  is the entropy for row (or bin)  $i$ , defined as:

$$E_i = -\sum(G_i * \log_2(G_i/n_i) + B_i * \log_2(B_i/n_i)) / N, i=1..n$$

- **Chi2:** Chi2 is computed pairwise for each pair of bins and measures the statistical difference between two groups. Splitting is selected at a point (cutpoint or category indexing) where the maximum Chi2 value is:

$$Chi2 = \sum(\sum((A_{ij} - E_{ij})^2 / E_{ij}, j=1..k), i=m, m+1)$$

where

$m$  takes values from 1 ...  $n-1$ , where  $n$  is the number of bins.

$k$  is the number of classes. Here  $k = 2$  for the (Goods, Bads).

$A_{ij}$  is the number of observations in bin  $i$ ,  $j$ th class.

$E_{ij}$  is the expected frequency of  $A_{ij}$ , which is equal to  $(R_i * C_j) / N$ .

$R_i$  is the number of observations in bin  $i$ , which is equal to  $\sum(A_{ij}, j=1..k)$ .

$C_j$  is the number of observations in the  $j$ th class, which is equal to  $\sum(A_{ij}, I = m, m+1)$ .

$N$  is the total number of observations, which is equal to  $\sum(C_j, j=1..k)$ .

The Chi2 measure for the entire sample (as opposed to the pairwise Chi2 measure for adjacent bins) is:

$$\text{Chi2} = \text{sum}(\text{sum}((A_{ij} - E_{ij})^2/E_{ij}, j=1..k), i=1..n)$$

## Merge

Merge is a supervised automatic binning algorithm, where a measure is used to merge bins into buckets. The supported measures are chi2, gini, infovalue, and entropy.

Internally, the merge algorithm proceeds as follows:

- 1 All categories are initially in separate bins.
- 2 The user selected information function (Chi2, Gini, InfoValue or Entropy) is computed for any pair of adjacent bins.
- 3 At each iteration, the pair with the smallest information change measured by the selected information function is merged.
- 4 The merging continues until either:
  - a All pairwise information values are greater than the threshold set by the significance level or the relative change is smaller than the tolerance.
  - b If at the end, the number of bins is still greater than the MaxNumBins allowed, merging is forced until there are at most MaxNumBins bins. Similarly, merging stops when there are only MinNumBins bins.
- 5 For categorical, original bins/categories are pre-sorted according to the sorting of choice set by the user. For numeric data, the data is preprocessed to get InitialNumBins bins of equal frequency before the merging algorithm starts.

The following table for a categorical predictor summarizes the values of the change function at each iteration. In this example, 'Chi2' is the measure of choice. The default sorting by Odds is applied as a preprocessing step. The Chi2 value reported below at row  $i$  is for bins  $i$  and  $i+1$ . The significance level is 0.9 (90%), so that the inverse Chi2 value is 2.705543. This is the threshold below which adjacent pairs of bins are merged. The minimum number of bins is 2.

| Iteration<br>0 Bin<br>Number | Member          | Chi2     | Iteration<br>1 Bin<br>Number | Member          | Chi2     | Iteration<br>2 Bin<br>Number | Member          | Chi2     |
|------------------------------|-----------------|----------|------------------------------|-----------------|----------|------------------------------|-----------------|----------|
| 1                            | 'Tenant'        | 1.007613 | 1                            | 'Tenant'        | 0.795920 | 1                            | 'Tenant'        |          |
| 2                            | 'Subletter'     | 0.257347 | 2                            | 'Subletter'     |          | 1                            | 'Subletter'     |          |
| 3                            | 'Home<br>Owner' | 1.566330 | 2                            | 'Home<br>Owner' | 1.522914 | 1                            | 'Home<br>Owner' | 1.797395 |
| 4                            | 'Other'         |          | 3                            | 'Other'         |          | 2                            | 'Other'         |          |
| <i>Total Chi2</i>            |                 | 2.573943 |                              |                 | 2.317717 |                              |                 | 1.797395 |

The following table for a numeric predictor summarizes the values of the change function at each iteration. In this example, 'Chi2' is the measure of choice.

| Iteration 0 Bin Number | Chi2     | Iteration 1 Bins | Chi2    |     | Final Iteration Bins | Chi2   |
|------------------------|----------|------------------|---------|-----|----------------------|--------|
| '[- Inf,22]'           | 0.11814  | '[- Inf,22]'     | 0.11814 |     | '[- Inf,33]'         | 8.4876 |
| '[22,23]'              | 1.6464   | '[22,23]'        | 1.6464  |     | '[33, 48]'           | 7.9369 |
| ...                    |          | ...              |         |     | '[48,64]'            | 9.956  |
| '[58,59]'              | 0.311578 | '[58,59]'        | 0.27489 |     | '[64,65]'            | 9.6988 |
| '[59,60]'              | 0.068978 | '[59,61]'        | 1.8403  |     | '[65,Inf]'           | NaN    |
| '[60,61]'              | 1.8709   | '[61,62]'        | 5.7946  | ... |                      |        |
| '[61,62]'              | 5.7946   | ...              |         |     |                      |        |
| ...                    |          | '[69,70]'        | 6.4271  |     |                      |        |
| '[69,70]'              | 6.4271   | '[70,Inf]'       | NaN     |     |                      |        |
| '[70,Inf]'             | NaN      |                  |         |     |                      |        |
|                        |          |                  |         |     |                      |        |
| <i>Total Chi2</i>      | 67.467   |                  | 67.399  |     |                      | 23.198 |

The resulting merging must be such that any pair of adjacent bins is statistically different from each other, according to the chosen measure. The measures supported for Merge are:

- Chi2: Chi2 is computed pairwise for each pair of bins and measures the statistical difference between two groups. Merging is selected at a point (cutpoint or category indexing) where the maximum Chi2 value is:

$$\text{Chi2} = \sum(\sum((A_{ij} - E_{ij})^2/E_{ij}, j=1..k), i=m,m+1)$$

where

m takes values from 1 ... n-1, and n is the number of bins.

k is the number of classes. Here k = 2 for the (Goods, Bads).

$A_{ij}$  is the number of observations in bin i, jth class.

$E_{ij}$  is the expected frequency of  $A_{ij}$ , which is equal to  $(R_i * C_j) / N$ .

$R_i$  is the number of observations in bin i, which is equal to  $\sum(A_{ij}, j=1..k)$ .

$C_j$  is the number of observations in the jth class, which is equal to  $\sum(A_{ij}, I = m,m+1)$ .

N is the total number of observations, which is equal to  $\sum(C_j, j=1..k)$ .

The Chi2 measure for the entire sample (as opposed to the pairwise Chi2 measure for adjacent bins) is:

$$\text{Chi2} = \sum(\sum((A_{ij} - E_{ij})^2/E_{ij}, j=1..k), i=1..n)$$

- Gini: Each merge results in a decrease in the Gini Ratio, defined as:

$$G_r = 1 - G_{\text{hat}}/G_p$$

$G_p$  is the Gini measure of the parent node, that is, of the given bins/categories prior to merging.  
 $G_{\hat{}}$  is the weighted Gini measure for the current merge:

$$G_{\hat{}} = \text{Sum}((n_j/N) * \text{Gini}(j), j=1..m)$$

where

$n_j$  is the total number of observations in the  $j$ th bin.

$N$  is the total number of observations in the dataset.

$m$  is the number of merges for the given variable.

$\text{Gini}(j)$  is the Gini measure for the  $j$ th bin.

The Gini measure for the merge/node  $j$  is:

$$\text{Gini}(j) = 1 - (G_j^2 + B_j^2) / (n_j)^2$$

where  $G_j, B_j$  = Number of Goods and Bads for bin  $j$ .

- **InfoValue:** The information value for each merge will result in a decrease in the total information. The merge that is retained is the one which results in the minimum gain, within the acceptable gain tolerance. The Information Value (IV) for a given observation  $j$  is defined as:

$$IV = \text{sum}((pG_i - pB_i) * \log(pG_i/pB_i), i=1..n)$$

where

$pG_i$  is the distribution of Goods at observation  $i$ , that is  $\text{Goods}(i)/\text{Total\_Goods}$ .

$pB_i$  is the distribution of Bads at observation  $i$ , that is  $\text{Bads}(i)/\text{Total\_Bads}$ .

$n$  is the total number of bins.

- **Entropy:** Each merge results in an increase in entropy variance defined as:

$$E = -\text{sum}(n_i * E_i, i=1..n)$$

where

$n_i$  is the total count for bin  $i$ , that is  $(n_i = G_i + B_i)$ .

$E_i$  is the entropy for row (or bin)  $i$ , defined as:

$$E_i = -\text{sum}(G_i * \log_2(G_i/n_i) + B_i * \log_2(B_i/n_i)) / N, \\ i=1..n$$

---

**Note** When using the Merge algorithm, if there are pure bins (bins that have either zero count of Goods or zero count of Bads), the statistics such as Information Value and Entropy have non-finite values. To account for this, a frequency shift of .5 is applied for computing various statistics whenever the algorithm finds pure bins.

---

## Equal Frequency

Unsupervised algorithm that divides the data into a predetermined number of bins that contain approximately the same number of observations.

EqualFrequency is defined as:

Let  $v[1], v[2], \dots, v[N]$  be the sorted list of different values or categories observed in the data. Let  $f[i]$  be the frequency of  $v[i]$ . Let  $F[k] = f[1] + \dots + f[k]$  be the cumulative sum of frequencies up to the  $k$ th sorted value. Then  $F[N]$  is the same as the total number of observations.

Define  $\text{AvgFreq} = F[N] / \text{NumBins}$ , which is the ideal average frequency per bin after binning. The  $n$ th cut point index is the index  $k$  such that the distance  $\text{abs}(F[k] - n * \text{AvgFreq})$  is minimized.

This rule attempts to match the cumulative frequency up to the  $n$ th bin. If a single value contains too many observations, equal frequency bins are not possible, and the above rule yields less than  $\text{NumBins}$  total bins. In that case, the algorithm determines  $\text{NumBins}$  bins by breaking up bins, in the order in which the bins were constructed.

The preprocessing of categorical predictors consists in sorting the categories according to the 'SortCategories' criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the "Sort Categories" on page 19-1760 definition or the description of AlgorithmOptions option for 'SortCategories' for more information.

### Equal Width

Unsupervised algorithm that divides the range of values in the domain of the predictor variable into a predetermined number of bins of "equal width." For numeric data, the width is measured as the distance between bin edges. For categorical data, width is measured as the number of categories within a bin.

The EqualWidth option is defined as:

For numeric data, if `MinValue` and `MaxValue` are the minimum and maximum data values, then

$$\text{Width} = (\text{MaxValue} - \text{MinValue}) / \text{NumBins}$$

and the `CutPoints` are set to `MinValue + Width`, `MinValue + 2*Width`, ... `MaxValue - Width`. If a `MinValue` or `MaxValue` have not been specified using the `modifybins` function, the `EqualWidth` option sets `MinValue` and `MaxValue` to the minimum and maximum values observed in the data.

For categorical data, if there are  $\text{NumCats}$  numbers of original categories, then

$$\text{Width} = \text{NumCats} / \text{NumBins},$$

and set cut point indices to the rounded values of `Width`, `2*Width`, ..., `NumCats - Width`, plus 1.

The preprocessing of categorical predictors consists in sorting the categories according to the 'SortCategories' criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the "Sort Categories" on page 19-1760 definition or the description of AlgorithmOptions option for 'SortCategories' for more information.

### Sort Categories

As a preprocessing step for categorical data, 'Monotone', 'EqualFrequency', and 'EqualWidth' support the 'SortCategories' input. This serves the purpose of reordering the categories before applying the main algorithm. The default sorting criterion is to sort by 'Odds'. For example, suppose that the data originally looks like this:

| Bin          | Good | Bad | Odds  |
|--------------|------|-----|-------|
| 'Home Owner' | 365  | 177 | 2.062 |
| 'Tenant'     | 307  | 167 | 1.838 |
| 'Other'      | 131  | 53  | 2.472 |

After the preprocessing step, the rows would be sorted by 'Odds' and the table looks like this:

| Bin          | Good | Bad | Odds  |
|--------------|------|-----|-------|
| 'Tenant'     | 307  | 167 | 1.838 |
| 'Home Owner' | 365  | 177 | 2.062 |
| 'Other'      | 131  | 53  | 2.472 |

The three algorithms only merge adjacent bins, so the initial order of the categories makes a difference for the final binning. The 'None' option for 'SortCategories' would leave the original table unchanged. For a description of the sorting criteria supported, see the description of the AlgorithmOptions option for 'SortCategories'.

Upon the construction of a scorecard, the initial order of the categories, before any algorithm or any binning modifications are applied, is the order shown in the first output of `bininfo`. If the bins have been modified (either manually with `modifybins` or automatically with `autobinning`), use the optional output (cg, 'category grouping') from `bininfo` to get the current order of the categories.

The 'SortCategories' option has no effect on categorical predictors for which the 'Ordinal' parameter is set to true (see the 'Ordinal' input parameter in MATLAB categorical arrays for `categorical`). Ordinal data has a natural order, which is honored in the preprocessing step of the algorithms by leaving the order of the categories unchanged. Only categorical predictors whose 'Ordinal' parameter is false (default option) are subject to reordering of categories according to the 'SortCategories' criterion.

### Using autobinning with Weights

When observation weights are defined using the optional `WeightsVar` argument when creating a `creditscorecard` object, instead of counting the rows that are good or bad in each bin, the `autobinning` function accumulates the weight of the rows that are good or bad in each bin.

The "frequencies" reported are no longer the basic "count" of rows, but the "cumulative weight" of the rows that are good or bad and fall in a particular bin. Once these "weighted frequencies" are known, all other relevant statistics (Good, Bad, Odds, WOE, and InfoValue) are computed with the usual formulas. For more information, see "Credit Scorecard Modeling Using Observation Weights" on page 8-54.

### **Introduced in R2014b**

# probdefault

Likelihood of default for given data set

## Syntax

```
pd = probdefault(sc)
pd = probdefault(sc,data)
```

## Description

`pd = probdefault(sc)` computes the probability of default for `sc`, the data used to build the `creditscorecard` object.

`pd = probdefault(sc,data)` computes the probability of default for a given data set specified using the optional argument `data`.

By default, the data used to build the `creditscorecard` object are used. You can also supply input data, to which the same computation of probability of default is applied.

## Examples

### Compute Probability for Default Using Credit ScoreCard Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
  creditscorecard with properties:

      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x11 table]
```

Perform automatic binning using the default options. By default, autobinning uses the Monotone algorithm.

```
sc = autobinning(sc);
```

Fit the model.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06

## Compute Probability for Default Using Credit ScoreCard Data When Using the 'BinMissingData' Option

This example describes both the assignment of points for missing data when the 'BinMissingData' option is set to `true`, and the corresponding computation of probabilities of default.

- Predictors that have missing data in the training set have an explicit bin for `<missing>` with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the `<missing>` bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values, and the final score is mapped to a probability of default when using `probdefault`.
- Predictors with no missing data in the training set have no `<missing>` bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to `NaN`, and this leads to a score of `NaN` when running `score`. For predictors that have no explicit `<missing>` bin, use the name-value argument 'Missing' in `formatpoints` to indicate how missing data should be treated for scoring purposes. The final score is then mapped to a probability of default when using `probdefault`.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
```

|   | CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | OtherCC |
|---|--------|---------|-------------|-------------|-----------|------------|---------|---------|
| 1 |        | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Yes     |
| 2 |        | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Yes     |
| 3 |        | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No      |
| 4 |        | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Yes     |
| 5 |        | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Yes     |

Use `creditscorecard` with the name-value argument 'BinMissingData' set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Set a minimum value of 0 for `CustAge` and `CustIncome`. With this, any negative age or income information becomes invalid or "out-of-range". For scoring and probability of default computations, out-of-range values are given the same points as missing values.

```
sc = modifybins(sc, 'CustAge', 'MinValue', 0);
sc = modifybins(sc, 'CustIncome', 'MinValue', 0);
```

Display bin information for numeric data for '`CustAge`' that includes missing data in a separate bin labelled `<missing>`.

```
bi = bininfo(sc, 'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| { '[0,33)' }    | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |
| { '[33,37)' }   | 63   | 45  | 1.4    | -0.36795 | 0.012839   |
| { '[37,40)' }   | 72   | 47  | 1.5319 | -0.2779  | 0.0079824  |
| { '[40,46)' }   | 172  | 89  | 1.9326 | -0.04556 | 0.0004549  |
| { '[46,48)' }   | 59   | 25  | 2.36   | 0.15424  | 0.0016199  |
| { '[48,51)' }   | 99   | 41  | 2.4146 | 0.17713  | 0.0035449  |
| { '[51,58)' }   | 157  | 62  | 2.5323 | 0.22469  | 0.0088407  |
| { '[58,Inf]' }  | 93   | 25  | 3.72   | 0.60931  | 0.032198   |
| { '<missing>' } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| { 'Totals' }    | 803  | 397 | 2.0227 | NaN      | 0.087112   |

Display bin information for categorical data for '`ResStatus`' that includes missing data in a separate bin labelled `<missing>`.

```
bi = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin              | Good | Bad | Odds   | WOE       | InfoValue  |
|------------------|------|-----|--------|-----------|------------|
| { 'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| { 'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| { 'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| { '<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| { 'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

For the '`CustAge`' and '`ResStatus`' predictors, there is missing data (NaNs and `<undefined>`) in the training data, and the binning process estimates a WOE value of -0.15787 and 0.026469 respectively for missing data in these predictors, as shown above.

For `EmpStatus` and `CustIncome` there is no explicit bin for missing values because the training data has no missing values for these predictors.

```
bi = bininfo(sc, 'EmpStatus');
disp(bi)
```

| Bin            | Good | Bad | Odds   | WOE      | InfoValue |

| { 'Totals' }        | 803  | 397 | 2.0227  | NaN       | 0.12285    |

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 88.5, p-value = 2.55e-16

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the `'PointsOddsAndPDO'` argument of `formatpoints`. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]);
PointsInfo = displaypoints(sc)
```

```
PointsInfo=38x3 table
    Predictors      Bin      Points
    _____  _____  _____
    {'CustAge' }    {' [0,33)' }    54.062
    {'CustAge' }    {' [33,37)' }    56.282
    {'CustAge' }    {' [37,40)' }    60.012
    {'CustAge' }    {' [40,46)' }    69.636
    {'CustAge' }    {' [46,48)' }    77.912
    {'CustAge' }    {' [48,51)' }    78.86
    {'CustAge' }    {' [51,58)' }    80.83
    {'CustAge' }    {' [58,Inf]' }    96.76
    {'CustAge' }    {' <missing>' }    64.984
    {'ResStatus'}    {'Tenant' }    62.138
    {'ResStatus'}    {'Home Owner'}  73.248
    {'ResStatus'}    {'Other' }    90.828
    {'ResStatus'}    {'<missing>' }    74.125
    {'EmpStatus'}    {'Unknown' }    58.807
    {'EmpStatus'}    {'Employed' }    86.937
    {'EmpStatus'}    {'<missing>' }    NaN
    :
```

Notice that points for the <missing> bin for CustAge and ResStatus are explicitly shown (as 64.9836 and 74.1250, respectively). These points are computed from the WOE value for the <missing> bin and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin. By default the points are set to NaN for missing data, and they lead to a score of NaN when running `score`. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in `formatpoints` to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range, values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall 'MinValue' was earlier set to 0 for CustAge and CustIncome). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

```
tdata = dataMissing(11:18,mdl.PredictorNames); % Keep only the predictors retained in the model
% Set some missing values
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)
```

| CustAge | ResStatus   | EmpStatus   | CustIncome | TmWBank | OtherCC | AMBalance |
|---------|-------------|-------------|------------|---------|---------|-----------|
| NaN     | Tenant      | Unknown     | 34000      | 44      | Yes     | 119.8     |
| 48      | <undefined> | Unknown     | 44000      | 14      | Yes     | 403.62    |
| 65      | Home Owner  | <undefined> | 48000      | 6       | No      | 111.88    |
| 44      | Other       | Unknown     | NaN        | 35      | No      | 436.41    |
| -100    | Other       | Employed    | 46000      | 16      | Yes     | 162.21    |
| 33      | House       | Employed    | 36000      | 36      | Yes     | 845.02    |
| 39      | Tenant      | Freelancer  | 34000      | 40      | Yes     | 756.26    |
| 24      | Home Owner  | Employed    | -1         | 19      | Yes     | 449.61    |

Score the new data and see how points are assigned for missing CustAge and ResStatus, because we have an explicit bin with points for <missing>. However, for EmpStatus and CustIncome the score function sets the points to NaN. The corresponding probabilities of default are also set to NaN.

```
[Scores,Points] = score(sc,tdata);

```

Use the name-value argument 'Missing' in formatpoints to choose how to assign points to missing values for predictors that do not have an explicit <missing> bin. In this example, use the 'MinPoints' option for the 'Missing' argument. The minimum points for EmpStatus in the scorecard displayed above are 58.8072, and for CustIncome the minimum points are 29.3753. All rows now have a score and a corresponding probability of default.

```
sc = formatpoints(sc, 'Missing', 'MinPoints');
[Scores,Points] = score(sc,tdata);

## Input Arguments

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. To create this object, use `creditscorecard`.

### **data** — Dataset to apply probability of default rules

table

(Optional) Dataset to apply probability of default rules, specified as a MATLAB table, where each row corresponds to individual observations. The data must contain columns for each of the predictors in the `creditscorecard` object.

Data Types: table

## Output Arguments

### pd — Probability of default

array

Probability of default, returned as a NumObs-by-1 numerical array of default probabilities.

## More About

### Default Probability

After the unscaled scores are computed (see “Algorithms for Computing and Scaling Scores” on page 19-1586), the probability of the points being “Good” is represented by the following formula:

$$\text{ProbGood} = 1. / (1 + \exp(-\text{UnscaledScores}))$$

Thus, the probability of default is

$$\text{pd} = 1 - \text{ProbGood}$$

### Introduced in R2015a

## validatemodel

Validate quality of credit scorecard model

### Syntax

```
Stats = validatemodel(sc)
Stats = validatemodel(sc,data)
[Stats,T] = validatemodel(sc,Name,Value)
[Stats,T,hf] = validatemodel(sc,Name,Value)
```

### Description

`Stats = validatemodel(sc)` validates the quality of the `creditscorecard` model.

By default, the data used to build the `creditscorecard` object is used. You can also supply input data to which the validation is applied.

`Stats = validatemodel(sc,data)` validates the quality of the `creditscorecard` model for a given data set specified using the optional argument `data`.

`[Stats,T] = validatemodel(sc,Name,Value)` validates the quality of the `creditscorecard` model using the optional name-value pair arguments, and returns `Stats` and `T` outputs.

`[Stats,T,hf] = validatemodel(sc,Name,Value)` validates the quality of the `creditscorecard` model using the optional name-value pair arguments, and returns the figure handle `hf` to the CAP, ROC, and KS plots.

### Examples

#### Validate a Credit Scorecard Model

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar','CustID')

sc =
  creditscorecard with properties:

      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x11 table]
```

Perform automatic binning using the default options. By default, autobinning uses the Monotone algorithm.

```
sc = autobinning(sc);
```

Fit the model.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601

### Validate a Credit Score Card Model With Weights

Use the `CreditCardData.mat` file to load the data (`dataWeights`) that contains a column (`RowWeights`) for the weights (using a dataset from Refaat 2011).

```
load CreditCardData
```

Create a `creditscorecard` object using the optional name-value pair argument for `'WeightsVar'`.

```
sc = creditscorecard(dataWeights, 'IDVar', 'CustID', 'WeightsVar', 'RowWeights')
```

```
sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: 'RowWeights'
    VarNames: {1x12 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x12 table]
```

Perform automatic binning.

```
sc = autobinning(sc)
```

```
sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: 'RowWeights'
    VarNames: {1x12 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x12 table]
```

Fit the model.

```
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 764.3187, Chi2Stat = 15.81927, PValue = 6.968927e-05
2. Adding `TmWBank`, Deviance = 751.0215, Chi2Stat = 13.29726, PValue = 0.0002657942
3. Adding `AMBBalance`, Deviance = 743.7581, Chi2Stat = 7.263384, PValue = 0.007037455

Generalized linear regression model:  
`logit(status) ~ 1 + CustIncome + TmWBank + AMBalance`  
 Distribution = Binomial

Estimated Coefficients:

|             | Estimate | SE       | tStat  | pValue     |
|-------------|----------|----------|--------|------------|
| (Intercept) | 0.70642  | 0.088702 | 7.964  | 1.6653e-15 |
| CustIncome  | 1.0268   | 0.25758  | 3.9862 | 6.7132e-05 |
| TmWBank     | 1.0973   | 0.31294  | 3.5063 | 0.0004543  |
| AMBalance   | 1.0039   | 0.37576  | 2.6717 | 0.0075464  |

1200 observations, 1196 error degrees of freedom  
 Dispersion: 1  
 Chi^2-statistic vs. constant model: 36.4, p-value = 6.22e-08

Format the unscaled points.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500,2,50]);
```

Score the data.

```
scores = score(sc);
```

Validate the credit scorecard model by generating the CAP, ROC, and KS plots. When the optional name-value pair argument 'WeightsVar' is used to specify observation (sample) weights, the T table uses statistics, sums, and cumulative sums that are weighted counts.

```
[Stats,T] = validatemodel(sc, 'Plot', {'CAP', 'ROC', 'KS'});
```

### Validate a Credit Score Card Model When Using the 'BinMissingData' Option

This example describes both the assignment of points for missing data when the 'BinMissingData' option is set to `true`, and the corresponding computation of model validation statistics.

- Predictors that have missing data in the training set have an explicit bin for `<missing>` with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the `<missing>` bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values, and the final score is used to compute model validation statistics with `validateModel`.
- Predictors with no missing data in the training set have no `<missing>` bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to `NaN`, and this leads to a score of `NaN` when running `score`. For predictors that have no explicit `<missing>` bin, use the name-value argument 'Missing' in `formatPoints` to indicate how missing data should be treated for scoring purposes. The final score is used to compute model validation statistics with `validateModel`.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

ans=5×11 table

|   | CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | OtherCC |
|---|--------|---------|-------------|-------------|-----------|------------|---------|---------|
| 1 |        | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Yes     |
| 2 |        | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Yes     |
| 3 |        | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No      |
| 4 |        | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Yes     |
| 5 |        | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Yes     |

Use `creditscorecard` with the name-value argument 'BinMissingData' set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
```

```
IDVar: 'CustID'
PredictorVars: {1x9 cell}
Data: [1200x11 table]
```

Set a minimum value of zero for CustAge and CustIncome. With this, any negative age or income information becomes invalid or "out-of-range". For scoring and probability of default computations, out-of-range values are given the same points as missing values.

```
sc = modifybins(sc, 'CustAge', 'MinValue', 0);
sc = modifybins(sc, 'CustIncome', 'MinValue', 0);
```

Display bin information for numeric data for 'CustAge' that includes missing data in a separate bin labelled <missing>.

```
bi = bininfo(sc, 'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the 'PointsOddsAndPDO' argument of formatpoints. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]);
PointsInfo = displaypoints(sc)
```

PointsInfo=38x3 table

| { 'EmpStatus' } | { '<missing>' }  | NaN    |
|                 | :                |        |

Notice that points for the <missing> bin for CustAge and ResStatus are explicitly shown (as 64.9836 and 74.1250, respectively). These points are computed from the WOE value for the <missing> bin, and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin. By default the points are set to NaN for missing data, and they lead to a score of NaN when running score. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in formatpoints to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range, values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall 'MinValue' was earlier set to 0 for CustAge and CustIncome). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

This is a very small validation data set, only used to illustrate the scoring of rows with missing and out-of-range values, and its relationship with model validation.

```
tdata = dataMissing(11:18,mdl.PredictorNames); % Keep only the predictors retained in the model
tdata.status = dataMissing.status(11:18); % Copy the response variable value, needed for validation
% Set some missing values
tdata.CustAge(1) = NaN;
```

```

tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)

```

| CustAge | ResStatus   | EmpStatus   | CustIncome | TmWBank | OtherCC | AMBalance | st |
|---------|-------------|-------------|------------|---------|---------|-----------|----|
| NaN     | Tenant      | Unknown     | 34000      | 44      | Yes     | 119.8     | :  |
| 48      | <undefined> | Unknown     | 44000      | 14      | Yes     | 403.62    | 0  |
| 65      | Home Owner  | <undefined> | 48000      | 6       | No      | 111.88    | 0  |
| 44      | Other       | Unknown     | NaN        | 35      | No      | 436.41    | 0  |
| -100    | Other       | Employed    | 46000      | 16      | Yes     | 162.21    | 0  |
| 33      | House       | Employed    | 36000      | 36      | Yes     | 845.02    | 0  |
| 39      | Tenant      | Freelancer  | 34000      | 40      | Yes     | 756.26    | :  |
| 24      | Home Owner  | Employed    | -1         | 19      | Yes     | 449.61    | 0  |

Score the new data and see how points are assigned for missing `CustAge` and `ResStatus`, because we have an explicit bin with points for `<missing>`. However, for `EmpStatus` and `CustIncome` the score function sets the points to `NaN`.

The validation results are unreliable, the scores with `NaN` values are kept (see the validation table `ValTable` below), but it is unclear what impact these `NaN` values have in the validation statistics (`ValStats`). This is a very small validation data set, but `NaN` scores could still influence the validation results on a larger data set.

| NaN    | NaN         | 1        | 3         | 3         | 1          | 0.5         |
| 481.22 | 0.39345     | 2        | 3         | 3         | 0          | 1           |
| 487.96 | 0.3714      | 2        | 4         | 2         | 0          | 1           |
| 520.84 | 0.2725      | 2        | 5         | 1         | 0          | 1           |
| 551.79 | 0.19605     | 2        | 6         | 0         | 0          | 1           |

Use the name-value argument 'Missing' in formatpoints to choose how to assign points to missing values for predictors that do not have an explicit <missing> bin. In this example, use the 'MinPoints' option for the 'Missing' argument. The minimum points for EmpStatus in the scorecard displayed above are 58.8072 and for CustIncome the minimum points are 29.3753.

The validation results are no longer influenced by NaN values, since all rows now have a score.

```
sc = formatpoints(sc, 'Missing', 'MinPoints');
[Scores,Points] = score(sc, tdata);
disp(Scores)
```

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. To create this object, use `creditscorecard`.

### data — Validation data

table

(Optional) Validation data, specified as a MATLAB table, where each table row corresponds to individual observations. The `data` must contain columns for each of the predictors in the credit scorecard model. The columns of data can be any one of the following data types:

- Numeric
- Logical
- Cell array of character vectors
- Character array
- Categorical
- String
- String array

In addition, the table must contain a binary response variable.

---

**Note** When observation weights are defined using the optional `WeightsVar` name-value pair argument when creating a `creditscorecard` object, the weights stored in the `WeightsVar` column are used when validating the model on the training data. If a different validation data set is provided using the optional `data` input, observation weights for the validation data must be included in a

column whose name matches `WeightsVar`, otherwise unit weights are used for the validation data. For more information, see “Using `validatemodel` with `Weights`” on page 19-1792.

---

Data Types: `table`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `sc = validatemodel(sc,data,'AnalysisLevel','Deciles','Plot','CAP')`

### AnalysisLevel — Type of analysis level

'Scores' (default) | character vector with values 'Deciles', 'Scores'

Type of analysis level, specified as the comma-separated pair consisting of 'AnalysisLevel' and a character vector with one of the following values:

- 'Scores' — Returns the statistics (`Stats`) at the observation level. Scores are sorted from riskiest to safest, and duplicates are removed.
- 'Deciles' — Returns the statistics (`Stats`) at decile level. Scores are sorted from riskiest to safest and binned with their corresponding statistics into 10 deciles (10%, 20%, ..., 100%).

Data Types: `char`

### Plot — Type of plot

'None' (default) | character vector with values 'None', 'CAP', 'ROC', 'KS' | cell array of character vectors with values 'None', 'CAP', 'ROC', 'KS'

Type of plot, specified as the comma-separated pair consisting of 'Plot' and a character vector with one of the following values:

- 'None' — No plot is displayed.
- 'CAP' — Cumulative Accuracy Profile. Plots the fraction of borrowers up to score “s” versus the fraction of defaulters up to score “s” ('PctObs' versus 'Sensitivity' columns of T optional output argument). For more details, see “Cumulative Accuracy Profile (CAP)” on page 19-1791.
- 'ROC' — Receiver Operating Characteristic. Plots the fraction of non-defaulters up to score “s” versus the fraction of defaulters up to score “s” ('FalseAlarm' versus 'Sensitivity' columns of T optional output argument). For more details, see “Receiver Operating Characteristic (ROC)” on page 19-1791.
- 'KS' — Kolmogorov-Smirnov. Plots each score “s” versus the fraction of defaulters up to score “s,” and also versus the fraction of non-defaulters up to score “s” ('Scores' versus both 'Sensitivity' and 'FalseAlarm' columns of the optional output argument T). For more details, see “Kolmogorov-Smirnov statistic (KS)” on page 19-1791.

---

**Tip** For the Kolmogorov-Smirnov statistic option, you can enter 'KS' or 'K-S'.

---

Data Types: `char` | `cell`

## Output Arguments

### Stats — Validation measures

table

Validation measures, returned as a 4-by-2 table. The first column, 'Measure', contains the names of the following measures:

- Accuracy ratio (AR)
- Area under the ROC curve (AUROC)
- The KS statistic
- KS score

The second column, 'Value', contains the values corresponding to these measures.

### T — Validation statistics data

array

Validation statistics data, returned as an N-by-9 table of validation statistics data, sorted, by score, from riskiest to safest. When `AnalysisLevel` is set to 'Deciles', N is equal to 10. Otherwise, N is equal to the total number of unique scores, that is, scores without duplicates.

The table T contains the following nine columns, in this order:

- 'Scores' — Scores sorted from riskiest to safest. The data in this row corresponds to all observations up to, and including the score in this row.
- 'ProbDefault' — Probability of default for observations in this row. For deciles, the average probability of default for all observations in the given decile is reported.
- 'TrueBads' — Cumulative number of "bads" up to, and including, the corresponding score.
- 'FalseBads' — Cumulative number of "goods" up to, and including, the corresponding score.
- 'TrueGoods' — Cumulative number of "goods" above the corresponding score.
- 'FalseGoods' — Cumulative number of "bads" above the corresponding score.
- 'Sensitivity' — Fraction of defaulters (or the cumulative number of "bads" divided by total number of "bads"). This is the distribution of "bads" up to and including the corresponding score.
- 'FalseAlarm' — Fraction of non-defaulters (or the cumulative number of "goods" divided by total number of "goods"). This is the distribution of "goods" up to and including the corresponding score.
- 'PctObs' — Fraction of borrowers, or the cumulative number of observations, divided by total number of observations up to and including the corresponding score.

---

**Note** When creating the `creditscorecard` object with `creditscorecard`, if the optional name-value pair argument `WeightsVar` was used to specify observation (sample) weights, then the T table uses statistics, sums, and cumulative sums that are weighted counts.

---

### hf — Handle to the plotted measures

figure handle

Figure handle to plotted measures, returned as a figure handle or array of handles. When `Plot` is set to 'None', hf is an empty array.

## More About

### Cumulative Accuracy Profile (CAP)

CAP is generally a concave curve and is also known as the Gini curve, Power curve, or Lorenz curve.

The scores of given observations are sorted from riskiest to safest. For a given fraction  $M$  (0% to 100%) of the total borrowers, the height of the CAP curve is the fraction of defaulters whose scores are less than or equal to the maximum score of the fraction  $M$ , also known as "Sensitivity."

The area under the CAP curve, known as the AUCAP, is then compared to that of the perfect or "ideal" model, leading to the definition of a summary index known as the accuracy ratio ( $AR$ ) or the Gini coefficient:

$$AR = \frac{A_R}{A_P}$$

where  $A_R$  is the area between the CAP curve and the diagonal, and  $A_P$  is the area between the perfect model and the diagonal. This represents a "random" model, where scores are assigned randomly and therefore the proportion of defaulters and non-defaulters is independent of the score. The perfect model is the model for which all defaulters are assigned the lowest scores, and therefore, perfectly discriminates between defaulters and nondefaulters. Thus, the closer to unity  $AR$  is, the better the scoring model.

### Receiver Operating Characteristic (ROC)

To find the receiver operating characteristic (ROC) curve, the proportion of defaulters up to a given score "s," or "Sensitivity," is computed.

This proportion is known as the true positive rate (TPR). Additionally, the proportion of nondefaulters up to score "s," or "False Alarm Rate," is also computed. This proportion is also known as the false positive rate (FPR). The ROC curve is the plot of the "Sensitivity" vs. the "False Alarm Rate." Computing the ROC curve is similar to computing the equivalent of a confusion matrix at each score level.

Similar to the CAP, the ROC has a summary statistic known as the area under the ROC curve (AUROC). The closer to unity, the better the scoring model. The accuracy ratio ( $AR$ ) is related to the area under the curve by the following formula:

$$AR = 2(AUROC) - 1$$

### Kolmogorov-Smirnov statistic (KS)

The Kolmogorov-Smirnov (KS) plot, also known as the fish-eye graph, is a common statistic used to measure the predictive power of scorecards.

The KS plot shows the distribution of defaulters and the distribution of non-defaulters on the same plot. For the distribution of defaulters, each score "s" is plotted versus the proportion of defaulters up to "s," or "Sensitivity." For the distribution of non-defaulters, each score "s" is plotted versus the proportion of non-defaulters up to "s," or "False Alarm." The statistic of interest is called the KS statistic and is the maximum difference between these two distributions ("Sensitivity" minus "False Alarm"). The score at which this maximum is attained is also of interest.

## Using `validatemodel` with Weights

Model validation statistics incorporate observation weights when these are provided by the user.

Without weights, the validation statistics are based on how many good and bad observations fall below a particular score. On the other hand, when observation weights are provided, the weight (not the count) is accumulated for the good and the bad observations that fall below a particular score.

When observation weights are defined using the optional `WeightsVar` name-value pair argument when creating a `creditscorecard` object, the weights stored in the `WeightsVar` column are used when validating the model on the training data. When a different validation data set is provided using the optional `data` input, observation weights for the validation data must be included in a column whose name matches `WeightsVar`, otherwise unit weights are used for the validation data set.

Not only the validation statistics, but the credit scorecard scores themselves depend on the observation weights of the training data. For more information, see “Using `fitmodel` with Weights” on page 19-1645 and “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

## Introduced in R2015a

# fillmissing

Replace missing values for credit scorecard predictors

## Syntax

```
sc = fillmissing(sc,PredictorNames,Statistics)
sc = fillmissing( ___,ConstantValue)
```

## Description

`sc = fillmissing(sc,PredictorNames,Statistics)` replaces missing values of the predictor `PredictorNames` with values defined by `Statistics` and returns an updated credit scorecard object (`sc`). Standard missing data is defined as follows:

- NaN for numeric arrays
- <undefined> for categorical arrays

---

**Note** If you run `fillmissing` after binning a predictor, the existing cutpoints and bin edges are preserved and the "Good" and "Bad" counts from the <missing> bin are added to the corresponding bin.

---

`sc = fillmissing( ___,ConstantValue)` uses arguments from the previous syntax and a value for a `ConstantValue` to replace missing values.

## Examples

### Fill Missing Data in a creditScorecard Object

This example shows how to use `fillmissing` to replace missing values in the `CustAge` and `ResStatus` predictors with user-defined values. For additional information on alternative approaches for "treating" missing data, see "Credit Scorecard Modeling with Missing Values" on page 8-56.

Load the credit scorecard data and use `dataMissing` for the training data.

```
load CreditCardData.mat
disp(head(dataMissing));
```

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | Othe |
|--------|---------|-------------|-------------|-----------|------------|---------|------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Ye   |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Ye   |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No   |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Ye   |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Ye   |
| 6      | 65      | 13          | Home Owner  | Employed  | 48000      | 59      | Ye   |
| 7      | 34      | 32          | Home Owner  | Unknown   | 32000      | 26      | Ye   |
| 8      | 50      | 57          | Other       | Employed  | 51000      | 33      | No   |

Create a `creditscorecard` object with `'BinMissingData'` set to `true`.

```
sc = creditscorecard(dataMissing, 'BinMissingData', true);
sc = autobin视角(sc);
```

Use `bininfo` and `plotbins` to display the `CustAge` and `ResStatus` predictors with missing data.

```
bininfo(sc, 'CustAge')
```

```

{'CustIncome' } {'[35000,40000)'} } 101.44
:

```

When a validation data set has missing values and you use `fillmissing` with the training dataset, the missing values in the validation data set are assigned the same points as the corresponding bins containing the filled values.

As the table shows, the '`<missing>`' bin for the `CustAge` predictor is assigned the same points as the '`[40,46)`' bin because the missing data is filled with the median value 45.

The points assigned to the '`<missing>`' bin for the `EmpStatus` predictor are `NaN` because `fillmissing` is not used for that predictor. The assigned points are decided by the default '`NoScore`' for the '`Missing`' name-value pair argument in `formatpoints`.

Create a test validation data set (`tdata`) and add missing values.

```

tdata = data(1:10,:);
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
[scr,pts] = score(sc,tdata)

```

```
scr = 10×1

## Handling of Missing Values in Validation Data Sets

This example shows different possibilities for handling missing data in validation data.

When scoring data from a validation data set, you have several options. If you choose to do nothing, the points assigned to the missing data are NaN, which comes from the default 'NoScore' for the 'Missing' name-value pair argument in `formatpoints`.

If you want to score missing values of all the predictors with one consistent metric, you can use the options 'ZeroWOE', 'MinPoints', or 'MaxPoints' for the 'Missing' name-value pair argument in `formatpoints`.

```

load CreditCardData.mat
sc = creditscorecard(data);
predictorinfo(sc, 'CustAge')

```

```
ans=1x4 table
```

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object.

### PredictorNames — Name of creditscorecard predictor whose missing data is filled

character vector | string | cell array of character vectors | string array

Name of `creditscorecard` predictor to fill missing data for, specified as a scalar character vector, scalar string, cell array of character vectors, or string array.

Data Types: `char` | `string` | `cell`

### Statistics — Statistic to use to fill missing data for predictors

character vector with a value of 'mean', 'median', 'mode', 'original', or 'constant' | string with a value of "mean", "median", "mode", "original", or "constant"

Statistic to use to fill missing data for the predictors, specified as a character vector or string with one of the following values.

- 'mean' — Replace missing data with the average or mean value. The option is valid only for numeric data. The 'mean' calculates the weighted mean of the predictor by referring to the

predictor column and the `Weights` column from the `creditscorecard` object. For more information, see “Weighted Mean” on page 19-1803.

- `'median'` — Replace missing data with the median value. Valid for numeric and ordinal data. The `'median'` calculates the weighted median of the predictor by referring to the predictor column and the `Weights` column from the `creditscorecard` object. For more information, see “Weighted Median” on page 19-1804.
- `'mode'` — Replace missing data with the mode. Valid for numeric and both nominal and ordinal categorical data. The `'mode'` calculates the weighted mode of the predictor by referring to the predictor column and the `Weights` column from the `creditscorecard` object. For more information, see “Weighted Mode” on page 19-1804.
- `'original'` — Set the missing data for numeric and categorical predictors back to its original value: `NaN` if numeric, `<undefined>` or `<missing>` if categorical.
- `'constant'` — Set the missing data for numeric and categorical predictors to a constant value that you specify in the optional argument for `ConstantValue`.

Data Types: `char` | `string`

### **ConstantValue** — Value to fill missing entries in predictors specified in `PredictorNames`

[ ] (default) | numeric | character vector | string | cell array of character vectors | string array

(Optional) Value to fill missing entries in predictors specified in `PredictorNames`, specified as a numeric value, character vector, string, or cell array of character vectors.

---

**Note** You can use `ConstantValue` only if you set the `Statistics` argument to `'constant'`.

---

Data Types: `char` | `double` | `string` | `cell`

## **Output Arguments**

### **sc** — Updated `creditscorecard`

`creditscorecard` object

Updated `creditscorecard` object, returned as an object.

## **More About**

### **Weighted Mean**

The weighted mean is similar to an ordinary mean except that instead of each of the data points contributing equally to the final average, some data points contribute more than others.

The weighted mean for a nonempty finite multiset of data ( $x$ ) with corresponding nonnegative weights ( $w$ ) is

$$\bar{x} = \frac{\sum_{i=1}^n w_i x_i}{\sum_{i=1}^n w_i}$$

## Weighted Median

The weighted median is the 50% weighted percentile, where the percentage in the total weight is counted instead of the total number.

For  $n$  distinct ordered elements ( $x$ ) positive weights ( $w$ ) such that  $\sum_{i=1}^n w_i = 1$ , the weighted median is the element  $x_k$ :

$$\sum_{i=1}^{k-1} w_i \leq \frac{1}{2} \text{ and } \sum_{i=k+1}^n w_i \leq \frac{1}{2}$$

In the case where the respective weights of both elements border the midpoint of the set of weights without encapsulating it, each element defines a partition equal to  $1/2$ . These elements are referred to as the lower weighted median and upper weighted median. The weighted median is chosen based on which element keeps the partitions most equal. This median is always the weighted median with the lowest weight. In the event that the upper and lower weighted medians are equal, the lower weighted median is accepted.

## Weighted Mode

The weighted mode of a set of weighted data values is the value that appears most often.

The mode of a sample is the element that occurs most often in the collection. For example, the mode of the sample [1, 3, 6, 6, 6, 6, 7, 7, 12, 12, 17] is 6.

## Introduced in R2020a

# creditscorecard

Create `creditscorecard` object to build credit scorecard model

## Description

Build a credit scorecard model by creating a `creditscorecard` object and specify input data in a table format.

After creating a `creditscorecard` object, you can use the associated object functions to bin the data and perform logistic regression analysis to develop a credit scorecard model to guide credit decisions. This workflow shows how to develop a credit scorecard model.

- 1 Use `screenpredictors` from Risk Management Toolbox to pare down a potentially large set of predictors to a subset that is most predictive of the credit score card response variable. Use this subset of predictors when creating the `creditscorecard` object.
- 2 Create a `creditscorecard` object (see “Create `creditscorecard`” on page 19-1805 and “Properties” on page 19-1808).
- 3 Bin the data using `autobinning`.
- 4 Fit a logistic regression model using `fitmodel` or `fitConstrainedModel`.
- 5 Review and format the credit scorecard points using `displaypoints` and `formatpoints`. At this point in the workflow, if you have a license for Risk Management Toolbox, you have the option to create a `compactCreditScorecard` object (`csc`) using the `compact` function. You can then use the following functions `displaypoints`, `score`, and `probdefault` from the Risk Management Toolbox with the `csc` object.
- 6 Score the data using `score`.
- 7 Calculate the probabilities of default for the data using `probdefault`.
- 8 Validate the quality of the credit scorecard model using `validatemodel`.

For more detailed information on this workflow, see “Credit Scorecard Modeling Workflow” on page 8-51.

## Creation

### Syntax

```
sc = creditscorecard(data)
sc = creditscorecard( ___, Name, Value)
```

### Description

`sc = creditscorecard(data)` creates a `creditscorecard` object by specifying `data`. The credit scorecard model, returned as a `creditscorecard` object, contains the binning maps or rules (cut points or category groupings) for one or more predictors.

`sc = creditscorecard( ___, Name, Value)` sets Properties on page 19-1808 using name-value pairs and any of the arguments in the previous syntax. For example, `sc =`

`creditscorecard(data, 'GoodLabel', 0, 'IDVar', 'CustID', 'ResponseVar', 'status', 'PredictorVars', {'CustAge', 'CustIncome'}, 'WeightsVar', 'RowWeights', 'BinMissingData', true)`. You can specify multiple name-value pairs.

---

**Note** To use observation (sample) weights in the credit scorecard workflow, when creating a `creditscorecard` object, you must use the optional name-value pair `WeightsVar` to define which column in the `data` contains the weights.

---

## Input Arguments

### **data** — Data for `creditscorecard` object

table

Data for the `creditscorecard` object, specified as a MATLAB table, where each column of data can be any one of the following data types:

- Numeric
- Logical
- Cell array of character vectors
- Character array
- Categorical
- String

In addition, the table must contain a binary response variable. Before creating a `creditscorecard` object, perform a data preparation task to have appropriately structured data as input to a `creditscorecard` object. The `data` input sets the `Data` on page 19-0 property.

Data Types: table

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `sc =`

```
creditscorecard(data, 'GoodLabel', 0, 'IDVar', 'CustAge', 'ResponseVar', 'status', 'PredictorVars', {'CustID', 'CustIncome'}, 'WeightsVar', 'RowWeights', 'BinMissingData', true)
```

### **GoodLabel** — Indicator for which of two possible values in response variable correspond to “Good” observations

set to the response value with the highest count (default) | character vector | numeric scalar | logical

Indicator for which of the two possible values in the response variable correspond to “Good” observations, specified as the comma-separated pair consisting of `'GoodLabel'` and a numeric scalar, logical, or character vector. The `GoodLabel` name-value pair argument sets the `GoodLabel` on page 19-0 property.

When specifying `GoodLabel`, follow these guidelines.

| If Response Variable is...      | GoodLabel Must be... |
|---------------------------------|----------------------|
| numeric                         | numeric              |
| logical                         | logical or numeric   |
| cell array of character vectors | character vector     |
| character array                 | character vector     |
| categorical                     | character vector     |

If not specified, `GoodLabel` is set to the response value with the highest count. However, if the optional `WeightsVar` argument is provided when creating the `creditscorecard` object, then counts are replaced with weighted frequencies. For more information, see “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

`GoodLabel` can only be set when creating the `creditscorecard` object. This parameter cannot be set using dot notation.

Data Types: `char` | `double`

### **IDVar — Variable name used as ID or tag for observations**

empty character vector `''` (default) | character vector

Variable name used as ID or tag for the observations, specified as the comma-separated pair consisting of `'IDVar'` and a character vector. The `IDVar` data could be an ordinal number (for example, 1,2,3...), a Social Security number. This is provided as a convenience to remove this column from the predictor variables. `IDVar` is case-sensitive. The `IDVar` name-value pair argument sets the `IDVar` on page 19-0 property.

You can set this optional parameter using the `creditscorecard` function or by using dot notation at the command line, as follows.

Example: `sc.IDVar = 'CustID'`

Data Types: `char`

### **ResponseVar — Response variable name for “Good” or “Bad” indicator**

last column of the data input (default) | character vector

Response variable name for the “Good” or “Bad” indicator, specified as the comma-separated pair consisting of `'ResponseVar'` and a character vector. The response variable data must be binary. The `ResponseVar` name-value pair argument sets the `ResponseVar` on page 19-0 property.

If not specified, `ResponseVar` is set to the last column of the data input. `ResponseVar` can only be set when creating the `creditscorecard` object using the `creditscorecard` function. `ResponseVar` is case-sensitive.

Data Types: `char`

### **WeightsVar — Weights variable name**

empty character vector `''` (default) | character vector

Weights variable name, specified as the comma-separated pair consisting of `'WeightsVar'` and a character vector to indicate which column name in the `data` table contains the row weights. `WeightsVar` is case-sensitive. The `WeightsVar` name-value pair argument sets the `WeightsVar` on page 19-0 property, and this property can only be set at the creation of a `creditscorecard`

object. If the name-value pair argument `WeightsVar` is not specified when creating a `creditscorecard` object, then observation weights are set to unit weights by default.

The `WeightsVar` values are used in the credit scorecard workflow by `autobinning`, `bininfo`, `fitmodel`, and `validatemodel`. For more information, see “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

Data Types: `char`

**BinMissingData** — Indicates if missing data is removed or displayed in a separate bin  
`false` (missing data removed) (default) | logical with value `true` or `false`

Indicates if missing data is removed or displayed in a separate bin, specified as the comma-separated pair consisting of `'BinMissingdata'` and a logical scalar with a value of `true` or `false`. If `BinMissingData` is `true`, the missing data for a predictor is displayed in a separate bin labeled `<missing>`.

Data Types: `logical`

## Properties

**Data** — Data used to create the `creditscorecard` object  
`table`

Data used to create the `creditscorecard` object, specified as a table when creating a `creditscorecard` object. In the `Data` property, categorical predictors are stored as categorical arrays.

Example: `sc.Data(1:10, :)`

Data Types: `table`

**IDVar** — Name of the variable used as ID or tag for the observations  
empty character vector `''` (default) | character vector

Name of the variable used as ID or tag for the observations, specified as a character vector. This property can be set as an optional parameter when creating a `creditscorecard` object or by using dot notation at the command line. `IDVar` is case-sensitive.

Example: `sc.IDVar = 'CustID'`

Data Types: `char`

**VarNames** — All variable names from the data input  
`VarNames` come directly from data input to `creditscorecard` object (default)

This property is read-only.

`VarNames` is a cell array of character vectors containing the names of all variables in the data. The `VarNames` come directly from the data input to the `creditscorecard` object. `VarNames` is case-sensitive.

Data Types: `cell`

**ResponseVar** — Name of the response variable, “Good” or “Bad” indicator  
last column of the data input (default) | character vector

Name of the response variable, “Good” or “Bad” indicator, specified as a character vector. The response variable data must be binary. If not specified, `ResponseVar` is set to the last column of the data input. This property can only be set with an optional parameter when creating a `creditscorecard` object. `ResponseVar` is case-sensitive.

Data Types: `char`

### **WeightsVar — Name of the variable used as ID or tag for weights**

empty character vector `''` (default) | character vector

Name of the variable used as ID or tag to indicate which column name in the `data` table contains the row weights, specified as a character vector. This property can be set as an optional parameter (`WeightsVar`) when creating a `creditscorecard` object. `WeightsVar` is case-sensitive.

Data Types: `char`

### **GoodLabel — Indicator for which of the two possible values in the response variable correspond to “Good” observations**

set to the response value with the highest count (default) | character vector | numeric scalar | logical

Indicator for which of the two possible values in the response variable correspond to “Good” observations. When specifying `GoodLabel`, follow these guidelines:

| If Response Variable is...      | GoodLabel must be: |
|---------------------------------|--------------------|
| numeric                         | numeric            |
| logical                         | logical or numeric |
| cell array of character vectors | character vector   |
| character array                 | character vector   |
| categorical                     | character vector   |

If not specified, `GoodLabel` is set to the response value with the highest count. This property can only be set with an optional parameter when creating a `creditscorecard` object. This property cannot be set using dot notation.

Data Types: `char` | `double`

### **PredictorVars — Predictor variable names**

set difference between `VarNames` and `{IDVar,ResponseVar}` (default) | cell array of character vectors containing names

Predictor variable names, specified using a cell array of character vectors containing names. By default, when you create a `creditscorecard` object, all variables are predictors except for `IDVar` and `ResponseVar`. This property can be modified using a name-value pair argument for the `fitmodel` function or by using dot notation. `PredictorVars` is case-sensitive and the predictor variable name cannot be the same as the `IDVar` or `ResponseVar`.

Example: `sc.PredictorVars = {'CustID', 'CustIncome'}`

Data Types: `cell`

### **NumericPredictors — Name of numeric predictors**

empty character vector `''` (default) | character vector

Name of numeric predictors, specified as a character vector. This property cannot be set by using dot notation at the command line. It can only be modified using the `modifypredictor` function.

Data Types: char

### **CategoricalPredictors** — Name of categorical predictors

empty character vector '' (default) | character vector

Name of categorical predictors, specified as a character vector. This property cannot be set by using dot notation at the command line. It can only be modified using the `modifypredictor` function.

Data Types: char

### **BinMissingData** — Indicates if missing data is removed or displayed in a separate bin

false (missing data removed) (default) | logical with value true or false

Indicates if missing data is removed or displayed in a separate bin, specified as the comma-separated pair consisting of 'BinMissingdata' and a logical scalar with a value of true or false. If `BinMissingData` is true, the missing data for a predictor is displayed in a separate bin labeled `<missing>`. For more information on working with missing data, see “Credit Scorecard Modeling with Missing Values” on page 8-56.

Data Types: logical

| <b>creditscorecard Property</b> | <b>Set/Modify Property from Command Line Using creditscorecard Function</b> | <b>Modify Property Using Dot Notation</b> | <b>Property Not User-Defined and Value Is Defined Internally</b> |
|---------------------------------|-----------------------------------------------------------------------------|-------------------------------------------|------------------------------------------------------------------|
| Data                            | No                                                                          | No                                        | Yes, copy of data input                                          |
| IDVar                           | Yes                                                                         | Yes                                       | No, but the user specifies this                                  |
| VarNames                        | No                                                                          | No                                        | Yes                                                              |

| NumericPredictors               | No (can only be modified using <code>modifypredictor</code> function)       | No                                        | Yes, but the user can modify this                                |
| CategoricalPredictors           | No (can only be modified using <code>modifypredictor</code> function)       | No                                        | Yes, but the user can modify this                                |

| creditscorecard Property | Set/Modify Property from Command Line Using creditscorecard Function | Modify Property Using Dot Notation | Property Not User-Defined and Value Is Defined Internally |
|--------------------------|----------------------------------------------------------------------|------------------------------------|-----------------------------------------------------------|
| BinMissingData           | Yes                                                                  | No                                 | False by default, but the user can modify this            |

## Object Functions

|                     |                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| autobinning         | Perform automatic binning of given predictors                                                               |
| bininfo             | Return predictor's bin information                                                                          |
| predictorinfo       | Summary of credit scorecard predictor properties                                                            |
| modifypredictor     | Set properties of credit scorecard predictors                                                               |
| fillmissing         | Replace missing values for credit scorecard predictors                                                      |
| modifybins          | Modify predictor's bins                                                                                     |
| bindata             | Binned predictor variables                                                                                  |
| plotbins            | Plot histogram counts for predictor variables                                                               |
| fitmodel            | Fit logistic regression model to Weight of Evidence (WOE) data                                              |
| fitConstrainedModel | Fit logistic regression model to Weight of Evidence (WOE) data subject to constraints on model coefficients |
| setmodel            | Set model predictors and coefficients                                                                       |
| displaypoints       | Return points per predictor per bin                                                                         |
| formatpoints        | Format scorecard points and scaling                                                                         |
| score               | Compute credit scores for given data                                                                        |
| probdefault         | Likelihood of default for given data set                                                                    |
| validatemodel       | Validate quality of credit scorecard model                                                                  |
| compact             | Create compact credit scorecard                                                                             |

## Examples

### Create a creditscorecard Object

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data)

sc =
  creditscorecard with properties:
      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x7 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: ''
      PredictorVars: {1x10 cell}
      Data: [1200x11 table]
```

### Create a creditscorecard Object Containing Weights

Use the `CreditCardData.mat` file to load the data (`dataWeights`) that contains a column (`RowWeights`) for the weights (using a dataset from Refaat 2011).

```
load CreditCardData
```

Create a `creditscorecard` object using the optional name-value pair argument for `'WeightsVar'`.

```
sc = creditscorecard(dataWeights, 'WeightsVar', 'RowWeights')
```

```
sc =
  creditscorecard with properties:
      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: 'RowWeights'
      VarNames: {1x12 cell}
      NumericPredictors: {1x7 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: ''
      PredictorVars: {1x10 cell}
      Data: [1200x12 table]
```

### Display creditscorecard Object Properties

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
```

```
sc = creditscorecard(data)
```

```
sc =
  creditscorecard with properties:
      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x7 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: ''
      PredictorVars: {1x10 cell}
      Data: [1200x11 table]
```

To display the `creditscorecard` object properties, use dot notation.

```
sc.PredictorVars
```

```
ans = 1x10 cell
Columns 1 through 4
    {'CustID'}    {'CustAge'}    {'TmAtAddress'}    {'ResStatus'}
Columns 5 through 8
    {'EmpStatus'}    {'CustIncome'}    {'TmWBank'}    {'OtherCC'}
Columns 9 through 10
    {'AMBalance'}    {'UtilRate'}
```

### sc.VarNames

```
ans = 1x11 cell
Columns 1 through 4
    {'CustID'}    {'CustAge'}    {'TmAtAddress'}    {'ResStatus'}
Columns 5 through 8
    {'EmpStatus'}    {'CustIncome'}    {'TmWBank'}    {'OtherCC'}
Columns 9 through 11
    {'AMBalance'}    {'UtilRate'}    {'status'}
```

## Change a Property Value for a creditscorecard Object

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data)
```

```
sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: ''
    PredictorVars: {1x10 cell}
    Data: [1200x11 table]
```

Since the `IDVar` property has public access, you can change its value at the command line.

```
sc.IDVar = 'CustID'
```

```

sc =
  creditscorecard with properties:

        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: ''
        VarNames: {1x11 cell}
        NumericPredictors: {1x6 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
        BinMissingData: 0
        IDVar: 'CustID'
        PredictorVars: {1x9 cell}
        Data: [1200x11 table]

```

### Create a creditscorecard Object

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```

load CreditCardData
sc = creditscorecard(data)

```

```

sc =
  creditscorecard with properties:

        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: ''
        VarNames: {1x11 cell}
        NumericPredictors: {1x7 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
        BinMissingData: 0
        IDVar: ''
        PredictorVars: {1x10 cell}
        Data: [1200x11 table]

```

In this example, the default values for the properties `ResponseVar`, `PredictorVars` and `GoodLabel` are assigned when this object is created. By default, the property `ResponseVar` is set to the variable name that is in the last column of the input data ('`status`' in this example). The property `PredictorVars` contains the names of all the variables that are in `VarNames`, but excludes `IDVar` and `ResponseVar`. Also, by default in the previous example, `GoodLabel` is set to 0, since it is the value in the response variable (`ResponseVar`) with the highest count.

Display the `creditscorecard` object properties using dot notation.

```

sc.PredictorVars

ans = 1x10 cell
      Columns 1 through 4

      {'CustID'}      {'CustAge'}      {'TmAtAddress'}      {'ResStatus'}

      Columns 5 through 8

```

```

    {'EmpStatus'}    {'CustIncome'}    {'TmWBank'}    {'OtherCC'}
Columns 9 through 10
    {'AMBalance'}    {'UtilRate'}

```

### sc.VarNames

```

ans = 1x11 cell
Columns 1 through 4
    {'CustID'}    {'CustAge'}    {'TmAtAddress'}    {'ResStatus'}
Columns 5 through 8
    {'EmpStatus'}    {'CustIncome'}    {'TmWBank'}    {'OtherCC'}
Columns 9 through 11
    {'AMBalance'}    {'UtilRate'}    {'status'}

```

Since `IDVar` and `PredictorVars` have public access, you can change their values at the command line.

```
sc.IDVar = 'CustID'
```

```

sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]

```

```
sc.PredictorVars = {'CustIncome', 'ResStatus', 'AMBalance'}
```

```

sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {'CustIncome' 'AMBalance'}
    CategoricalPredictors: {'ResStatus'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {'ResStatus' 'CustIncome' 'AMBalance'}

```

```
Data: [1200x11 table]
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {'CustIncome' 'AMBalance'}
    CategoricalPredictors: {'ResStatus'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {'ResStatus' 'CustIncome' 'AMBalance'}
    Data: [1200x11 table]

```

### Create a creditscorecard Object and Set GoodLabel and ResponseVar

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Then use name-value pair arguments for `creditscorecard` to define `GoodLabel` and `ResponseVar`.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID', 'GoodLabel', 0, 'ResponseVar', 'status')
```

```
sc =
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]

```

`GoodLabel` and `ResponseVar` can only be set (enforced) when creating a `creditscorecard` object using `creditscorecard`.

### Create a creditscorecard Object and Set the 'BinMissingData' Property

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData
head(dataMissing,5)
```

ans=5x11 table

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | Other |
|--------|---------|-------------|-------------|-----------|------------|---------|-------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Ye    |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Ye    |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | N     |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Ye    |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Ye    |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

Number of rows: 1200

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

Number of missing values CustAge: 30

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

Number of missing values ResStatus: 40

Use creditscorecard with the name-value argument 'BinMissingData' set to true to bin the missing data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
disp(sc)
```

creditscorecard with properties:

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Display bin information for numeric data for 'CustAge' that includes missing data in a separate bin labelled <missing>.

```
bi = bininfo(sc,'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue |
|-----------------|------|-----|--------|----------|-----------|
| {'[-Inf,33)'} } | 69   | 52  | 1.3269 | -0.42156 | 0.018993  |
| {'[33,37)'} }   | 63   | 45  | 1.4    | -0.36795 | 0.012839  |
| {'[37,40)'} }   | 72   | 47  | 1.5319 | -0.2779  | 0.0079824 |
| {'[40,46)'} }   | 172  | 89  | 1.9326 | -0.04556 | 0.0004549 |
| {'[46,48)'} }   | 59   | 25  | 2.36   | 0.15424  | 0.0016199 |
| {'[48,51)'} }   | 99   | 41  | 2.4146 | 0.17713  | 0.0035449 |
| {'[51,58)'} }   | 157  | 62  | 2.5323 | 0.22469  | 0.0088407 |

|                 |     |     |        |          |            |
|-----------------|-----|-----|--------|----------|------------|
| { '[58,Inf]' }  | 93  | 25  | 3.72   | 0.60931  | 0.032198   |

**Note** For the well-known algorithms and formulas used in Financial Toolbox software (such as how to compute a loan payment given principal, interest rate, and length of the loan), no references are given here. The references here pertain to less common formulas.

---

### Bond Pricing and Yields

The pricing and yield formulas for fixed-income securities come from:

- [1] Golub, B.W. and L.M. Tilman. *Risk Management: Approaches for Fixed Income Markets*. Wiley, 2000.
- [2] Martellini, L., P. Priaulet, and S. Priaulet. *Fixed Income Securities*. Wiley, 2003.
- [3] Mayle, Jan. *Standard Securities Calculation Methods*. New York: Securities Industry Association, Inc. Vol. 1, 3rd ed., 1993, ISBN 1-882936-01-9. Vol. 2, 1994, ISBN 1-882936-02-7.
- [4] Tuckman, B. *Fixed Income Securities: Tools for Today's Markets*. Wiley, 2002.

In many cases these formulas compute the price of a security given yield, dates, rates, and other data. These formulas are nonlinear, however; so when solving for an independent variable within a formula, Financial Toolbox software uses Newton's method. See any elementary numerical methods textbook for the mathematics underlying Newton's method.

### Term Structure of Interest Rates

The formulas and methodology for term structure functions come from:

- [5] Fabozzi, Frank J. "The Structure of Interest Rates." Ch. 6 in Fabozzi, Frank J. and T. Dossa Fabozzi, eds. *The Handbook of Fixed Income Securities*. 4th ed. New York, Irwin Professional Publishing, 1995, ISBN 0-7863-0001-9.
- [6] McEnally, Richard W. and James V. Jordan. "The Term Structure of Interest Rates." Ch. 37 in Fabozzi and Fabozzi, *ibid*.
- [7] Das, Satyajit. "Calculating Zero Coupon Rates." *Swap and Derivative Financing*. Appendix to Ch. 8, pp. 219-225, New York, Irwin Professional Publishing., 1994, ISBN 1-55738-542-4.

## Derivatives Pricing and Yields

The pricing and yield formulas for derivative securities come from:

[8] Chriss, Neil A. *Black-Scholes and Beyond: Option Pricing Models*. Chicago, Irwin Professional Publishing, 1997, ISBN 0-7863-1025-1.

[9] Cox, J., S. Ross, and M. Rubenstein. "Option Pricing: A Simplified Approach." *Journal of Financial Economics*. Vol. 7, Sept. 1979, pp. 229-263.

[10] Hull, John C. *Options, Futures, and Other Derivatives*. 5th edition, Prentice Hall, 2003, ISBN 0-13-009056-5.

## Portfolio Analysis

The Markowitz model is used for portfolio analysis computations. For a discussion of this model see Chapter 7 of:

[11] Bodie, Zvi, Alex Kane, and Alan J. Marcus. *Investments*. 2nd. Edition. Burr Ridge, IL, Irwin Professional Publishing, 1993, ISBN 0-256-08342-8.

## Investment Performance Metrics

The risk and ratio formulas for investment performance metrics come from:

[12] Daniel Bernoulli. "Exposition of a New Theory on the Measurement of Risk." *Econometrica*. Vol. 22, No 1, January 1954, pp. 23-36 (English translation of "Specimen Theoriae Novae de Mensura Sortis." *Commentarii Academiae Scientiarum Imperialis Petropolitanae*. Tomus V, 1738, pp. 175-192).

[13] Martin Eling and Frank Schuhmacher. *Does the Choice of Performance Measure Influence the Evaluation of Hedge Funds?* Working Paper, November 2005.

[14] John Lintner. "The Valuation of Risk Assets and the Selection of Risky Investments in Stocks Portfolios and Capital Budgets." *Review of Economics and Statistics*. Vol. 47, No. 1, February 1965, pp. 13-37.

[15] Malik Magdon-Ismail, Amir F. Atiya, Amrit Pratap, and Yaser S. Abu-Mostafa. "On the Maximum Drawdown of a Brownian Motion." *Journal of Applied Probability*. Volume 41, Number 1, March 2004, pp. 147-161.

## Glossary

### **basis**

Day count basis determines how interest accrues over time for various instruments and the amount transferred on interest payment dates. The calculation of accrued interest for dates between payments also uses day count basis. Day count basis is a fraction of Number of interest accrual days / Days in the relevant coupon period. Supported day count conventions and basis values are:

| <b>Basis Value</b> | <b>Day Count Convention</b>                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                  | actual/actual (default) — Number of days in both a period and a year is the actual number of days.                                                                                                                                                                                                                                                                                                                                                                     |
| 1                  | 30/360 SIA — Year fraction is calculated based on a 360 day year with 30-day months, after applying the following rules: If the first date and the second date are the last day of February, the second date is changed to the 30th. If the first date falls on the 31st or is the last day of February, it is changed to the 30th. If after the preceding test, the first day is the 30th and the second day is the 31st, then the second day is changed to the 30th. |
| 2                  | actual/360 — Number of days in a period is equal to the actual number of days, however the number of days in a year is 360.                                                                                                                                                                                                                                                                                                                                            |
| 3                  | actual/365 — Number of days in a period is equal to the actual number of days, however the number of days in a year is 365 (even in a leap year).                                                                                                                                                                                                                                                                                                                      |

| Basis Value | Day Count Convention                                                                                                                                                                                                                                                                                                                                              |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4           | 30/360 PSA — Number of days in every month is set to 30 (including February). If the start date of the period is either the 31st of a month or the last day of February, the start date is set to the 30th, while if the start date is the 30th of a month and the end date is the 31st, the end date is set to the 30th. The number of days in a year is 360.    |
| 5           | 30/360 ISDA — Number of days in every month is set to 30, except for February where it is the actual number of days. If the start date of the period is the 31st of a month, the start date is set to the 30th while if the start date is the 30th of a month and the end date is the 31st, the end date is set to the 30th. The number of days in a year is 360. |
| 6           | 30E /360 — Number of days in every month is set to 30 except for February where it is equal to the actual number of days. If the start date or the end date of the period is the 31st of a month, that date is set to the 30th. The number of days in a year is 360.                                                                                              |
| 7           | actual/365 Japanese — Number of days in a period is equal to the actual number of days, except for leap days (29th February) which are ignored. The number of days in a year is 365 (even in a leap year).                                                                                                                                                        |
| 8           | actual/actual ICMA — Number of days in both a period and a year is the actual number of days and the compounding frequency is annual.                                                                                                                                                                                                                             |

| <b>Basis Value</b> | <b>Day Count Convention</b>                                                                                                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9                  | actual/360 ICMA — Number of days in a period is equal to the actual number of days, however the number of days in a year is 360 and the compounding frequency is annual.                                                                                                                                         |
| 10                 | actual/365 ICMA — Number of days in a period is equal to the actual number of days, however the number of days in a year is 365 (even in a leap year) and the compounding frequency is annual.                                                                                                                   |
| 11                 | 30/360 ICMA — Number of days in every month is set to 30, except for February where it is equal to the actual number of days. If the start date or the end date of the period is the 31st of a month, that date is set to the 30th. The number of days in a year is 360 and the compounding frequency is annual. |
| 12                 | actual/365 ISDA — The day count fraction is calculated using the following formula: (Actual number of days in period that fall in a leap year / 366) + (Actual number of days in period that fall in a normal year / 365).                                                                                       |
| 13                 | bus/252 — The number of days in a period is equal to the actual number of business days. The number of business days in a year is 252.                                                                                                                                                                           |
