The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See www.mathworks.com/trademarks for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

Patents

MathWorks products are protected by one or more U.S. patents. Please see www.mathworks.com/patents for more information.

Revision History

July 2002	Online only	Revised for Simulink 5 (Release 13)
April 2003	Online only	Revised for Simulink 5.1 (Release 13SP1)
April 2004	Online only	Revised for Simulink 5.1.1 (Release 13SP1+)
June 2004	Online only	Revised for Simulink 6 (Release 14)
October 2004	Online only	Revised for Simulink 6.1 (Release 14SP1)
March 2005	Online only	Revised for Simulink 6.2 (Release 14SP2)
September 2005	Online only	Revised for Simulink 6.3 (Release 14SP3)
March 2006	Online only	Revised for Simulink 6.4 (Release 2006a)
September 2006	Online only	Revised for Simulink 6.5 (Release 2006b)
March 2007	Online only	Revised for Simulink 6.6 (Release 2007a)
September 2007	Online only	Revised for Simulink 7.0 (Release 2007b)
March 2008	Online only	Revised for Simulink 7.1 (Release 2008a)
October 2008	Online only	Revised for Simulink 7.2 (Release 2008b)
March 2009	Online only	Revised for Simulink 7.3 (Release 2009a)
September 2009	Online only	Revised for Simulink 7.4 (Release 2009b)
March 2010	Online only	Revised for Simulink 7.5 (Release 2010a)
September 2010	Online only	Revised for Simulink 7.6 (Release 2010b)
April 2011	Online only	Revised for Simulink 7.7 (Release 2011a)
September 2011	Online only	Revised for Simulink 7.8 (Release 2011b)
March 2012	Online only	Revised for Simulink 7.9 (Release 2012a)
September 2012	Online only	Revised for Simulink 8.0 (Release 2012b)
March 2013	Online only	Revised for Simulink 8.1 (Release 2013a)
September 2013	Online only	Revised for Simulink 8.2 (Release 2013b)
March 2014	Online only	Revised for Simulink 8.3 (Release 2014a)
October 2014	Online only	Revised for Simulink 8.4 (Release 2014b)
March 2015	Online only	Revised for Simulink 8.5 (Release 2015a)
September 2015	Online only	Revised for Simulink 8.6 (Release 2015b)
October 2015	Online only	Rereleased for Simulink 8.5.1 (Release 2015aSP1)
March 2016	Online only	Revised for Simulink 8.7 (Release 2016a)
September 2016	Online only	Revised for Simulink 8.8 (Release 2016b)
March 2017	Online only	Revised for Simulink 8.9 (Release 2017a)
September 2017	Online only	Revised for Simulink 9.0 (Release 2017b)
March 2018	Online only	Revised for Simulink 9.1 (Release 2018a)
September 2018	Online only	Revised for Simulink 9.2 (Release 2018b)
March 2019	Online only	Revised for Simulink 9.3 (Release 2019a)
September 2019	Online only	Revised for Simulink 10.0 (Release 2019b)
March 2020	Online only	Revised for Simulink 10.1 (Release 2020a)

Model Advisor Checks

9

Simulink Checks	9-2
Simulink Check Overview	9-4
Migrating to Simplified Initialization Mode Overview	9-4
Identify unconnected lines, input ports, and output ports	9-4
Check root model Inport block specifications	9-5
Check optimization settings	9-6
Check diagnostic settings ignored during accelerated model reference simulation	9-8
Check for parameter tunability information ignored for referenced models	9-9
Check for implicit signal resolution	9-9
Check for optimal bus virtuality	9-10
Check for Discrete-Time Integrator blocks with initial condition uncertainty	9-10
Identify disabled library links	9-11
Check for large number of function arguments from virtual bus across model reference boundary	9-12
Identify parameterized library links	9-12
Identify unresolved library links	9-13
Identify configurable subsystem blocks for converting to variant subsystem blocks	9-14
Identify Variant Model blocks and convert those to Variant Subsystem containing Model block choices	9-14
Identify Variant blocks using Variant objects with empty conditions	9-14
Check usage of function-call connections	9-15
Check Data Store Memory blocks for multitasking, strong typing, and shadowing issues	9-15
Check if read/write diagnostics are enabled for data store blocks	9-16
Check data store block sample times for modeling errors	9-17
Check for potential ordering issues involving data store access	9-18
Check structure parameter usage with bus signals	9-19
Check Delay, Unit Delay and Zero-Order Hold blocks for rate transition .	9-20
Check for calls to slDataTypeAndScale	9-21
Check bus signals treated as vectors	9-22

Check for potentially delayed function-call subsystem return values	9-23
Identify block output signals with continuous sample time and non-floating point data type	9-24
Check usage of Merge blocks	9-25
Check usage of Outport blocks	9-27
Check usage of Discrete-Time Integrator blocks	9-34
Check model settings for migration to simplified initialization mode	9-35
Check S-functions in the model	9-36
Check for non-continuous signals driving derivative ports	9-37
Runtime diagnostics for S-functions	9-38
Check model for foreign characters	9-38
Identify unit mismatches in the model	9-39
Identify automatic unit conversions in the model	9-40
Identify disallowed unit systems in the model	9-40
Identify undefined units in the model	9-41
Identify ambiguous units in the model	9-41
Check model for block upgrade issues	9-42
Check model for block upgrade issues requiring compile time information	9-42
Check that the model is saved in SLX format	9-43
Check model for SB2SL blocks	9-44
Check Model History properties	9-44
Identify Model Info blocks that can interact with external source control tools	9-45
Identify Model Info blocks that use the Configuration Manager	9-45
Check model for upgradable SerDes Toolbox blocks	9-46
Check model for legacy 3DoF or 6DoF blocks	9-46
Check model and local libraries for legacy Aerospace Blockset blocks . . .	9-47
Check model for Aerospace Blockset navigation blocks	9-47
Check and update masked blocks in library to use promoted parameters	9-48
Check and update mask image display commands with unnecessary imread() function calls	9-49
Check and update mask to affirm icon drawing commands dependency on mask workspace	9-49
Identify masked blocks that specify tabs in mask dialog using MaskTabNames parameter	9-50
Identify questionable operations for strict single-precision design	9-51
Check get_param calls for block CompiledSampleTime	9-52
Check if all simulation outputs are returned as a single Simulink.SimulationOutput object	9-53
Check model for parameter initialization and tuning issues	9-54
Check for virtual bus across model reference boundaries	9-55
Check model for custom library blocks that rely on frame status of the signal	9-56
Check model for S-function upgrade issues	9-56
Check Rapid accelerator signal logging	9-57
Check virtual bus inputs to blocks	9-58
Check for root outports with constant sample time	9-61
Analyze model hierarchy and continue upgrade sequence	9-61
Check Access to Data Stores	9-63
Check relative execution orders for Data Store Read and Data Store Write blocks	9-63
Check for case mismatches in references to models and libraries	9-64

Check Conversion Input Parameters	10-2

Performance Advisor Checks

11

Simulink Performance Advisor Checks	11-2
Simulink Performance Advisor Check Overview	11-2
Baseline	11-3
Checks that Require Update Diagram	11-3
Checks that Require Simulation to Run	11-3
Check Simulation Modes Settings	11-3
Check Compiler Optimization Settings	11-3
Create baseline	11-3
Identify resource-intensive diagnostic settings	11-4
Check optimization settings	11-4
Identify inefficient lookup table blocks	11-4
Check MATLAB System block simulation mode	11-4
Identify Interpreted MATLAB Function blocks	11-5
Identify simulation target settings	11-5
Check model reference rebuild setting	11-5
Identify Scope blocks	11-6
Identify active instrumentation settings on the model	11-6
Check model reference parallel build	11-6
Check Delay block circular buffer setting	11-7
Check continuous and discrete rate coupling	11-8
Check zero-crossing impact on continuous integration	11-8
Check discrete signals driving derivative port	11-9
Check solver type selection	11-9
Select multi-thread co-simulation setting on or off	11-10
Identify co-simulation signals for numerical compensation	11-10
Select simulation mode	11-10
Select compiler optimizations on or off	11-11
Final Validation	11-12

Block Reference Page Examples

13

Create Mux Signal and Extract Elements	13-5
Manage Bus-to-Vector Conversions	13-6
Assign Signal Values to a Bus	13-8
Initialize Your Model Using the Callback Button Block	13-9
Control a Parameter Value with Callback Button Blocks	13-10
Control the Duty Cycle of a PWM Signal Using Dashboard Blocks	13-11
Control Merging Signals with the Push Button Block	13-13
Tune the Relative Slip for an Anti-Lock Braking System	13-15
Interactively Simulate a Vehicle Climate Control System	13-17

Interactively Simulate a Thermal Model of a House	13-20
Create a Realistic Dashboard Using the Custom Gauge Block	13-22
Solve a Linear System of Algebraic Equations	13-25
Model a Planar Pendulum	13-26
Improved Linearization with Transfer Fcn Blocks	13-29
View Dead Zone Output on Sine Wave	13-30
View Backlash Output on Sine Wave	13-31
Prelookup With External Breakpoint Specification	13-32
Prelookup with Evenly Spaced Breakpoints	13-33
Configure the Prelookup Block to Output Index and Fraction as a Bus	13-34
Approximating the sinh Function Using the Lookup Table Dynamic Block	13-35
Create a Logarithm Lookup Table	13-36
Providing Table Data as an Input to the Direct Lookup Table Block ..	13-37
Specifying Table Data in the Direct Lookup Table Block Dialog Box ..	13-38
Using the Quantizer and Saturation blocks in sldemo_boiler	13-39
Scalar Expansion with the Coulomb and Viscous Friction Block	13-40
Sum Block Reorders Inputs	13-41
Iterated Assignment with the Assignment Block	13-42
View Sample Time Using the Digital Clock Block	13-43
Bit Specification Using a Positive Integer	13-44
Bit Specification Using an Unsigned Integer Expression	13-45
Track Running Minimum Value of Chirp Signal	13-46
Horizontal Matrix Concatenation	13-47
Vertical Matrix Concatenation	13-48
Multidimensional Matrix Concatenation	13-49
Unary Minus of Matrix Input	13-50

Sample Time Math Operations Using the Weighted Sample Time Math Block	13-51
Construct Complex Signal from Real and Imaginary Parts	13-52
Construct Complex Signal from Magnitude and Phase Angle	13-53
Find Nonzero Elements in an Array	13-54
Calculate the Running Minimum Value with the MinMax Running Resettable Block	13-55
Find Maximum Value of Input	13-57
Permute Array Dimensions	13-59
Multiply Inputs of Different Dimensions with the Product Block	13-60
Multiply and Divide Inputs Using the Product Block	13-61
Divide Inputs of Different Dimensions Using the Divide Block	13-62
Complex Division Using the Product of Elements Block	13-63
Element-Wise Multiplication and Division Using the Product of Elements Block	13-64
sin Function with Floating-Point Input	13-65
sincos Function with Fixed-Point Input	13-66
Trigonometric Function Block Behavior for Complex Exponential Output	13-67
Create Bus Object from Constant Block	13-68
Control Algorithm Execution Using Enumerated Signal	13-69
Integer and Enumerated Data Type Support in the Ground Block	13-71
Fixed-Point Data Type Support in the Ground Block	13-72
Read 1-D Array and Structure From Workspace	13-73
Read Structure From Workspace Using Model Sample Time	13-74
Read 2-D Signals in Structure Format From Workspace	13-75
From File Block Loading Timeseries Data	13-76
Eliminate Singleton Dimension with the Squeeze Block	13-77
Difference Between Time- and Sample-Based Pulse Generation	13-78

Specify a Waveform with the Repeating Sequence Block	13-80
Tune Phase Delay on Pulse Generator During Simulation	13-81
Difference Sine Wave Signal	13-82
Discrete-Time Derivative of Floating-Point Input	13-83
First-Order Sample-and-Hold of a Sine Wave	13-84
Calculate and Display Simulation Step Size using Memory and Clock Blocks	13-85
Capture the Velocity of a Bouncing Ball with the Memory Block	13-86
Implement a Finite-State Machine with the Combinatorial Logic and Memory Blocks	13-88
Discrete-Time Integration Using the Forward Euler Integration Method	13-90
Signal Routing with the From, Goto, and Goto Tag Visibility Blocks ..	13-91
Zero-Based and One-Based Indexing with the Index Vector Block	13-93
Noncontiguous Values for Data Port Indices of Multiport Switch Block	13-94
Using Variable-Size Signals on the Delay Block	13-95
Bus Signals with the Delay Block for Frame-Based Processing	13-96
Control Execution of Delay Block with Enable Port	13-97
Zero-Based Indexing for Multiport Switch Data Ports	13-98
One-Based Indexing for Multiport Switch Data Ports	13-99
Enumerated Names for Data Port Indices of the Multiport Switch Block	13-100
Prevent Block Windup in Multiloop Control	13-101
Bumpless Control Transfer	13-102
Bumpless Control Transfer with a Two-Degree-of-Freedom PID Controller	13-103
Using a Bit Set block	13-104
Using a Bit Clear block	13-105
Two-Input AND Logic	13-106

Circuit Logic	13-107
Unsigned Inputs for the Bitwise Operator Block	13-108
Signed Inputs for the Bitwise Operator Block	13-109
Merge Block with Input from Atomic Subsystems	13-110
Index Options with the Selector Block	13-111
Switch Block with a Boolean Control Port Example	13-112
Merge Block with Unequal Input Widths Example	13-113
Detect Rising Edge of Signals	13-115
Detect Falling Edge Using the Detect Fall Nonpositive Block	13-117
Detect Increasing Signal Values with the Detect Increase Block	13-118
Extract Bits from Stored Integer Value	13-119
Detect Signal Values Within a Dynamically Specified Interval	13-120
Model a Digital Thermometer Using the Polynomial Block	13-122
Convert Data Types in Simulink Models	13-123
Control Data Types with the Data Type Duplicate Block	13-125
Probe Sample Time of a Signal	13-126
Convert Signals Between Continuous Time and Discrete Time	13-127
Convert Muxed Signal to a Vector	13-129
Create Contiguous Copy of a Bus Signal	13-130
Convert Virtual Bus to a Nonvirtual Bus	13-131
Convert Nonvirtual Bus to Virtual Bus	13-132
Remove Scaling from a Fixed-Point Signal	13-133
Stop Simulation Block with Relational Operator Block	13-134
Output Simulation Data with Blocks	13-135
Increment and Decrement Real-World Values	13-139
Increment and Decrement Stored Integer Values	13-141
Specify a Vector of Initial Conditions for a Discrete Filter Block	13-142

Generate Linear Models for a Rising Edge Trigger Signal	13-144
Generate Linear Models at Predetermined Times	13-146
Capture Measurement Descriptions in a DocBlock	13-147
Square Root of Negative Values	13-148
Signed Square Root of Negative Values	13-149
rSqrt of Floating-Point Inputs	13-150
rSqrt of Fixed-Point Inputs	13-151
Model a Series RLC Circuit	13-152
Extract Vector Elements and Distribute Evenly Across Outputs	13-155
Extract Vector Elements Using the Demux Block	13-156
Detect Change in Signal Values	13-157
Detect Fall to Negative Signal Values	13-158
Detect Decreasing Signal Values	13-159
Function-Call Blocks Connected to Branches of the Same Function-Call Signal	13-160
Function-Call Feedback Latch on Feedback Signal Between Child and Parent	13-161
Single Function-Call Subsystem	13-162
Function-Call Subsystem with Merged Signal As Input	13-163
Partitioning an Input Signal with the For Each Block	13-164
Specifying the Concatenation Dimension in the For Each Block	13-165
Working with the Initialize Function, Reset Function, and Terminate Function Blocks	13-166
Reading and Writing States with the Initialize Function and Terminate Function Blocks	13-167

Simulink Featured Examples

14

Simulation of a Bouncing Ball	14-6
--------------------------------------------	-------------

Single Hydraulic Cylinder Simulation	14-12
Thermal Model of a House	14-22
Approximating Nonlinear Relationships: Type S Thermocouple	14-28
Digital Waveform Generation: Approximating a Sine Wave	14-37
Accurate Zero-Crossing Detection	14-47
Spiral Galaxy Formation Simulation Using MATLAB Function Blocks	14-48
Modulo-4 Counter Using Flip-Flops	14-52
Counters Using Conditionally Executed Subsystems	14-54
Friction Model with Hard Stops	14-56
State Events	14-58
Bang-Bang Control Using Temporal Logic	14-59
Inverted Pendulum with Animation	14-60
Double Spring Mass System	14-62
Tank Fill and Empty with Animation	14-64
Simulating Systems with Variable Transport Delay Phenomena	14-67
Modeling a Foucault Pendulum	14-71
Foucault Pendulum Model with VRML Visualization	14-79
Exploring Variable-Step Solvers Using a Stiff Model	14-82
Exploring the Solver Jacobian Structure of a Model	14-88
Double Bouncing Ball: Use of Adaptive Zero-Crossing Location	14-97
Four Hydraulic Cylinder Simulation	14-104
Two Cylinder Model with Load Constraints	14-109
Modeling a Fault-Tolerant Fuel Control System	14-116
Using a Data Dictionary to Manage the Data for a Fuel Control System	14-131
Modeling Engine Timing Using Triggered Subsystems	14-134
Engine Timing Model with Closed Loop Control	14-144

Building a Clutch Lock-Up Model	14-148
Modeling Clutch Lock-Up Using If Blocks	14-158
Modeling an Anti-Lock Braking System	14-163
Automotive Suspension	14-169
Modeling an Automatic Transmission Controller	14-175
Vehicle Electrical System	14-186
Simulating Automatic Climate Control Systems	14-188
Vehicle Electrical and Climate Control Systems	14-192
Power Window Control Project	14-198
Developing the Apollo Lunar Module Digital Autopilot	14-205
Designing a High Angle of Attack Pitch Mode Control	14-210
Six Degrees of Freedom (6-DoF) Motion Platform	14-223
Aircraft Longitudinal Flight Control	14-226
Radar Tracking Using MATLAB Function Block	14-228
Optical Sensor Image Generation	14-230
Air Traffic Control Radar Design	14-238
Designing a Guidance System in MATLAB and Simulink	14-244
Airframe Trim and Linearize	14-260
Anti-Windup Control Using a PID Controller	14-264
Bumpless Control Transfer Between Manual and PID Control	14-280
Two Degree-of-Freedom PID Control for Setpoint Tracking	14-289
Data Typing in Simulink	14-295
Data Typing Filter	14-299
Simulink Bus Signals	14-301
Modeling Arrays of Buses	14-311
Matrix Signals	14-313
Variable-Size Signal Basic Operations	14-314

Variable-Size Signal Length Adaptation	14-316
Multimode Variable-Size Signal	14-317
Parallel Channel Power Allocation	14-318
Merging Signals	14-320
Migration to Structure Parameters	14-333
Share Data Store Between Instances of a Reusable Algorithm	14-338
Attaching Input Data to External Inputs via Custom Input Mappings	14-343
Using Mapping Modes with Custom-Mapped External Inputs	14-347
Converting Harness-Driven Models to Use Harness-Free External Inputs	14-351
Logging States in Structure Format	14-356
Saving and Restoring Simulation Operating Point	14-360
Logging Intervals	14-364
Working with Big Data	14-367
Simulink Subsystem Semantics	14-372
If-Then-Else Blocks	14-373
Triggered Subsystems	14-375
Enabled Subsystems	14-377
Advanced Enabled Subsystems	14-379
Resettable Subsystems	14-382
Discrete and Continuous Resettable Subsystems	14-384
Variant Subsystems	14-387
Block Priority	14-392
Monitoring Ink Status on a Shared Printer Using Simulink Functions	14-393
Modeling Services and Access from Application Software	14-395
Modeling Reusable Components Using Multiply Instanced Simulink Functions	14-397

Dynamic Priority Scheduling of Functions	14-399
Component-Based Modeling with Model Reference	14-400
Viewing Signals in Model Reference Instances	14-404
Visualizing Model Reference Architectures	14-412
Introduction to Managing Data with Model Reference	14-417
Detailed Workflow for Managing Data with Model Reference	14-429
Interface Specification Using Bus Objects	14-446
Converting Subsystems to Model Reference	14-452
Using Data Stores Across Multiple Models	14-454
Model Reference Function-Call	14-460
Protected Models for Model Reference	14-463
Model Reference Variants	14-469
Assigning Tasks to Cores for Multicore Programming	14-473
Implement an FFT on a Multicore Processor and an FPGA	14-476
Multicore Programming of a Field-Oriented Control on Zynq	14-480
Multicore Deployment of a Plant Model	14-486
Modeling Objects with Identical Dynamics Using For Each Subsystem	14-490
Vectorizing a Scalar Algorithm with For Each Subsystem	14-495
Tiled Processing of 2D Signals with For Each Subsystem	14-497
Neighborhood Processing Using For Each Subsystems	14-498
Using a Project with SVN	14-501
Using a Project with Git	14-505
Using a Project	14-509
Perform Impact Analysis with a Project	14-514
Referencing Projects from Another Project	14-521
Automate Label Management in a Project	14-522
Running Custom Tasks with a Project	14-525

Upgrade Simulink Models Using a Project	14-528
Convert from MDL to SLX in a Project and Preserve Revision History	14-530
Export a Subset of a Project Using an Export Profile	14-534
Create and Reference a Project Programmatically	14-536
Compare and Merge Simulink Models	14-539
Compare and Merge Simulink Models Containing Stateflow	14-542
Resolve Conflicts with Simulink Three-Way Merge	14-545
Call C Functions Using C Caller Block	14-549
Bring Custom Image Filter Algorithms as Reusable Blocks in Simulink	14-553
Custom Code and Hand Coded Blocks using the S-function API	14-555
Inputs Passed by Value or Address to Legacy Functions	14-556
Output Passed by Return Argument from Legacy Functions	14-559
Fixed Point Signals in Legacy Functions	14-562
Fixed Point Parameters in Legacy Functions	14-565
Lookup Tables Implemented in Legacy Functions	14-568
Start and Terminate Actions Within Legacy Functions	14-571
Using Buses with Legacy Functions Having Structure Arguments	14-575
Inherited Signal Dimensions for Legacy Function Arguments	14-578
C++ Object Methods as Legacy Functions	14-581
Persistent Memory Within Legacy Functions	14-585
Multi-Dimensional Signals in Legacy Functions	14-588
Complex Signals in Legacy Function	14-590
Specified or Inherited Sample Time with Legacy Functions	14-592
System Identification for an FIR System Using MATLAB System Blocks	14-595
MATLAB System Block with Variable-Size Input and Output Signals	14-597
Illustration of Law of Large Numbers	14-598

Using Buses with MATLAB System Blocks	14-600
Run Quality Checks on S-Functions	14-601
Interpolation Algorithm Selection and Trajectory Animation	14-603
Using the Prelookup and Interpolation Blocks	14-605
Saving Memory in Prelookup and Interpolation Blocks by Using Smaller Data	14-610
Model Advisor	14-611
Simulink Model Discretizer	14-612
Introduction to Profiling Models	14-613
Introduction to Accelerating Models	14-615
Determining Why Simulink Accelerator Is Regenerating Code	14-618
Parallel Simulations Using Parsim: Test-Case Sweep	14-624
Parallel Simulations Using Parsim: Parameter Sweep in Normal Mode	14-628
Parallel Simulations Using Parsim: Parameter Sweep in Rapid Accelerator Mode	14-632

Blocks

Abs

Output absolute value of input

Library: Simulink / Math Operations
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Abs block outputs the absolute value of the input.

For signed-integer data types, the absolute value of the most negative value is not representable by the data type. In this case, the **Saturate on integer overflow** check box controls the behavior of the block.

If you...	The block...	And...
Select this check box	Saturates to the most positive value of the integer data type	<ul style="list-style-type: none"> For 8-bit signed integers, -128 maps to 127. For 16-bit signed integers, -32768 maps to 32767. For 32-bit signed integers, -2147483648 maps to 2147483647.
Do not select this check box	Wraps to the most negative value of the integer data type	<ul style="list-style-type: none"> For 8-bit signed integers, -128 remains -128. For 16-bit signed integers, -32768 remains -32768. For 32-bit signed integers, -2147483648 remains -2147483648.

The Abs block supports zero-crossing detection. However, when you select **Enable zero-crossing detection** on the dialog box, the block does not report the simulation minimum or maximum in the Fixed-Point Tool. If you want to use the Fixed-Point Tool to analyze a model, disable zero-crossing detection for all Abs blocks in the model first.

Ports

Input

Port_1 — Input signal

scalar | vector

Input signal to the absolute value block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Absolute value output signal

scalar | vector

Absolute value of the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main

Enable zero-crossing detection — Enable zero-crossing detection

on (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector, string

Values: 'off' | 'on'

Default: 'on'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Signal Attributes

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.

- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Same as input (default) | Inherit: Inherit via back propagation | double | single | int8 | int32 | uint32 | int64 | uint64 | fixdt(1,16,2^0,0) | <data type expression> | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Same as input', 'Inherit: Inherit via back propagation', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', 'uint64', 'fixdt(1,16,0)', 'fixdt(1,16,2^0,0)', 'fixdt(1,16,2^0,0)'. '<data type expression>'

Default: 'Inherit: Same as input'

Lock output data type setting against changes by the fixed-point tools – Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode – Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB® rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow – Choose the behavior when integer overflow occurs

off (default) | on

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Action	Reason for Taking This Action	What Happens	Example
Select this check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to the maximum value that the data type can represent.	The number 130 does not fit in a signed 8-bit integer and saturates to 127.
Do not select this check box.	You want to optimize efficiency of your generated code.	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	yes

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder™ provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also "LatencyStrategy" (HDL Coder).

Complex Data Support

This block does not support code generation for complex signals. To calculate the magnitude of a complex number, use the Complex to Magnitude-Angle HDL Optimized block instead.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Action Port

Add control port for action signal to subsystem

Library: Ports & Subsystems

Description

The Action Port block controls the execution of these subsystem blocks:

- If Action Subsystem blocks connected to If blocks.
- Switch Case Action Subsystem blocks connected to Switch Case blocks.
- Simulink based states in Stateflow® charts. See “Create and Edit Simulink Based States” (Stateflow).

Parameters

States when execution is resumed — Select handling of internal states

held (default) | reset

Select how to handle internal states when a subsystem with an Action Port block reenables.

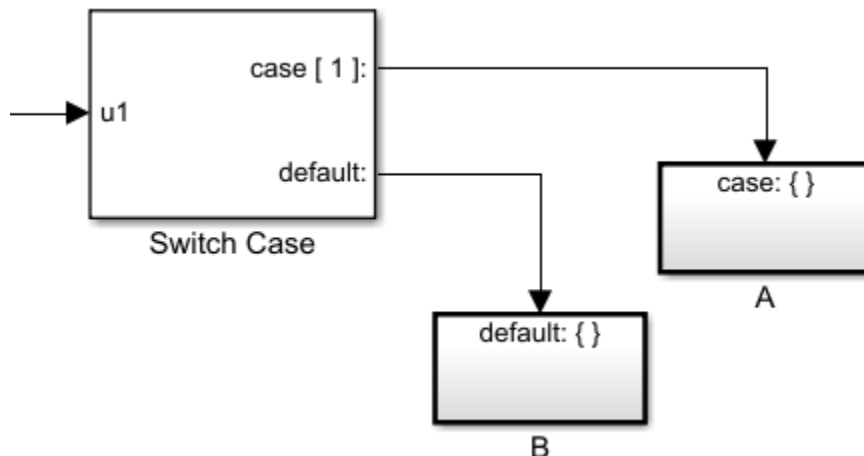

held

When the subsystem reenables, retain the previous state values of the subsystem. Previous state values between calls are retained even if you call other subsystem blocks connected to the If or Switch Case block.

reset

When the subsystem reenables, reinitialize the state values.

A subsystem reenables when the logical expression for its action port evaluates to true after having been previously false. In the following example, the Action Port blocks for both subsystems A and B have the **States when execution is resumed** parameter set to reset.

When **case[1]** is true, subsystem **A** is executed. Repeated calls to subsystem **A** while **case [1]** continues to be true, does not reset its state values. The same behavior applies to subsystem **B**.

Programmatic Use**Block Parameter:** InitializeStates**Type:** character vector**Value:** 'held' | 'reset'**Default:** 'held'**Propagate sizes of variable-size signals – Select when to propagate a variable-size signal**`Only when execution is resumed (default) | During execution`

Select when to propagate a variable-size signal.

Only when execution is resumed

Propagate variable-size signals only when reenabling the subsystem containing the Action Port block.

During execution

Propagate variable-size signals at each time step.

Programmatic Use**Block Parameter:** PropagateVarSize**Type:** character vector**Values:** 'Only when execution is resumed' | 'During execution'**Default:** 'Only when execution is resumed'**See Also**

If | If Action Subsystem | Switch Case | Switch Case Action Subsystem

Algebraic Constraint

Constrain input signal

Library: Simulink / Math Operations

Description

The Algebraic Constraint block constrains the input signal $f(z)$ to z or 0 and outputs an algebraic state z . The block outputs a value that produces 0 or z at the input. The output must affect the input through a direct feedback path. In other words, the feedback path only contains blocks with direct feedthrough. For example, you can specify algebraic equations for index 1 differential-algebraic systems (DAEs).

Ports

Input

$f(z)$ — Input signal

real scalar or vector

Signal is subjected to the constraint $f(z) = 0$ or $f(z) = z$ to solve the algebraic loop.

Data Types: double

Output

z — Output state

real scalar or vector

Solution to the algebraic loop when the input signal $f(z)$ is subjected to the constraint $f(z) = 0$ or $f(z) = z$.

Data Types: double

Parameters

Constraint — Constraint on input signal

$f(z) = 0$ (default) | $f(z) = z$

Type of constraint for which to solve. You can solve for $f(z) = 0$ or $f(z) = z$

Programmatic Use

Block Parameter: Constraint

Type: character vector

Values: 'f(z) = 0' | 'f(z) = z'

Default: 'f(z) = 0'

Solver — Algebraic Loop Solver

auto (default) | Trust region | Line search

Choose between the Trust region [1], [2] or Line search [3] algorithms to solve the algebraic loop. By default this value is set to auto, which selects the solver based on the model configuration

Programmatic Use

Block Parameter: Solver

Type: character vector

Values: 'auto' | 'Trust region' | 'Line search'

Default: 'auto'

Tolerance – Solver Tolerance

auto (default) | positive scalar

This option is visible when you explicitly specify a solver to be used (Trust region or Line Search) in the **Solver** dropdown menu. Specify a smaller value for higher accuracy or a larger value for faster execution. By default it is set to auto.

Programmatic Use

Block Parameter: Tolerance

Type: character vector

Values: 'auto' | positive scalar

Default: 'auto'

Initial Guess – Initial guess of solution value

0 (default) | scalar

Initial guess for the algebraic state z that is close to the expected solution value to improve the efficiency of the algebraic loop solver. By default, this value is set to 0

Programmatic Use

Block Parameter: InitialGuess

Type: character vector

Values: scalar

Default: '0'

Block Characteristics

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Argument Inport

Argument input port for Simulink Function block

Library: User-Defined Functions

Description

This block is an argument input port for a function that you define in the Simulink Function block.

Ports

Input

u — Argument input

scalar | vector | matrix

The Argument Inport block accepts complex or real signals of any data type that Simulink supports, including fixed-point and enumerated data types. The Argument Inport block also accepts a bus object as a data type.

The complexity and data type of the block output are the same as the argument input. You can specify the signal type and data type of an input argument to an Argument Inport block using the **Signal type** and **Data type** parameters.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Output

out — Block output

scalar | vector | matrix

Block output signal from this block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Parameters

Port number — Specify port number of block

1 (default) | integer

Specify the order in which the port that corresponds to the block appears in the parent subsystem or model block.

1

Specify the first port location for this block.

integer

Specify location of port.

Programmatic Use**Block parameter:** Port**Type:** character vector**Value:** '1' | '<integer>'**Default:** '1'**Argument name — Specify input argument name**

u (default) | character vector

Specify input argument name for the function prototype displayed on the face of the Simulink Function block.

u

Default name for the input argument.

character vector

Name of the input argument.

Programmatic Use**Block parameter:** ArgumentName**Type:** character vector**Value:** 'u' | '<character vector>'**Default:** 'u'**Minimum — Specify minimum value for block output**

[] (default) | number

Specify the minimum value for the block output signal.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking and automatic scaling of fixed-point data types.

[]

Minimum value not specified.

number

Finite real double scalar value.

Programmatic Use**Block parameter:** OutMin**Type:** character vector**Value:** '[]' | '<number>'**Default:** '[]'**Maximum — Specify maximum value for block output**

[] (default) | number

Specify the maximum value for the block output signal.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking and automatic scaling of fixed-point data types.

[]

Maximum value not specified.

number

Finite real double scalar value.

Programmatic Use

Block parameter: OutMax

Type: character vector

Value: '[]' | '<number>'

Default: '[]'

Data type — Specify block output data type

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^,0) | Enum: <class name> | Bus: <object name> | <data type expression>

Specify the block output data type.

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

int32

Data type is int32.

uint32

Data type is uint32.

int64

Data type is int64.

uint64

Data type is uint64.

boolean

Data type is boolean.

fixdt(1,16,0)

Data type is fixed point `fixdt(1,16,0)`.

fixdt(1,16,2^0,0)

Data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: <class name>

Data type is enumerated, for example, Enum: Basic Colors.

Bus: <object name>

Data type is a bus object.

<data type expression>

The name of a data type object, for example `Simulink.NumericType`

Do not specify a bus object as the expression.

Programmatic Use

Block parameter: `OutDataTypeStr`

Type: character vector

Value: `'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`

Default: `'double'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data type

`off` (default) | `on`

Control changes to data type settings from the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

On

Locks all data type settings for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change data type settings for this block.

Programmatic Use

Block parameter: `LockScale`

Type: character vector

Value: `'off' | 'on'`

Default: `'off'`

Port dimensions — Specify port dimensions

`1` (default) | `n` | `[m n]`

Specify the dimensions of the argument input signal to the block. For more information, see Output.

1

Inherit port dimensions.

`n`

Vector signal of width `n`.

`[m n]`

Matrix signal having `m` rows and `n` columns.

Programmatic Use

Block parameter: PortDimensions

Type: character vector

Value: '1' | 'n' | '[m n]'

Default: '1'

Signal type — Select real or complex signal

`real` (default) | `complex`

Select real or complex signal.

`real`

Specify the signal type as a real number.

`complex`

Specify the signal type as a complex number.

Programmatic Use

Block parameter: SignalType

Type: character vector

Value: 'real' | 'complex'

Default: 'real'

Argument Output

Argument output port for Simulink Function block

Library: User-Defined Functions

Description

This block is an output argument port for a function that you define in the Simulink Function block.

Ports

Input

in – Block input

scalar | vector | matrix

Block input signal to this block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Output

y – Argument output

scalar | vector | matrix

The Argument Output block accepts real or complex signals of any data type that Simulink supports. An Argument Output block can also accept fixed-point and enumerated data types when the block is not a root-level output port. The Argument Output block also accepts a bus object as a data type.

The complexity and data type of the block input are the same as the argument output. You can specify the signal type and data type of an output argument from an Argument Output block using the **Signal type** and **Data type** parameters. For more information, see “Data Types Supported by Simulink”.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Parameters

Port number – Specify port number of block

1 (default) | integer

Specify the order in which the port that corresponds to the block appears in the parent subsystem or model block.

1

Specify the first port location for this block.

integer

Specify location of port.

Programmatic Use

Block parameter: Port

Type: character vector

Value: '1' | '<integer>'

Default: '1'

Argument name — Specify output argument name

u (default) | character vector

Specify output argument name for the function prototype displayed on the face of the Simulink Function block.

u

Default name of the output argument.

character vector

Name of the output argument.

Programmatic Use

Block parameter: ArgumentName

Type: character vector

Value: 'u' | '<character vector>'

Default: 'u'

Minimum — Specify minimum value for block input

[] (default) | number

Specify the minimum value for the block input signal.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking (see “Specify Signal Ranges”) and automatic scaling of fixed-point data types.

[]

Minimum value not specified.

number

Finite real double scalar value.

Programmatic Use

Block parameter: OutMin

Type: character vector

Value: '[]' | '<number>'

Default: '[]'

Maximum — Specify maximum value for block input

[] (default) | number

Specify the maximum value for the block input signal.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking (see “Specify Signal Ranges”) and automatic scaling of fixed-point data types.

[]

Max mum value not specified.

number

Finite real double scalar value.

Programmatic Use**Block parameter:** OutMax**Type:** character vector**Value:** ' [] ' | '<number>'**Default:** ' [] '**Data type — Specify block input data type**

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^,0) | Enum: <class name> | Bus: <object name> | <data type expression>

Specify block input data type. For more information, see

- Outport
- “Specify Data Types Using Data Type Assistant”

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

`int32`

Data type is `int32`.

`uint32`

Data type is `uint32`.

`int64`

Data type is `int64`.

`uint64`

Data type is `uint64`.

`boolean`

Data type is `boolean`.

`fixdt(1,16,0)`

Data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: `<class name>`

Data type is enumerated, for example, Enum: Basic Colors.

Bus: `<object name>`

Data type is a bus object.

`<data type expression>`

The name of a data type object, for example `Simulink.NumericType`

Do not specify a bus object as the expression.

Programmatic Use

Block parameter: `OutDataTypeStr`

Type: character vector

Value: `'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | '<fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`

Default: `'double'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data type

`off` (default) | `on`

Control changes to data type settings from the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

On

Locks all data type settings for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change data type settings for this block.

Programmatic Use**Block parameter:** LockScale**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Port dimensions — Specify port dimensions**

1 (default) | n | [m n]

Specify the dimensions of the output argument signal from the block. For more information, see [Output](#).

ASCII to String

Uint8 vector signal to string signal

Library: Simulink / String

Description

The ASCII to String block converts uint8 vector signals to string signals. The block treats each element in the input vector as an ASCII value during the conversion. For example, the block converts an input vector of [72 101 108 108 111] to the string "Hello".

Ports

Input

Port_1 – ASCII signal

vector

ASCII signal, specified as a vector.

While using dynamic strings, if the length of the input vector exceeds the number of characters specified in the configuration parameter **Buffer size of dynamically-sized string (bytes)** (256 by default), the ASCII to String block truncates the string output to the buffer size-1 (for example, 255), for generated code. To avoid truncation, increase the value of the **Buffer size of dynamically-sized string (bytes)** configuration parameter.

Example: [088 099]

Data Types: uint8

Output

Port_1 – Converted string signal

scalar

Converted string signal from input ASCII signal, specified as a scalar. The block converts each ASCII element in the vector into its alphanumeric equivalent and outputs all elements concatenated into one string.

Data Types: string

Block Characteristics

Data Types	integer string
Direct Feedthrough	yes
Multidimensional Signals	no

Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Coder / Model Verification

Description

The Assertion block checks whether any of the elements of the input signal are zero. If all elements are nonzero, the block does nothing. If any element is zero, the block halts the simulation, by default, and displays an error message. Use the block parameter dialog box to:

- Specify that the block displays a warning message when the assertion fails but allows the simulation to continue.
- Specify a MATLAB expression to evaluate when the assertion fails.
- Enable or disable the assertion.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal to the assertion check.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

Enable assertion — Enable or disable the check

on (default) | off

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information**Parameter:** enabled**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails**

' ' (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information**Parameter:** callback**Type:** character vector**Values:** MATLAB expression**Default:** ' '**Stop simulation when assertion fails — Halt simulation when check fails**

on (default) | off

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information**Parameter:** stopWhenAssertionFail**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Sample time — Specify sample time as a value other than -1**

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar or vector**Default:** '-1'**Block Characteristics**

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes

Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For information about how Simulink Coder™ generated code handles Model Verification blocks, see “Configure Model for Debugging” (Simulink Coder).

Not recommended for production code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block can be used for checking whether the input signal is zero during simulation, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Assignment

Assign values to specified elements of signal

Library: Simulink / Math Operations
HDL Coder / Math Operations

Description

The Assignment block assigns values to specified elements of the signal. You specify the indices of the elements to be assigned values either by entering the indices in the block dialog box or by connecting an external indices source or sources to the block. The signal at the block data port, U, specifies values to be assigned to Y. The block replaces the specified elements of Y with elements from the data signal.

Based on the value you enter for the **Number of output dimensions** parameter, a table of index options is displayed. Each row of the table corresponds to one of the output dimensions in **Number of output dimensions**. For each dimension, you can define the elements of the signal to work with. Specify a vector signal as a 1-D signal and a matrix signal as a 2-D signal. To enable an external index port, in the corresponding row of the table, set **Index Option** to **Index vector (port)**.

For example, assume a 5-D signal with a one-based index mode. The table in the Assignment block dialog changes to include one row for each dimension. If you define each dimension with the following entries:

Row	Index Option	Index
1	Assign all	
2	Index vector (dialog)	[1 3 5]
3	Starting index (dialog)	4
4	Starting index (port)	
5	Index vector (port)	

The assigned values are $Y(1:\text{end}, [1\ 3\ 5], 4:3+\text{size}(U,3), \text{Idx}4:\text{Idx}4+\text{size}(U,4)-1, \text{Idx}5)=U$, where $\text{Idx}4$ and $\text{Idx}5$ are the input ports for dimensions 4 and 5.

When using the Assignment block in normal mode, Simulink initializes block outputs to zero even if the model does not explicitly initialize them. In accelerator mode, Simulink converts the model into an S-Function. This involves code generation. The code generated may not do implicit initialization of block outputs. In such cases, you must explicitly initialize the model outputs.

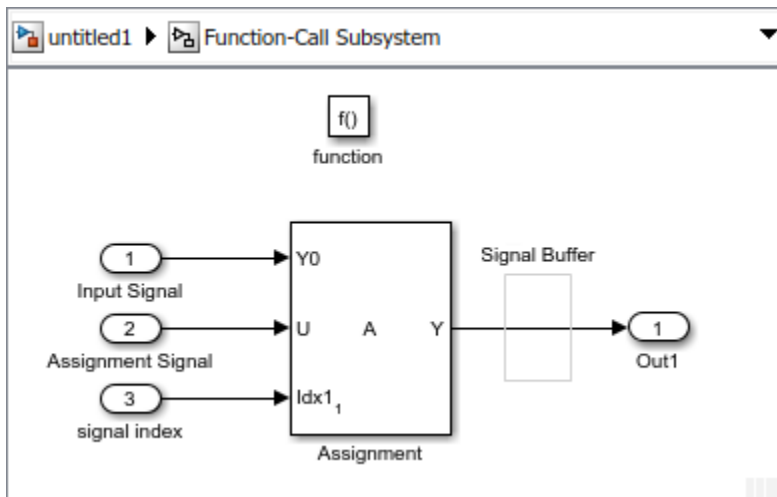

You can use the block to assign values to vector, matrix, or multidimensional signals.

You can use an array of buses as an input signal to an Assignment block.

Assignment Block in Conditional Subsystem

If you place an Assignment block in a conditional subsystem block, a signal buffer can be inserted in many cases, and merging of signals from Assignment blocks with partial writes can cause an error.

However, if you select the **Ensure output is virtual** check box for the conditional subsystem Output block, such cases are supported and partial writes to arrays using Assignment blocks are possible.

Ports

Input

Y0 — Input initialization signal

scalar | vector

The initialization signal for the output signal. If an element is not assigned another value, then the value of the output element matches this input signal value.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed_point | Boolean | enumerated | bus

U — Input data port

scalar | vector

Value assigned to the output element when specified.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed_point | Boolean | enumerated | bus

IdxN — Nth index signal

scalar | vector

External port specifying an index for the assignment of the corresponding output element.

Dependencies

To enable an external index port, in the corresponding row of the **Index Option** table, set **Index Option** to Index vector (port) or Starting index (port).

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | enumerated

Output

Y – Output signal with assigned values

scalar | vector

The output signal with assigned values for the specified elements.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | enumerated | bus

Parameters

Number of output dimensions – Number of dimensions of the output signal

1 (default) | integer

Enter the number of dimensions of the output signal.

Command-Line Information

Parameter: NumberOfDimensions

Type: character vector

Values: integer

Default: '1'

Index mode – Index mode

One-based (default) | Zero-based

Select the indexing mode. If One-based is selected, an index of 1 specifies the first element of the input vector. If Zero-based is selected, an index of 0 specifies the first element of the input vector.

Command-Line Information

Parameter: IndexMode

Type: character vector

Values: 'Zero-based' | 'One-based'

Default: 'One-based'

Index Option – Index method for elements

Index vector (dialog) (default) | Assign all | Index vector (port) | Starting index (dialog) | Starting index (port)

Define, by dimension, how the elements of the signal are to be indexed. From the list, select:

Menu Item	Action
Assign all	This is the default. All elements are assigned.
Index vector (dialog)	Enables the Index column. Enter the indices of elements.
Index vector (port)	Disables the Index column. The index port defines the indices of elements.

Menu Item	Action
Starting index (dialog)	Enables the Index column. Enter the starting index of the range of elements to be assigned values.
Starting index (port)	Disables the Index column. The index port defines the starting index of the range of elements to be assigned values.

If you choose **Index vector (port)** or **Starting index (port)** for any dimension in the table, you can specify one of these values for the **Initialize output (Y)** parameter:

- Initialize using input port <Y0>
- Specify size for each dimension in table

Otherwise, Y0 always initializes output port Y.

The **Index** and **Output Size** columns are displayed as relevant.

Command-Line Information

Parameter: IndexOptionArray

Type: character vector

Values: 'Assign all' | 'Index vector (dialog)' | 'Index option (port)' | 'Starting index (dialog)' | 'Starting index (port)'

Default: 'Index vector (dialog)'

Index — Index of elements

1 (default) | integer

If the **Index Option** is **Index vector (dialog)**, enter the index of each element you are interested in.

If the **Index Option** is **Starting index (dialog)**, enter the starting index of the range of elements to be selected. The number of elements from the starting point is determined by the size of this dimension at U.

Command-Line Information

Parameter: IndexParamArray

Type: character vector

Values: cell array

Default: '{ }'

Output Size — Width of the block output signal

1 (default) | integer

Enter the width of the block output signal.

Dependencies

To enable this column, select **Specify size for each dimension in table** for the **Initialize output (Y)** parameter.

Command-Line Information

Parameter: OutputSizeArray

Type: character vector

Values: cell array

Default: '{ }'

Initialize output (Y) — How to initialize the output signal

Initialize using input port <Y0> (default) | Specify size for each dimension in the table

Specify how to initialize the output signal.

- Initialize using input port <Y0> - Signal at the input port Y0 initializes the output.
- Specify size for each dimension in table - Requires you to specify the width of the block's output signal in the **Output Size** parameter. If the output has unassigned elements, the value of those elements is undefined.

Dependency

Enabled when you set **Index Option** to Index vector (port) or Starting index (port).

Command-Line Information

Parameter: OutputInitialize

Type: character vector

Values: 'Initialize using input port <Y0>' | 'Specify size for each dimension in table'

Default: 'Initialize using input port <Y0>'

Action if any output element is not assigned — Specify whether to produce a warning or error if you have not assigned all output elements

Error (default) | Warning | None

Specify whether to produce a warning or error if you have not assigned all output elements. Options include:

- Error — Simulink software terminates the simulation and displays an error.
- Warning — Simulink software displays a warning and continues the simulation.
- None — Simulink software takes no action.

Command-Line Information

Parameter: DiagnosticForDimensions

Type: character vector

Values: 'Error' | 'Warning' | 'None'

Default: 'None'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Restrictions

- 3-dimensional matrix inputs are not supported. You can use 1-D vectors and 2-D matrices with the block.

- Variable-size signals are not supported for code generation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Backlash

Model behavior of system with play

Library: Simulink / Discontinuities
HDL Coder / Discontinuities

Description

The Backlash block implements a system in which a change in input causes an equal change in output, except when the input changes direction. When the input changes direction, the initial change in input has no effect on the output. The amount of side-to-side play in the system is referred to as the *deadband*. The deadband is centered about the output. This figure shows an initial state, with the default deadband width of 1 and initial output of 0.

A system with play can be in one of three modes.

Mode	Input	Output
Disengaged	Inside deadband zone.	Remains constant.
Engaged-positive direction	Outside deadband zone and increasing.	Equals input <i>minus</i> half of deadband width.
Engaged-negative direction	Outside deadband zone and decreasing.	Equals input <i>plus</i> half of deadband width.

The **Initial output** parameter value defines the initial center of the deadband zone.

This table shows output values when initial conditions are: **Deadband width** = 2 and **Initial output** = 5.

Output Value	Condition
5	$4 \leq \text{input} \leq 6$
$\text{input} + 1$	$\text{input} < 4$
$\text{input} - 1$	$\text{input} > 6$

For example, you can use the Backlash block to model the meshing of two gears. The input and output are both shafts with a gear on one end, and the input shaft drives the output shaft. Extra space between the gear teeth introduces *play*. The width of this spacing is the **Deadband width** parameter. If the system is disengaged initially, the **Initial output** parameter defines the output.

These figures illustrate operation when the initial input is within the deadband and the system begins in disengaged mode.

When the input increases and reaches the end of the deadband, it engages the output. The output remains at its previous value.

After the input engages the output, the output changes by the same amount as the input.

If the input reverses direction, it disengages from the output. The output remains constant until the input reaches the end of the deadband and engages again.

Ports

Input

Port_1 — Input signal

scalar | vector

Input signal to the backlash algorithm. The value of this signal is either in the deadband or engaging the output in a positive or negative direction.

Data Types: double | single | int8 | int16 | int32 | uint8 | uint16 | uint32

Output

Port_1 — Output signal

scalar | vector

Output signal after the backlash algorithm is applied to the input signal. When the input is in the deadband, then the output remains unchanged. If the input is engaged with the output, then the output changes an equal amount as the input.

Data Types: double | single | int8 | int16 | int32 | uint8 | uint16 | uint32

Parameters

Deadband width — Specify the width of the deadband

1 (default) | scalar | vector

Specify the size of the deadband zone centered on the output value. When the input signal is inside the deadband, then a change in input does not cause a change in output. When the input signal is outside of the deadband, then the output changes an equal amount as the input.

Programmatic Use

Block Parameter: BacklashWidth

Type: character vector

Values: real scalar or vector

Default: '1'

Initial output — Specify the initial output value

0 (default) | scalar | vector

Specify the initial center of the deadband zone. If the initial input value is in the deadband zone, then the output value is equal to **Initial output**. If the initial input value is outside of the deadband zone, then the output value is **Initial output** plus or minus half of the deadzone width.

Programmatic Use

Block Parameter: InitialOutput

Type: character vector

Values: real scalar or vector

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox™ license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input *u*. All other input signals must be sample-based.

Input Signal <i>u</i>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Enable zero-crossing detection — Enable zero-crossing detection

on (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector, string

Values: 'off' | 'on'

Default: 'on'

Block Characteristics

Data Types	double integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on memcpy or memset function (string.h) in certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
----------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Restrictions

The **Deadband width** and **Initial output** parameters support only scalar values.

Unresolved Link

Indicate unresolved reference to library block

Description

This block indicates an unresolved reference to a library block (see “Linked Blocks”). You can use this block's parameter dialog box to fix the reference to point to the actual location of the library block.

Parameters

Details

The **Details** field contains a description of the cause of the unresolved link. Simulink tries to help you find and install missing products that a model needs to run. For missing products, the block description provides a link. Click the link to open Add-On Explorer and install the missing products.

The image shows a Simulink model with an unresolved link. The block is labeled "Aerospace Blockset not installed" and "Angle Conversion". It is connected to a "Roll Flightpath" block. A tooltip over the block reads: "Cannot find library called 'aerolibconvert2'. 'Aerospace Blockset' is not installed. Double-click block for more information."

The Diagnostic Viewer shows the following error messages:

```

aeroblk_HL20_Gauges
Update Diagram 21 26
03:41 PM Elapsed: 1 sec
Cannot find library called 'aerolibactuator'. To use the library, install 'Aerospace Blockset'. [20 similar]
Component: Simulink | Category: Model warning
Failed to load library 'aerolibactuator' referenced by 'aeroblk_HL20_Gauges/Actuators/Nonlinear Second-Order Actuator'
Component: Simulink | Category: Model error

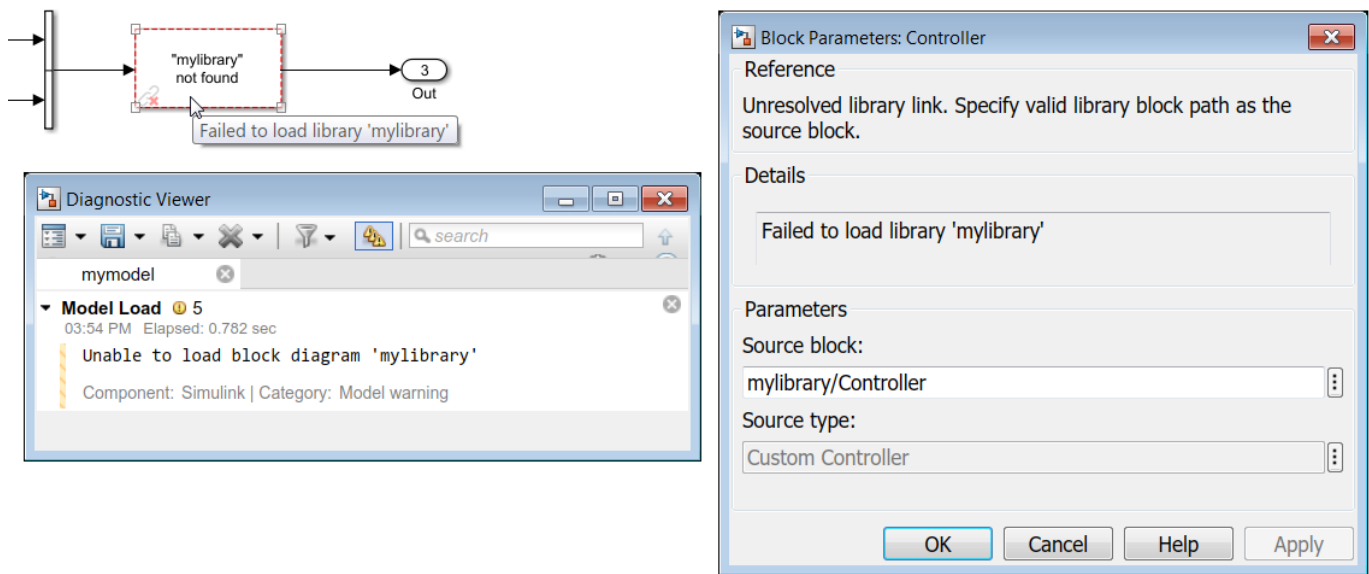

```

The Block Parameters dialog box for "Angle Conversion1" shows the following details:

```

Block Parameters: Angle Conversion1
Reference
Unresolved library link. Specify valid library block path as the source block.
Details
Cannot find library called 'aerolibconvert2'. To use the library, install 'Aerospace Blockset'.
Parameters
Source block:
aerolibconvert2/Angle Conversion
Source type:
Angle Conversion
OK Cancel Help Apply

```

You can customize the Unresolved Link block description for your library to include URLs as follows:

```
set_param(library1, 'libraryinfo', 'https://www.mathworks.com');
```

Here, `library1` is the name of the library for which you want to change the description, and `libraryinfo` is the property that provides the description of the unresolved link.

Source block

Path of the library block that this link represents. To fix a bad link, either click the link in the description to open Add-On Explorer and install a missing product, or edit the **Source block** field to the correct path of the library block. Then select Apply or OK to apply the fix and close the dialog box.

Alternatively, to fix an unresolved link, you can:

- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path and then, in the **Modeling** tab, click **Update Model**.

Source type

Type of library block that this link represents.

Band-Limited White Noise

Introduce white noise into continuous system

Library: Simulink / Sources

Description

The Band-Limited White Noise block generates normally distributed random numbers that are suitable for use in continuous or hybrid systems.

Simulation of White Noise

Theoretically, continuous white noise has a correlation time of 0, a flat power spectral density (PSD), and a total energy of infinity. In practice, physical systems are never disturbed by white noise, although white noise is a useful theoretical approximation when the noise disturbance has a correlation time that is very small relative to the natural bandwidth of the system.

In Simulink software, you can simulate the effect of white noise by using a random sequence with a correlation time much smaller than the shortest time constant of the system. The Band-Limited White Noise block produces such a sequence. The correlation time of the noise is the sample rate of the block. For accurate simulations, use a correlation time much smaller than the fastest dynamics of the system. You can get good results by specifying

$$tc \approx \frac{1}{100} \frac{2\pi}{f_{max}}$$

where f_{max} is the bandwidth of the system in rad/sec.

Comparison with the Random Number Block

The primary difference between this block and the Random Number block is that the Band-Limited White Noise block produces output at a specific sample rate. This rate is related to the correlation time of the noise.

Usage with the Averaging Power Spectral Density Block

The Band-Limited White Noise block specifies a two-sided spectrum, where the units are Hz. The Averaging Power Spectral Density block specifies a one-sided spectrum, where the units are the square of the magnitude per unit radial frequency: $\text{mag}^2/(\text{rad}/\text{sec})$. When you feed the output of a Band-Limited White Noise block into an Averaging Power Spectral Density block, the average PSD value is π times smaller than the **Noise power** of the Band-Limited White Noise block. This difference is the result of converting the units of one block to the units of the other, $1/(1/2)(2\pi) = 1/\pi$, where:

- $1/2$ is the factor for converting from a two-sided to one-sided spectrum.
- 2π is the factor for converting from Hz to rad/sec.

Ports

Output

Port_1 — Normally distributed random numbers

scalar | vector | matrix | N-D array

Normally distributed random numbers specified as a scalar, vector, matrix, or N-D array.

Data Types: double

Parameters

Noise power — Height of PSD of white noise

[0.1] (default) | scalar | vector | matrix | N-D array

Specify the height of the PSD of the white noise as a scalar, vector, matrix, or N-D array of positive values.

Programmatic Use

Block Parameter: Cov

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '[0.1]'

Sample time — Correlation time of noise

0.1 (default) | scalar | vector

Correlation time of the noise. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: Ts

Type: character vector

Values: scalar | vector

Default: '0.1'

Seed — Starting seed

[23341] (default) | scalar | vector | matrix | N-D array

Specify the starting seed for the random number generator as a scalar, vector, matrix, or N-D array. Values must be positive, real-valued, and finite.

Programmatic Use

Block Parameter: seed

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '[23341]'

Interpret vector parameters as 1-D — Treat vector parameters as 1-D

on (default) | off

Select to output a 1-D array when the block parameters are vectors. Otherwise, output a 2-D array one of whose dimensions is 1. For more information, see “Determine the Output Dimensions of Source Blocks”.

Programmatic Use**Block Parameter:** VectorParams1D**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Block Characteristics**

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

To produce the correct intensity of this noise, the covariance of the noise is scaled to reflect the implicit conversion from a continuous PSD to a discrete noise covariance. The appropriate scale factor is $1/tc$, where tc is the correlation time of the noise. This scaling ensures that the response of a continuous system to the approximate white noise has the same covariance as the system would have to true white noise. Because of this scaling, the covariance of the signal from the Band-Limited White Noise block is not the same as the **Noise power** (intensity) parameter. This parameter is actually the height of the PSD of the white noise. This block approximates the covariance of white noise as the **Noise power** divided by tc .

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Cannot use inside a triggered subsystem hierarchy.

Bias

Add bias to input

Library: Simulink / Math Operations
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Bias block adds a bias, or offset, to the input signal according to

$$Y = U + bias$$

where U is the block input and Y is the output.

Ports

Input

Port_1 – Input signal

scalar | vector

Input signal to which the bias is added to create the output signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Output signal

scalar | vector

Output signal resulting from adding the bias to the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Bias – Offset to add to the input signal

0.0 (default) | scalar | vector

Specify the value of the offset to add to the input signal.

Programmatic Use

Block Parameter: Bias

Type: character vector

Values: real, finite

Default: '0.0'

Saturate on integer overflow – Choose the behavior when integer overflow occurs

on (default) | boolean

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Value: 'off' | 'on'

Default: 'on'

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	no

Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

Bit Clear

Set specified bit of stored integer to zero

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Bit Clear block sets the specified bit, given by its index, of the stored integer to zero. Scaling is ignored.

You can specify the bit to be set to zero with the **Index of bit** parameter, where bit zero is the least significant bit.

Ports

The Bit Clear block supports Simulink integer, fixed-point, and Boolean data types. The block does not support true floating-point data types or enumerated data types.

Input

Port_1 — Input signal

scalar or vector

The input signal is the specified bit of the stored integer.

Data Types: `single` | `double` | `Boolean` | `fixed point`

Output

Port_1 — Output signal

scalar or vector

The output consists of the specified bit set to zero.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Index of bit — Index of bit

0 (default) | scalar or vector

Index of bit where bit 0 is the least significant bit.

Programmatic Use

Block Parameter: `iBit`

Type: scalar or vector

Values: {'0'}

Default: '0'

Block Characteristics

Data Types	Boolean ^a fixed point integer
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

a. Bit operations are not recommended for use with Boolean signals.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

Bit Set

Set specified bit of stored integer to one

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Bit Set block sets the specified bit of the stored integer to one. Scaling is ignored.

You can specify the bit to be set to one with the **Index of bit** parameter, where bit zero is the least significant bit.

Ports

Input

Port_1 — Input signal

scalar or vector

Input signal with the specified bit of the stored integer.

Data Types: `single` | `double` | `Boolean` | `fixed point`

Output

Port_1 — Output signal

scalar or vector

Output signal with the specified bit set to 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Index of bit — Index of bit

0 (default) | scalar or vector

Index of bit where bit 0 is the least significant bit.

Programmatic Use

Block Parameter: `iBit`

Type: character vector

Values: positive integer

Default: `'0'`

Block Characteristics

Data Types	Boolean ^a fixed point integer
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

a. Bit operations are not recommended for use with Boolean signals.

Extended Capabilities

Bit Clear | Bit Rotate | Bit Shift | Bitwise Operator

Introduced before R2006a

Bitwise Operator

Specified bitwise operation on inputs

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Bitwise Operator block performs the bitwise operation that you specify on one or more operands. Unlike logic operations of the Logical Operator block, bitwise operations treat the operands as a vector of bits rather than a single value.

Restrictions on Block Operations

The Bitwise Operator block does not support shift operations. For shift operations, use the Shift Arithmetic block.

When configured as a multi-input XOR gate, this block performs modulo-2 addition according to the IEEE[®] Standard for Logic Elements.

Ports

Input

Port_1 — Input signal

scalar | vector

Input signal, specified as a scalar or vector.

- The NOT operator accepts only one input, which can be a scalar or a vector. If the input is a vector, the output is a vector of the same size containing the bitwise logical complements of the input vector elements.
- For a single vector input, the block applies the operation (except the NOT operator) to all elements of the vector.
- For two or more inputs, the block performs the operation between all of the inputs. If the inputs are vectors, the block performs the operation between corresponding elements of the vectors to produce a vector output.

Data Types: int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector

The output signal specified as the output data type, which the block inherits from the driving block, must represent zero exactly. Data types that satisfy this condition include signed and unsigned integer data types.

The size of the block output depends on the number of inputs, the vector size, and the operator you select. If you do not specify a bit mask, the output is a scalar. If you do specify a bit mask, the output is a vector.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Operator – Bitwise logical operator

`AND` (default) | `OR` | `NOR` | `NAND` | `XOR` | `NOT`

Specify the bitwise logical operator for the block operands.

You can select one of these bitwise operations:

Bitwise Operation	Description
AND	TRUE if the corresponding bits are all TRUE
OR	TRUE if at least one of the corresponding bits is TRUE
NAND	TRUE if at least one of the corresponding bits is FALSE
NOR	TRUE if no corresponding bits are TRUE
XOR	TRUE if an odd number of corresponding bits are TRUE
NOT	TRUE if the input is FALSE (available only for single input)

Programmatic Use

Block Parameter: `logicop`

Type: character vector

Values: `'AND'` | `'OR'` | `'NAND'` | `'NOR'` | `'XOR'` | `'NOT'`

Default: `'AND'`

Use bit mask – Select to use bit mask

`checked` (default) | `unchecked`

Select to use the bit mask. Clearing this check box enables **Number of input ports** and disables **Bit Mask** and **Treat mask as**.

Programmatic Use

Block Parameter: `UseBitMask`

Type: character vector

Values: `'off'` | `'on'`

Default: `'on'`

Number of input ports – Number of input signals

`1` (default) | integer

Specify the number of inputs. You can have more than one input ports.

Dependency

Clearing the **Use bit mask** check box enables **Number of input ports** and disables **Bit Mask** and **Treat mask as**.

Programmatic Use

Block Parameter: NumInputPorts

Type: character vector

Values: positive integer

Default: '1'

Bit Mask — Bit mask to associate with a single input

bin2dec (default)

Specify the bit mask to associate with a single input.

You can use the bit mask to set, get, or clear a bit on the input.

To perform a...	Set the Operator parameter to...	And create a bit mask with...
Bit set	OR	A 1 for each corresponding input bit that you want to set to 1
Bit clear	AND	A 0 for each corresponding input bit that you want to set to 0
Bit get	AND	A 1 for each corresponding input bit that you want to get

Suppose you want to set the fourth bit of an 8-bit input vector. The bit mask would be 00010000, which you can specify as 2^4 for the **Bit Mask** parameter. To clear the bit, the bit mask would be 11101111, which you can specify as $2^7+2^6+2^5+2^3+2^2+2^1+2^0$ for the **Bit Mask** parameter.

Tip Do not use a mask greater than 53 bits. Otherwise, an error message appears during simulation.

Dependency

This parameter is available only when you select **Use bit mask**.

Programmatic Use

Block Parameter: BitMask

Type: character vector

Values: positive integer

Default: 'bin2dec('11011001')'

Treat mask as — Treat the mask as a real-world value or a stored integer

Stored Integer (default) | Real World Value

Specify whether to treat the mask as a real-world value or a stored integer.

The encoding scheme is $V = SQ + B$, as described in “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer™ documentation. Real World Value treats the mask as V . Stored Integer treats the mask as Q .

Dependency

This parameter is available only when you select **Use bit mask**.

Programmatic Use

Block Parameter: BitMaskRealWorld

Type: character vector

Values: 'Real World Value' | 'Stored Integer'

Default: 'Stored Integer'

Block Characteristics

Data Types	Boolean ^a fixed point integer
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

a. Bit operations are not recommended for use with Boolean signals.

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Bus Assignment

Replace specified bus elements

Library: Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The Bus Assignment block assigns the values of a signal to bus elements. Use a Bus Assignment block to change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble them into a bus.

Connect the bus signal to the first input port. To other input ports, connect one or more signals whose values you want to assign to a bus element. Use the Block Parameters dialog box to specify the bus elements to be replaced. The block displays an assignment input port for each such element. For an example of a model that uses a Bus Assignment block, see “Replace Signal Values of Bus Elements”.

By default, Simulink repairs broken selections in the Bus Assignment Block Parameters dialog boxes that are due to upstream bus hierarchy changes. Simulink generates a warning to highlight that it modified the model. To prevent Simulink from making these repairs automatically, in the **Model Configuration Parameters > Diagnostics > Connectivity** pane, set the “Repair bus selections” diagnostic to Error without repair.

Limitations

When using arrays of buses with a Bus Assignment block, these limitations apply:

- You can assign or replace a nested bus that is an array of buses. For a bus that is nested inside an array of buses, see “Assign into Arrays of Buses”.
- To replace a signal in an array of buses, use a Selector block to select the index for the bus element that you want to use with the Bus Assignment block. Then, use that selected bus element with the Bus Assignment block.

Ports

Input

Bus — Accept bus signal for bus element value assignment

real or complex values of any data type supported by Simulink

Input bus signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. For details about data types, see Simulink, “Data Types Supported by Simulink”.

The signal connected to the assignment port must have the same structure, data type, and sample time as the bus element to which it corresponds. You can use a Rate Transition block to change the sample time of an individual signal or signals in a bus, to include the signal or bus in a nonvirtual bus.

:= — Accept signals whose value are assigned to bus elements

real or complex values of any data type supported by Simulink

Assignment input ports can accept signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. You cannot use the Bus Assignment block to replace a bus that is nested within an array of buses. For details about data types, see Simulink, “Data Types Supported by Simulink”.

The Bus Assignment block assigns signals connected to its assignment input ports to specified elements of the bus connected to its bus input port. The block replaces the signals previously assigned to those elements. The change does not affect the composition of the bus; it affects only the values of the signals themselves. Signals not replaced are unaffected by the replacement of other signals.

Output**Bus — Output bus signal**

virtual or nonvirtual bus

Bus that includes the assigned bus element values and the values of the bus elements of the input bus that you did not assign values to.

Parameters**Signals in the bus — Bus element signals of input bus**

list of signal names

List of the bus element signals of the input bus signal. An arrow next to a signal name indicates that the input signal is a bus. To display the signals in an input bus, click the arrow.

Click any item in the list to select it. To find the source of the selected signal, click **Find**. Simulink opens and highlights the system containing the signal source. To move the currently selected signal into the adjacent list of signals to be assigned values (see **Signals that are being assigned** below), click **Select**. To refresh the display to reflect modifications to the bus connected to the block, click **Refresh**.

Filter by name — Filter set of displayed signals

text

Specify a search term to use for filtering a long list of input signals. Do not enclose the search term in quotation marks. The filter does a partial string search. To access filtering options, including using a regular expression for specifying the search term, click the  button on the right of the **Filter by name** edit box.

Enable regular expression — Filter set of displayed input signals

off (default) | on

Enable the use of MATLAB regular expressions for filtering signal names. For example, entering `t$` in the **Filter by name** edit box displays all signals whose names end with a lowercase `t` (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

Dependencies

To access this parameter, click the  button on the right of the **Filter by name** edit box.

Show filtered results as a flat list – Filter set of displayed input signals

off (default) | on

By default, the list displays as a tree list of filtered signals, based on the search text in the **Filter by name** edit box. To use a flat list format that uses dot notation to reflect the hierarchy of bus signals, select this parameter.

Dependencies

To access this parameter, click the  button on the right of the **Filter by name** edit box

Signals that are being assigned – Names of bus elements to be assigned values

list of signal names

Names of bus elements to be assigned values. This block displays an assignment input port for each bus element in this list. The label of the corresponding input port contains the name of the element. You can order the signals by using the **Up**, **Down**, or **Remove** buttons. Port connectivity is maintained when you change the signal order.

If an input bus no longer contains a bus element, three question marks (???) appear before the name of that bus element. The bus has changed since the last time you refreshed the Bus Assignment block input and bus element assignment lists. To address this issue, either modify the bus to include a signal of the specified name or remove the name from the list of bus elements designated to be assigned values.

Programmatic Use**Block Parameter:** OutputSignals**Type:** character vector**Values:** 'signal1'|'signal2'**Default:** none**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

To learn more about using buses for HDL code generation, see “Buses” (HDL Coder) and “Use Bus Signals to Improve Readability of Model and Generate HDL Code” (HDL Coder).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

 “Share and Reuse Bus-Routing Blocks”

Introduced before R2006a

Bus Creator

Create bus from input signals

Library: Simulink / Commonly Used Blocks
 Simulink / Signal Routing
 HDL Coder / Signal Routing

Description

The Bus Creator block combines a set of input signals into a bus. You can connect any signal types to the input ports, including other buses. You can access signals in a bus by using a Bus Selector block.

Elements of a bus must have unique names. By default, each element of the bus inherits the name of the signal connected to the Bus Creator block. If duplicate names are present, the Bus Creator block appends the port number to all input signal names. For signals that do not have names, the Bus Creator block generates names in the form `signaln`, where `n` is the port number connected to the signal. You can refer to signals by name when you search for their sources or select signals for connection to other blocks. For signal naming guidelines, see “Signal Names and Labels”.

Ports

Input

Port_1 — Input signal to include in bus

scalar | vector | matrix | array | bus

Input signal to include in the bus, specified as a scalar, vector, matrix, *N*-D array, or bus.

The number of input ports is driven by the **Number of inputs** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output bus

virtual bus | nonvirtual bus

Output bus composed of the combined input signals, specified as a virtual or nonvirtual bus. For more information on the types of buses, see “Types of Composite Signals”.

Data Types: bus

Parameters

Number of inputs — Number of input signals

2 (default) | integer

Number of input signals, not fewer than two, specified as an integer. Increasing the number of inputs adds empty input ports to the block. Before you simulate the model, make sure that an input signal is connected to each input port.

When you modify the **Number of inputs** parameter, click **Refresh** to update the list of signals.

Tip If all input ports are already connected, you can add an input port to the Bus Creator block by connecting another signal line to it.

Interactively adding a port updates the **Number of inputs** parameter and adds the new signal to the list of signals in the bus.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: integer greater than or equal to 2, comma-separated list of signal names

Default: '2'

By default, the Inputs parameter specifies the number of inputs. When you use it to specify the names of signals in the bus, the number of inputs matches the number of signal names you specify.

Signals in the bus — List of input signals

list of signal names

List of input signals to combine into a bus. You can view all signals entering the block, including the signals contained in nested buses. An arrow next to a signal indicates that an input signal is a bus. To display the contents of that bus, click the arrow.

To rearrange the signals in the output bus, use the **Up** and **Down** buttons. You can select multiple top-level adjacent signals in the **Signals in the bus** list to reorder or remove.

To find the source of any signal entering the block, select the signal in the **Signals in the bus** list and click the **Find** button. Simulink highlights the icon of the source, opening the subsystem that contains the signal source, if necessary.

If you change a signal name while the Block Parameters dialog box is open, you can see the updated name by clicking **Refresh**.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: integer greater than or equal to 2, comma-separated list of signal names

Default: '2'

By default, the Inputs parameter specifies the number of inputs. When you use it to specify the names of signals in the bus, the number of inputs matches the number of signal names you specify.

Filter by name — Search term for filtering displayed input signals

text

Search term for filtering displayed input signals, specified as text. Do not enclose the search term in quotation marks. The filter does a partial string search.

To access the filtering options, click the **Show filtering options**  button to the right of the **Filter by name** box.

Enable regular expression — Option to filter displayed input signals by regular expression

off (default) | on

Option to filter the displayed input signals by regular expression.

When this parameter is enabled, entering `t$` in the **Filter by name** box displays all signals whose names end with a lowercase `t` (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

Dependencies

To access this parameter, click the **Show filtering options**  button to the right of the **Filter by name** box.

Show filtered results as a flat list — Option to display filtered results as a flat list

off (default) | on

Option to display filtered results as a flat list that uses dot notation to reflect the hierarchy of buses. By default, the filtered signals appear in a hierarchical tree.

Dependencies

To access this parameter, click the **Show filtering options**  button to the right of the **Filter by name** box.

Output data type — Data type of output bus

'Inherit: auto' (default) | 'Bus: <object name>' | <data type expression>

Data type of the output bus.

If you select 'Bus: <object name>', specify a Simulink.Bus object. The Bus object must be accessible when you update the diagram or simulate the model. To define a Bus object using the **Bus**

Editor, click the **Show data type assistant** button , and then click the **Edit** button.

If you select '<data type expression>', specify an expression that evaluates to a data type. Do not specify a Bus object as the expression.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>'

Default: 'Inherit: auto'

Require input signal names to match signals above — Check that input signal names match names listed in dialog box

off (default) | on

Check that the input signal names match the names listed in the Block Parameters dialog box. If the signal names do not match, Simulink returns an error.

Tip The **Require input signal names to match signals above** parameter might be removed in a future release. To enforce strong data typing, consider using the **Override bus signal names from inputs** parameter.

Dependencies

If you select **Override bus signal names from inputs**, the Simulink software ignores the **Require input signal names to match signals above** setting.

If you change the **Number of inputs** programmatically, this parameter reverts to 'off'.

Rename selected signal — New name for selected input signal

' ' (default) | character vector

New name for the selected input signal. See “Signal Names and Labels” for signal name guidelines.

Dependencies

To display this parameter, enable the **Require input signal names to match signals above** parameter.

Override bus signal names from inputs — Option to override names from Simulink.Bus object with input signal names

on (default) | off

By default, the Bus Creator block overrides the names specified by the `Simulink.Bus` object and uses the input signal names as the output bus element names.

To inherit bus element names from the `Bus` object, clear this parameter. Clearing the parameter:

- Enforces strong data typing.
- Avoids having to enter a signal name multiple times: in the `Bus` object and in the model. Entering the name multiple times can accidentally create signal name mismatches.
- Supports the array of buses requirement to have consistent signal names across array elements.

Alternatively, you can enforce strong data typing by checking that input signal names match the `Bus` object element names.

- Keep the **Override bus signal names from inputs** check box selected.
- Set the **Element name mismatch** configuration parameter to error.

Dependencies

To display this parameter, set the **Output data type** parameter to a `Bus` object.

Programmatic Use**Block Parameter:** InheritFromInputs**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Output as nonvirtual bus — Output nonvirtual bus**

off (default) | on

Output a nonvirtual bus instead of a virtual bus.

All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated Bus object specify inherited sample times for some elements. Any operation resulting in a nonvirtual bus containing signals with different sample rates generates an error. To change the sample time of a signal or bus that has a different sample time than the other nonvirtual bus input signals, use a Rate Transition block. For details, see “Modify Sample Times for Nonvirtual Buses”.

To generate code that uses a C structure to define the structure of the bus that this block creates, enable this parameter.

Dependencies

To display this parameter, set the **Output data type** parameter to a Bus object.

Programmatic Use**Block Parameter:** NonVirtualBus**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Tips

For buses at subsystem and model interfaces, you can use Out Bus Element blocks instead of a Bus Creator block with an Outport block. Out Bus Element blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.

Bus Selector

Select signals from incoming bus

Library: Simulink / Commonly Used Blocks
 Simulink / Signal Routing
 HDL Coder / Signal Routing

Description

The Bus Selector block outputs the signals you select from the input bus. The block can output the selected elements separately or in a new virtual bus.

Ports

Input

Port_1 — Input bus

virtual bus | nonvirtual bus

Input bus, which can be virtual or nonvirtual.

For arrays of buses, you must use a Selector block to select the bus that you want to use with the Bus Selector block.

Data Types: bus

Output

Port_1 — Selected bus elements of input bus

scalar | vector | matrix | array | bus

Selected bus elements of an input bus.

For each output signal, this block uses a separate port from the top to the bottom of the block. If the block is rotated, see “Port Location After Rotating or Flipping” for the port order of various block orientations.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Signals in the bus — List of elements in input bus

list of signal names

List of elements in the input bus from which to select output signals.

If you change a signal name while the Block Parameters dialog box is open, you can see the updated name by clicking **Refresh**.

To highlight the source of a signal entering the block, select the signal in the list and click **Find**.

Programmatic Use

Block Parameter: InputSignals

Type: cell array

Values: signal names

Filter by name — Search term for filtering displayed input signals

text

Search term for filtering displayed input signals, specified as text. Do not enclose the search term in quotation marks. The filter does a partial string search.

To access the filtering options, click the **Show filtering options**  button to the right of the **Filter by name** box.

Enable regular expression — Option to filter displayed input signals by regular expression

off (default) | on

Option to filter the displayed input signals by regular expression.

When this parameter is enabled, entering `t$` in the **Filter by name** box displays all signals whose names end with a lowercase `t` (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

Dependencies

To access this parameter, click the **Show filtering options**  button on the right side of the **Filter by name** box.

Show filtered results as a flat list — Option to display filtered results as a flat list

off (default) | on

Option to display filtered results as a flat list that uses dot notation to reflect the hierarchy of buses. By default, the filtered signals appear in a hierarchical tree.

Dependencies

To access this parameter, click the **Show filtering options**  button on the right side of the **Filter by name** box.

Selected signals — Selected elements of input bus

list of signal names

The selected elements of the input bus.

To specify an output signal, select a signal from the **Signals in the bus** list, and then click the **Select** button. The signal is added at the end of the **Selected signals** list. To add signals below an existing signal, select a signal in the **Selected signals** list before you click **Select**. Signals are added below the signal you selected.

If you select multiple signals from the **Signals in the bus** list, the order in which you select them is the order in which Simulink inserts them in the **Selected signals** list.

If an output signal listed in the **Selected signals** list is not an input to the Bus Selector block, the signal name starts with three question marks (???).

To change the order of the output bus elements, use the **Up** and **Down** buttons. Port connectivity with downstream blocks is maintained when you change the signal order.

To remove bus elements from the block output, use the **Remove** button. You can select multiple contiguous signals to move or remove.

Tip In the Simulink Editor, as you draw a new signal line close to the output side of a Bus Selector block when all output ports are already connected, Simulink:

- Adds a port
- Prompts you to specify the signal to be selected

You cannot use this automatic port addition approach if:

- A bus input is not connected to the Bus Selector block.
 - You do not specify a signal in response to the prompt that appears when you draw a signal line close to the Bus Selector block icon.
 - You select the **Output as virtual bus** parameter.
-

Programmatic Use

Block Parameter: OutputSignals

Type: character vector

Values: character vector in the form of 'signal1,signal2'

Default: none

Output as virtual bus — Option to output selected elements as virtual bus

off (default) | on

Option to output the selected elements as a virtual bus.

By default, the block outputs each of the selected elements from a separate output port that is labeled with the corresponding bus element name. When this parameter is enabled, the block outputs the selected elements from one port, grouped in a virtual bus.

The output bus is virtual. To convert the output to a nonvirtual bus, insert a Signal Conversion block after the Bus Selector block. Set the Signal Conversion block **Output** parameter to **Nonvirtual bus** and set the **Data type** to a `Simulink.Bus` object.

When the **Selected signals** list includes only one signal and you enable **Output as virtual bus**, then that signal is not wrapped in a bus. For example, if the signal is a bus, the output signal is that bus. If the signal is not a bus, the output signal is not a bus.

Programmatic Use

Block Parameter: OutputAsBus

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Tips

For buses at subsystem and model interfaces, you can use In Bus Element blocks instead of an Inport block with a Bus Selector block. In Bus Element blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

To learn more about using buses for HDL code generation, see “Buses” (HDL Coder) and “Use Bus Signals to Improve Readability of Model and Generate HDL Code” (HDL Coder).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
----------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Bus to Vector

Convert virtual bus to vector

Library: Simulink / Signal Attributes
HDL Coder / Signal Attributes

Description

The Bus to Vector block converts a virtual bus to a vector signal. The input bus must consist of scalars or 1-D, row, or column vectors that have the same data type, signal type, and sampling mode. If the input bus contains row or column vectors, the output is a row or column vector, respectively. Otherwise, the output is a 1-D array.

Use the Bus to Vector block only to replace an implicit bus-to-vector conversion with an explicit conversion. To identify and correct buses used as vectors without manually inserting Bus to Vector blocks, you can use the Simulink Model Advisor “**Check bus signals treated as vectors**” on page 9-22 check. Alternatively, you can use the `Simulink.BlockDiagram.addBusToVector` function, which automatically inserts Bus to Vector blocks wherever needed.

Note If you use **Save As** to save a model in a version of the Simulink product before R2007a, a null subsystem that outputs nothing replaces each Bus to Vector block. Before you can use the model, reconnect or otherwise correct each path that used to contain a Bus to Vector block but now is interrupted by a null subsystem.

Ports

Input

Port_1 — Accept signal to convert to vector

virtual bus | nonbus signal

The input bus signals must consist of scalars or 1-D, row, or column vectors that have the same data type, signal type, and sampling mode. If the input is a nonbus signal, the block does no conversion.

Output

Port_1 — Output vector signal

vector | 1-D array

Output a vector signal, based on input bus signal. If the input bus contains row or column vectors, the block output is a row or column vector, respectively. Otherwise, the output is a 1-D array.

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single
-------------------	----------------------------------------------------------------------

Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Callback Button

Execute MATLAB code based on user input

Library: Simulink / Dashboard

Description

The Callback Button block executes MATLAB code based on user input. The Callback Button block reacts to clicks and presses from the user. You can specify separate code to execute for each action. The Callback Button block repeats the code specified for the press action at a specified rate as long as you continue to press the button.

The Callback Button block registers a click when you release the left mouse button with the cursor on the Callback Button. The code for a press executes when you click the Callback Button and hold for the specified **Press Delay**.

Double-clicking the Callback Button block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Parameters

Button Text — Text on button

'Callback Button' (default) | character array

Text that appears on the button.

Mouse Action — Mouse action to run code

'ClickFcn' (default) | 'PressFcn'

Mouse action that causes the MATLAB code to execute.

- Select `ClickFcn` to view and edit the code that executes when the Callback Button block is clicked.
- Select `PressFcn` to view and edit the code that executes when the button is pressed.

MATLAB Code — Code to execute based on user input

empty (default) | MATLAB Code

MATLAB code that executes based on user input.

Dependency

The MATLAB code displayed depends on the Mouse Action parameter selection.

- Select `ClickFcn` to view and edit the code that executes when the Callback Button block is clicked.
- Select `PressFcn` to view and edit the code that executes when the button is pressed.

Press Delay (ms) – Time to hold button for press

500 (default) | scalar

Amount of time required to cause the PressFcn code to execute.

Dependency

Press Delay (ms) is only visible when PressFcn is selected as the Mouse Action.

Repeat Interval (ms) – Time interval to repeat PressFcn code

0 (default) | scalar

Time interval after which the PressFcn code executes again if the Callback Button block is still pressed.

Dependency

Repeat Interval (ms) is only visible when PressFcn is selected as the Mouse Action.

Block Characteristics

Data Types	
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no

C Caller

Integrate C code in Simulink

Library: Simulink / User-Defined Functions

Description

The C Caller block integrates your external C code into Simulink. This block imports and lists the functions in your external C code, and allows you to select your resolved C functions to integrate in your Simulink models. The C Caller block standalone supports code generation. For more complex models, code generation depends on the capabilities of your Simulink model.

To use the C Caller block, define your source code and any supporting files using **Simulation Target** under **Configuration Parameters**. Then, bring a C Caller block to the Simulink canvas, using **Library Browser > Simulink > User Defined Functions**. To change the defined source code file and its dependencies, go to **Simulation Target** tab in **Configuration Parameters** by clicking the

from the block dialog. After changing your source code or any of its dependencies, refresh the

list of functions by clicking the  on the block dialog. To browse and modify the list of functions in

your source code, use the  icon to access your header files.

Ports

Input

Input argument — Input argument for the corresponding C Caller block

scalar | vector | matrix

Input argument to the C Caller block.

Number of input arguments and their names are inferred through the selected function in your external C code. To receive data to a C Caller block, connect an input signal to the input ports.

Input label has the same name as your input argument unless changed by editing the **Label** column under **Port Specification** from the **Block Dialog**. If you rename the label to an input port, the C Caller block changes the name of the port.

For input variables, you can change the input scope to parameters or constants using the **Scope** column.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Output argument — Output argument for the corresponding C Caller block

scalar | vector | matrix

Output argument from the C Caller block.

Number of output arguments and their names are inferred through the selected function in your external C code. To send data from your C Caller block, connect a block to the output port of your C Caller block.

Output port label has the same name as your output argument unless you change it by editing the **Label** column under **Port Specification** from the **Block Dialog**. If you rename the label to an input port, the C Caller block changes the name of the port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus

Parameters

Function name — Name of the functions in source code

character vector

The C Caller block in your model imports all functions in your external source code, and shows the names of functions under **Function name** in the block dialog. To select and use a function in your block, confirm that the function names appear at the **Function name** table. In case you are missing

one of the functions, reload the source code by clicking  on the block dialog. To change the names of your functions, modify your source code and click the refresh button to reload.

Port specification — Specify port properties

string

The **Port specification** table indicates the attributes of each input and output element for the selected block. These properties include **Argument name**, **scope**, **input/output label**, **type** and **size** of the input/output variables. **Argument name**, **scope**, **type**, and **size** are inferred from your source code. If the **scope** is an **input**, you can modify this variable to a **parameter** or a **constant**.

Arg name — Demonstrates the variable name inferred from your source code.

Scope — Indicates the role of the variables from your source code. If the variable is an input argument in the C Caller block source code, you can change the **scope type** to a **constant** or a **parameter**. If the variable is an output argument in the source code, you cannot change the **scope type**.

Label — Labels the input or output variable for the Simulink model. You can change the labels using this table. If the **scope** is a **parameter**, enter the parameter name in this field. If the **scope** is a **constant**, enter the constant value.

Type — Indicates the data type coming from the ports.

Size — Indicates the size of the input and output data.

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a integer ^a single ^a
Direct Feedthrough	no

“Integrate C Code Using C Caller Blocks”

Introduced in R2018b

C Function

Integrate and call external C code from a Simulink model

Library: Simulink / User-Defined Functions

Description

The C Function block integrates and calls external C code from a Simulink model. Use this block to define external code and customize the integration of your code by preprocessing or postprocessing the data. In addition, you can specify customized code for simulation and C code generation. You can call functions defined in your code conditionally, and you can also call multiple functions in one block. Using this block, you can initialize the block's persistent data and pass it to an external function.

The C Function block supports initializing persistent data and calling external functions from the block dialog. The C Function block supports only initializing and terminating persistent data; the block does not support updating the data during simulation. To model a dynamic system with continuous states, use an S-Function block. To learn more about S-functions, see “What Is an S-Function?”.

Define the source code and supporting files to be called by the C Function block in the **Simulation Target** pane of the configuration parameters.

Limitations

The following features of Simulink are not compatible with the C Function block.

- Simulink Coverage™
Only execution coverage is measured.
- Simulink Code Inspector™
- Simulink Design Verifier™
- Simulink Test™
 - Test harness
- Use of the C Function block in Simulink Report Generator™

In addition, the following limitations apply to the source code referenced by a C Function block.

- The C keyword `static` is not supported.

To cache values across time steps, define the symbol as **Persistent** in the **Symbols** table of the block dialog.

- Files cannot be included in the script.

External functions must be specified in the **Simulation Target** pane of the Configuration Parameters dialog.

If you have existing includes defined in the **Simulation Target** pane that cannot be mixed with the new include, consider adding the include and C Function block in a library model and use a link to the block in the main model. For more information, see “Create a Custom Library”.

- Pointers of different types cannot be assigned to each other. The pointer types should match when you call external functions.
- The code cannot take the address of a constant.
- Directly calling C library functions from the C Function block is not supported. To call C library functions, create a wrapper function that calls the C library function.

Ports

Input

Input port — Input of the C Function block

scalar | vector

Input to the C Function block.

The number of inputs and their names are determined by the definitions in your external C code and the definitions of the symbols in the **Symbols** table in the block parameters dialog.

The input port label is the same as the name of the input symbol unless you change it by editing the **Label** field in the **Symbols** table of the blocks dialog.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus

Output

Output port — Output of the C Function block

scalar | vector

Output from the C Function block.

Number of outputs and their names are determined by the definitions in your external C code and the definitions of the symbols in the **Symbols** table in the block parameters dialog.

The output port label is the same as the name of the output symbol unless you change it by editing the **Label** field in the **Symbols** table of the block parameters dialog.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus

Parameters

Output Code — Output code

character array | string

Specifies the code that the C Function block executes during simulation. For example, you can call a function from the external C code specified in the **Simulation Target** pane, make modifications to the results, and perform operations to pass the results to other blocks.

Start Code — Initialization code

character array | string

Specifies the initialization code of the C Function block. This code executes one time at the start of simulation. For example, you can initialize persistent data.

Terminate Code — Termination code

character array | string

Specifies cleanup code that the C Function block runs at model termination. This code executes once at the end of a simulation. For example, use this code to free the memory cached on persistent symbols specified as void pointers.

Symbols — Specify symbol properties

table

The **Symbols** table specifies the attributes of the symbols in the C code. You must enter the attributes of each symbol in the table.

- **Name** — Symbol name in the source code.
- **Scope** — Scope of the symbol. You can change the scope of a symbol at any time. The following scopes are available:
 - **Input** — Input symbol to the C Function block.
 - **Output** — Output symbol to the C Function block.
 - **Parameter** — Define a symbol as a parameter. The parameter name is defined by the **Label** property of the symbol.
 - **Persistent** — Define a symbol as persistent data.

You can define a void pointer using the **Persistent** scope. A *void pointer* is a pointer that can store any type of data that you create or allocate.

- **Constant** — Define a symbol as constant using value-size or numeric expressions.
- **Label** — Label of the symbol. For symbols with their scope set to **Input** or **Output**, this label appears as the port name on the block. For symbols with their scope set to **Parameter**, this label is the label that appears on the block parameter mask. If the scope is **Constant**, the label is the constant expression. You cannot define a label for **Persistent** symbols.
- **Type** — Data type of the symbol. Select a data type from the drop-down list or specify a `Simulink.AliasType` object.
- **Size** — Size of the symbol data. The C Function block supports only scalars and vectors; matrices and higher-dimension arrays are not supported. You can use a size expression to define the size of an output or use `-1` to inherit size.
- **Port** — For input and output symbols, **Port** indicates the port index on the block of the symbol data. For parameter symbols, **Port** indicates the order that the symbol appears in the block parameter mask.

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a integer ^a single ^a

Check Box

Select parameter or variable value

Library: Simulink / Dashboard

Description

The Check Box block allows you to set the value of a parameter or variable during simulation by checking or clearing the box. Use the Check Box block with other Dashboard blocks to create an interactive dashboard for your model.

Double-clicking the Check Box block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to make connections. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above it.

In connect mode, when you select one or more signals or blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block. To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a variable or parameter to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.
- When you specify a block parameter value by indexing a variable array, the parameter does not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect
variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.
- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

Check Box Label — Description of check box action

Label (default) | character vector

Label that appears next to the check box. You can use the **Check Box Label** to describe what happens in your model when you check the check box.

Example: `Enable sound`

Programmatic Use

Block Parameter: Label

Type: character vector

Default: `'Label'`

Checked/Unchecked Values — Values to assign for checked and unchecked states

Unchecked: 0 Checked: 1 (default) | scalar

Value to assign to the connected variable or parameter for the checked and unchecked block states.

- Unchecked — Value assigned to the connected parameter when the Check Box block is not checked.
- Checked — Value assigned to the connected parameter when the Check Box block is checked.

Programmatic Use

You set the **Unchecked** and **Checked** values programmatically using a 2-by-1 vector that contains the **Unchecked** and **Checked** values, in that order.

Block Parameter: Values

Type: 2×1 vector

Default: `[0 1]`

Label — Block label position

Hide (default) | Bottom | Top

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Hide' | 'Bottom' | 'Top'**Default:** 'Hide'**Block Characteristics**

Data Types	double integer single

Check Discrete Gradient

Check that absolute value of difference between successive samples of discrete signal is less than upper bound

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Discrete Gradient block checks each signal element at its input to determine whether the absolute value of the difference between successive samples of the element is less than an upper bound. Specify the value of the upper bound (1 by default) by setting the **Maximum gradient** parameter. If the verification condition is true, the block does nothing. Otherwise, the block halts the simulation, by default, and displays an error in the Diagnostic Viewer.

Enable or disable all model verification blocks by changing the **Model Verification block enabling** setting in the Configuration Parameters.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal the block checks to determine if the difference of each element between successive samples is less than the upper bound. Specify the upper bound by setting the **Maximum gradient** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a Boolean. Otherwise the data type of the signal is a double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Maximum gradient — Upper bound of allowed differences

1 (default) | scalar

Specify the upper bound on the allowed gradient of the input signal.

Command-Line Information

Parameter: gradient

Type: character vector

Values: real scalar

Default: '1'

Enable assertion — Enable or disable the check

on (default) | off

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information

Parameter: enabled

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

' ' (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information

Parameter: callback

Type: character vector

Values: MATLAB expression

Default: ' '

Stop simulation when assertion fails — Halt simulation when check fails

on (default) | off

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information

Parameter: stopWhenAssertionFail

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Output assertion signal — Create output signal

off (default) | on

Selecting this check box causes the block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is Boolean if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is double.

Command-Line Information

Parameter: export

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Select icon type — Select icon type

graphic (default) | text

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information

Parameter: icon

Type: character vector

Values: 'graphic' | 'text'

Default: 'graphic'

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

Check Dynamic Gap | Check Dynamic Range

Introduced before R2006a

Check Dynamic Gap

Check that gap of possibly varying width occurs in range of signal's amplitudes

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Dynamic Gap block checks that a gap of possibly varying width occurs in the range of a signal's amplitudes. The test signal is connected to **u**. The inputs **min** and **max** specify the lower and upper bounds of the dynamic gap. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

max — Upper bound of dynamic gap

scalar | vector | matrix

Signal specifying the upper bound of the gap. All three input signals must be the same data type.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

min — Lower bound of dynamic gap

scalar | vector | matrix

Signal specifying the lower bound of the gap. All three input signals must be the same data type and dimension.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u — Input signal

scalar | vector | matrix

Input signal checked for a gap of width specified by **max** and **min**. All three input signals must be the same data type and dimension.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a `Boolean`. Otherwise the data type of the signal is a `double`.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: `double` | `Boolean`

Parameters

Enable assertion — Enable or disable the check

`on` (default) | `off`

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information

Parameter: `enabled`

Type: character vector

Values: `'on'` | `'off'`

Default: `'on'`

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information

Parameter: `callback`

Type: character vector

Values: MATLAB expression

Default: `' '`

Stop simulation when assertion fails — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information

Parameter: `stopWhenAssertionFail`

Type: character vector

Values: `'on'` | `'off'`

Default: `'on'`

Output assertion signal – Create output signal

off (default) | on

Selecting this check box causes the block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is Boolean if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is double.

Command-Line Information**Parameter:** export**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'**Select icon type – Select icon type**

graphic (default) | text

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information**Parameter:** icon**Type:** character vector**Values:** 'graphic' | 'text'**Default:** 'graphic'**Block Characteristics**

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

[Check Dynamic Lower Bound](#) | [Check Dynamic Range](#) | [Check Dynamic Upper Bound](#)

Introduced before R2006a

Check Dynamic Lower Bound

Check that one signal is always less than another signal

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Dynamic Lower Bound block checks that the amplitude of a reference signal, **min**, is less than the amplitude of a test signal, **u**, at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

min — Lower bound of check

scalar | vector | matrix

Signal specifying the lower bound of the check against the input signal **u** amplitude. Signal data type and dimension must be the same as **u**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u — Input signal

scalar | vector | matrix

Input signal checked against the lower bound specified by **min**. Both input signals must be the same data type and dimension.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a Boolean. Otherwise the data type of the signal is a double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Enable assertion — Enable or disable the check

on (default) | off

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information

Parameter: enabled

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

' ' (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information

Parameter: callback

Type: character vector

Values: MATLAB expression

Default: ' '

Stop simulation when assertion fails — Halt simulation when check fails

on (default) | off

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information

Parameter: stopWhenAssertionFail

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Output assertion signal — Create output signal

off (default) | on

Selecting this check box causes the block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is Boolean if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is double.

Command-Line Information**Parameter:** export**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'**Select icon type — Select icon type**

graphic (default) | text

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Check Dynamic Range

Check that signal falls inside range of amplitudes that varies from time step to time step

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Dynamic Range block checks that a test signal falls inside a range of amplitudes at each time step. The width of the range can vary from time step to time step. The input labeled **u** is the test signal. The inputs labeled **min** and **max** are the lower and upper bounds of the valid range at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

max — Upper bound of dynamic range check

scalar | vector | matrix

Signal specifying the upper bound of the range that the block checks the input signal **u** amplitude. All three input signals must be the same data type.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

min — Lower bound of dynamic range check

scalar | vector | matrix

Signal specifying the lower bound of the range that the block checks the input signal **u** amplitude. All three input signals must be the same data type and dimension.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u — Input signal

scalar | vector | matrix

Input signal checked against the range specified by **max** and **min**. All three input signals must be the same data type and dimension.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a `Boolean`. Otherwise the data type of the signal is a `double`.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: `double` | `Boolean`

Parameters

Enable assertion — Enable or disable the check

`on` (default) | `off`

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information

Parameter: `enabled`

Type: character vector

Values: `'on'` | `'off'`

Default: `'on'`

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information

Parameter: `callback`

Type: character vector

Values: MATLAB expression

Default: `' '`

Stop simulation when assertion fails — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information

Parameter: `stopWhenAssertionFail`

Type: character vector

Values: `'on'` | `'off'`

Default: `'on'`

Output assertion signal – Create output signal

off (default) | on

Selecting this check box causes the block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is Boolean if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is double.

Command-Line Information**Parameter:** export**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'**Select icon type – Select icon type**

graphic (default) | text

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Check Dynamic Upper Bound

Check that one signal is always greater than another signal

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Dynamic Upper Bound block checks that the amplitude of a reference signal, **max**, is greater than the amplitude of a test signal, **u**, at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Configure Model for Debugging” (Simulink Coder).

Ports

Input

max — Upper bound of range check

scalar | vector | matrix

Signal specifying the lower bound of the range that the block checks the input signal **u** amplitude. Signal data type and dimension must be the same as **u**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u — Input signal

scalar | vector | matrix

Input signal checked against the lower bound specified by **min**. Both input signals must be the same data type and dimension.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a Boolean. Otherwise the data type of the signal is a double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters**Enable assertion – Enable or disable the check**

on (default) | off

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information

Parameter: enabled

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Simulation callback when assertion fails (optional) – Expression to evaluate when assertion fails

' ' (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information

Parameter: callback

Type: character vector

Values: MATLAB expression

Default: ' '

Stop simulation when assertion fails – Halt simulation when check fails

on (default) | off

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information

Parameter: stopWhenAssertionFail

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Output assertion signal – Create output signal

off (default) | on

Selecting this check box causes the block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is

Boolean if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is double.

Command-Line Information

Parameter: export

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Select icon type – Select icon type

graphic (default) | text

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information

Parameter: icon

Type: character vector

Values: 'graphic' | 'text'

Default: 'graphic'

[Check Dynamic Lower Bound](#) | [Check Dynamic Range](#)

Introduced before R2006a

Check Input Resolution

Check that input signal has specified resolution

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Input Resolution block checks whether the input signal has a specified scalar or vector resolution. If the resolution is a scalar, the input signal must be a multiple of the resolution within a $10e-3$ tolerance. If the resolution is a vector, the input signal must equal an element of the resolution vector. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal that the block checks the resolution specified by the **Resolution** parameter.

Data Types: double

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a Boolean. Otherwise the data type of the signal is a double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Resolution — Resolution

scalar

Specify the resolution requirement for the input signal.

Command-Line Information

Parameter: resolution

Type: character vector

Values: '1' | real value

Default: '1'

Enable assertion — Enable or disable the check

on (default) | off

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information

Parameter: enabled

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

' ' (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information

Parameter: callback

Type: character vector

Values: MATLAB expression

Default: ' '

Stop simulation when assertion fails — Halt simulation when check fails

on (default) | off

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information

Parameter: stopWhenAssertionFail

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Output assertion signal — Create output signal

off (default) | on

Selecting this check box causes the block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is Boolean if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is double.

Command-Line Information

Parameter: export

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Check Static Gap

Check that gap exists in signal's range of amplitudes

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Static Gap block checks that each element of the input signal is less than (or optionally equal to) a static lower bound or greater than (or optionally equal to) a static upper bound at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Input

Port_1 — Input

scalar | vector | matrix

Input signal the block checks if the signal value is less than a static lower bound or greater than a static upper bound.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a Boolean. Otherwise the data type of the signal is a double.

Dependencies

To enable this output port, set the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Upper bound — Upper boundary value

scalar | vector | matrix

Specify the upper bound on the range of amplitudes that the input signal can have.

Command-Line Information

Parameter: max

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Inclusive upper bound — Include the upper bound in range

on (default) | off

Select this check box to make the range of valid input amplitudes include the upper bound.

Command-Line Information

Parameter: max_included

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Lower bound — Lower boundary value

scalar | vector | matrix

Specify the lower bound on the range of amplitudes that the input signal can have.

Command-Line Information

Parameter: min

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Inclusive lower bound — Include the lower bound in range

on (default) | off

Select this check box to make the range of valid input amplitudes include the lower bound.

Command-Line Information

Parameter: min_included

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Enable assertion — Enable or disable the check

on (default) | off

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information

Parameter: enabled

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

' ' (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information

Parameter: callback

Type: character vector

Values: MATLAB expression

Default: ' '

Stop simulation when assertion fails — Halt simulation when check fails

on (default) | off

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information

Parameter: stopWhenAssertionFail

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Output assertion signal — Create output signal

off (default) | on

Selecting this check box causes the block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is Boolean if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is double.

Command-Line Information

Parameter: export

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Select icon type — Select icon type

graphic (default) | text

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information

Parameter: icon

Type: character vector

Values: 'graphic' | 'text'

Default: 'graphic'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

Check Dynamic Range | Check Static Lower Bound | Check Static Upper Bound

Introduced before R2006a

Check Static Lower Bound

Check that signal is greater than (or optionally equal to) static lower bound

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Static Lower Bound block checks that each element of the input signal is greater than (or optionally equal to) a specified lower bound at the current time step. Specify the value of the lower bound with the **Lower bound** parameter. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal checked against the lower bound specified by the **Lower bound** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a Boolean. Otherwise the data type of the signal is a double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Lower bound — Lower boundary value

scalar | vector | matrix

Specify the lower bound on the range of amplitudes that the input signal can have.

Command-Line Information

Parameter: min

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Inclusive boundary — Include the lower bound in range

on (default) | off

Select this check box to make the range of valid input amplitudes include the lower bound.

Command-Line Information

Parameter: min_included

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Enable assertion — Enable or disable the check

on (default) | off

Clearing this check box disables the block and causes the model to behave as if the block does not exist. Check Static Range

Check that signal falls inside fixed range of amplitudes

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Static Range block checks that each element of the input signal falls inside the same range of amplitudes at each time step. Specify the upper and lower bounds with the parameters **Upper bound** and **Lower bound**. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal checked against the range specified by the **Upper bound** and **Lower bound** parameters.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a Boolean. Otherwise the data type of the signal is a double.

Dependencies

To enable this output port, set the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Upper bound — Upper boundary value

scalar | vector | matrix

Specify the upper bound on the range of amplitudes that the input signal can have.

Command-Line Information

Parameter: max

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Inclusive upper boundary — Include the upper bound in range

on (default) | off

Select this check box to make the range of valid input amplitudes include the lower bound.

Command-Line Information

Parameter: min_included

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Lower bound — Lower boundary value

scalar | vector | matrix

Specify the lower bound on the range of amplitudes that the input signal can have.

Command-Line Information

Parameter: min

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Inclusive lower bound — Include the lower bound in range

on (default) | off

Select this check box to make the range of valid input amplitudes include the lower bound.

Command-Line Information

Parameter: min_included

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Enable assertion — Enable or disable the check

on (default) | off

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information

Parameter: enabled

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

' ' (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information

Parameter: callback

Type: character vector

Values: MATLAB expression

Default: ' '

Stop simulation when assertion fails – Halt simulation when check fails

on (default) | off

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information

Parameter: stopWhenAssertionFail

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Output assertion signal – Create output signal

off (default) | on

Selecting this check box causes the block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is Boolean if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is double.

Command-Line Information

Parameter: export

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Select icon type – Select icon type

graphic (default) | text

Specify the type of icon used to display this block in a block diagram. The **graphic** option displays a graphical representation of the assertion condition on the icon. The **text** option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information

Parameter: icon

Type: character vector

Values: 'graphic' | 'text'

Default: 'graphic'

Check Static Upper Bound

Check that signal is less than (or optionally equal to) static upper bound

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Static Upper Bound block checks that each element of the input signal is less than (or optionally equal to) a specified upper bound at the current time step. Use the block parameter dialog box to specify the value of the upper bound and whether the bound is inclusive. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal checked against the upper bound specified by the **Upper bound** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a Boolean. Otherwise the data type of the signal is a double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Upper bound — Upper boundary value

scalar | vector | matrix

Specify the upper bound on the range of amplitudes that the input signal can have.

Command-Line Information

Parameter: max

Type: character vector

Values: scalar | vector | matrix

Introduced before R2006a

Chirp Signal

Generate sine wave with increasing frequency

Library: Simulink / Sources

Description

The Chirp Signal block generates a sine wave whose frequency increases at a linear rate with time. You can use this block for spectral analysis of nonlinear systems. The block generates a scalar or vector output.

The parameters, **Initial frequency**, **Target time**, and **Frequency at target time**, determine the block's output. You can specify any or all of these variables as scalars or arrays. All the parameters specified as arrays must have the same dimensions. The block expands scalar parameters to have the same dimensions as the array parameters. The block output has the same dimensions as the parameters unless you select the **Interpret vector parameters as 1-D** check box. If you select this check box and the parameters are row or column vectors, the block outputs a vector (1-D array) signal.

Limitations

- The start time of the simulation must be 0. To confirm this value, go to the **Solver** pane in the Configuration Parameters dialog box and view the **Start time** field.
- Suppose that you use a Chirp Signal block in an enabled subsystem. Whenever the subsystem is enabled, the block output matches what would appear if the subsystem were enabled throughout the simulation.

Ports

Output

Port_1 — Chirp signal

scalar | vector | matrix | N-D array

Sine wave whose frequency increases at a linear rate with time. The chirp signal can be a scalar, vector, matrix, or N-D array.

Data Types: double

Parameters

Initial frequency — Initial frequency (Hz)

0.1 (default) | scalar | vector | matrix | N-D array

The initial frequency of the signal, specified as a scalar, vector, matrix, or N-D array.

Programmatic Use**Block Parameter:** f1**Type:** character vector**Values:** scalar | vector | matrix | N-D array**Default:** '0.1'**Target time — Target time (seconds)**

100 (default) | scalar | vector | matrix | N-D array

Time, in seconds, at which the frequency reaches the **Frequency at target time** parameter value. You specify the **Target time** as a scalar, vector, matrix, or N-D array. After the target time is reached, the frequency continues to change at the same rate.

Programmatic Use**Block Parameter:** T**Type:** character vector**Values:** scalar | vector | matrix | N-D array**Default:** '100'**Frequency at target time — Frequency (Hz)**

1 (default) | scalar | vector | matrix | N-D array

Frequency, in Hz, of the signal at the target time, specified as a scalar, vector, matrix, or N-D array.

Programmatic Use**Block Parameter:** f2**Type:** character vector**Values:** scalar | vector | matrix | N-D array**Default:** '1'**Interpret vector parameters as 1-D — Treat vector parameters as 1-D**

on (default) | off

When you select this check box, any column or row matrix values you specify for the **Initial frequency**, **Target time**, and **Frequency at target time** parameters result in a vector output whose elements are the elements of the row or column. For more information, see “Determine the Output Dimensions of Source Blocks”.

Programmatic Use**Block Parameter:** VectorParams1D**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Block Characteristics**

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no

Zero-Crossing Detection	no
--------------------------------	----

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Clock

Display and provide simulation time

Library: Simulink / Sources

Description

The Clock block outputs the current simulation time at each simulation step. This block is useful for other blocks that need the simulation time.

When you need the current time within a discrete system, use the Digital Clock block.

Ports

Output

Port_1 — Sample time

scalar

Sample time, specified as the current simulation time at each simulation time step.

Data Types: double

Parameters

Display time — Display simulation time on block icon

off (default) | on

Select this check box to display the simulation time as part of the Clock block icon. When you clear this check box, the simulation time does not appear on the block icon.

Programmatic Use

Block Parameter: DisplayTime

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Decimation — Interval at which to update block icon

10 (default) | positive integer

Specify the interval at which Simulink updates the Clock icon as a positive integer.

Suppose that the decimation is 1000. For a fixed integration step of 1 millisecond, the Clock icon updates at 1 second, 2 seconds, and so on.

Dependencies

To display the simulation time on the block icon, you must select the **Display time** check box.

Programmatic Use**Block Parameter:** Decimation**Type:** character vector**Value:** scalar**Default:** '10'**Block Characteristics**

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no

Combinatorial Logic

Implement truth table

Library: Simulink / Logic and Bit Operations

Description

The Combinatorial Logic block implements a standard truth table for modeling programmable logic arrays (PLAs), logic circuits, decision tables, and other Boolean expressions. You can use this block in conjunction with Memory blocks to implement finite-state machines or flip-flops.

Ports

Input

Port_1 – Input signal

vector

Input signal, specified as a vector. The type of signals accepted by a Combinatorial Logic block depends on whether you selected the Boolean logic signals option (see “Implement logic signals as Boolean data (vs. double)”). If this option is enabled, the block accepts real signals of type `Boolean` or `double`.

Data Types: `double` | `Boolean`

Output

Port_2 – Output signal

scalar | vector

Output signal, `double` if the truth table contains non-Boolean values of type `double`; `Boolean` otherwise. The type of the output is the same as that of the input except that the block outputs `double` if the input is `Boolean` and the truth table contains non-Boolean values.

Data Types: `double` | `Boolean`

Parameters

Truth table – Matrix of outputs

matrix

You specify a matrix that defines all possible block outputs as the **Truth table** parameter. Each row of the matrix contains the output for a different combination of input elements. You must specify outputs for every combination of inputs. The number of columns is the number of block outputs.

The **Truth table** parameter can have Boolean values (0 or 1) of any data type, including fixed-point data types. If the table contains non-Boolean values, the data type of the table must be `double`.

The relationship between the number of inputs and the number of rows is:

$$\text{number of rows} = 2^{(\text{number of inputs})}$$

Simulink returns a row of the matrix by computing the row's index from the input vector elements. Simulink computes the index by building a binary number where input vector elements having zero values are 0 and elements having nonzero values are 1, then adding 1 to the result. For an input vector, u , of m elements:

$$\text{row index} = 1 + u(m)*2^0 + u(m-1)*2^1 + \dots + u(1)*2^{m-1}$$

Programmatic Use

Block Parameter: TruthTable

Type: character vector

Values: matrix

Default: '[0 0;0 1;0 1;1 0;0 1;1 0;1 0;1 1]'

Block Characteristics

Data Types	Boolean double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Bit Clear | Bit Set | Compare To Constant | Compare To Zero

Introduced before R2006a

Combo Box

Select parameter value from drop-down menu

Library: Simulink / Dashboard

Description

The Combo Box block lets you set the value of a parameter to one of several values. You can define each selectable value and its label through the Combo Box block parameters. Use the Combo Box block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Double-clicking the Combo Box block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

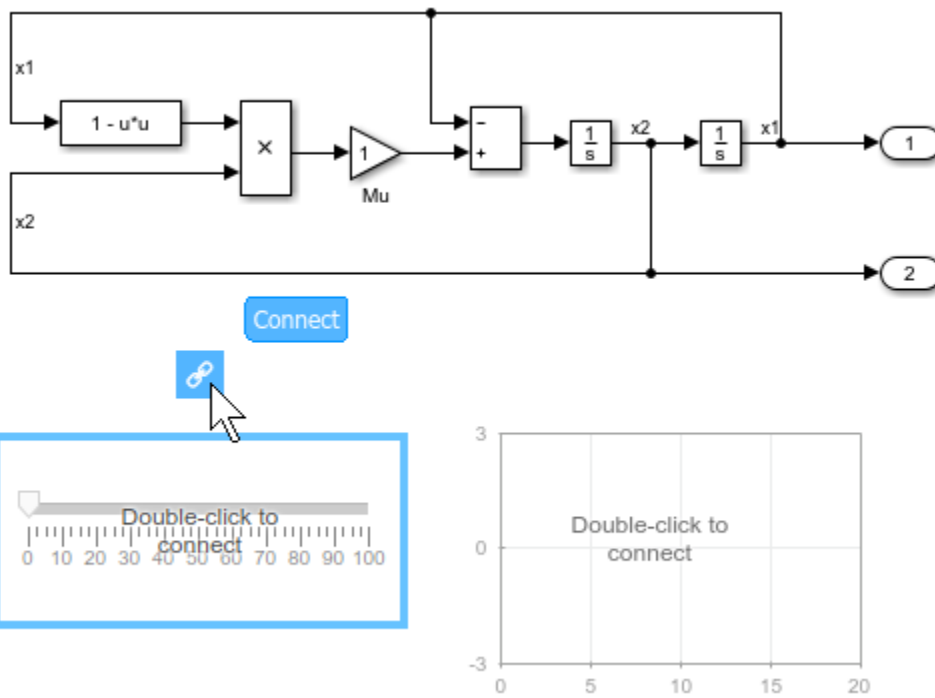

Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to make connections. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above it.

In connect mode, when you select one or more signals or blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block. To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a variable or parameter to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.
- When you specify a block parameter value by indexing a variable array, the parameter does not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect
variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.
- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

States — Set of states to select for connected parameter

scalar and character vector

Set of states from which to select a value for the connected parameter. Each **State** consists of a **State Value** and a **State Label**.

- **State Value** — Value assigned to the connected variable or parameter when you select the state with the corresponding **Label**.
- **State Label** — Label for each state. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the bottom, or you can enter a descriptive text label.

Click the **+** button to add additional **States**.

The default configuration for the block includes these **States**.

States

State Value	State Label
0	Label1
1	Label2
2	Label3

Programmatic Use

To programmatically configure the **States** for a block, use an array of structures containing the fields `Value` and `Label`. Include a structure in the array for each state you want to configure on the block.

```
state1.Value = 1;
state1.Label = 'State 1';
state2.Value = 2;
state2.Label = 'State 2';
radioStates = [state1 state2];
```

Block Parameter: States**Type:** structure**Default:** 3x1 structure array**Enumerated Data Type — Specify state values and labels using an enumerated data type**

off (default) | on

You can use an enumerated data type that pairs a numeric value with each enumeration to configure the state values and labels for the block. To specify the states for the block using an enumerated data type, first select the **Enumerated Data Type** option. Then, specify the name of the enumerated data type in the text box. The definition for the specified enumerated data type must be saved on the MATLAB path or in the base workspace.

Example: myEnumType

Programmatic Use

To programmatically specify the state labels and values for the block using an enumerated data type, specify 'on' for the UseEnumeratedDataType parameter and the name of the enumerated data type for the EnumeratedDataType parameter.

Block Parameter: UseEnumeratedDataType**Type:** string or character array**Values:** 'on' | 'off'**Default:** 'off'**Block Parameter:** EnumeratedDataType**Type:** string or character array**Default:** ''**Label — Block label position**

Hide (default) | Bottom | Top

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Hide' | 'Bottom' | 'Top'**Default:** 'Hide'**Block Characteristics**

Data Types	double integer single

Compare To Constant

Determine how signal compares to specified constant

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Compare To Constant block compares an input signal to a constant. Specify the constant in the **Constant value** parameter. Specify how the input is compared to the constant value with the **Operator** parameter.

Ports

Input

Port_1 — Input signal

scalar

Input signal, specified as a scalar, is compared with zero. The block first converts its **Constant value** parameter to the input data type, and then performs the specified operation.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal

0 | 1

The output is 0 if the comparison is false, and 1 if it is true.

Data Types: uint8 | Boolean

Parameters

Operator — Logical operator

<= (default) | == | ~= | < | >= | >

This parameter can have these values:

- == — Determine whether the input is equal to the specified constant.
- ~= — Determine whether the input is not equal to the specified constant.
- < — Determine whether the input is less than the specified constant.
- <= — Determine whether the input is less than or equal to the specified constant.
- > — Determine whether the input is greater than the specified constant.

- `>=` — Determine whether the input is greater than or equal to the specified constant.

Programmatic Use**Block Parameter:** `relop`**Type:** character vector**Values:** `'=='` | `'~='` | `'<'` | `'<='` | `'>='` | `'>'`**Default:** `'<='`**Constant value — Constant to compare with**`constant`

Specify the constant value to which the input is compared.

Programmatic Use**Block Parameter:** `const`**Type:** character vector**Value:** scalar | vector | matrix | N-D array**Default:** `'3.0'`**Output data type — Data type of the output**`boolean (default) | uint8`

Specify the data type of the output, `boolean` or `uint8`.

Programmatic Use**Block Parameter:** `OutDataTypeStr`**Type:** character vector**Values:** `'boolean'` | `'uint8'`**Default:** `'boolean'`**Enable zero-crossing detection — Select to enable zero-crossing detection**`check (default) | uncheck`

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use**Block Parameter:** `ZeroCross`**Type:** character vector**Values:** `'off'` | `'on'`**Default:** `'on'`**Block Characteristics**

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	yes

Combinatorial Logic | Compare To Zero | Logical Operator

Introduced before R2006a

Compare To Zero

Determine how signal compares to zero

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Compare To Zero block compares an input signal to zero. Specify how the input is compared to zero with the **Operator** parameter.

The output is 0 if the comparison is false, and 1 if it is true.

Ports

Input

Port_1 — Input signal

scalar

Input signal, specified as scalar, is compared with zero. If the input data type cannot represent zero, parameter overflow occurs. To detect this overflow, go to the **Diagnostics > Data Validity** pane of the Configuration Parameters dialog box and set **Parameters > Detect overflow** to warning or error.

In this case, the block compares the input signal to the *ground value* of the input data type. For example, if you have an input signal of type `fixdt(0,8,2^0,10)`, the input data type can represent unsigned 8-bit integers from 10 to 265 due to a bias of 10. The ground value is 10, instead of 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Port_1 — Output signal

0 | 1

The output is 0 if the comparison is false, and 1 if it is true.

The block output is `uint8` or `boolean`, depending on your selection for the **Output data type** parameter.

Data Types: `uint8` | `Boolean`

Parameters

Operator — Logical operator

`<=` (default) | `==` | `~=` | `<` | `>=` | `>`

This parameter can have the following values:

- == — Determine whether the input is equal to zero.
- ~= — Determine whether the input is not equal to zero.
- < — Determine whether the input is less than zero.
- <= — Determine whether the input is less than or equal to zero.
- > — Determine whether the input is greater than zero.
- >= — Determine whether the input is greater than or equal to zero.

Programmatic Use

Block Parameter: relop

Type: character vector

Values: '==' | '~=' | '<' | '<=' | '>=' | '>'

Default: '<='

Output data type — Data type of the output

boolean (default) | uint8

Specify the data type of the output, boolean or uint8.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Enable zero-crossing detection — Select to enable zero-crossing detection

on (default) | off

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Block Characteristics

Complex to Magnitude-Angle

Compute magnitude and/or phase angle of complex signal

Library: Simulink / Math Operations

Description

The Complex to Magnitude-Angle block outputs the magnitude and/or phase angle of the input signal, depending on the setting of the **Output** parameter. The outputs are real values of the same data type as the block input. The input can be an array of complex signals, in which case the output signals are also arrays. The magnitude signal array contains the magnitudes of the corresponding complex input elements. The angle output similarly contains the angles of the input elements.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Complex input signal that the block computes and outputs the magnitude and/or the phase angle.

Data Types: single | double

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal that is the magnitude and/or phase angle of the input signal. To choose the output, set the **Output** parameter.

Data Types: single | double

Parameters

Output — Magnitude and/or phase angle output specification

Magnitude and angle (default) | Magnitude | Angle

Specify if the output is the magnitude and/or the phase angle in radians of the input signal.

Command-Line Information

Parameter: Output

Type: character vector

Values: 'Magnitude and angle' | 'Magnitude' | 'Angle'

Default: 'Magnitude and angle'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar or vector**Default:** '-1'**Block Characteristics**

Complex to Real-Imag

Output real and imaginary parts of complex input signal

Library: Simulink / Math Operations
HDL Coder / Math Operations

Description

The Complex to Real-Imag block outputs the real and/or imaginary part of the input signal, depending on the setting of the **Output** parameter. The real outputs are of the same data type as the complex input. The input can be an array (vector or matrix) of complex signals, in which case the output signals are arrays of the same dimensions. The real array contains the real parts of the corresponding complex input elements. The imaginary output similarly contains the imaginary parts of the input elements.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Complex input signal that the block computes and outputs the real and/or imaginary part.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 – Output signal

scalar | vector | matrix

Output signal that is the real and/or imaginary part of the input signal. To choose which part is output, set the **Output** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Output – Real and/or imaginary output specification

Real and imag (default) | Real | Imag

Specify if the output is the real and/or imaginary part of the input signal.

Command-Line Information

Parameter: Output

Type: character vector

Values: 'Real and imag' | 'Real' | 'Imag'

Default: 'Real and imag'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Compose String

Compose output string signal based on specified format and input signals

Library: Simulink / String

Description

The Compose String block composes output string signal based on the format specifier listed in the **Format** parameter. The **Format** parameter determines the number of input signals. If there are multiple inputs, the block constructs the string by combining these multiple inputs in order, and applying the associated format specifier, one format specifier for each input. Each format specifier starts with a percent sign, %, followed by the conversion character. For example, %f formats the input as a floating point output. To supplement the string output, you can also add a character to the format specification. Use this block to compose and format an output string signal from a multiple inputs.

For example, if the **Format** parameter contains "%s is %f", the block expects two inputs, a string signal and a single or double signal. If the first input is the string "Pi" and the second input is a double value 3.14, the output is "Pi is 3.14".

When a MinGW® compiler compiles code generated from the block, running the compiled code may produce nonstandard results for floating-point inputs. For example, a numeric input of 501.987 returns the string "5.019870e+002" instead of the expected string "5.019870e+02".

Ports

Input

d — Data for first part of string

scalar

Data for the first part of string, specified as a scalar. The **Format** parameter determines the port label and the format of the input data. For example, if the first item in the **Format** parameter is %d, the port label is d.

The data type of the input signal must be compatible with the format specifier in the **Format** parameter. For more information, see the **Format** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

f — Data for second part of string

scalar

Data for the second part of string, specified as a scalar. The **Format** parameter determines the port label and the format of the input data. For example, if the first item in the **Format** parameter is %f, the port label is f.

The data type of the input signal must be compatible with the format specifier specified in the **Format** parameter. For more information, see the **Format** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Port_N — Data for N parts of string

`scalar` (default)

Data for N parts of string, specified as a scalar. The **Format** parameter determines the port label and the format of the input data. For example, if the corresponding item in the **Format** parameter is `%f`, the port label is `f`.

The data type of the input signal must be compatible with the format specifier in the **Format** parameter. For more information, see the **Format** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

str — Output string

`scalar`

Output string composed of inputs, specified as a scalar.

Data Types: `string`

Parameters

Format — Format input data

`"%d %f"` (default) | `scalar`

Format of input data, specified as a scalar.

For more information about acceptable format specifiers, see the Algorithms section.

Output data type — Output data type

`string` (default) | `scalar`

Output data type, specified using the string data type to specify a string with no maximum length.

To specify a string data type with a maximum length, specify `stringtype(N)`. For example, `stringtype(31)` creates a string data type with a maximum length of 31 characters.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Block Characteristics

Data Types	<code>double</code> <code>integer</code> <code>single</code> <code>string</code>
Direct Feedthrough	<code>yes</code>
Multidimensional Signals	<code>no</code>

Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

A formatting specifier starts with a percent sign, %, and ends with a conversion character. The conversion character is required. Optionally, you can specify identifier, flags, field width, precision, and subtype specifiers between % and the conversion character. (Spaces are invalid between specifiers and are shown here only for readability).

The Compose String block uses this format specifier prototype:

```
%[flags][width][.precision][length]specifier
```

Conversion Character

This table shows conversion characters to format numeric and character data as text.

Value Type	Conversion	Details
Integer, signed	%d or %i	Base 10
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal), lowercase letters a-f
	%X	Same as %x, uppercase letters A-F
Floating-point number	%f	Floating-point notation (Use a precision operator to specify the number of digits after the decimal point.)
	%e	Exponential notation, such as 3.141593e+00 (Use a precision operator to specify the number of digits after the decimal point.)
	%E	Same as %e, but uppercase, such as 3.141593E+00 (Use a precision operator to specify the number of digits after the decimal point.)
	%g	The more compact of %e or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
	%G	The more compact of %E or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
String	%s	The type of the output text is the same as the type of Format .

Optional Operators

The optional identifier, flags, field width, precision, and operators further define the format of the output text.

- **Flags**

'-'	Left-justify. Works with all specifiers. Example: %-5.2f Example: %-10s
'+'	Always print a sign character (+ or -) for any numeric value. Works with all specifiers except u, o, x, X, and s. Example: %+5.2f Right-justify text. Example: %+10s
' '	Insert a space before the value. Works with all specifiers except u, o, x, X, and s. Example: % 5.2f
'0'	Pad to field width with zeros before the value. Works with all specifiers except s. Example: %05.2f
'#'	Modify selected numeric conversions: <ul style="list-style-type: none"> • For %o, %x, or %X, print 0, 0x, or 0X prefix. • For %f, %e, or %E, print decimal point even when precision is 0. • For %g or %G, do not remove trailing zeros or decimal point. Works with all specifiers except d, i, u, and s. Example: %#5.0f

- **Field Width**

Minimum number of characters to print.

The function pads to field width with spaces before the value unless otherwise specified by flags.

- **Precision**

For %f, %e, or %E	Number of digits to the right of the decimal point Example: "%.4f" prints pi as '3.1416'
d, i, o, u, x, X	Minimum number of digits to be written. Outputs shorter than the specified precision are padded with leading zeros. Example: "%.4d" prints 5 as '0005'
For %g or %G	Number of significant digits Example: "%.4g" prints pi as '3.142'
s	Maximum number of characters to be written to the output. Example: "%.2s" prints "Hello!" as "He"

Note If you specify a precision operator for floating-point values that exceeds the precision of the input numeric data type, the results might not match the input values to the precision you specified. The result depends on your computer hardware and operating system.

Text Before or After Formatting Operators

Special Character	Representation
Single quotation mark	' '
Percent character	%%
Backslash	\\
Alarm	\a
Backspace	\b
Form feed	\f
New line	\n
Carriage return	\r
Horizontal tab	\t
Vertical tab	\v
Character whose Unicode® numeric value can be represented by the hexadecimal number, N	\xN Example: <code>printf('\x5A')</code> returns 'Z'
Character whose Unicode numeric value can be represented by the octal number, N	\N Example: <code>printf('\132')</code> returns 'Z'

Format can also include additional text before a percent sign, %, or after a conversion character. The text can be:

- Ordinary text to print.
- Special characters that you cannot enter as ordinary text. This table shows how to represent special characters in `formatSpec`.

Length Specifiers

The Format String block supports the `h` and `l` length subspecifiers. These specifiers can change according to the **Configuration Parameters > Hardware Implementation > Number of bits** settings

Length	d i	u o x X	f e E g G	s
No length specifier	int	unsigned int	double (default), single	string
h	short	unsigned short	—	—
l	long	unsigned long	—	—

Note for Specifiers that Specify Integer Data Types (d, i, u, o, x, X)

Target `int`, `long`, and `short` type sizes are controlled by settings in the **Configuration Parameters > Hardware Implementation** pane. For example, if the target `int` is 32 bits and the specifier is `%u`, then the expected input type will be `uint32`. However, the input port accepts any built-in integer type of that size or smaller with the `%u` specifier

Notes for Specifiers that Specify Floating Point Data Types (f, e, E, g, F)

- Do not use `l` and `h` with these specifiers. Do not use the length subspecifier (for example, `%f` is allowed, but `%hf` and `%lf` are not allowed).
- Ports that correspond with these specifiers accept both single and double data types.

Note for Specifiers that Specify the String Data Type (s)

- The `s` specifier does not work with the `l` or `h` subspecifiers, and only accepts a string input data type.

Configurable Subsystem

Represent any block selected from user-specified library of blocks

Library: Simulink / Ports & Subsystems

Description

Note Configurable Subsystem block will be removed in a future release. It is recommended to use Variant Subsystem instead of Configurable Subsystem. Variant Subsystems offer more capabilities than Configurable Subsystems with these advantages:

- You can mix Model blocks and Subsystem blocks as variant choices.
- You can specify variants that have different numbers of input and output ports.

For more information on converting Configurable Subsystem block to a Variant Subsystem block, see “Convert Configurable Subsystem to Variant Subsystem”.

For more information on Variant Subsystem, see Variant Subsystem, Variant Model.

The Configurable Subsystem block represents one of a set of blocks contained in a specified library of blocks. The context menu of the Configurable Subsystem block lets you choose which block the configurable subsystem represents.

Configurable Subsystem blocks simplify creation of models that represent families of designs. For example, suppose that you want to model an automobile that offers a choice of engines. To model such a design, you would first create a library of models of the engine types available with the car. You would then use a Configurable Subsystem block in your car model to represent the choice of engines. To model a particular variant of the basic car design, a user need only choose the engine type, using the configurable engine block's dialog box.

To create a configurable subsystem in a model, you must first create a library containing a master configurable subsystem and the blocks that it represents. You can then create configurable instances of the master subsystem by dragging copies of the master subsystem from the library and dropping them into models.

You can add any type of block to a master configurable subsystem library. Simulink derives the port names for the configurable subsystem by making a unique list from the port names of all the choices. However, Simulink uses default port names for non-subsystem block choices.

You cannot break library links in a configurable subsystem because Simulink uses those links to reconfigure the subsystem when you choose a new configuration. Breaking links would be useful only if you do not intend to reconfigure the subsystem. In this case, you can replace the configurable subsystem with a nonconfigurable subsystem that implements the permanent configuration.

Creating a Master Configurable Subsystem

To create a master configurable subsystem:

- 1 Create a library of blocks representing the various configurations of the configurable subsystem.
- 2 Save the library.
- 3 Create an instance of the Configurable Subsystem block in the library.

To do so, drag a copy of the Configurable Subsystem block from the Simulink Ports & Subsystems library into the library you created in the previous step.

- 4 Display the Configurable Subsystem block dialog box by double-clicking it. The dialog box displays a list of the other blocks in the library.
- 5 Under **List of block choices** in the dialog box, select the blocks that represent the various configurations of the configurable subsystems you are creating.
- 6 To apply the changes and close the dialog box, click the **OK** button.
- 7 Select **Block Choice** from the context menu of the Configurable Subsystem block.

The context menu displays a submenu listing the blocks that the subsystem can represent.

- 8 Select the block that you want the subsystem to represent by default.
- 9 Save the library.

Note If you add or remove blocks from a library, you must recreate any Configurable Subsystem blocks that use the library.

If you modify a library block that is the default block choice for a configurable subsystem, the change does not immediately propagate to the configurable subsystem. To propagate this change, do one of the following:

- Change the default block choice to another block in the subsystem, then change the default block choice back to the original block.
- Recreate the configurable subsystem block, including the selection of the updated block as the default block choice.

If a configurable subsystem in your model contains a broken link to a library block, editing the link and saving the model does not fix the broken link the next time you open the model. To fix a broken library link in your configurable subsystem, use one of the following approaches.

- Convert the configurable subsystem to a variant subsystem. Right-click the configurable subsystem, and select **Subsystem and Model Reference > Convert Subsystem to > Variant Subsystem**.
- Remove the library block from the master configurable subsystem library, add the library block back to the master configurable subsystem library, and then resave the master configurable subsystem library.

Creating an Instance of a Configurable Subsystem

To create an instance of a configurable subsystem in a model:

- 1 Open the library containing the master configurable subsystem.
- 2 Drag a copy of the master into the model.
- 3 Select **Block Choice** from the context menu of that Configurable Subsystem instance.
- 4 Select the block that you want the configurable subsystem to represent.

The instance of the configurable system displays the icon and parameter dialog box of the block that it represents.

Setting Instance Block Parameters

As with other blocks, you can use the parameter dialog box of a configurable subsystem instance to set its parameters interactively and the `set_param` command to set the parameters from the MATLAB command line or in a MATLAB file. If you use `set_param`, you must specify the full path name of the configurable subsystem's current block choice as the first argument of `set_param`, for example:

```
curr_choice = get_param('mymod/myconfigsys', 'BlockChoice');
curr_choice = ['mymod/myconfigsys/' curr_choice];
set_param(curr_choice, 'MaskValues', ...);
```

Mapping I/O Ports

A configurable subsystem displays a set of input and output ports corresponding to input and output ports in the selected library. Simulink uses the following rules to map library ports to Configurable Subsystem block ports:

- Map each uniquely named input/output port in the library to a separate input/output port of the same name on the Configurable Subsystem block.
- Map all identically named input/output ports in the library to the same input/output ports on the Configurable Subsystem block.
- Terminate any input/output port not used by the currently selected library block with a Terminator/Ground block.

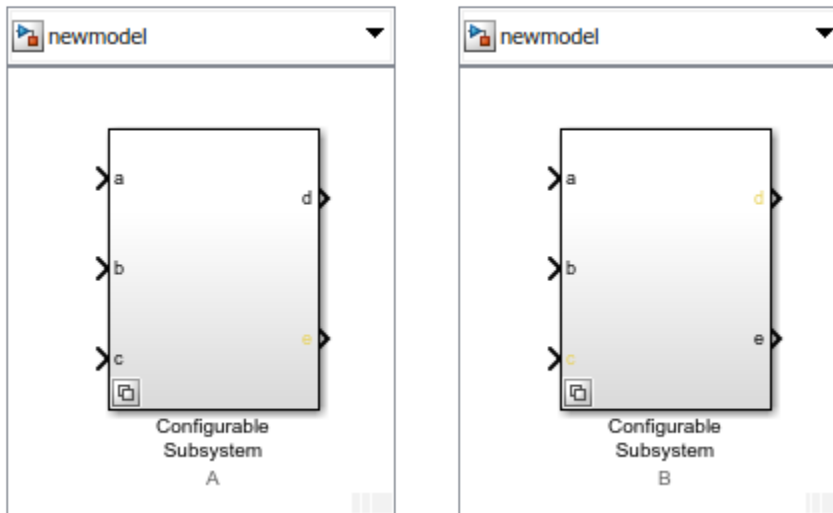

This mapping allows a user to change the library block represented by a Configurable Subsystem block without having to rewire connections to the Configurable Subsystem block.

For example, suppose that a library contains two blocks A and B and that block A has input ports labeled a, b, and c and an output port labeled d and that block B has input ports labeled a and b and an output port labeled e.

A Configurable Subsystem block based on this library would have three input ports labeled a, b, and c, respectively, and two output ports labeled d and e.

In this example, port a on the Configurable Subsystem block connects to port a of the selected library block no matter which block is selected. Port c on the Configurable Subsystem block functions only if library block A is selected. Otherwise, it simply terminates.

Note A Configurable Subsystem block does not provide ports that correspond to non-I/O ports, such as the trigger and enable ports on triggered and enabled subsystems. Thus, you cannot use a Configurable Subsystem block directly to represent blocks that have such ports. You can do so indirectly, however, by wrapping such blocks in subsystem blocks that have input or output ports connected to the non-I/O ports.

Convert to Variant Subsystem

Right-click a configurable subsystem and select **Subsystems and Model Reference > Convert Subsystem To > Variant Subsystem**.

During conversion, Simulink performs the following operations:

- Replaces the Subsystem block with a Variant Subsystem block, preserving ports and connections.
- Adds the original subsystem as a variant choice in the Variant Subsystem block.
- Overrides the Variant Subsystem block to use the subsystem that was originally the active choice.
- Preserves links to libraries. For linked subsystems, Simulink adds the linked subsystem as a variant choice.

Simulink also preserves the subsystem block masks, and it copies the masks to the variant choice.

See Variant Subsystem for more information on variant choices.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array | bus

Input signal to the Configurable Subsystem. The block that the Configurable Subsystem represents determines the supported data types and dimensions of the input signal.

Dependencies

The number of input ports depends on the blocks in the library that the Configurable Subsystem represents. For more information, see “Mapping I/O Ports” on page 1-164.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

Port_1 – Output signal

`scalar` | `vector` | `matrix` | `N-D array` | `bus`

Output signal from the Configurable Subsystem. The block that the Configurable Subsystem represents determines the output data types and dimensions.

Dependencies

The number of output ports depends on the blocks in the library that the Configurable Subsystem represents. For more information, see “Mapping I/O Ports” on page 1-164.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

List of block choices – Block members of the configurable subsystem

no default

Select the blocks you want to include as members of the configurable subsystem. You can include user-defined subsystems as blocks.

Programmatic Use

Block Parameter: `MemberBlocks`

Type: cell array of character vectors

Values: cell array of block names as character vectors

Default: `{ '' }`

Port names – Port names

no default

Lists of input and output ports of member blocks. In the case of multiports, you can rearrange selected port positions by clicking the **Up** and **Down** buttons.

Block Characteristics

Data Types	<code>Boolean^a</code> <code>bus^a</code> <code>double^a</code> <code>enumerated^a</code> <code>fixed point^a</code> <code>integer^a</code> <code>single^a</code> <code>string^a</code>

Constant

Generate constant value

Library: Simulink / Commonly Used Blocks
 Simulink / Sources
 DSP System Toolbox / Sources
 HDL Coder / Commonly Used Blocks
 HDL Coder / Sources

Description

The Constant block generates a real or complex constant value signal. Use this block to provide a constant signal input. The block generates scalar, vector, or matrix output, depending on:

- The dimensionality of the **Constant value** parameter
- The setting of the **Interpret vector parameters as 1-D** parameter

The output of the block has the same dimensions and elements as the **Constant value** parameter. If you specify for this parameter a vector that you want the block to interpret as a vector, select the **Interpret vector parameters as 1-D** check box. Otherwise, if you specify a vector for the **Constant value** parameter, the block treats that vector as a matrix.

Tip To output a constant enumerated value, consider using the Enumerated Constant block instead. The Constant block provides block parameters that do not apply to enumerated types, such as **Output minimum** and **Output maximum**.

Using Bus Objects as the Output Data Type

The Constant block supports nonvirtual buses as the output data type. Using a bus object as the output data type can help simplify your model. If you use a bus object as the output data type, set the **Constant value** to 0 or to a MATLAB structure that matches the bus object.

Using Structures for the Constant Value of a Bus

The structure you specify must contain a value for every element of the bus represented by the bus object. The block output is a nonvirtual bus signal.

You can use the `Simulink.Bus.createMATLABStruct` to create a full structure that corresponds to a bus.

You can use `Simulink.Bus.createObject` to create a bus object from a MATLAB structure.

If the signal elements in the output bus use numeric data types other than `double`, you can specify the structure fields by using typed expressions such as `uint16(37)` or untyped expressions such as `37`. To control the field data types, you can use the bus object as the data type of a `Simulink.Parameter` object. To decide whether to use typed or untyped expressions, see “Control Data Types of Initial Condition Structure Fields”.

Setting Configuration Parameters to Support Using a Bus Object Data Type

To enable the use of a bus object as an output data type, before you start a simulation, set **Configuration Parameters > Diagnostics > Data Validity > Advanced parameters > Underspecified initialization detection** to Simplified. For more information, see “Underspecified initialization detection”.

Ports

Output

Port_1 – Constant value

scalar | vector | matrix | N-D array

Constant value, specified as a real or complex valued scalar, vector, matrix, or N-D array. By default, the Constant block outputs a signal whose dimensions, data type, and complexity are the same as those of the **Constant value** parameter. However, you can specify the output to be any data type that Simulink supports, including fixed-point and enumerated data types.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For more information, see `Simulink.BusElement`.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Main

Constant value – Constant output value

1 (default) | scalar | vector | matrix | N-D array

Specify the constant value output of the block.

- You can enter any expression that MATLAB evaluates as a matrix, including the Boolean keywords `true` and `false`.
- If you set the **Output data type** to be a bus object, you can specify one of these options:
 - A full MATLAB structure corresponding to the bus object
 - `0` to indicate a structure corresponding to the ground value of the bus object

For details, see “Using Bus Objects as the Output Data Type” on page 1-168.

- For nonbus data types, Simulink converts this parameter from its value data type to the specified output data type offline, using a rounding method of nearest and overflow action of saturate.

Programmatic Use

Block Parameter: Value

Type: character vector

Value: scalar | vector | matrix | N-D array

Default: '1'

Interpret vector parameters as 1-D — Treat vectors as 1-D

on (default) | off

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.
- When you clear this check box, the block does not output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

Programmatic Use

Block Parameter: VectorParams1D

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Sample time — Sampling interval

inf (default) | scalar | vector

Specify the interval between times that the Constant block output can change during simulation (for example, due to tuning the **Constant value** parameter).

The default value of `inf` indicates that the block output can never change. This setting speeds simulation and generated code by avoiding the need to recompute the block output.

See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: 'inf'

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Specify the lower value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Specify the upper value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** scalar**Default:** '[]'**Output data type — Output data type**

Inherit: Inherit from 'Constant value' (default) | Inherit: Inherit via back propagation | double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | Bus: <object name> | <data type expression>

Specify the output data type. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit from 'Constant value'' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>'

Default: 'Inherit: Inherit from 'Constant value''**Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Tunable Parameters

You can use a tunable parameter in a Constant block intended for HDL code generation. For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder).

HDL Architecture

Architecture	Parameters	Description
default Constant	None	This implementation emits the value of the Constant block.
Logic Value	None	By default, this implementation emits the character 'Z' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'ZZZZ'.
	{'Value', 'Z'}	If the signal is in a high-impedance state, use this parameter value. This implementation emits the character 'Z' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'ZZZZ'.
	{'Value', 'X'}	If the signal is in an unknown state, use this parameter value. This implementation emits the character 'X' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'XXXX'.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
-----------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Complex Data Support

This block supports code generation for complex signals.

Restrictions

- The `Logic Value` implementation does not support the `double` data type. If you specify this implementation for a constant value of type `double`, a code generation error occurs.
- For **Sample time**, enter -1. Delay balancing does not support an `inf` sample time.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Coulomb and Viscous Friction

Model discontinuity at zero, with linear gain elsewhere

Library: Simulink / Discontinuities
HDL Coder / Discontinuities

Description

The Coulomb and Viscous Friction block models Coulomb (static) and viscous (dynamic) friction. The block models a discontinuity at zero and a linear gain otherwise.

The block output matches the MATLAB result for:

$$y = \text{sign}(x) .* (\text{Gain} .* \text{abs}(x) + \text{Offset})$$

where y is the output, x is the input, Gain is the signal gain for nonzero input values, and Offset is the Coulomb friction.

The block accepts one input and generates one output. The input can be a scalar, vector, or matrix with real and complex elements.

- For a scalar input, Gain and Offset can have dimensions that differ from the input. The output is a scalar, vector, or matrix depending on the dimensions of Gain and Offset .
- For a vector or matrix input, Gain and Offset must be scalar or have the same dimensions as the input. The output is a vector or matrix of the same dimensions as the input.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

The input signal to the model of Coulomb and viscous friction.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

The output signal calculated by applying the friction models to the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

To edit the parameters for the Coulomb and Viscous Friction block, double-click the block icon.

Coulomb friction value — Static friction offset

[1320] (default) | real values

Specify the offset that applies to all input values.

Programmatic Use

Block Parameter: offset

Type: character vector

Value: real values

Default: '[1 3 2 0]'

Coefficient of viscous friction — Dynamic friction coefficient

1 (default) | real values

Specify the signal gain for nonzero input values.

Programmatic Use

Block Parameter: gain

Type: character vector

Value: real values

Default: '1'

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).

Counter Free-Running

Count up and overflow back to zero after reaching maximum value for specified number of bits

Library: Simulink / Sources
HDL Coder / Sources

Description

The Counter Free-Running block counts up until reaching the maximum value, $2^{Nbits} - 1$, where $Nbits$ is the number of bits. Then the counter overflows to zero and begins counting up again.

After overflow, the counter always initializes to zero. However, if you select the global doubles override, the Counter Free-Running block does not wrap back to zero.

Note This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Ports

Output

Port_1 — Count value

scalar

Count value, specified as an unsigned integer of 8 bits, 16 bits, or 32 bits.

Data Types: `uint8` | `uint16` | `uint32`

Parameters

Number of Bits — Number of bits

16 (default) | scalar

Specify the number of bits as a finite, real-valued. When you specify:

- A positive integer, for example 8, the block counts up to $2^8 - 1$, which is 255.
- An unsigned integer expression, for example `uint8(8)`, the block counts up to `uint8(2uint8(8) - 1)`, which is 254.

Programmatic Use

Block Parameter: NumBits

Type: character vector

Values: scalar

Default: '16'

Sample time – Interval between samples

-1 (default) | scalar | vector

Specify the time interval between samples as a scalar (**sampling period**), or a two-element vector (**[sampling period, initial offset]**). To inherit the sample time, set this parameter to -1. For more information, see “Specify Sample Time”.

Programmatic Use**Block Parameter:** tsamp**Type:** character vector**Values:** scalar | vector**Default:** '-1'**Block Characteristics**

Data Types	fixed point integer
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Counter Limited | MATLAB Function

Introduced before R2006a

Counter Limited

Count up and wrap back to zero after outputting specified upper limit

Library: Simulink / Sources
HDL Coder / Sources

Description

The Counter Limited block counts up until the specified upper limit is reached. Then the counter wraps back to zero, and restarts counting up. The counter always initializes to zero.

Note This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Ports

Output

Port_1 – Count value

scalar

Count value, specified as an unsigned integer of 8 bits, 16 bits, or 32 bits. The block uses the smallest number of bits required to represent the upper limit.

Data Types: `uint8` | `uint16` | `uint32`

Parameters

Upper limit – Upper limit

7 (default) | scalar

Specify the upper limit for the block to count to as a finite, real-valued scalar.

Programmatic Use

Block Parameter: `uplimit`

Type: character vector

Values: scalar

Default: '7'

Sample time – Interval between samples

-1 (default) | scalar | vector

Specify the time interval between samples as a scalar (sampling period), or a two-element vector (sampling period, initial offset). To inherit the sample time, set this parameter to -1. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: `tsamp`

Type: character vector

Values: scalar | vector

Default: '- 1'

Block Characteristics

Data Types	Boolean fixed point integer
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
- Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Custom Gauge

Display signal value on a customized gauge

Library: Simulink / Dashboard

Description

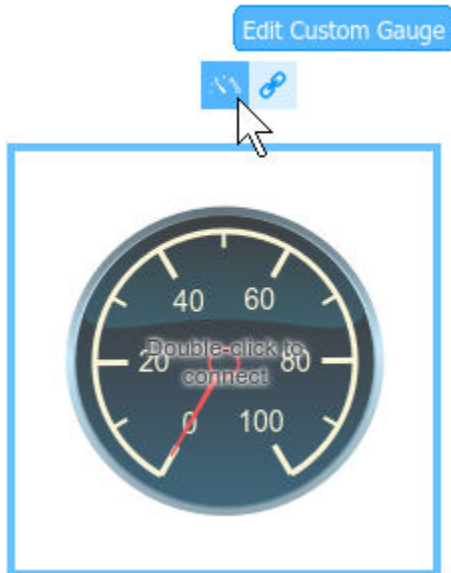

The Custom Gauge block displays the value of the connected signal on a gauge face that you can customize to look like a gauge in a real system. For example, you could create an engine rpm gauge or fuel indicator for an automotive model.

The Custom Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range and tick values on the Custom Gauge block to fit your data. Use the Custom Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

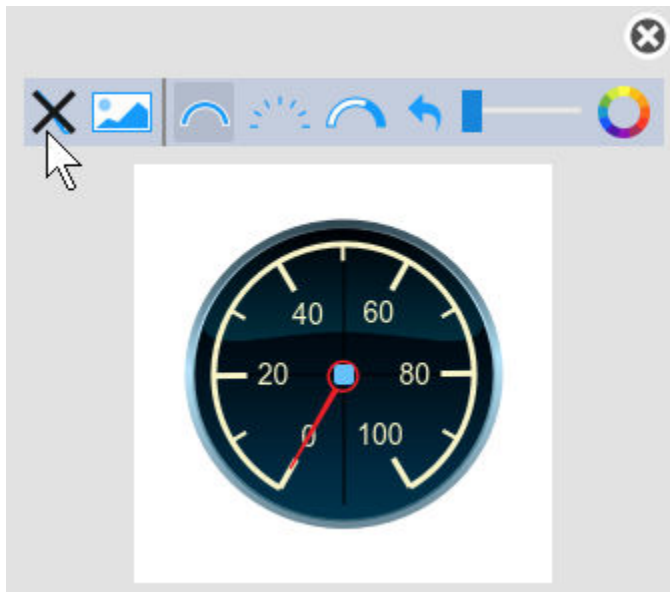

Create A Custom Gauge

When you add a Custom Gauge block to your model, the block is preconfigured with a default design. You can use the preconfigured Custom Gauge block like you would other Dashboard blocks, or you can customize the appearance. To customize the block, click the **Edit Custom Gauge** button that appears above the Custom Gauge block when you pause on it.

In Custom Gauge edit mode, the customization menu appears above the block. Separate images specify the appearance of the needle and the background. You can also customize the size of the dial arc and the color and transparency of the arc and tick marks. To build from the default design, you can individually select the needle image, background image, and arc to reposition and resize each

feature. If you want to start from a blank canvas, you can remove the arc with the **Clear Arc**  button. You can remove the needle and background images by clicking the **X** that appears when you pause on the needle or background image buttons.

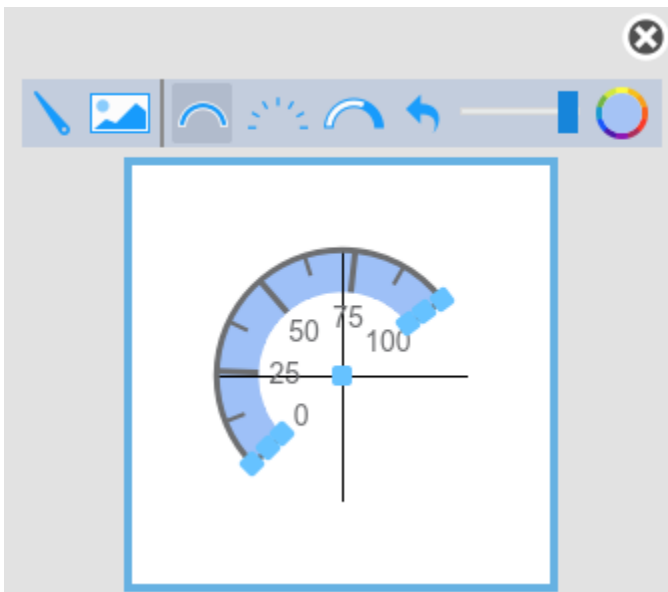

The blank canvas for the Custom Gauge block shows a circle with its center marked to help guide alignment as you build your customized gauge. You can drag the center marker to align the center of your arc with the center of the arc in your background image. To add an image for the needle or the gauge background, click the button for the type of image you want to add. Then, select the image you

want to use. When you add a gauge background image, the Custom Gauge block **Lock Aspect Ratio** parameter is selected. You can resize the block without distorting the image. If you want to change the aspect ratio of the block after adding a gauge background image, clear the **Lock Aspect Ratio** parameter.

To draw the arc for your gauge, click and drag along the guide circle. As you draw the arc, crosshairs appear to assist you with aligning the start and end points of the arc. After you release the mouse, you can continue to adjust the arc position and size. The arc options on the toolbar control the appearance of the arc, tick marks, and the value arc that indicates the value of the connected signal or parameter during simulation. The slider adjusts the transparency of the selected feature, and the color wheel allows you to specify the color. You can configure the arc as fully transparent when your background image includes the representation of the gauge face you want to use.

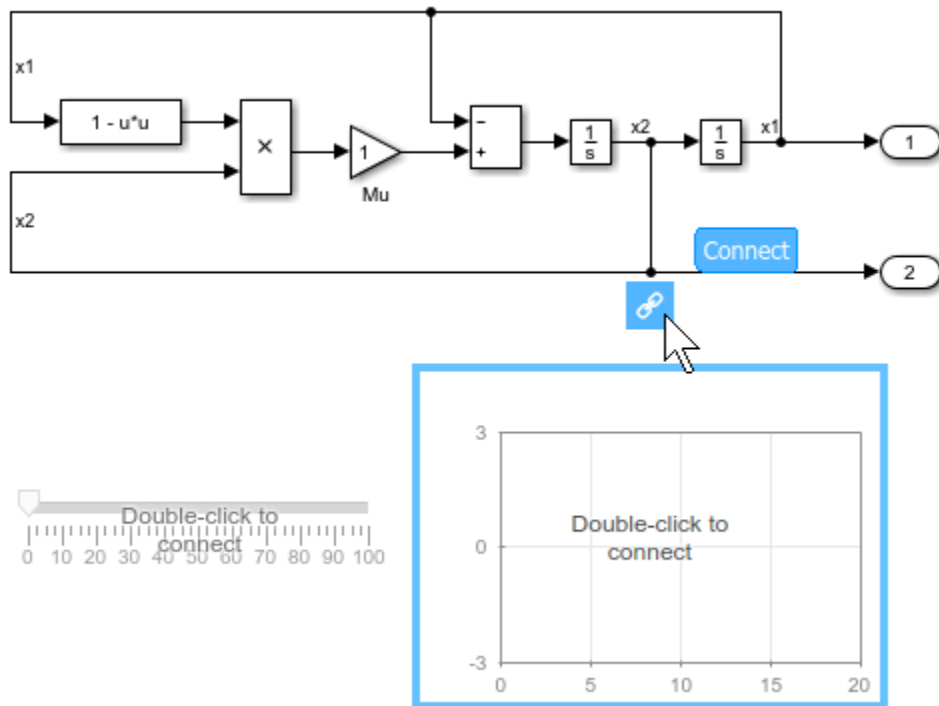

When you finish editing the appearance of your Custom Gauge block, click the **Exit** button in the upper-right of the model canvas or press **Esc** to exit Custom Gauge edit mode.

Connecting Dashboard Blocks

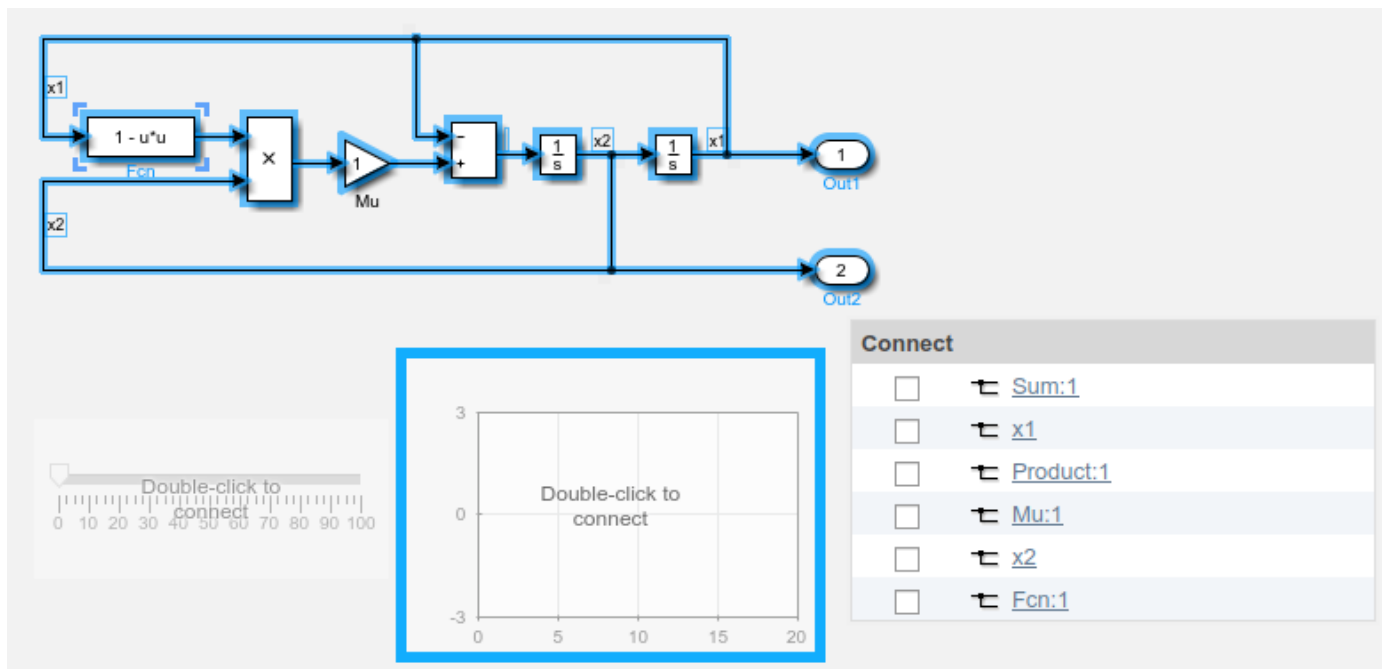

Dashboard blocks do not use ports to connect to signals. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above the block.

In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.

- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the Tick Interval parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Scale Colors — Color indications on gauge scale

colors for scale ranges

Color specifications for value ranges on the scale. Press the + button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the **Scale Colors** parameter, use an array of structures with the fields:

- **Min** — Minimum value for the color range on the scale
- **Max** — Maximum value for the color range on the scale
- **Color** — 1-by-3 vector of double values between 0 and 1 that specify the color for the range in the form [r g b]

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;
range1.Max = 10;
range1.Color = [0 0 1];
range2.Min = 10;
range2.Max = 15;
range2.Color = [0 1 0];
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors

Type: structure array

Default: 0x1 struct array

Lock Aspect Ratio — Maintain background image aspect ratio

on (default) | off

Maintain the background image aspect ratio when resizing the block. By default, when you specify a background image for the block, the **Lock Aspect Ratio** check box is selected.

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
-------------------	----------------------------------------------------------------

Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Dashboard Scope

Trace signals during simulation

Library: Simulink / Dashboard

Description

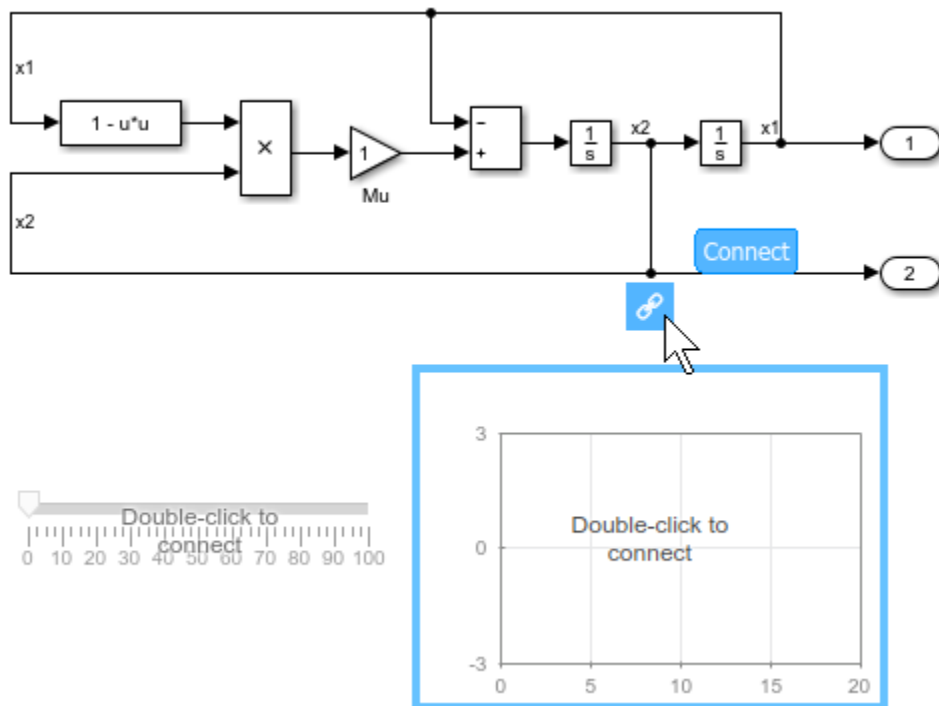

The Dashboard Scope block shows connected signals during simulation on a scope display. You can use the Dashboard Scope block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Dashboard Scope block provides a complete picture of a signal's behavior over the course of the simulation. Use the Dashboard Scope block to display signals of any data type that Simulink supports, including enumerated data types. The Dashboard Scope block can display up to eight signals from a matrix or bus.

Connecting Dashboard Blocks

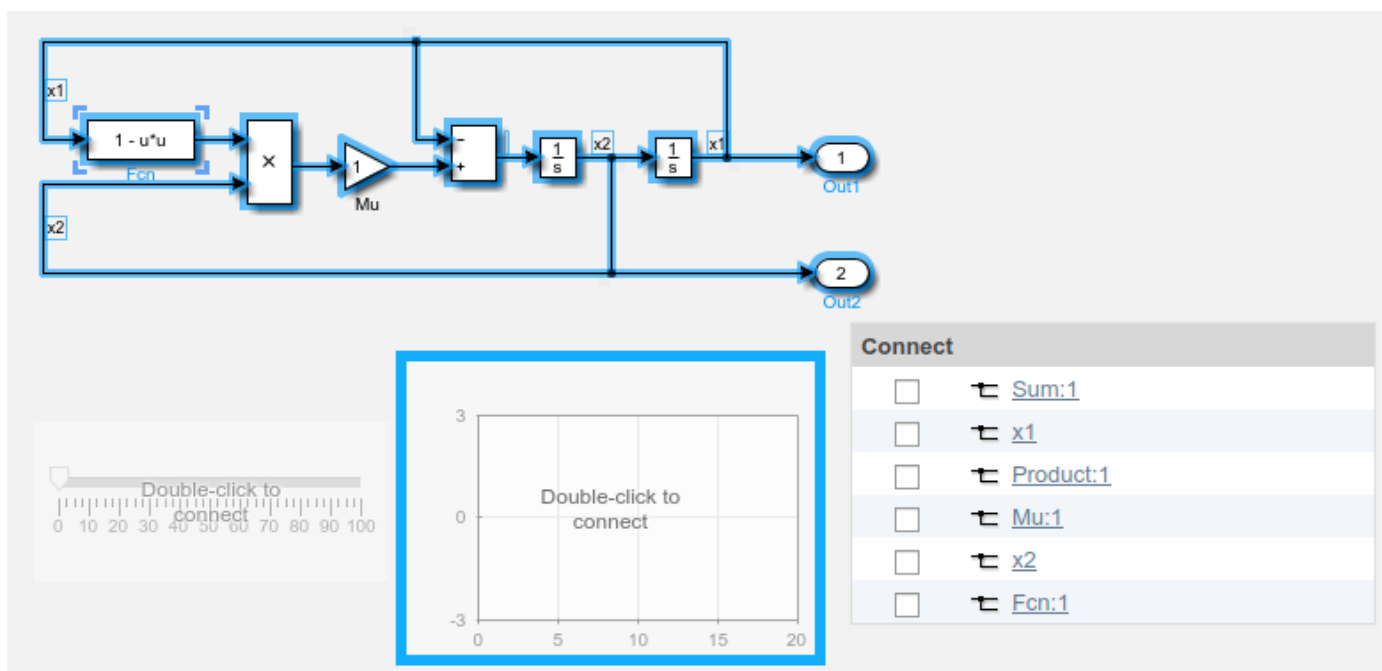

Dashboard blocks do not use ports to connect to signals. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above the block.

In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Data Cursors

You can add data cursors to a Dashboard Scope block to inspect the displayed signals. The data cursors show when the Dashboard Scope block is selected. With the Dashboard Scope block selected, you can move cursors along the displayed signals to see the data values corresponding to each time sample. When you display two cursors, a box between the cursors along the time axis displays the time difference between the two cursors.

To add data cursors, right-click the Dashboard Scope block. Under the **Data Cursors** menu, select the number of cursors you want to add.

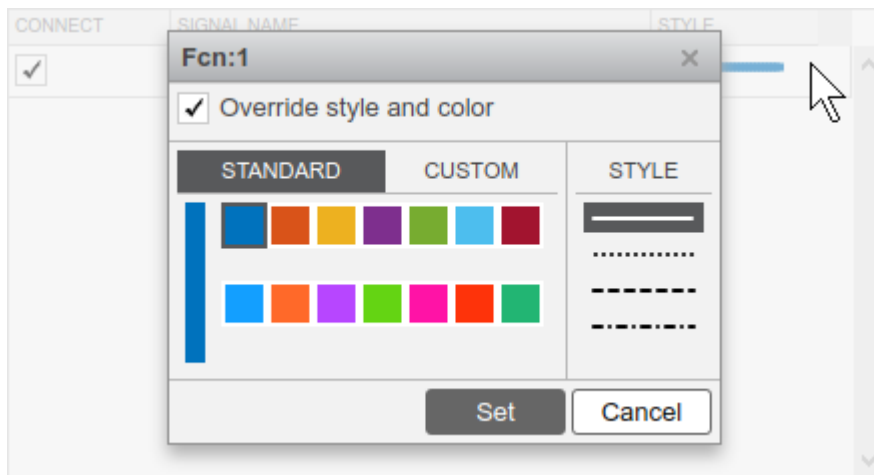

Zoom and Pan

You can also zoom and pan to inspect your signals. To change zoom and pan modes, right-click the Dashboard Scope block, and select the zoom or pan mode you want.

Signal Appearance

You can modify the color and line style for signals connected to a Dashboard Scope block from the **Connection** table in the block dialog box. To modify the appearance of a connected signal:

- 1 Click the signal appearance preview for the signal in the **Style** column of the **Connection** table.

- 2 Choose a signal color from the palette of standard colors or specify a custom color using RGB values between 0 and 255.
- 3 Select the line style from the solid, dotted, dashed, and dot-dashed options under the **Style** section in the signal appearance dialog.

Signal color and line style remain consistent for a signal throughout a model. You can configure the line style and color for a signal through the Instrumentation Properties for a logged signal and through the Dashboard Scope block dialog of a Dashboard Scope block connected to the signal. The **Override style and color** setting is selected by default and controls whether signal appearance options chosen through that Dashboard Scope block dialog override signal appearance options configured elsewhere in the model. When you clear the **Override style and color** setting, changes made using the dialog box for that Dashboard Scope block are not applied.

When you connect signals to a Dashboard Scope block using the block dialog box, the connection table shows the default signal color and line style used for a signal you connect. As you check signals to connect, the **Connection** table updates the default style and color to be used for the next signal you connect from the remaining signals in the selection.

CONNECT	SIGNAL NAME	STYLE
<input checked="" type="checkbox"/>	Fcn:1	
<input checked="" type="checkbox"/>	Mu:1	
<input type="checkbox"/>	Mux:1	
<input type="checkbox"/>	Product:1	
<input type="checkbox"/>	Sum:1	
<input type="checkbox"/>	x1	
<input type="checkbox"/>	x2	

Complex Signals

The Dashboard Scope block displays complex signals according to their **Complex Format**. You can configure the **Complex Format** for a signal using the **Instrumentation Properties** dialog box, accessible when you right-click the logging badge for the signal and select **Properties**.

A signal can have a **Complex Format** that is:

- **Real-Imaginary**
- **Magnitude-Phase**
- **Magnitude**
- **Phase**

When you set the **Complex Format** for a signal to **Real-Imaginary** or **Magnitude-Phase**, the Dashboard Scope block displays both components of the signal. The real or magnitude component displays in the color indicated in the **Connection** table. The imaginary or phase component displays in a different shade of the color indicated in the **Connection** table.

Limitations

- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using connect mode, the Dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, Dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view such signals on a Dashboard block, mark the signal for logging.

Parameters

Connection — Select signals to connect and display

signal connection options

Select one or more signals to connect using the **Connection** table. Populate the **Connection** table by selecting signals of interest in your model. Select the check box next to the signal you want to display. Click **Apply** to connect the signal. To facilitate understanding and debugging your model, you can connect signals to a Dashboard Scope block during simulation.

You can also configure the line style and color for signals connected to a Dashboard Scope block using the **Connection** table. For more information, see “Signal Appearance” on page 1-194.

Programmatic Use

To programmatically specify one or more signals to connect to the Dashboard Scope block, use a cell array of `Simulink.HMI.SignalSpecification` objects.

Block Parameter: Binding

Type: cell array of `Simulink.HMI.SignalSpecification` objects

Default: []

To programmatically configure the line style and color for connected signals, use the `Colors` parameter. Specify the value for the `Colors` parameter as an array of structures, where each

structure specifies the line style and color for one signal. Settings specified using the `Colors` parameter apply to the signal at the same index in the value for the `Binding` parameter.

Specify the line style and color for each signal as a structure with the fields:

- `Color` — 1-by-3 [r g b] vector with values between 0 and 1 specifying the signal color.
- `LineStyle` — Character vector specifying one of these line style options:
 - Solid: '-'
 - Dashed: '—'
 - Dotted: ':'
 - Dash-dotted: '-.'

```
sig1Colors.Color = [0 0 1];
sig1Colors.LineStyle = '--';
sig2Colors.Color = [1 0 1];
sig2Colors.LineStyle = '-.';
sigColors = [sig1Colors sig2Colors];
```

Block Parameter: Colors

Type: array of structures

Time Span — Set horizontal axis span

auto (default) | scalar

A finite, real, double, scalar value that sets the time span of the scope display.

When **Time Span** is set to auto, the block sets its time span to the model's simulation stop time.

Programmatic Use

Block Parameter: TimeSpan

Type: string or character array

Values: 'auto' or numeric value

Default: 'auto'

Min — Set y-axis minimum

-3 (default) | scalar

A finite, real, double, scalar value that sets the minimum of the vertical axis on the scope display.

Dependencies

The **Min** value must be less than the **Max** value.

Programmatic Use

To specify the `Min` parameter for the Dashboard Scope block programmatically, use a 1-by-2 vector containing the minimum y-axis value and maximum y-axis value, in that order.

Block Parameter: YLimits

Type: 1x2 vector

Default: [-3 3]

Max — Set y-axis maximum

3 (default) | scalar

A finite, real, double, scalar value that sets the maximum of the vertical axis on the scope display.

Dependencies

The **Max** value must be greater than the **Min** value.

Programmatic Use

To specify the **Max** parameter for the Dashboard Scope block programmatically, use a 1-by-2 vector containing the minimum y-axis value and maximum y-axis value, in that order.

Block Parameter: YLimits

Type: 1x2 vector

Default: [-3 3]

Legend — Set position of legend

Top (default) | Right | Hide

Options from the drop-down menu specify the position of the legend in the scope display. The legend shows the color chosen for each connected signal next to the signal's name.

Programmatic Use

Block Parameter: LegendPosition

Type: string or character vector

Values: 'Top' | 'Right' | 'Hide'

Default: 'Top'

Scale axes limits at stop — Autoscale axes limits when simulation finishes

on (default) | off

When on, performs a fit-to-view operation on the data displayed in the scope when the simulation stops.

Programmatic Use

Block Parameter: ScaleAtStop

Type: string or character vector

Values: 'on' | 'off'

Default: 'on'

Show "Double-click to connect" message — Show or hide message

on (default) | off

When on, shows instructional text if the block is not connected. When the block is not connected, you can specify this parameter as off to hide the text.

Programmatic Use

Block Parameter: ShowInitialText

Type: string or character vector

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no

Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Introduced in R2015a

Data Store Memory

Define data store

Library: Simulink / Signal Routing

Description

The Data Store Memory block defines and initializes a named shared data store, which is a memory region usable by Data Store Read and Data Store Write blocks that specify the same data store name.

The location of the Data Store Memory block that defines a data store determines which Data Store Read and Data Store Write blocks can access the data store:

- If the Data Store Memory block is in the *top-level system*, Data Store Read and Data Store Write blocks anywhere in the model can access the data store.
- If the Data Store Memory block is in a *subsystem*, Data Store Read and Data Store Write blocks in the same subsystem or in any subsystem below it in the model hierarchy can access the data store.

Data Store Read or Data Store Write blocks cannot access a Data Store Memory block that is either in a model that contains a Model block or in a referenced model.

Do not include a Data Store Memory block in a For Each subsystem.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. For details, see:

- “Order Data Store Access”
- “Data Store Diagnostics”
- “Log Data Stores”

You can use `Simulink.Signal` objects in addition to, or instead of, Data Store Memory blocks to define data stores. A data store defined in the *base* workspace with a signal object is a *global* data store. Global data stores are accessible to every model, including all referenced models. See “Data Stores” for more information.

Parameters

Main

Data store name — Name for the data store

A (default) | character vector | string

Specify a name for the data store you are defining with this block. Data Store Read and Data Store Write blocks with the same name can read from, and write to, the data store initialized by this block. The name can represent a Data Store Memory block or a sign object defined to be a data store.

Programmatic Use**Block Parameter:** DataStoreName**Type:** character vector**Values:** 'A' | ...**Default:** 'A'**Rename All — Rename this data store throughout the model**

button

Rename this data store everywhere the Data Store Read and Data Store Write blocks use it in a model.

Limitations

You cannot use **Rename All** to rename a data store if you:

- Use a `Simulink.Signal` object in a workspace to control the code generated for the data store
- Use a `Simulink.Signal` object instead of a Data Store Memory block to define the data store

You must instead rename the corresponding `Simulink.Signal` object from Model Explorer. For an example, see “Rename Data Store Defined by Signal Object”.

Corresponding Data Store Read/Write blocks — Path to connected Data Store Read/Write blocks

block path

List all the Data Store Read and Data Store Write blocks that have the same data store name as the current block, and that are in the current system or in any subsystem below it in the model hierarchy. Clicking a block path displays and highlights that block in your model.

Signal Attributes**Initial value — Initial value of data store**

0 (default) | scalar | vector | matrix | N-D array

Specify the initial value or values of the data store. The **Minimum** parameter specifies the minimum value for this parameter, and the **Maximum** parameter specifies the maximum value.

If you specify a nonscalar value and set **Dimensions** to -1 (the default), the data store has the same dimensions as the array. Data that you write to the data store (by using Data Store Write blocks) must have these dimensions.

If you set the **Dimensions** parameter to a value other than -1, the initial value dimensions must match the dimensions that you specify, unless the initial value is a scalar or a MATLAB structure. If you specify a scalar, each element of the data store uses the scalar as the initial value. Use this technique to apply the same initial value (the scalar that you specify) to each element without manually matching the dimensions of the initial value with the dimensions of the data store.

To use this block to initialize a nonvirtual bus signal, specify the initial value as a MATLAB structure and set the model configuration parameter “Underspecified initialization detection” to `Simplified`. For more information about initializing nonvirtual bus signals using structures, see “Specify Initial Conditions for Bus Signals”.

Programmatic Use**Block Parameter:** InitialValue

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '0'

Minimum — Minimum output value for range checking

[] (default) | scalar

Specify the minimum value that the block should output. The default value is [] (unspecified). This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: scalar

Default: '[]'

Maximum — Maximum output value for range checking

[] (default) | scalar

Specify the maximum value that the block should output. The default value is [] (unspecified). This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: scalar

Default: '[]'

Data type — Output data type

Inherit: auto (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name>

Specify the output data type. You can set it to:

- A rule that inherits a data type (for example, Inherit: auto).
- The name of a built-in data type (for example, single).
- The name of a data type object (for example, a Simulink.NumericType object).
- An expression that evaluates to a data type (for example, fixdt(1,16,0)). Do not specify a bus object as the data type in an expression; use Bus: <object name> to specify a bus data type.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>'

Default: 'Inherit: auto'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Dimensions (-1 to infer from Initial value) — Dimensions of data store

-1 (default) | scalar | vector | matrix

Dimensions of the data store. The default value, -1, enables you to set the dimensions of the data store by using the **Initial value** parameter. However, in this case, you cannot use scalar expansion with the initial value. You must specify the initial value by using an array that has the dimensions that you want.

If you use a value other than -1, specify the same dimensions as the dimensions of the **Initial value** parameter, unless you specify the initial value as a scalar (for scalar expansion) or a MATLAB structure. If the data store represents an array of buses, and if you use a MATLAB structure for the initial value, you can specify dimensions to initialize the array of buses with this structure.

Programmatic Use**Block Parameter:** Dimensions**Type:** character vector**Values:** scalar | vector | matrix**Default:** '-1'**Interpret vector parameters as 1-D – Interpret vectors as 1-D**

on (default) | off

Specify that the data store interpret vector initial values as one-dimensional.

By default, MATLAB represents vector data as matrices, which have two dimensions. For example, MATLAB represents the vector [1 2 3] as a 1-by-3 matrix.

When you select this parameter, the data store represents vector data by using only one dimension instead of two. For example, if you specify an initial value of [1 2 3], the data store stores a one-dimensional vector with three elements.

For more information, see “Determine the Output Dimensions of Source Blocks”.

Programmatic Use**Block Parameter:** VectorParams1D**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Signal type – Complexity of data store values**

auto (default) | real | complex

Specify the numeric type, real or complex, of the values in the data store.

Programmatic Use**Block Parameter:** SignalType**Type:** character vector**Values:** 'auto' | 'real' | 'complex'**Default:** 'auto'**Share across model instances – Allow Model blocks to read from the same data store**

off (default) | on

In a single model reference hierarchy, when you use multiple Model blocks to refer to a model that contains a Data Store Memory block, by default, each instance of the referenced model (each Model block) reads from and writes to a separate copy of the data store. When you select **Share across model instances**, instead of interacting with a separate copy, all of the instances read from and write to the same data store.

When you set the model configuration parameter **Code interface packaging** to Reusable function to generate reentrant code from a model (Simulink Coder), a data store with **Share across model instances** selected appears in the code as a global symbol that the generated entry-point functions access directly. For example, a global symbol is a global variable or a field of a global

structure variable. Therefore, each call that your code makes to the entry-point functions (each instance of the model) shares the data.

For an example, see “Share Data Store Between Instances of a Reusable Algorithm” on page 14-338. For more information, see “Share Data Among Referenced Model Instances”.

Programmatic Use

Block Parameter: `ShareAcrossModelInstances`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Data store name must resolve to Simulink signal object — Require data store name resolve to Simulink signal object

off (default) | on

Specify that Simulink software, when compiling the model, searches the model and base workspace for a `Simulink.Signal` object having the same name, as described in “Symbol Resolution”. If Simulink does not find such an object, the compilation stops with an error. Otherwise, Simulink compares the attributes of the signal object to the corresponding attributes of the Data Store Memory block. If the block and the object attributes are inconsistent, Simulink halts model compilation and displays an error.

Programmatic Use

Block Parameter: `StateMustResolveToSignalObject`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Signal object class — Custom storage class package

`Simulink.Signal` (default) | object of a class that is derived from `Simulink.Signal`

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder® software, custom storage classes do not affect the generated code.

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Programmatic Use

Block Parameter: `StateSignalObject`

Type: character vector

Values: 'Simulink.Signal' | ...

Default: 'Simulink.Signal'

Storage class — Storage class for code generation

Auto (default) | Model default | ExportedGlobal | ImportedExtern | ImportedExternPointer | BitField (Custom) | Volatile (Custom) | ExportToFile (Custom) | ImportFromFile (Custom) | FileScope (Custom) | AutoScope (Custom) | Struct (Custom) | GetSet (Custom) | Reusable (Custom)

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data

Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use

Block Parameter: `StateStorageClass`

Type: character vector

Values: 'Auto' | 'Model default' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...

Default: 'Auto'

TypeQualifier — Storage type qualifier

' ' (default) | const | volatile | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Minimum and Maximum values of the signal object

For more information, see “Data Objects”.

Dependencies

To enable this parameter, set **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `Model default`. This parameter is hidden unless you previously set its value.

Programmatic Use

Block Parameter: `RTWStateStorageTypeQualifier`

Type: character vector

Values: ' ' | 'const' | 'volatile' | ...

Default: ' '

Diagnostics

Detect Read Before Write — Action when model attempts to read data before writing in current time step

warning (default) | none | error

Select the diagnostic action to take if the model attempts to read data from a data store to which it has not written data in this time step. See also the “Detect read before write” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use**Block Parameter:** ReadBeforeWriteMsg**Type:** character vector**Values:** 'none' | 'warning' | 'error'**Default:** 'warning'**Detect Write After Read — Action when block attempts to write after reading in same time step**

warning (default) | none | error

Select the diagnostic action to take if the model attempts to write data to the data store after previously reading data from it in the current time step. See also the “Detect write after read” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use**Block Parameter:** WriteAfterReadMsg**Type:** character vector**Values:** 'none' | 'warning' | 'error'**Default:** 'warning'**Detect Write After Write — Action when model writes twice in same time step**

warning (default) | none | error

Select the diagnostic action to take if the model attempts to write data to the data store twice in succession in the current time step. See also the “Detect write after write” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use**Block Parameter:** WriteAfterWriteMsg**Type:** character vector**Values:** 'none' | 'warning' | 'error'**Default:** 'warning'**Logging****Log data store data — Log data store data**

off (default) | on

Select this option to save the values of this signal to the MATLAB workspace during simulation. See “Signal Logging” for details.

Programmatic Use**Block Parameter:** DataLogging**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Logging name — Name associated with logged signal data**

Use data store name (default) | Custom

Use this pair of controls, consisting of a list box and an edit field, to specify the name associated with logged signal data.

Simulink uses the signal name as its logging name by default. To specify a custom logging name, select Custom from the list box and enter the custom name in the adjacent edit field.

Programmatic Use**Block Parameter:** DataLoggingNameMode**Type:** character vector**Values:** 'SignalName' | 'Custom'**Default:** ''

Note If you set DataLoggingNameMode to Custom, you must specify the name associated with logged signal data using the DataLoggingName parameter.

Block Parameter: DataLoggingName**Type:** character vector**Values:** character vector**Default:** ''**Limit data points to last — Discard all but the last N data points**

5000 | non-zero integer

Discard all but the last N data points, where N is the number that you enter in the adjacent edit field. For more information, see “Log Data Stores”.

Programmatic Use**Block Parameter:** DataLoggingMaxPoints**Type:** character vector**Values:** nonzero integer**Default:** '5000'**Decimation — Log every Nth data point**

2 (default) | integer

Log every Nth data point, where N is the number that you enter in the adjacent edit field. For example, suppose that your model uses a fixed-step solver with a step size of 0.1 s. If you select this option and accept the default decimation value (2), Simulink records data points for this signal at times 0.0, 0.2, 0.4, and so on. For more information, see “Log Data Stores”.

Programmatic Use**Block Parameter:** DataLoggingLimitDataPoints**Type:** character vector**Values:** non-zero integer**Default:** '2'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

To generate PLC code for a model that uses a Data Store Memory block, first define a `Simulink.Signal` in the base workspace. Then in the **Signal Attributes** tab of the block parameters, set the data store name to resolve to that of the `Simulink.Signal` object.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Data Store Read

Read data from data store

Library: Simulink / Signal Routing

Description

The Data Store Read block copies data from the named data store to its output. More than one Data Store Read block can read from the same data store.

The data store from which the data is read is determined by the location of the Data Store Memory block or signal object that defines the data store. For more information, see “Data Stores” and Data Store Memory.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. See “Order Data Store Access” and “Data Store Diagnostics” for details.

Ports

Output

Port_1 — Values from specified data store

scalar | vector | matrix | N-D array

Values from the specified data store, output with the same data type and dimensions as in the data store. The block supports both real and complex signals. You can choose whether to output the entire data store, or only selected elements from the data store.

You can use arrays of buses with a Data Store Read block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Arguments

Data store name — Name of data store from which this block reads

A (default) | name of data store

Specifies the name of the data store from which this block reads data. The adjacent drop-down list provides the names of Data Store Memory blocks that exist at the same level in the model as the Data Store Read block or at higher levels. The list also includes all `Simulink.Signal` objects in the base and model workspaces. To change the name, select a name from the list or enter the name directly in the edit field.

When Simulink software compiles the model containing this block, Simulink searches the model upwards from this block's level for a Data Store Memory block having the specified data store name. If Simulink software does not find such a block, it searches the model workspace and the MATLAB workspace for a `Simulink.Signal` object having the same name. See “Symbol Resolution” for more information about the search path.

If Simulink finds the signal object, it creates a hidden Data Store Memory block at the model's root level having the properties specified by the signal object and an initial value of 0. If Simulink software finds neither the Data Store Memory block nor the signal object, it halts the compilation and displays an error.

Programmatic Use

Block Parameter: DataStoreName

Type: character vector

Values: data store name

Default: 'A'

Data store memory block — Data Store Memory block name

block path

This field lists the Data Store Memory block that initialized the store from which this block reads.

Data store write blocks — Corresponding Data Store Write blocks

block path

This field lists the path to all Data Store Write blocks with the same data store name as this block that are in the same (sub)system or in any subsystem below it in the model hierarchy. Click any entry in this list to highlight the corresponding block in your model.

Sample time — Sample time

-1 (default) | scalar | vector

The sample time, which controls when the block reads from the data store. A value of -1 indicates that the sample time is inherited. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

Element Selection

Elements in the array (Signals in the bus) — Elements in the associated data store

no default

List of elements in the associated data store. For data stores containing arrays, you can read the whole data store, or you can specify one or more elements of the data store. For bus signals, lists the elements in the associated data store. The list displays the maximum dimensions for each element, in parentheses.

You can select an element and then use one of the following approaches:

- Click **Select>>** to display that element (and all its subelements) in the **Selected element(s)** list.

- Use the **Specify element(s) to select** edit box to specify the elements that you want to select for reading. Then click **Select>>**.

To refresh the display and reflect modifications to the array or bus used in the data store, click **Refresh**.

Dependencies

The prompt for this section (**Elements in the array** or **Signals in the bus**) depends on the type of data in the data store.

Programmatic Use

Block Parameter: DataStoreElements

Type: character vector

Values: pound-delimited list of elements (See “Specification using the command line”.)

Default: ''

Specify element(s) to select – MATLAB expression defining the elements to select

no default

Enter a MATLAB expression to define the specific element that you want to read. For example, for a data store named DSM that has maximum dimensions of [3, 5], you could enter expressions such as DSM(2, 4) or DSM([1 3], 2) in the edit box and then click **Select>>**.

To apply the element selection, click **OK** or **Apply**.

Programmatic Use

Block Parameter: DataStoreElements

Type: character vector

Values: pound-delimited list of elements (See “Specification using the command line”.)

Default: ''

Selected element(s) – List of selected elements

no default

Displays the elements that you select from the data store. The Data Store Read block icon displays a port for each element that you specify.

To change the order of bus or matrix elements in the list, select the element in the list and click **Up** or **Down**. Changing the order of the elements in the list changes the order of the ports. To remove an element, click **Remove**.

Programmatic Use

Block Parameter: DataStoreElements

Type: character vector

Values: pound-delimited list of elements (See “Specification using the command line”.)

Default: ''

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string

Data Store Write

Write data to data store

Library: Simulink / Signal Routing

Description

The Data Store Write block copies the value at its input to the named data store. Each write operation performed by a Data Store Write block writes over the data store, replacing the previous contents.

The data store to which this block writes is determined by the location of the Data Store Memory block or signal object that defines the data store. For more information, see “Data Stores” and Data Store Memory. The size of the data store is set by the signal object or the Data Store Memory block that defines and initializes the data store. Each Data Store Write block that writes to that data store must write the same amount of data.

More than one Data Store Write block can write to the same data store. However, if two Data Store Write blocks attempt to write to the same data store during the same simulation step, results are unpredictable.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. For details, see “Order Data Store Access” and “Data Store Diagnostics”.

You can log the values of a local or global data store data variable for all the steps in a simulation. For details, see “Log Data Stores”.

Ports

Input

Port_1 — Values to write to data store

scalar | vector | matrix | N-D array

Values to write to the specified data store. The Data Store Write block accepts a real or complex signal.

You can use an array of buses with a Data Store Write block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

To assign a subset of the bus or matrix elements to the associated data store, use the **Element Assignment** pane. The Data Store Write block icon reflects the elements that you specify. For details, see “Accessing Specific Bus and Matrix Elements”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Arguments

Data store name — Name of data store from which this block writes

A (default) | name of data store

Specifies the name of the data store to which this block writes data. The adjacent drop-down list provides the names of Data Store Memory blocks that exist at the same level in the model as the Data Store Write block or at higher levels. The drop-down list also includes all `Simulink.Signal` objects in the base and model workspaces. To change the name, select a name from the drop-down or enter the name directly in the edit field.

When Simulink software compiles the model containing this block, Simulink searches the model upwards from this block's level for a Data Store Memory block having the specified data store name. If Simulink does not find such a block, it searches the model workspace and the MATLAB workspace for a `Simulink.Signal` object having the same name. If Simulink finds neither the Data Store Memory block nor the signal object, it halts the compilation and displays an error. See “Symbol Resolution” for more information about the search path.

If Simulink finds a signal object, it creates a hidden Data Store Memory block at the model's root level having the properties specified by the signal object and an initial value set to a matrix of zeros. The dimensions of that matrix are inherited from the `Dimensions` property of the signal object.

Programmatic Use

Block Parameter: DataStoreName

Type: character vector

Values: data store name

Default: 'A'

Data store memory block — Data Store Memory block name

block path

This field lists the Data Store Memory block that initialized the store to which this block writes.

Data store read blocks — Corresponding Data Store Read blocks

block path

This field lists the path to all Data Store Read blocks with the same data store name as this block that are in the same (sub)system or in any subsystem below it in the model hierarchy. Click any entry in this list to highlight the corresponding block in your model.

Sample time — Sample time

-1 (default) | scalar | vector

The sample time, which controls when the block writes to the data store. A value of -1 indicates that the sample time is inherited. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

Element Assignment

, Elements in the array (Signals in the bus) – Elements in the associated data store
no default

List of elements in the associated data store. For data stores with arrays, you can write the whole data store, or you can assign one or more elements to the whole data store. For data stores with a bus data type, you can expand the tree to view the bus elements. The list displays the maximum dimensions for each element, in parentheses.

You can select an element and then use one of the following approaches:

- Click **Select>>** to display that element (and all its subelements) in the **Selected element(s)** list.
- Use the **Specify element(s) to select** edit box to specify the elements that you want to select for writing. Then click **Select>>**.

To refresh the display and reflect modifications to the array or bus used in the data store, click **Refresh**.

Dependencies

The prompt for this section (**Elements in the array** or **Signals in the bus**) depends on the type of data in the data store.

Programmatic Use

Block Parameter: DataStoreElements

Type: character vector

Values: pound-delimited list of elements (See “Specification using the command line”.)

Default: ''

Specify element(s) to assign – MATLAB expression defining the elements to assign
no default

Enter a MATLAB expression to define the specific element that you want to write. For example, for a data store named DSM that has maximum dimensions of [3, 5], you could enter expressions such as DSM(2, 4) or DSM([1 3], 2) in the edit box. Then click **Select>>**.

To apply the element selection, click **OK** or **Apply**.

Programmatic Use

Block Parameter: DataStoreElements

Type: character vector

Values: pound-delimited list of elements (See “Specification using the command line”.)

Default: ''

Assigned element(s) – List of selected elements
no default

Displays the elements that you selected for assignment. The Data Store Write block icon displays a port for each element that you specify.

To change the order of bus or matrix elements in the list, select the element in the list and click **Up** or **Down**. Changing the order of the elements in the list changes the order of the ports. To remove an element, click **Remove**.

Programmatic Use**Block Parameter:** DataStoreElements**Type:** character vector**Values:** pound-delimited list of elements (See “Specification using the command line”.)**Default:** ''**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point integer single string

Data Type Conversion

Convert input signal to specified data type

Library: Simulink / Commonly Used Blocks
 Simulink / Signal Attributes
 HDL Coder / Commonly Used Blocks
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Signal Attributes

Description

The Data Type Conversion block converts an input signal of any Simulink data type to the data type that you specify.

Note To control the output data type by specifying block parameters, or to inherit a data type from a downstream block, use the Data Type Conversion block. To inherit a data type from a different signal in the model, use the Data Type Conversion Inherited block.

Convert Fixed-Point Signals

When you convert between fixed-point data types, the **Input and output to have equal** parameter controls block behavior. This parameter does not change the behavior of the block when:

- The input and output do not have a fixed-point data type.
- The input or output has a fixed-point data type with trivial scaling.

For more information about fixed-point numbers, see “Fixed-Point Numbers in Simulink” (Fixed-Point Designer).

To convert a signal from one data type to another by attempting to preserve the real-world value of the input signal, select **Real World Value (RWV)**, the default setting. The block accounts for the limits imposed by the scaling of the input and output and attempts to generate an output of equal real-world value.

To change the real-world value of the input signal by performing a scaling reinterpretation of the stored integer value, select **Stored Integer (SI)**. Within the limits of the specified data types, the block attempts to preserve the stored integer value of the signal during conversion. A best practice is to specify input and output data types using the same word length and signedness. Doing so ensures that the block changes only the scaling of the signal. Specifying a different signedness or word length for the input and output could produce unexpected results such as range loss or unexpected sign extensions. For an example, see “Convert Data Types in Simulink Models” on page 13-123.

If you select **Stored Integer (SI)**, the block does not perform a lower-level bit reinterpretation of a floating-point input signal. For example, if the input is `single` and has value 5, the bits that store the input in memory are given in hexadecimal by the following command.

```
num2hex(single(5))
```

```
40a00000
```

However, the Data Type Conversion block does not treat the stored integer value as 40a00000, but instead as the real-world value, 5. After conversion, the stored integer value of the output is 5.

Cast Enumerated Signals

Use a Data Type Conversion block to cast enumerated signals as follows:

- 1 To cast a signal of enumerated type to a signal of any numeric type.

The underlying integers of all enumerated values input to the Data Type Conversion block must be within the range of the numeric type. Otherwise, an error occurs during simulation.

- 2 To cast a signal of any integer type to a signal of enumerated type.

The value input to the Data Type Conversion block must match the underlying value of an enumerated value. Otherwise, an error occurs during simulation.

You can enable the **Saturate on integer overflow** parameter so that Simulink uses the default value of the enumerated type when the value input to the block does not match the underlying value of an enumerated value. See “Type Casting for Enumerations” (Simulink Coder).

You cannot use a Data Type Conversion block in these cases:

- To cast a noninteger numeric signal to an enumerated signal.
- To cast a complex signal to an enumerated signal, regardless of the data types of the real and imaginary parts of the complex signal.

See “Simulink Enumerations” for information on working with enumerated types.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. The input can be any real- or complex-valued signal. If the input is real, the output is real. If the input is complex, the output is complex. The block converts the input signal to the **Output data type** you specify.

When you are converting fixed-point data types, use the **Input and output to have equal** parameter to determine whether the conversion happens based on the Real World Value (RWV) or Stored Integer (SI) value of the signal. For more information, see “Convert Fixed-Point Signals” on page 1-218.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Output signal

scalar | vector | matrix | N-D array

Output signal, converted to the data type you specify, with the same dimensions as the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Parameters

Output minimum — Minimum output value for range checking

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`

Type: character vector

Values: `'[]'` | scalar

Default: `'[]'`

Output maximum — Maximum output value for range checking

`[]` (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type — Output data type**

Inherit: Inherit via back propagation (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | '<data type expression>'

Default: 'Inherit: Inherit via back propagation'**Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Input and output to have equal — Constraint for converting fixed-point data types**

Real World Value (RWV) (default) | Stored Integer (SI)

Specify which type of input and output must be equal, in the context of fixed-point data representation.

- Real World Value (RWV) — Specifies the goal of making the Real World Value (RWV) of the input equal to the Real World Value (RWV) of the output.
- Stored Integer (SI) — Specifies the goal of making the Stored Integer (SI) value of the input equal to the Stored Integer (SI) value of the output.

Programmatic Use**Block Parameter:** ConvertRealWorld**Type:** character vector**Values:** 'Real World Value (RWV)' | 'Stored Integer (SI)'**Default:** 'Real World Value (RWV)'

Integer rounding mode — Specify the rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Floor'**See Also**

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- **off** — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- **on** — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Note If you use double data types in your model, use this block for conversion between double and single data types. You cannot use the block to convert between double and fixed-point data types.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Note With the HDL Code Advisor, you can replace Data Type Conversion blocks that use the Stored Integer (SI) mode and convert between floating-point and fixed-point data types with Float Typecast blocks.

Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to <i>inherit</i> , <i>Max</i> , <i>Min</i> , <i>Zero</i> , or <i>Custom</i> for the floating-point operator. The default is <i>inherit</i> . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <i>Custom</i> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Restrictions

If you configure a Data Type Conversion block for double to fixed-point conversion or fixed-point to double conversion, a warning is displayed during code generation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Data Type Conversion Inherited

Convert from one data type to another using inherited data type and scaling

Library: Simulink / Signal Attributes

Description

The Data Type Conversion Inherited block converts one input to the data type and scaling of the other input. The first input is used as the reference signal. The second input, **u**, is converted to the reference type by inheriting the data type and scaling information. (For a description of the port order for various block orientations, see “Port Location After Rotating or Flipping”.)

Inheriting the data type and scaling provides these advantages:

- It makes reusing existing models easier.
- It allows you to create new fixed-point models with less effort since you can avoid the detail of specifying the associated parameters.

Ports

Input

Port_1 — Reference signal

scalar | vector | matrix | N-D array

Reference signal, defining the data type used to convert input signal **u**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u — Input signal to convert

scalar | vector | matrix | N-D array

Input signal to convert to the reference data type, specified as a scalar, vector, matrix, or N-D array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

y — Output signal

scalar | vector | matrix | N-D array

Output is the input signal **u**, converted to the reference data type.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

Input and Output to have equal — Constraint for converting fixed-point data types

Real World Value (RWV) (default) | Stored Integer (SI)

Specify which type of input and output must be equal, in the context of fixed-point data representation.

- Real World Value (RWV) — Specifies the goal of making the Real World Value (RWV) of the input equal to the Real World Value (RWV) of the output.
- Stored Integer (SI) — Specifies the goal of making the Stored Integer (SI) value of the input equal to the Stored Integer (SI) value of the output.

Programmatic Use

Block Parameter: ConvertRealWorld

Type: character vector

Values: 'Real World Value (RWV)' | 'Stored Integer (SI)'

Default: 'Real World Value (RWV)'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no

Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

Data Type Duplicate

Force all inputs to same data type

Library: Simulink / Signal Attributes
HDL Coder / Signal Attributes

Description

The Data Type Duplicate block forces all inputs to have the same data type. Other attributes of input signals, such as dimension, complexity, and sample time, are independent.

You can use the Data Type Duplicate block to check for consistency of data types among blocks. If all signals do not have the same data type, the block returns an error message.

The Data Type Duplicate block is typically used such that one signal to the block controls the data type for all other blocks. The other blocks are set to inherit their data types via backpropagation.

The block can also be useful in a user created library. These library blocks can be placed in any model, and the data type for all library blocks are configured according to the usage in the model. To create a library block with more complex data type rules than duplication, use the Data Type Propagation block.

Ports

Input

Port_1 — First input signal

scalar | vector | matrix | N-D array

First input signal, specified as a scalar, vector, matrix, or N-D array. If all signals do not have the same data type, the block returns an error message.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

Port_N — Nth input signal

scalar | vector | matrix | N-D array

Nth input signal, specified as a scalar, vector, matrix, or N-D array. If all signals do not have the same data type, the block returns an error message.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

Parameters

Number of input ports — Number of block inputs

2 (default) | real-valued positive integer

Specify the number of inputs to this block as a real-valued positive integer.

Programmatic Use**Block Parameter:** NumInputPorts**Type:** character vector**Values:** real-valued positive integer**Default:** '2'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Data Type Propagation

Set data type and scaling of propagated signal based on information from reference signals

Library: Simulink / Signal Attributes

Description

The Data Type Propagation block allows you to control the data type and scaling of signals in your model. You can use this block along with fixed-point blocks that have their **Output data type** parameter configured to **Inherit: Inherit via back propagation**.

The block has three inputs: **Ref1** and **Ref2** are the reference inputs, while the **Prop** input back-propagates the data type and scaling information gathered from the reference inputs. This information is then passed on to other fixed-point blocks.

The block provides many choices for propagating data type and scaling information. For example, you can use:

- The number of bits from the **Ref1** reference signal or the number of bits from widest reference signal
- The range from the **Ref2** reference signal or the range of the reference signal with the greatest range
- A bias of zero, regardless of the biases used by the reference signals
- The precision of the reference signal with the least precision

You specify how data type information is propagated using the **Propagated data type** parameter:

- If you select **Specify via dialog**, then you manually specify the data type via the **Propagated data type** edit field.
- If you select **Inherit via propagation rule**, then you must use the parameters described in “Parameters” on page 1-233.

You specify how scaling information is propagated using the **Propagated scaling** parameter:

- If you select **Specify via dialog**, then you manually specify the scaling via the **Propagated scaling** edit field.
- If you select **Inherit via propagation rule**, then you must use the parameters described in “Parameters” on page 1-233.

After you use the information from the reference signals, you can apply a second level of adjustments to the data type and scaling. To do so, use individual multiplicative and additive adjustments. This flexibility has various uses. For example, if you are targeting a DSP, then you can configure the block so that the number of bits associated with a multiply and accumulate (MAC) operation is twice as wide as the input signal, and has a specific number of guard bits added to it.

The Data Type Propagation block also provides a mechanism to force the computed number of bits to a useful value. For example, if you are targeting a 16-bit micro, then the target C compiler is likely to support sizes of only 8 bits, 16 bits, and 32 bits. The block forces these three choices to be used. For example, suppose that the block computes a data type size of 24 bits. Since 24 bits is not directly usable by the target chip, the signal is forced up to 32 bits, which is natively supported.

There is also a method for dealing with floating-point reference signals. This method makes it easier to create designs that are easily retargeted between fixed-point chips and floating-point chips.

The Data Type Propagation block allows you to set up libraries of useful subsystems that are properly configured based on the connected signals. Without this data type propagation process, subsystems from a library are unlikely to work as desired with most integer or fixed-point signals. Manual intervention would be required to configure the data type and scaling. In many situations, this block can eliminate the manual intervention.

Precedence Rules

The precedence of the dialog box parameters decreases from top to bottom. Also:

- Double-precision reference inputs have precedence over all other data types.
- Single-precision reference inputs have precedence over integer and fixed-point data types.
- Multiplicative adjustments are carried out before additive adjustments.
- The number of bits is determined before the precision or positive range is inherited from the reference inputs.
- PosRange is one bit higher than the exact maximum positive range of the signal.
- The computed number-of-bits are promoted to the smallest allowable value that is greater than or equal to the computation. If none exists, then the block returns an error.

Ports

Input

Ref1 — First reference signal

scalar | vector | matrix | N-D array

First reference signal, from which to gather data type and scaling information.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Ref2 — Second reference signal

scalar | vector | matrix | N-D array

Second reference signal from which to gather data type and scaling information.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Prop — Propagated data type and scaling

data type and scaling

Data type and scaling information, back-propagated to the model. After the block gathers data type and scaling information from the reference signals, you can apply a second level of adjustments to the

data type and scaling. To do so, specify individual multiplicative and additive adjustments in the block dialog box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Propagated Type

1. Propagated data type — Mode of specifying propagated data type

`Inherit via propagation rule` (default) | `Specify via dialog`

Specify whether to propagate the data type via the dialog box, or inherit the data type from the reference signals.

Dependencies

Setting this parameter to `Specify via dialog` enables the **1.1. Propagated data type (e.g. `fixdt(1,16)`, `fixdt('single')`)**.

Programmatic Use

Block Parameter: `PropDataTypeMode`

Type: character vector

Values: `'Specify via dialog'` | `'Inherit via propagation rule'`

Default: `'Inherit via propagation rule'`

1.1. Propagated data type (e.g. `fixdt(1,16)`, `fixdt('single')`) — Propagated data type

`fixdt(1,16)` (default) | data type string

Specify the data type to propagate.

Dependencies

To enable this parameter, set **1. Propagated data type** to `Specify via dialog`.

Programmatic Use

Block Parameter: `PropDataTypeMode`

Type: character vector

Values: `'Specify via dialog'` | `'Inherit via propagation rule'`

Default: `'Inherit via propagation rule'`

1.1 If any reference input is double, output is — Output data type when a reference input is double

`double` (default) | `single`

Specify the output data type as `single` or `double`. This parameter makes it easier to create designs that are easily retargeted between fixed-point chips and floating-point chips.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit via propagation rule`.

Programmatic Use

Block Parameter: `IfRefDouble`

Type: character vector
Values: 'double' | 'single'
Default: 'double'

1.2 If any reference input is single, output is — Output data type when a reference input is single

single (default) | double

Specify the output data type as `single` or `double`. This parameter makes it easier to create designs that are easily retargeted between fixed-point chips and floating-point chips.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `IfRefSingle`
Type: character vector
Values: 'double' | 'single'
Default: 'single'

1.3 Is-Signed — Signedness of propagated data type

`IsSigned1` or `IsSigned2` (default) | `IsSigned1` | `IsSigned2` | `TRUE` | `FALSE`

Specify the sign of **Prop** as one of the following values.

Parameter Value	Description
<code>IsSigned1</code>	Prop is a signed data type if Ref1 is a signed data type.
<code>IsSigned2</code>	Prop is a signed data type if Ref2 is a signed data type.
<code>IsSigned1</code> or <code>IsSigned2</code>	Prop is a signed data type if either Ref1 or Ref2 are signed data types.
<code>TRUE</code>	Ref1 and Ref2 are ignored, and Prop is always a signed data type.
<code>FALSE</code>	Ref1 and Ref2 are ignored, and Prop is always an unsigned data type.

For example, if the **Ref1** signal is `ufix(16)`, the **Ref2** signal is `sfix(16)`, and the **Is-Signed** parameter is `IsSigned1` or `IsSigned2`, then **Prop** is forced to be a signed data type.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `IsSigned`
Type: character vector
Values: 'IsSigned1' | 'IsSigned2' | 'IsSigned1 or IsSigned2' | 'TRUE' | 'FALSE'
Default: 'IsSigned1 or IsSigned2'

1.4.1 Number-of-bits: Base — Number of bits for the base of the propagated data type

`max([NumBits1 NumBits2])` (default) | `NumBits1` | `NumBits2` | `min([NumBits1 NumBits2])` | `NumBits1+NumBits2`

Specify the number of bits used by **Prop** for the base data type as one of the following values.

Parameter Value	Description
NumBits1	The number of bits for Prop is given by the number of bits for Ref1 .
NumBits2	The number of bits for Prop is given by the number of bits for Ref2 .
max([NumBits1 NumBits2])	The number of bits for Prop is given by the reference signal with largest number of bits.
min([NumBits1 NumBits2])	The number of bits for Prop is given by the reference signal with smallest number of bits.
NumBits1+NumBits2	The number of bits for Prop is given by the sum of the reference signal bits.

For more information about the base data type, refer to Targeting an Embedded Processor (Fixed-Point Designer).

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: NumBitsBase

Type: character vector

Values: 'NumBits1' | 'NumBits2' | 'max([NumBits1 NumBits2])' | 'min([NumBits1 NumBits2])' | 'NumBits1+NumBits2'

Default: 'max([NumBits1 NumBits2])'

1.4.2 Number-of-bits: Multiplicative adjustment — Number of bits for multiplicative adjustment of propagated data type

1 (default) | positive integer

Specify the number of bits used by **Prop** by including a multiplicative adjustment that uses a data type of `double`. For example, suppose that you want to guarantee that the number of bits associated with a multiply and accumulate (MAC) operation is twice as wide as the input signal. To do this, set this parameter to 2.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: NumBitsMult

Type: character vector

Values: positive integer

Default: '1'

1.4.3 Number-of-bits: Additive adjustment — Number of bits for additive adjustment of propagated data type

0 (default) | positive integer

Specify the number of bits used by **Prop** by including an additive adjustment that uses a data type of `double`. For example, if you are performing multiple additions during a MAC operation, the result could overflow. To prevent overflow, you can associate guard bits with the propagated data type. To associate four guard bits, you specify the value 4.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `NumBitsAdd`

Type: character vector

Values: scalar

Default: `'0'`

1.4.4 Number-of-bits: Allowable final values — Allowable number of bits in propagated data type

`'1:128'` (default) | scalar or vector of positive integers

Force the computed number of bits used by **Prop** to a useful value. For example, if you are targeting a processor that supports only 8 bits, 16 bits, and 32 bits, then you configure this parameter to `[8,16,32]`. The block always propagates the smallest specified value that fits. If you want to allow all fixed-point data types, you would specify the value `1:128`.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `NumBitsAllowFinal`

Type: character vector

Values: scalar or vector of positive integers

Default: `'1:128'`

Propagated Scaling**2. Propagated scaling — Propagated scaling mode**

`Inherit via propagation rule` (default) | `Specify via dialog` | `Obtain via best precision`

Choose to propagate the scaling via the dialog box, inherit the scaling from the reference signals, or calculate the scaling to obtain best precision.

Programmatic Use

Block Parameter: `PropScalingMode`

Type: character vector

Values: `Inherit via propagation rule` | `Specify via dialog` | `Obtain via best precision`

Default: `Inherit via propagation rule`

2.1. Propagated scaling (Slope or [Slope Bias]) — Slope or slope and bias

`2^-10` | `Slope` | `[Slope Bias]`

Specify the scaling as either a slope or a slope and bias.

Dependencies

To enable this parameter, set **Propagated scaling** to `Specify via dialog`.

Programmatic Use

Block Parameter: `PropScaling`

Type: character vector
Values: Slope | [Slope Bias]
Default: '2^-10'

2.1. Values used to determine best precision scaling — Values to constrain precision

[5 -7] (default)

Specify any values to be used to constrain the precision, such as the upper and lower limits on the propagated input. Based on the data type, the block selects a scaling such that these values can be represented with no overflow error and minimum quantization error.

Dependencies

To enable this parameter, set **Propagated scaling** to Obtain via best precision.

Programmatic Use

Block Parameter: ValuesUsedBestPrec

Type: character vector

Values: vector of values

Default: '[5 -7]'

2.1.1. Slope: Base — Slope for base of the propagated data type

min([Slope1 Slope2]) (default) | Slope1 | Slope2 | min([Slope1 Slope2]) | max([Bias1 Bias2]) | Slope1*Slope2 | Slope1/Slope2 | PosRange1 | PosRange2 | max([PosRange1 PosRange2]) | min([PosRange1 PosRange2]) | PosRange1*PosRange2 | PosRange1/PosRange2

Specify the slope used by **Prop** for the base data type as one of the following values.

Parameter Value	Description
Slope1	The slope of Prop is given by the slope of Ref1 .
Slope2	The slope of Prop is given by the slope of Ref2 .
max([Slope1 Slope2])	The slope of Prop is given by the maximum slope of the reference signals.
min([Slope1 Slope2])	The slope of Prop is given by the minimum slope of the reference signals.
Slope1*Slope2	The slope of Prop is given by the product of the reference signal slopes.
Slope1/Slope2	The slope of Prop is given by the ratio of the Ref1 slope to the Ref2 slope.
PosRange1	The range of Prop is given by the range of Ref1 .
PosRange2	The range of Prop is given by the range of Ref2 .
max([PosRange1 PosRange2])	The range of Prop is given by the maximum range of the reference signals.
min([PosRange1 PosRange2])	The range of Prop is given by the minimum range of the reference signals.
PosRange1*PosRange2	The range of Prop is given by the product of the reference signal ranges.

Parameter Value	Description
PosRange1/PosRange2	The range of Prop is given by the ratio of the Ref1 range to the Ref2 range.

You control the precision of **Prop** with `Slope1` and `Slope2`, and you control the range of **Prop** with `PosRange1` and `PosRange2`. Also, `PosRange1` and `PosRange2` are one bit higher than the maximum positive range of the associated reference signal.

Dependencies

To enable this parameter, set **Propagated scaling** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `SlopeBase`

Type: character vector

Values: `'Slope1'` | `'Slope2'` | `'max([Slope1 Slope2])'` | `'min([Slope1 Slope2])'` | `'Slope1*Slope2'` | `'Slope1/Slope2'` | `'PosRange1'` | `'PosRange2'` | `'max([PosRange1 PosRange2])'` | `'min([PosRange1 PosRange2])'` | `'PosRange1*PosRange2'` | `'PosRange1/PosRange2'`

Default: `'min([Slope1 Slope2])'`

2.1.2. Slope: Multiplicative adjustment — Slope of multiplicative adjustment of propagated data type

1 (default) | scalar

Specify the slope used by **Prop** by including a multiplicative adjustment that uses a data type of `double`. For example, if you want 3 bits of additional precision (with a corresponding decrease in range), the multiplicative adjustment is 2^{-3} .

Dependencies

To enable this parameter, set **Propagated scaling** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `SlopeMult`

Type: character vector

Values: scalar

Default: `'1'`

2.1.3. Slope: Additive adjustment — Slope of additive adjustment of propagated data type

0 (default) | scalar

Specify the slope used by **Prop** by including an additive adjustment that uses a data type of `double`. An additive slope adjustment is often not needed. The most likely use is to set the multiplicative adjustment to 0, and set the additive adjustment to force the final slope to a specified value.

Dependencies

To enable this parameter, set **Propagated scaling** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `SlopeAdd`

Type: character vector

Values: scalar

Default: '0'

2.2.1. Bias: Base — Base bias for Prop

Bias1 (default) | Bias2 | max([Bias1 Bias2]) | min([Bias1 Bias2]) | Bias1*Bias2 | Bias1/Bias2 | Bias1+Bias2 | Bias1-Bias2

Specify the bias used by **Prop** for the base data type. The parameter values are described as follows:

Parameter Value	Description
Bias1	The bias of Prop is given by the bias of Ref1 .
Bias2	The bias of Prop is given by the bias of Ref2 .
max([Bias1 Bias2])	The bias of Prop is given by the maximum bias of the reference signals.
min([Bias1 Bias2])	The bias of Prop is given by the minimum bias of the reference signals.
Bias1*Bias2	The bias of Prop is given by the product of the reference signal biases.
Bias1/Bias2	The bias of Prop is given by the ratio of the Ref1 bias to the Ref2 bias.
Bias1+Bias2	The bias of Prop is given by the sum of the reference biases.
Bias1-Bias2	The bias of Prop is given by the difference of the reference biases.

Dependencies

To enable this parameter, set **Propagated scaling** to **Inherit** via propagation rule.

Programmatic Use

Block Parameter: BiasBase

Type: character vector

Values: 'Bias1' | 'Bias2' | 'max([Bias1 Bias2])' | 'min([Bias1 Bias2])' | 'Bias1*Bias2' | 'Bias1/Bias2' | 'Bias1+Bias2' | 'Bias1-Bias2'

Default: 'Bias1'

2.2.2. Bias: Multiplicative adjustment — Multiplicative bias for propagated data type

1 (default) | scalar

Specify the bias used by Prop by including a multiplicative adjustment that uses a data type of double.

This parameter is visible only when you set **Propagated scaling** to **Inherit** via propagation rule.

Programmatic Use

Block Parameter: BiasMult

Type: character vector

Values: scalar

Default: '1'

2.3.2. Bias: Additive adjustment — Additive bias for propagated data type

0 (default) | scalar

Specify the bias used by **Prop** by including an additive adjustment that uses a data type of double.

If you want to guarantee that the bias associated with **Prop** is zero, configure both the multiplicative adjustment and the additive adjustment to 0.

Dependencies

To enable this parameter, set **Propagated scaling** to Inherit via propagation rule.

Programmatic Use

Block Parameter: BiasAdd

Type: character vector

Values: scalar

Default: '0'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block can be used to control scaling and data types of signals that are part of subsystems that generate HDL code, but is not included in the hardware implementation.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Data Type Scaling Strip

Remove scaling and map to built in integer

Library: Simulink / Signal Attributes

Description

The Data Type Scaling Strip block strips the scaling off a fixed-point signal. It maps the input data type to the smallest built-in data type that has enough data bits to hold the input. The stored integer value of the input is the value of the output. The output always has nominal scaling (slope = 1.0 and bias = 0.0), so the output does not distinguish between real world value and stored integer value.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The block strips the scaling off a fixed-point input signal, and outputs the stored integer value with the smallest possible built-in data type.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Input signal mapped to built-in data type

scalar | vector | matrix

Stored integer value of the input signal with the smallest possible built-in data type, and the same dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

Dead Zone

Provide region of zero output

Library: Simulink / Discontinuities
HDL Coder / Discontinuities

Description

The Dead Zone block generates zero output within a specified region, called its dead zone. You specify the lower limit (LL) and upper limit (UL) of the dead zone as the **Start of dead zone** and **End of dead zone** parameters. The block output depends on the input (U) and the values for the lower and upper limits.

Input	Output
$U \geq LL$ and $U \leq UL$	Zero
$U > UL$	$U - UL$
$U < LL$	$U - LL$

Ports

Input

Port_1 – Input signal

scalar | vector

Input signal to the dead-zone algorithm.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Output signal

scalar | vector

Output signal after the dead-zone algorithm is applied to the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Start of dead zone – Specify the lower bound of the dead zone

'-0.5' (default) | scalar | vector

Specify dead zone lower limit. Set the value for **Start of dead zone** less than or equal to **End of dead zone**. When the input value is less than **Start of dead zone**, then the block shifts the output value down by the **Start of dead zone** value.

Programmatic Use**Block Parameter:** LowerValue**Type:** character vector**Value:** scalar or vector less than or equal to UpperValue.**Default:** '-0.5'**End of dead zone — Specify the upper limit of the dead zone**

'0.5' (default) | scalar | vector

Specify dead zone upper limit. Set the value for **End of dead zone** greater than or equal to **Start of dead zone**. When the input value is greater than **End of dead zone**, then the block shifts the output value down by the **End of dead zone** value.

Programmatic Use**Block Parameter:** UpperValue**Type:** character vector**Value:** scalar or vector greater than or equal to LowerValue.**Default:** '0.5'**Saturate on integer overflow — Choose the behavior when integer overflow occurs**

on (default) | boolean

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'on'

Treat as gain when linearizing — Specify the gain value

On (default) | boolean

The linearization commands in Simulink software treat this block as a gain in state space. Select this check box to cause the commands to treat the gain as 1. Clear the box to have the commands treat the gain as 0.

Programmatic Use

Block Parameter: LinearizeAsGain

Type: character vector

Value: 'off' | 'on'

Default: 'on'

Enable zero-crossing detection — Enable zero-crossing detection

on (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector, string

Values: 'off' | 'on'

Default: 'on'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Block Characteristics

Data Types	double fixed point integer single
-------------------	-----------------------------------------

Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Dead Zone Dynamic

Provide dynamic region of zero output

Library: Simulink / Discontinuities
HDL Coder / Discontinuities

Description

The Dead Zone Dynamic block generates a region of zero output based on dynamic input signals that specify the upper and lower limit. The block output depends on the input **u**, and the values of the input signals **up** and **lo**.

Input	Output
$u \geq lo$ and $u \leq up$	Zero
$u > up$	$u - up$
$u < lo$	$u - lo$

The Dead Zone Dynamic block is a masked subsystem and does not have any parameters.

Ports

Input

u – Input signal

scalar | vector

Input signal to the dead zone algorithm.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

lo – Lower limit for the dead zone

scalar | vector

Dynamic value providing the lower bound of the region of zero output. When the input is less than **lo** then the output value is shifted down by value of **lo**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

up – Upper limit for the dead zone

scalar

Dynamic value providing the upper bound of the region of zero output. When the input is greater than **up** then the output value is shifted down by value of **up**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

y — Output signal

scalar | vector

Output signal after the dynamic dead zone algorithm is applied to the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no

Decrement Real World

Decrease real-world value of signal by one

Library: Simulink / Additional Math & Discrete / Additional Math:
Increment - Decrement
HDL Coder / Math Operations

Description

The Decrement Real World block decreases the real-world value of the signal by one. Overflows always wrap.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Output signal

scalar | vector | matrix

Output is the real-world value of the input signal decreased by one. Overflows always wrap. The output has the same data type and dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Decrement Stored Integer

Decrease stored integer value of signal by one

Library: Simulink / Additional Math & Discrete / Additional Math:
Increment - Decrement
HDL Coder / Math Operations

Description

The Decrement Stored Integer block decreases the stored integer value of a signal by one.

Floating-point signals also decrease by one, and overflows always wrap.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output is the stored integer value of the input signal decreased by one. Floating-point signals also decrease by one, and overflows always wrap. The output has the same data type and dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no

Decrement Time To Zero

Decrease real-world value of signal by sample time, but only to zero

Library: Simulink / Additional Math & Discrete / Additional Math:
Increment - Decrement

Description

The Decrement Time To Zero block decreases the real-world value of the signal by the sample time, T_s . The output never goes below zero.

Limitations

The Decrement Time To Zero block works only with fixed sample rates and does not work inside a triggered subsystem.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Output signal

scalar | vector | matrix

Output is the real-world value of the input signal decreased by the sample time, T_s . The output never goes below zero. The output has the same data type and dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Delay

Delay input signal by fixed or variable sample periods

Library: Simulink / Commonly Used Blocks
 Simulink / Discrete
 HDL Coder / Commonly Used Blocks
 HDL Coder / Discrete

Description

The Delay block outputs the input of the block after a delay. The block determines the delay time based on the value of the **Delay length** parameter. The block supports:

- Variable delay length
- Specification of the initial condition from an input port
- State storage
- Using a circular buffer instead of an array buffer for state storage
- Resetting the state to the initial condition with an external reset signal
- Controlling execution of the block at every time step with an external enable signal

The initial block output depends on several factors such as the **Initial condition** parameter and the simulation start time. For more information, see “Initial Block Output” on page 1-259. The **External reset** parameter determines if the block output resets to the initial condition on triggering. The **Show enable port** parameter determines if the block execution is controlled in every time step by an external enable signal.

Initial Block Output

The output in the first few time steps of the simulation depends on the block sample time, the delay length, and the simulation start time. The block supports specifying or inheriting discrete sample times to determine the time interval between samples. For more information, see “Specify Sample Time”.

The table shows the Delay block output for the first few time steps with these settings. The block inherits a discrete sample time as $[T_{sampling}, T_{offset}]$, where $T_{sampling}$ is the sampling period and T_{offset} is the initial time offset. n is the value of the **Delay length** parameter and T_{start} is the simulation start time for the model

Simulation Time Range	Block Output
(T_{start}) to $(T_{start} + T_{offset})$	Zero
$(T_{start} + T_{offset})$ to $(T_{start} + T_{offset} + n * T_{sampling})$	Initial condition parameter
After $(T_{start} + T_{offset} + n * T_{sampling})$	Input signal

Behavior with External Enable Signal

Selecting the **Show enable port** check box enables the Enable port. If the enable port is enabled, the block operates in this order

- 1 Checks if the enable condition is satisfied.
- 2 If the reset port is enabled, checks the reset condition.
- 3 Performs the Delay block functionality.

The block has this operation with the Enable port:

- At the first block enable, the block output is the initial condition value (x_0).
- For consecutive enable signals, the block takes the last state of the input signal u .
- If the port is not enabled at the start of simulation, the Delay block outputs 0 .
- During simulation, if the port becomes disabled after having been enabled, the block does not execute and holds its last value.

Variable-Size Support

The Delay block provides the following support for variable-size signals:

- The data input port u accepts variable-size signals. The other input ports do not accept variable-size signals.
- The output port has the same signal dimensions as the data input port u for variable-size inputs.

The rules that apply to variable-size signals depend on the input processing mode of the Delay block.

Input Processing Mode	Rules for Variable-Size Signal Support
Elements as channels (sample based)	<ul style="list-style-type: none"> • The signal dimensions change only during state reset when the block is enabled. • The initial condition must be scalar.
Columns as channels (frame based)	<ul style="list-style-type: none"> • No support

Bus Support

The Delay block provides the following support for bus signals:

- The data input u accepts virtual and nonvirtual bus signals. Other than input port x_0 , the other input ports do not accept bus signals.
- The initial condition x_0 port accepts nonvirtual bus signals.
- The output port has the same bus type as the data input port u for bus inputs.
- Buses work with:
 - Sample-based and frame-based processing
 - Fixed and variable delay length
 - Array and circular buffers

To use a bus signal as the input to a Delay block, specify the initial condition on the dialog box or through the x_0 port. Support for virtual and nonvirtual buses depends on the initial condition that you specify and whether the **State name** parameter is empty or not. For the x_0 input port, only nonvirtual buses are supported.

Initial Condition	State Name	
	Empty	Not Empty
Zero	Virtual and nonvirtual bus support	Nonvirtual bus support only
Nonzero scalar	Virtual and nonvirtual bus support	No bus support
Nonscalar	No bus support	No bus support
Structure	Virtual and nonvirtual bus support	Nonvirtual bus support only
Partial structure	Virtual and nonvirtual bus support	Nonvirtual bus support only

String Support

The Delay block can accept and output string data type only if:

- The block is configured for the default value of the **Initial condition** parameter (0).
- The **Delay length** value is 1 or less.

Ports

Input

u — Data input signal

scalar | vector

Input data signal delayed according to parameters settings.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus

d — Delay length

scalar

Delay length specified as inherited from an input port. Enabled when you select the **Delay length: Source** parameter as Input port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Enable — External enable signal

scalar

Enable signal that enables or disables execution of the block. To create this port, select the **Show enable port** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

External reset — External reset signal

scalar

External signal that resets execution of the block to the initial condition. To create this port, select the **External reset** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

x0 — Initial condition

`scalar` | `vector`

Initial condition specified as inherited from an input port. Enabled when you select the **Initial Condition: Source** parameter as `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point` | `bus`

Output

Port_1 — Output signal

`scalar` | `vector`

Output signal that is the input signal delayed by the length of time specified by the parameter **Delay length**. The initial value of the output signal depends on several conditions. See “Initial Block Output” on page 1-259.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `string` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

Delay length — Delay length

`Dialog (default)` | `Input port`

Specify whether to enter the delay length directly on the dialog box (fixed delay) or to inherit the delay from an input port (variable delay).

- If you set **Source** to `Dialog`, enter the delay length in the edit field under **Value**.
- If you set **Source** to `Input port`, verify that an upstream signal supplies a delay length for the `d` input port. You can also specify its maximum value by specifying the parameter **Upper limit**.

Specify the scalar delay length as a real, non-negative integer. An out-of-range or non-integer value in the dialog box (fixed delay) returns an error. An out-of-range value from an input port (variable delay) casts it into the range. A noninteger value from an input port (variable delay) truncates it to the integer.

Programmatic Use

Block Parameter: `DelayLengthSource`

Type: `character vector`

Values: `'Dialog'` | `'Input port'`

Default: `'Dialog'`

Block Parameter: `DelayLength`

Type: `character vector`

Values: `scalar`

Default: `'2'`

Block Parameter: DelayLengthUpperLimit

Type: character vector

Values: scalar

Default: '100'

Initial condition — Initial condition

Dialog (default) | Input port

Specify whether to enter the initial condition directly on the dialog box or to inherit the initial condition from an input port.

- If you set **Source** to **Dialog**, enter the initial condition in the edit field under **Value**.
- If you set **Source** to **Input port**, verify that an upstream signal supplies an initial condition for the x0 input port.

Simulink converts offline the data type of **Initial condition** to the data type of the input signal *u* using a round-to-nearest operation and saturation.

Note When **State name must resolve to Simulink signal object** is selected on the **State Attributes** pane, the block copies the initial value of the signal object to the **Initial condition** parameter. However, when the source for **Initial condition** is **Input port**, the block ignores the initial value of the signal object.

Programmatic Use

Block Parameter: InitialConditionSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Block Parameter: InitialCondition

Type: character vector

Values: scalar

Default: '0.0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input *u*. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Use circular buffer for state — Circular buffer for storing state

off (default) | on

Select to use a circular buffer for storing the state in simulation and code generation. Otherwise, an array buffer stores the state.

Using a circular buffer can improve execution speed when the delay length is large. For an array buffer, the number of copy operations increases as the delay length goes up. For a circular buffer, the number of copy operations is constant for increasing delay length.

If one of the following conditions is true, an array buffer always stores the state because a circular buffer does not improve execution speed.

- For sample-based signals, the delay length is 1.
- For frame-based signals, the delay length is no larger than the frame size.

Programmatic Use

Block Parameter: UseCircularBuffer

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Prevent direct feedthrough — Prevent direct feedthrough

off (default) | on

Select to increase the delay length from zero to the lower limit for the **Input processing** mode.

- For sample-based signals, increase the minimum delay length to 1.
- For frame-based signals, increase the minimum delay length to the frame length.

Selecting this check box prevents direct feedthrough from the input port, u, to the output port. However, this check box cannot prevent direct feedthrough from the initial condition port, x0, to the output port.

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use**Block Parameter:** PreventDirectFeedthrough**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Remove delay length check in generated code – Remove delay length out-of-range check**

off (default) | on

Select to remove code that checks for out-of-range delay length.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range delay length.	For code efficiency
Cleared	Generated code includes conditional statements to check for out-of-range delay length.	For safety-critical applications

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use**Block Parameter:** RemoveDelayLengthCheckInGeneratedCode**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Diagnostic for delay length – Diagnostic checks for delay length**

None (default) | Warning | Error

Specify whether to produce a warning or error when the input d is less than the lower limit or greater than the **Delay length: Upper limit**. The lower limit depends on the setting for **Prevent direct feedthrough**.

- If the check box is cleared, the lower limit is zero.
- If the check box is selected, the lower limit is 1 for sample-based signals and frame length for frame-based signals.

Options for the diagnostic include:

- None — Simulink software takes no action.
- Warning — Simulink software displays a warning and continues the simulation.
- Error — Simulink software terminates the simulation and displays an error.

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use**Block Parameter:** DiagnosticForDelayLength**Type:** character vector**Values:** 'None' | 'Warning' | 'Error'**Default:** 'None'**Show enable port – Create enable port**

off (default) | on

Select to control execution of this block with an enable port. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

Programmatic Use**Block Parameter:** ShowEnablePort**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**External reset – External state reset**

None (default) | Rising | Falling | Either | Level | Level hold

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset
Rising	Reset on a rising edge
Falling	Reset on a falling edge
Either	Reset on either a rising or falling edge
Level	Reset in either of these cases: <ul style="list-style-type: none"> • When the reset signal is nonzero at the current time step • When the reset signal value changes from nonzero at the previous time step to zero at the current time step
Level hold	Reset when the reset signal is nonzero at the current time step

Programmatic Use**Block Parameter:** ExternalReset**Type:** character vector**Values:** 'None' | 'Rising' | 'Falling' | 'Either' | 'Level' | 'Level hold'**Default:** 'None'**Sample time (-1 for inherited) – Discrete interval between sample time hits**

-1 (default) | scalar

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. This block supports discrete sample time, but not continuous sample time.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Value:** real scalar**Default:** '-1'**State Attributes****State name — Unique name for block state**

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use**Block Parameter:** StateName**Type:** character vector**Values:** unique name**Default:** ''**State name must resolve to Simulink signal object — Require state name resolve to a signal object**

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

Programmatic Use**Block Parameter:** StateMustResolveToSignalObject**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Signal object class — Custom storage class package name**

Simulink.Signal (default) | <StorageClass.PackageName>

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select **Customize class lists**. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Programmatic Use

Block Parameter: StateSignalObject

Type: character vector

Values: 'Simulink.Signal' | '<StorageClass.PackageName>'

Default: 'Simulink.Signal'

Code generation storage class — State storage class for code generation

Auto (default) | Model default | ExportedGlobal | ImportedExtern | ImportedExternPointer | BitField (Custom) | Model default | ExportToFile (Custom) | ImportFromFile (Custom) | FileScope (Custom) | AutoScope (Custom) | Struct (Custom) | GetSet (Custom) | Reusable (Custom)

Select state storage class for code generation.

- Auto is the appropriate storage class for states that you do not need to interface to external code.
- *StorageClass* applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

Dependencies

To enable this parameter, specify a value for **State name**.

Programmatic Use

Block Parameter: StateStorageClass

Type: character vector

Values: 'Auto' | 'Model default' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...

Default: 'Auto'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Block Parameter Setting	Description
Set External reset to <code>Level</code> .	Generates a reset port in the HDL code.
Select Show enable port .	Generates an enable port in the HDL code.
For Initial condition , set Source to <code>Dialog</code> and enter the value.	Specifies an initial condition for the block.
Set Input processing to <code>Columns as channels (frame based)</code> or <code>Elements as channels (sample based)</code> .	Expects vector input data, where each element of the vector represents a sample in time.

Additional Settings When Using State Control Block

If you use a State Control block with the Delay block inside a subsystem in your Simulink model, use these additional settings.

Block Parameter Setting	Description
Set External reset to <code>Level hold for Synchronous mode</code> and <code>Level for Classic mode</code> of the State Control block.	Generates a reset port in the HDL code.
Set Delay length to zero for a Delay block with an external enable port.	Treated as a wire in only <code>Synchronous</code> mode of the State Control block.
Set Delay length to zero for a Delay block with an external reset port.	Treated as a wire in <code>Synchronous</code> and <code>Classic</code> modes of the State Control block.

For more information about the State Control block, see [State Control](#).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
----------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
ResetType	Suppress reset logic generation. The default is <code>default</code> , which generates reset logic. See also “ResetType” (HDL Coder).
UseRAM	Map delays to RAM instead of registers. The default is <code>off</code> . See also “UseRAM” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Restrictions

For **Initial condition** and **Delay length**, **Source** set to `Input port` is not supported for HDL code generation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Demux

Extract and output elements of virtual vector signal

Library: Simulink / Commonly Used Blocks
 Simulink / Signal Routing
 HDL Coder / Commonly Used Blocks
 HDL Coder / Signal Routing

Description

The Demux block extracts the components of an input vector signal and outputs separate signals. The output signal ports are ordered from top to bottom. For information about creating and decomposing vectors, see “Mux Signal”.

Ports

Input

Port_1 — Accept nonbus vector signal to extract and output signals from
 real or complex values of any nonbus data type supported by Simulink

Vector input signal from which the Demux block selects scalar signals or smaller vectors.

Output

Port_1 — Output signals extracted from input vector signal
 nonbus signal with real or complex values of any data type supported by Simulink

Output signals extracted from the input vector. The output signal ports are ordered from top to bottom. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

Parameters

Number of outputs — Number of outputs

2 (default) | scalar | vector

Specify the number and, optionally, the dimensionality of each output port. If you do not specify the dimensionality of the outputs, the block determines the dimensionality of the outputs.

The value can be a scalar specifying the number of outputs or a vector whose elements specify the widths of the block output ports. The block determines the size of its outputs from the size of the input signal and the value of the **Number of outputs** parameter.

If you specify a scalar for the **Number of outputs** parameter and all of the output ports are connected, as you draw a new signal line close to output side of a Demux block, Simulink adds a port and updates the **Number of outputs** parameter.

For an input vector of width n , here is what the block outputs.

Parameter Value	Block outputs...	Examples and Comments
$p = n$	p scalar signals	If the input is a three-element vector and you specify three outputs, the block outputs three scalar signals.
$p > n$	Error	This value is not supported.
$p < n$ $n \bmod p = 0$	p vector signals each having n/p elements	If the input is a six-element vector and you specify three outputs, the block outputs three two-element vectors.
$p < n$ $n \bmod p = m$	m vector signals each having $(n/p) + 1$ elements and $p - m$ signals having n/p elements	If the input is a five-element vector and you specify three outputs, the block outputs two two-element vector signals and one scalar signal.
$[p_1 \ p_2 \ \dots \ p_m]$ $p_1 + p_2 + \dots + p_m = n$ $p_i > 0$	m vector signals having widths p_1, p_2, \dots, p_m	If the input is a five-element vector and you specify $[3, 2]$ as the output, the block outputs three of the input elements on one port and the other two elements on the other port.
An array that has one or more of m elements with a value of -1, which specifies that Simulink infers the size for the element. For example, suppose that you have a four-element array with a total width of 14 and you specify the parameter to be $[p_1 \ p_2 \ -1 \ p_4]$. The value for the third element (the -1 element) is $14 - (p_1 + p_2 + p_4)$	m vector signals	If p_i is greater than zero, the corresponding output has width p_i . If p_i is -1, the width of the corresponding output is computed dynamically.
$[p_1 \ p_2 \ \dots \ p_m]$ $p_1 + p_2 + \dots + p_m \neq n$ $p_i = > 0$	Error	This value is not supported

If you specify the number of outputs that is smaller than the number of input elements, the block distributes the elements as evenly as possible over the outputs. For examples, see “Extract Vector Elements and Distribute Evenly Across Outputs” on page 13-155 and “Extract Vector Elements Using the Demux Block” on page 13-156.

Programmatic Use

Block Parameter: Outputs

Type: scalar or vector

Values: character vector

Default: { '2' } or vector

Display option — Displayed block icon

bar (default) | none

By default, the block icon is a solid bar of the block foreground color. To display the icon as a box containing the block type name, select none.

Programmatic Use**Block Parameter:** Display option**Type:** character vector**Values:** 'bar' | 'none'**Default:** 'bar'**Block Characteristics**

Derivative

Output time derivative of input

Library: Simulink / Continuous

Description

The Derivative block approximates the derivative of the input signal u with respect to the simulation time t . You obtain the approximation of

$$\frac{du}{dt}$$

by computing a numerical difference $\Delta u/\Delta t$, where Δu is the change in input value and Δt is the change in time since the previous simulation (major) time step.

This block accepts one input and generates one output. The initial output for the block is zero.

The precise relationship between the input and output of this block is:

$$y(t) = \frac{\Delta u}{\Delta t} = \frac{u(t) - u(T_{previous})}{t - T_{previous}} \Big|_{t > T_{previous}}$$

where t is the current simulation time and $T_{previous}$ is the time of the last output time of the simulation. The latter is the same as the time of the last major time step.

The Derivative block output might be sensitive to the dynamics of the entire model. The accuracy of the output signal depends on the size of the time steps taken in the simulation. Smaller steps allow for a smoother and more accurate output curve from this block. However, unlike with blocks that have continuous states, the solver does not take smaller steps when the input to this block changes rapidly. Depending on the dynamics of the driving signal and model, the output signal of this block might contain unexpected fluctuations. These fluctuations are primarily due to the driving signal output and solver step size.

Because of these sensitivities, structure your models to use integrators (such as Integrator blocks) instead of Derivative blocks. Integrator blocks have states that allow solvers to adjust the step size and improve simulation accuracy. See “Circuit Model” for an example of choosing the best-form mathematical model to avoid using Derivative blocks in your models.

If you must use the Derivative block with a variable step solver, set the solver maximum step size to a value such that the Derivative block can generate answers with adequate accuracy. To determine this value, you might need to repeatedly run the simulation using different solver settings.

If the input to this block is a discrete signal, the continuous derivative of the input exhibits an impulse when the value of the input changes. Otherwise, it is 0. Alternatively, you can define the discrete derivative of a discrete signal using the difference of the last two values of the signal:

$$y(k) = \frac{1}{\Delta t}(u(k) - u(k - 1))$$

Taking the z -transform of this equation results in:

$$\frac{Y(z)}{u(z)} = \frac{1 - z^{-1}}{\Delta t} = \frac{z - 1}{\Delta t \cdot z}$$

The Discrete Derivative block models this behavior. Use this block instead of the Derivative block to approximate the discrete-time derivative of a discrete signal.

Ports

Input

Port_1 — Input signal

real scalar or vector

Signal to be differentiated, specified as a real scalar or vector.

Data Types: `double`

Output

Port_1 — Time derivative of input signal

real scalar or vector

Time derivative of input signal, specified as a real scalar or vector. The input signal is differentiated with respect to time as:

$$y(t) = \frac{\Delta u}{\Delta t} = \frac{u(t) - u(T_{previous})}{t - T_{previous}} \Big|_{t > T_{previous}}$$

where t is the current simulation time and $T_{previous}$ is the time of the last output time of the simulation. The latter is the same as the time of the last major time step.

Data Types: `double`

Parameters

Coefficient c in the transfer function approximation $s/(c*s + 1)$ used for linearization — Specify the time constant c to approximate the linearization of your system

`inf` (default)

The exact linearization of the Derivative block is difficult because the dynamic equation for the block is $y = \dot{u}$, which you cannot represent as a state-space system. However, you can approximate the linearization by adding a pole to the Derivative block to create a transfer function $s/(c * s + 1)$. The addition of a pole filters the signal before differentiating it, which removes the effect of noise.

The default value `inf` corresponds to a linearization of θ .

Tips

- As a best practice, change the value of c to $\frac{1}{f_b}$, where f_b is the break frequency of the filter.
- The parameter must be a finite positive value.

Programmatic Use**Block Parameter:** CoefficientInTFapproximation**Type:** character vector, string**Values:** 'inf'**Default:** 'inf'**Block Characteristics**

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Consider using the Model Discretizer to map the continuous blocks into discrete equivalents that support code generation. To access the Model Discretizer, in the **Apps** tab, under **Control Systems**, click **Model Discretizer**.

Descriptor State-Space

Model linear implicit systems

Library: Simulink / Continuous

Description

The Descriptor State-Space block allows you to model linear implicit systems that can be expressed in the form $E\dot{x} = Ax + Bu$ where E is the mass matrix of the system. When E is nonsingular and therefore invertible, the system can be written in its explicit form $\dot{x} = E^{-1}Ax + E^{-1}Bu$ and modeled using the State-Space block.

When the mass matrix E is singular, one or more derivatives of the dependent variables of the system are not present in the equations. These variables are called algebraic variables. Differential equations that contain such algebraic variables are called differential algebraic equations. Their state space representation is of the form

$$\begin{aligned} E\dot{x} &= Ax + Bu \\ y &= Cx + Du \end{aligned}$$

where the variables have the following meanings:

- x is the state vector
- u is the input vector
- y is the output vector

Ports

Input

Input 1 — Input signal

scalar | vector

Real-valued input vector of type `double` whose width is the number of columns in the **B** and **D** matrices.

Data Types: `double`

Output

Output 1 — Output vector

scalar | vector

Real-valued input vector of type `double` whose width is the number of rows in the **C** and **D** matrices.

Data Types: `double`

Parameters

E — Mass matrix

1 (default) | scalar | matrix

Specify the mass matrix E as a real-valued n -by- n matrix, where n is the number of states in the system. E must be the same size as A . E can be singular or non-singular.

Programmatic Use

Block Parameter: E

Type: character vector, string

Values: scalar | matrix

Default: ' 1 '

A — Matrix coefficient, A

1 (default) | scalar | matrix

Specify the matrix coefficient A as a real-valued n -by- n matrix, where n is the number of states in the system. A must be the same size as E .

Programmatic Use

Block Parameter: A

Type: character vector, string

Values: scalar | matrix

Default: ' 1 '

B — Matrix coefficient, B

1 (default) | scalar | vector | matrix

Specify the matrix coefficient B as a real-valued n -by- m matrix, where n is the number of states in the system and m is the number of inputs.

Programmatic Use

Block Parameter: B

Type: character vector, string

Values: scalar | vector | matrix

Default: ' 1 '

C — Matrix coefficient, C

1 (default) | scalar | vector | matrix

Specify the matrix coefficient C as a real-valued r -by- n matrix, where n is the number of states in the system and r is the number of outputs.

Programmatic Use

Block Parameter: C

Type: character vector, string

Values: scalar | vector | matrix

Default: ' 1 '

D — Matrix coefficient, D

1 (default) | scalar | vector | matrix

Specify the matrix coefficient D as a real-valued r -by- m matrix, where r is the number of outputs of the system and m is the number of inputs to the system.

Programmatic Use**Block Parameter:** D**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** '1'**Initial condition — Initial condition of states**

0 (default) | scalar | vector | matrix

Specify initial condition of the block states. The minimum and maximum values are bound by the **Output minimum** and **Output maximum** block parameters.

Tip Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

To enable this parameter, set the **Initial condition source** to `internal`.

Programmatic Use**Block Parameter:** InitialCondition**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** '0'**Direct feedthrough — Set output signal dependency on input**

true (default) | false

Specify whether the output of the block has a direct dependency on the input signal. Use this parameter for systems having more than 500 continuous states in order to speed up simulation. For systems with 500 continuous states or less, Simulink automatically determines this setting.

Programmatic Use**Block Parameter:** DirectFeedthrough**Type:** character vector, string**Values:** 'True' | 'False'**Default:** 'True'**Absolute tolerance — Absolute tolerance for computing block states**

auto (default) | scalar | vector

Absolute tolerance for computing block states, specified as a positive, real-valued, scalar or vector. To inherit the absolute tolerance from the Configuration Parameters, specify `auto` or `-1`.

- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.

Programmatic Use**Block Parameter:** AbsoluteTolerance

Type: character vector, string

Values: 'auto' | '-1' | any positive real-valued scalar or vector

Default: 'auto'

State Name (e.g., 'position') — Assign unique name to each state

' ' (default) | 'position' | {'a', 'b', 'c'} | a | ...

Assign a unique name to each state. If this field is blank (' '), no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, 'position'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Limitations

- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

Programmatic Use

Block Parameter: ContinuousStateAttributes

Type: character vector, string

Values: ' ' | user-defined

Default: ' '

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Detect Change

Detect change in signal value

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Detect Change block determines if an input signal does not equal its previous value. The initial condition determines the initial value of the previous input U/z .

Ports

Input

Port_1 — Input signal

signal value

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | built-in integer | floating point

Output

Port_1 — Output signal

0 | 1

Output signal, true (equal to 1) when the input signal does not equal its previous value; false (equal to 0) when the input signal equals its previous value.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Initial condition — Initial condition for the previous input

0 (default) | scalar | vector

Set the initial condition for the previous input U/z .

Programmatic Use

Block Parameter: `vinit`

Type: character vector

Values: scalar | vector

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input *u*. All other input signals must be sample-based.

Input Signal <i>u</i>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Output data type — Data type of the output

`boolean` (default) | `uint8`

Set the output data type to `boolean` or `uint8`.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes

Zero-Crossing Detection	no
--------------------------------	----

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

Detect Decrease

Detect decrease in signal value

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Detect Decrease block determines if an input is strictly less than its previous value.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Output signal

0 | 1

Output signal, true (equal to 1) when the input signal is less than its previous value; false (equal to 0) when the input signal is greater than or equal to its previous value.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

Initial condition — Initial condition for the previous input

0 (default) | scalar | vector

Set the initial condition for the previous input U/z.

Programmatic Use

Block Parameter: vinit

Type: character vector

Values: scalar | vector

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input *u*. All other input signals must be sample-based.

Input Signal <i>u</i>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Output data type — Data type of the output

`boolean` (default) | `uint8`

Set the output data type to `boolean` or `uint8`.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes

Zero-Crossing Detection	no
--------------------------------	----

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Detect Change | Detect Fall Negative | Detect Fall Nonpositive | Detect Increase | Detect Rise Nonnegative | Detect Rise Positive

Introduced before R2006a

Detect Fall Negative

Detect falling edge when signal value decreases to strictly negative value, and its previous value was nonnegative

Library: Simulink / Logic and Bit Operations

Description

The Detect Fall Negative block determines if the input is less than zero, and its previous value is greater than or equal to zero.

Ports

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Input

Port_1 — Input signal

signal value

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Output signal

0 | 1

Output signal, true (equal to 1) when the input signal is less than zero, and its previous value was greater than or equal to zero; false (equal to 0) when the input signal is greater than or equal to zero, or if the input signal is negative, its previous value was also negative.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Initial condition — Initial condition for the previous input

0 (default) | scalar | vector

Set the initial condition of the Boolean expression $U/z < 0$.

Programmatic Use

Block Parameter: vinit

Type: character vector
Values: scalar | vector
Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input *u*. All other input signals must be sample-based.

Input Signal <i>u</i>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Output data type — Data type of the output

boolean (default) | uint8

Set the output data type to boolean or uint8.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Block Characteristics

Data Types	Boolean double fixed point integer single
-------------------	---------------------------------------------------

Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

Detect Change | Detect Decrease | Detect Fall Nonpositive | Detect Increase | Detect Rise Nonnegative | Detect Rise Positive

Introduced before R2006a

Detect Fall Nonpositive

Detect falling edge when signal value decreases to nonpositive value, and its previous value was strictly positive

Library: Simulink / Logic and Bit Operations

Description

The Detect Fall Nonpositive block determines if the input is less than or equal to zero, and its previous value was greater than zero.

- The output is true (equal to 1) when the input signal is less than or equal to zero, and its previous value was greater than zero.
- The output is false (equal to 0) when the input signal is greater than zero, or if it is nonpositive, its previous value was also nonpositive.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 – Output signal

scalar | vector | matrix

Output signal that detects a falling edge, specified as a scalar, vector, or matrix.

- The output is true (equal to 1) when the input signal is less than or equal to zero, and its previous value was greater than zero.
- The output is false (equal to 0) when the input signal is greater than zero, or if it is nonpositive, its previous value was also nonpositive.

Data Types: uint8 | Boolean

Parameters

Initial condition – Initial condition of Boolean expression $U/z \leq 0$

0 (default) | scalar | vector | matrix

Set the initial condition of the Boolean expression $U/z \leq 0$.

Programmatic Use

Block Parameter: `vinit`

Type: character vector

Values: scalar | vector | matrix

Default: `'0'`

Input processing — Specify sample- or frame-based processing

`Elements as channels (sample based) (default)` | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal <code>u</code>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: `InputProcessing`

Type: character vector

Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`

Default: `'Elements as channels (sample based)'`

Output data type — Output data type

`boolean (default)` | `uint8`

Specify the output data type as `boolean` or `uint8`.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'boolean'` | `'uint8'`

Default: `'boolean'`

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on memcpy or memset functions (string.h) under certain conditions.

Detect Change | Detect Decrease | Detect Fall Negative | Detect Increase | Detect Rise Nonnegative | Detect Rise Positive

Introduced before R2006a

Detect Increase

Detect increase in signal value

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Detect Increase block determines if an input is strictly greater than its previous value.

- The output is true (equal to 1) when the input signal is greater than its previous value.
- The output is false (equal to 0) when the input signal is less than or equal to its previous value.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal, detecting an increase in signal value, specified as a scalar, vector, or matrix.

- The output is true (equal to 1) when the input signal is greater than its previous value.
- The output is false (equal to 0) when the input signal is less than or equal to its previous value.

Data Types: uint8 | Boolean

Parameters

Initial condition — Initial condition of previous input

0.0 (default) | scalar | vector | matrix

Set the initial condition for the previous input U/z.

Programmatic Use

Block Parameter: vinit

Type: character vector

Values: scalar | vector | matrix

Default: '0.0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input *u*. All other input signals must be sample-based.

Input Signal <i>u</i>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Output data type — Output data type

boolean (default) | uint8

Specify the output data type as boolean or uint8.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	yes

Multidimensional Signals	yes
Variable-Size Signals	yes

Detect Change | Detect Decrease | Detect Fall Negative | Detect Fall Nonpositive | Detect Rise Nonnegative | Detect Rise Positive

Introduced before R2006a

Detect Rise Nonnegative

Detect rising edge when signal value increases to nonnegative value, and its previous value was strictly negative

Library: Simulink / Logic and Bit Operations

Description

The Detect Rise Nonnegative block determining if the input is greater than or equal to zero, and its previous value was less than zero.

- The output is true (equal to 1) when the input signal is greater than or equal to zero, and its previous value was less than zero.
- The output is false (equal to 0) when the input signal is less than zero, or if the input signal is nonnegative, its previous value was also nonnegative.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 – Output signal

scalar | vector | matrix

Output signal that indicates a rising edge whenever the signal value increases to a nonnegative value, and its previous value was strictly negative. The output can be a scalar, vector, or matrix.

- The output is true (equal to 1) when the input signal is greater than or equal to zero, and its previous value was less than zero.
- The output is false (equal to 0) when the input signal is less than zero, or if the input signal is nonnegative, its previous value was also nonnegative.

Data Types: uint8 | Boolean

Parameters

Initial condition — Initial condition of Boolean expression $U/z \geq 0$

0 (default) | scalar | vector | matrix

Set the initial condition of the Boolean expression $U/z \geq 0$.

Programmatic Use

Block Parameter: vinit

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input u . All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Output data type — Output data type

boolean (default) | uint8

Specify the output data type as boolean or uint8.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector**Values:** 'boolean' | 'uint8'**Default:** 'boolean'**Block Characteristics**

Detect Change | Detect Decrease | Detect Fall Negative | Detect Fall Nonpositive | Detect Increase | Detect Rise Positive

Introduced before R2006a

Detect Rise Positive

Detect rising edge when signal value increases to strictly positive value, and its previous value was nonpositive

Library: Simulink / Logic and Bit Operations

Description

The Detect Rise Positive block detects a rising edge by determining if the input is strictly positive, and its previous value was nonpositive.

- The output is true (equal to 1) when the input signal is greater than zero, and the previous value was less than or equal to zero.
- The output is false (equal to 0) when the input is negative or zero, or if the input is positive, the previous value was also positive.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal that detects a rising edge whenever the input is strictly positive, and its previous value was nonpositive. The output can be a scalar, vector, or matrix.

- The output is true (equal to 1) when the input signal is greater than zero, and the previous value was less than or equal to zero.
- The output is false (equal to 0) when the input is negative or zero, or if the input is positive, the previous value was also positive.

Data Types: uint8 | Boolean

Parameters

Initial condition — Initial condition of Boolean expression $U/z > 0$

0 (default) | scalar | vector | matrix

Set the initial condition of the Boolean expression $U/z > 0$.

Programmatic Use

Block Parameter: vinit

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input u . All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Output data type — Output data type

boolean (default) | uint8

Specify the output data type as boolean or uint8.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector**Values:** 'boolean' | 'uint8'**Default:** 'boolean'**Block Characteristics**

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes

Difference

Calculate change in signal over one time step

Library: Simulink / Discrete

Description

The Difference block outputs the current input value minus the previous input value.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array.

Dependencies

When you set **Input processing** to Columns as channels (frame based), the input signal must have two dimensions or less.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Current input minus previous input

scalar | vector | matrix | N-D array

Current input minus previous input, specified as a scalar, vector, matrix, or N-D array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Initial condition for previous input — Initial condition

0.0 (default) | scalar | vector | matrix | N-D array

Set the initial condition for the previous input.

Programmatic Use

Parameter: ICPprevInput

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '0.0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input *u*. All other input signals must be sample-based.

Input Signal <i>u</i>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.

- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output data type — Output data type

Inherit: `Inherit via internal rule (default)` | `Inherit via back propagation` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`

- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Parameter: `OutDataTypeStr`

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean ^a double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

a. This block is not recommended for use with Boolean signals.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the Treat as atomic unit option.

PLC Code Generation

Digital Clock

Output simulation time at specified sampling interval

Library: Simulink / Sources

Description

The Digital Clock block outputs the simulation time only at the specified sampling interval. At other times, the block holds the output at the previous value. To control the precision of this block, use the **Sample time** parameter in the block dialog box.

Use this block rather than the Clock block (which outputs continuous time) when you need the current simulation time within a discrete system.

Ports

Output

Port_1 — Sample time

scalar

Sample time, in seconds, at the specified sampling interval. At other times, the block holds the output at the previous value.

Data Types: `double`

Parameters

Sample time — Sampling interval

1 (default) | scalar | vector

Specify the sampling interval in seconds. You can specify the sampling interval in one of two ways:

- As the period, specified as a real-valued scalar with data type `double`.
- As the period and offset, specified as a real-valued vector of length 2 with data type `double`. The period and offset must be finite and non-negative, and the offset value must be less than the period.

For more information, see [Specifying Sample Time](#).

Tip Do not specify a continuous sample time, either `0` or `[0, 0]`. Also, avoid specifying `-1` (inheriting the sample time) because this block is a source.

Programmatic Use

Block Parameter: `SampleTime`

Type: character vector

Values: scalar | vector

Default: '1'

Block Characteristics

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Direct Lookup Table (n-D)

Index into n-dimensional table to retrieve element, vector, or 2-D matrix

Library: Simulink / Lookup Tables
HDL Coder / Lookup Tables

Description

The Direct Lookup Table (n-D) block indexes into an n-dimensional table to retrieve an element, vector, or 2-D matrix. The first selection index corresponds to the top (or left) input port. You can choose to provide the table data as an input to the block, or define the table data on the block dialog box. The number of input ports and the size of the output depend on the number of table dimensions and the output slice you select.

If you select a vector from a 2-D table, the output vector can be a column or a row, depending on the model configuration parameter setting **Math and Data Types > Use algorithms optimized for row-major array layout**. The block inputs are zero-based indices (for more information, see the **Inputs select this object from table** parameter).

The Direct Lookup Table block supports symbolic dimensions.

Block Inputs and Outputs

The Direct Lookup Table (n-D) block uses inputs as zero-based indices into an n -dimensional table. The number of inputs varies with the shape of the output: an element, vector, or 2-D matrix.

You define a set of output values as the **Table data** parameter. For the default column-major algorithm behavior, the first input specifies the zero-based index to the table dimension that is one higher than the output dimensionality. The next input specifies the zero-based index to the next table dimension, and so on.

Output Shape	Output Dimensionality	Table Dimension that Maps to the First Input
Element	0	1
Vector	1	2
Matrix	2	3

Suppose that you want to select a vector of values from a 4-D table.

The following mapping of block input port to table dimension applies.

This input port...	Is the index for this table dimension...
1	2
2	3
3	4

Changes in Block Icon Appearance

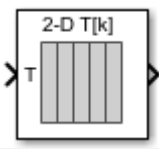

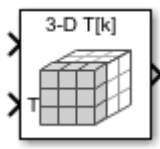

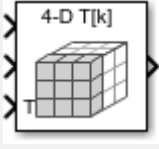

Depending on parameters you set, the block icon changes appearance. For table dimensions higher than 4, the icon matches the 4-D version but shows the exact number of dimensions at the top.

When you use the **Table data** parameter, you see these icons for the default column-major behavior. Some icons are different when you select the configuration parameter **Math and Data Types > Use algorithms optimized for row-major array layout**.

Object that Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
Element				
Vector				
2-D Matrix	Not applicable			

When you use the table input port, you see these icons.

Object that Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
Element				
Vector				

Object that Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
2-D Matrix	Not applicable			

Ports

Input

Port_1 – Index i1 input values

scalar | vector

For the default column-major algorithm, the first input port, specifying the zero-based index to the table dimension that is one higher than the output dimensionality (0, 1, or 2). The next input specifies the zero-based index to the next table dimension, and so on. All index inputs must be real-valued.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Port_N – Index N input values

scalar | vector

For the default column-major algorithm, the N-th input port, specifying the zero-based index to the table dimension that is N higher than the output dimensionality (0, 1, or 2). The number of inputs varies with the shape of the output. All index inputs must be real-valued.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

T – Table data

vector | matrix | N-D array

Table data, specified as a vector, matrix, or N-D array. The table size must match the dimensions of the **Number of dimensions** parameter. The block's output data type is the same as the table data type.

Dependencies

To enable this port, select the **Make table an input** check box.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 – Output element, vector, or 2-D matrix

scalar | vector | 2-D matrix

Output slice, provided as a scalar, vector, or 2-D matrix. The size of the block output is determined by the setting of the **Inputs select this object from table** parameter. The output data type is the same as the table data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Parameters

Main

Table

Number of table dimensions — Number of dimensions of table data

2 (default) | 1 | 3 | 4

Number of dimensions that the **Table data** parameter must have. This value determines the number of independent variables for the table and the number of inputs to the block.

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

Programmatic Use

Block Parameter: NumberOfTableDimensions

Type: character vector

Values: '1' | '2' | '3' | '4' | ... | '30'

Default: '2'

Make table an input — Provide table data as a block input

off (default) | on

Select this check box to provide table data to the Direct Lookup Table (n-D) block as a block input. When you select this check box, a new input port, T, appears. Use this port to input the table data.

Programmatic Use

Block Parameter: TableIsInput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Table data — Table of output values

[4 5 6; 16 19 20; 10 18 23] (default) | scalar, vector, matrix, or N-D array

Specify the table of output values. The table size must match the dimensions of the **Number of table dimensions** parameter.

Tip During block diagram editing, you can leave the **Table data** field empty. But for simulation, you must match the number of dimensions in **Table data** to the **Number of table dimensions**. For details on how to construct multidimensional MATLAB arrays, see “Multidimensional Arrays” (MATLAB).

Click **Edit** to open the Lookup Table Editor. For more information, see “Edit Lookup Tables”.

Dependencies

To enable the **Table data** field, clear the **Make table an input** check box.

Programmatic Use

Block Parameter: Table

Type: character vector

Values: scalar, vector, matrix, or N-D array

Default: '[4 5 6;16 19 20;10 18 23]'

Algorithm

Inputs select this object from table — Specify whether output is an element, vector, or 2-D matrix

Element (default) | Vector | 2-D Matrix

Specify whether the output data is a single element, a vector, or a 2-D matrix. The number of input ports for indexing depends on your selection.

Selection	Number of Input Ports for Indexing
Element	Number of table dimensions
Vector	Number of table dimensions -1
2-D Matrix	Number of table dimensions -2

This numbering matches MATLAB indexing. For example, if you have a 4-D table of data, follow these guidelines.

To access...	Specify...	As in...
An element	Four indices	array(1,2,3,4)
A vector	Three indices	array(:,2,3,4) (default column-major algorithm)
A 2-D matrix	Two indices	array(:, :, 3,4) (default column-major algorithm)

Tips

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the Direct Lookup Table block behavior changes from column-major to row-major. For this block, the column-major and row-major algorithms may differ semantically in output calculations, resulting in different numerical values. For example, assume that **Inputs select this object from table** parameter is set to **Vector**. The elements of the selected vector are contiguous in the table storage memory. This table shows the column-major and row-major algorithm depending on the table dimension:

Table Dimension	Column-Major Algorithm	Row-Major Algorithm
2-D table	Column vector is selected	Row vector is selected
3-D and higher table	Output vector is selected from the first dimension of the table	Output vector is selected from the last dimension of the table

Consider the row-major and column-major direct lookup algorithms with vector output from a 3-D table. The last dimension is the third dimension of a 3-D table. Due to semantic changes, column-major and row-major direct lookup may output different vector size and numerical values.

This figure shows a Direct Lookup Table (n-D) block configured with a 3-D table and a vector output. By default, the block icon shows the column-major algorithm.

To have the same block use the row-major algorithm, change the **Math and Data Types > Use algorithm optimized for row-major layout** configuration parameter of the model and recompile. The block icon changes to reflect the change to the algorithm optimized for row-major behavior.

For more information on row-major support, see “Row-Major Array Layout: Simplify integration with external C/C++ code for Lookup Table and other blocks” (Simulink Coder).

Programmatic Use

Block Parameter: InputsSelectThisObjectFromTable

Type: character vector

Values: 'Element' | 'Vector' | '2-D Matrix'

Default: 'Element'

Diagnostic for out-of-range input – Block action when input is out of range

Warning (default) | None | Error

Specify whether to show a warning or error when an index is out of range with respect to the table dimension. Options include:

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

When you select None or Warning, the block clamps out-of-range indices to fit table dimensions. For example, if the specified index is 5.3 and the maximum index for that table dimension is 4, the block clamps the index to 4.

Programmatic Use

Block Parameter: DiagnosticForOutOfRangeInput

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'Warning'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar or vector**Default:** '-1'**Code generation****Remove protection against out-of-range input in generated code — Remove code that checks for out-of-range input values**

off (default) | on

Specify whether or not to include code that checks for out-of-range input values.

Check Box	Result	When to Use
on	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code.	For code efficiency
off	Generated code includes conditional statements to check for out-of-range inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input is out of range, the behavior is undefined for generated code.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

Programmatic Use

Block Parameter: RemoveProtectionInput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Table Attributes

Note The parameters in the **Table Attributes** pane are not available if you select **Make table an input**. In this case, the block inherits all table attributes from the input port with the label T.

Table minimum — Minimum value table data can have

[] (default) | finite, real, double, scalar

Specify the minimum value for table data. The default value is [] (unspecified).

Programmatic Use

Block Parameter: TableMin

Type: character vector

Values: scalar

Default: ' [] '

Table maximum — Maximum value table data can have

[] (default) | finite, real, double, scalar

Specify the maximum value for table data. The default value is [] (unspecified).

Programmatic Use

Block Parameter: TableMax

Type: character vector

Values: scalar

Default: ' [] '

Table data type — Data type of table data

Inherit: Inherit from 'Table data' (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit from 'Table data'`
- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `TableDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit from 'Table data'' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | '<data type expression>'`

Default: `'Inherit: Inherit from 'Table data''`

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off (default) | on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off' | 'on'`

Default: `'off'`

Block Characteristics

Data Types	<code>Boolean double enumerated fixed point^a integer single</code>
Direct Feedthrough	<code>yes</code>
Multidimensional Signals	<code>yes</code>
Variable-Size Signals	<code>no</code>
Zero-Crossing Detection	<code>no</code>

a. This block supports fixed-point data types for 'Table' data only.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Restrictions

MAX 10 Device Settings

If you use Intel® MAX 10 device, to map the lookup table to RAM, add this Tcl command when creating the project in the Quartus tool:

```
set_global_assignment -name INTERNAL_FLASH_UPDATE_MODE "SINGLE IMAGE WITH ERAM"
```

Required Block Settings

- **Number of table dimensions:** HDL Coder supports a maximum dimension of 2.
- **Inputs select this object from table:** Select Element.
- **Make table an input:** Clear this check box.
- **Diagnostic for out-of-range input:** Select Error. If you select other options, the coder displays a warning.

Table Data Typing and Sizing

- It is good practice to size each dimension in the table to be a power of two. If the length of a dimension (*except* the innermost dimension) is not a power of two, HDL Coder issues a warning. By following this practice, you can avoid multiplications during table indexing operations and realize a more efficient table in hardware.
- All ports on the block require scalar values.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block supports fixed-point data types for **Table data** only. In addition to built-in data types, the index input also supports fixed-point data type with bias equal to 0, slope equal to 1.0, fractional length equal to 0, and word length less than or equal to 128.

Discrete Derivative

Compute discrete-time derivative

Library: Simulink / Discrete

Description

The Discrete Derivative block computes an optionally scaled discrete time derivative as follows

$$y(t_n) = K \left(\frac{u(t_n) - u(t_{n-1})}{T_s} \right)$$

where

- $u(t_n)$ and $y(t_n)$ are the block input and output at the current time step, respectively.
- $u(t_{n-1})$ is the block input at the previous time step.
- K is an optional scaling factor, specified using the **Gain value** parameter.
- T_s is the simulation's discrete step size, which must be fixed.

Note Do not use this block in subsystems with a nonperiodic trigger (for example, nonperiodic function-call subsystems). This configuration produces inaccurate results.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Scaled discrete time derivative

scalar | vector | matrix

Optionally scaled discrete-time derivative, specified as a scalar, vector, or matrix. For more information on how the block computes the discrete-time derivative, see “Description” on page 1-322. You specify the data type of the output signal with the **Output data type** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main

Gain value — Scaling factor

1.0 (default) | scalar

Scaling factor applied to the computed derivative, specified as a real scalar value.

Programmatic Use

Block Parameter: gainval

Type: character vector

Values: scalar

Default: '1.0'

Initial condition for previous weighted input $K*u/T_s$ — Initial condition

0.0 (default) | scalar

Initial condition for the previous scaled input, specified as a scalar.

Programmatic Use

Block Parameter: ICPprevScaledInput

Type: character vector

Values: scalar

Default: '0.0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input u . All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use**Block Parameter:** InputProcessing**Type:** character vector**Values:** 'Columns as channels (frame based)' | 'Elements as channels (sample based)'**Default:** 'Elements as channels (sample based)'**Signal Attributes****Output minimum — Minimum output value for range checking**

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output maximum — Maximum output value for range checking**

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type – Output data type

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | fixdt(1,16,2^0,0)

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via back propagation
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools – Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode – Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- Depends on absolute time when used inside a triggered subsystem hierarchy.
- Generated code relies on memcpy or memset functions (string.h) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Derivative | Discrete-Time Integrator

Introduced before R2006a

Discrete Filter

Model Infinite Impulse Response (IIR) filters

Library: Simulink / Discrete

Description

The Discrete Filter block independently filters each channel of the input signal with the specified digital IIR filter. You can specify the filter structure as **Direct form I**, **Direct form I transposed**, **Direct form II**, or **Direct form II transposed**. The block implements static filters with fixed coefficients. You can tune the coefficients of these static filters.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify how the block treats each element of the input. You can specify treating input elements as an independent channel (sample-based processing), or treating each column of the input as an independent channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

The output dimensions equal the input dimensions, except when you specify a matrix of filter taps for the **Numerator coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

Use the **Numerator coefficients** parameter to specify the coefficients of the discrete filter numerator polynomial. Use the **Denominator coefficients** parameter to specify the coefficients of the denominator polynomial of the function. The **Denominator coefficients** parameter must be a vector of coefficients.

Specify the coefficients of the numerator and denominator polynomials in ascending powers of z^{-1} . The Discrete Filter block lets you use polynomials in z^{-1} (the delay operator) to represent a discrete system. Signal processing engineers typically use this method. Conversely, the Discrete Transfer Fcn block lets you use polynomials in z to represent a discrete system. Control engineers typically use this method. When the numerator and denominator polynomials have the same length, the two methods are identical.

Specifying Initial States

In **Dialog parameters** and **Input port(s)** modes, the block initializes the internal filter states to zero by default, which is equivalent to assuming past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial states for the filter delays.

To determine the number of initial state values you must specify, and how to specify them, see the following table on valid initial states and Number of Delay Elements (Filter States). The **Initial states** parameter can take one of four forms as described in the following table.

Valid Initial States

Initial state	Examples	Description
Scalar	5 Each delay element for each channel is set to 5.	The block initializes all delay elements in the filter to the scalar value.
Vector (for applying the same delay elements to each channel)	For a filter with two delay elements: [$d_1 d_2$] The delay elements for all channels are d_1 and d_2 .	Each vector element specifies a unique initial condition for a corresponding delay element. The block applies the same vector of initial conditions to each channel of the input signal. The vector length must equal the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)).
Vector or matrix (for applying different delay elements to each channel)	For a three-channel input signal and a filter with two delay elements: [$d_1 d_2 D_1 D_2 d_1 d_2$] or $\begin{bmatrix} d_1 & D_1 & d_1 \\ d_2 & D_2 & d_2 \end{bmatrix}$ <ul style="list-style-type: none"> The delay elements for channel 1 are d_1 and d_2. The delay elements for channel 2 are D_1 and D_2. The delay elements for channel 3 are d_1 and d_2. 	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: <ul style="list-style-type: none"> The vector length must be equal to the product of the number of input channels and the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)). The matrix must have the same number of rows as the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)), and must have one column for each channel of the input signal.
Empty matrix	[] Each delay element for each channel is set to 0.	The empty matrix, [], is equivalent to setting the Initial conditions parameter to the scalar value 0.

The number of delay elements (filter states) per input channel depends on the filter structure, as indicated in the following table.

Number of Delay Elements (Filter States)

Filter Structure	Number of Delay Elements Per Channel
Direct form I Direct form I transposed	<ul style="list-style-type: none"> number of zeros - 1 number of poles - 1
Direct form II Direct form II transposed	$\max(\text{number of zeros, number of poles}) - 1$

The following tables describe the valid initial states for different sizes of input and different number of channels depending on whether you set the **Input processing** parameter to frame based or sample based.

Frame-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> Column vector (K-by-1) Unoriented vector (K) 	1	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) 	<ul style="list-style-type: none"> Scalar Column vector (M-by-1)
<ul style="list-style-type: none"> Row vector (1-by-N) Matrix (K-by-N) 	N	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-N) 	<ul style="list-style-type: none"> Scalar Matrix (M-by-N)

Sample-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> Scalar 	1	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) 	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M)
<ul style="list-style-type: none"> Row vector (1-by-N) Column vector (N-by-1) Unoriented vector (N) 	N	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-N) 	<ul style="list-style-type: none"> Scalar
<ul style="list-style-type: none"> Matrix (K-by-N) 	$K \times N$	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-$(K \times N)$) 	<ul style="list-style-type: none"> Scalar

When the **Initial states** is a scalar, the block initializes all filter states to the same scalar value. Enter 0 to initialize all states to zero. When the **Initial states** is a vector or a matrix, each vector or matrix element specifies a unique initial state. This unique state corresponds to a delay element in a corresponding channel:

- The vector length must equal the number of delay elements in the filter, $M = \max(\text{number of zeros, number of poles})$.
- The matrix must have the same number of rows as the number of delay elements in the filter, $M = \max(\text{number of zeros, number of poles})$. The matrix must also have one column for each channel of the input signal.

The “Specify a Vector of Initial Conditions for a Discrete Filter Block” on page 13-142 example shows the relationship between the initial filter output and the initial input and state. Given an initial input u_1 , the first output y_1 is related to the initial state $[x_1, x_2]$ and initial input by:

$$y_1 = b_1 \left[\frac{(u_1 - a_2 x_1 - a_3 x_2)}{a_1} \right] + b_2 x_1 + b_3 x_2$$

Ports

Input

u — Input signal

scalar | vector | matrix

Input signal to filter, specified as a scalar, vector, or matrix.

Dependencies

The name of this port depends on the source you specify for the numerator coefficients, denominator coefficients and initial states. When you set **Numerator**, **Denominator**, and **Initial states** to **Dialog**, there is only one input port, and the port is unlabeled. When you set **Numerator**, **Denominator**, or **Initial states** to **Input** port, this port is labeled **u**.

Data Types: single | double | int8 | int16 | int32 | fixed point

Num — Numerator coefficients

scalar | vector | matrix

Numerator coefficients of the discrete filter, specified as descending powers of z . Use a row vector to specify the coefficients for a single numerator polynomial.

Dependencies

To enable this port, set **Numerator** to **Input** port.

Data Types: single | double | int8 | int16 | int32 | fixed point

Den — Denominator coefficients

scalar | vector

Specify the denominator coefficients of the discrete filter as descending powers of z . Use a row vector to specify the coefficients for a single denominator polynomial.

Dependencies

To enable this port, set **Denominator** to **Input** port.

Data Types: single | double | int8 | int16 | int32 | fixed point

x0 — Initial states

scalar | vector | matrix

Initial states, specified as a scalar, vector, or matrix. For more information about specifying states, see “Specifying Initial States” on page 1-328.

Dependencies

To enable this port, set the **Filter structure** to **Direct form II** or **Direct form II transposed**, and set **Initial states** to **Input** port.

Data Types: single | double | int8 | int16 | int32 | fixed point

Output

Port_1 — Filtered output signal

scalar | vector | matrix

Filtered output signal. The output dimensions equal the input dimensions, except when you specify a matrix of filter taps for the **Numerator coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

Data Types: single | double | int8 | int16 | int32 | fixed point

Parameters

Main

Filter structure — Filter structure

Direct form II (default) | Direct form I transposed | Direct form I | Direct form II transposed

Specify the discrete IIR filter structure.

Dependencies

To use any filter structure other than Direct form II, you must have an available DSP System Toolbox license.

Programmatic Use

Block Parameter: FilterStructure

Type: character vector

Values: 'Direct form II' | 'Direct form I transposed' | 'Direct form I' | 'Direct form II transposed'

Default: 'Direct form II'

Numerator Source — Source of numerator coefficients

Dialog (default) | Input port

Specify the source of the numerator coefficients as Dialog or Input port.

Programmatic Use

Block Parameter: NumeratorSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Numerator Value — Numerator coefficients

[1] (default) | scalar | vector | matrix

Specify the numerator coefficients of the discrete filter as descending powers of z . Use a row vector to specify the coefficients for a single numerator polynomial.

Dependencies

To enable this parameter, set the **Numerator Source** to Dialog.

Programmatic Use

Block Parameter: Numerator

Type: character vector
Values: scalar | vector | matrix
Default: '[1]'

Denominator Source — Source of denominator coefficients

Dialog (default) | Input port

Specify the source of the denominator coefficients as Dialog or Input port.

Programmatic Use

Block Parameter: DenominatorSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Denominator Value — Denominator coefficients

[1 0.5] (default) | vector

Specify the denominator coefficients of the discrete filter as descending powers of z . Use a row vector to specify the coefficients for a single denominator polynomial.

Dependencies

To enable this parameter, set the **Denominator Source** to Dialog.

Programmatic Use

Block Parameter: Denominator

Type: character vector

Values: scalar | vector

Default: '[1 0.5]'

Initial states Source — Source of initial states

Dialog (default) | Input port

Specify the source of the initial states as Dialog or Input port.

Programmatic Use

Block Parameter: InitialStatesSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Initial states Value — Initial filter states

0 (default) | scalar | vector | matrix

Specify the initial filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-328.

Dependencies

To enable this parameter, set the **Filter structure** to Direct form II or Direct form II transposed, and set **Initial states Source** to Dialog.

Programmatic Use

Block Parameter: InitialStates

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Initial states on numerator side — Initial numerator states

0 (default) | scalar | vector | matrix

Specify the initial numerator filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-328.

Dependencies

To enable this port, set the **Filter structure** to Direct form I or Direct form I transposed.

Programmatic Use

Block Parameter: InitialStates

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Initial states on denominator side — Initial denominator states

0 (default) | scalar | vector | matrix

Specify the initial denominator filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-328.

Dependencies

To enable this port, set the **Filter structure** to Direct form I or Direct form I transposed.

Programmatic Use

Block Parameter: InitialDenominatorStates

Type: character vector

Values: scalar | vector | matrix

Default: '0'

External reset — External state reset

None (default) | Rising | Falling | Either | Level | Level hold

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset
Rising	Reset on a rising edge
Falling	Reset on a falling edge
Either	Reset on either a rising or falling edge
Level	Reset in either of these cases: <ul style="list-style-type: none"> When the reset signal is nonzero at the current time step When the reset signal value changes from nonzero at the previous time step to zero at the current time step

Reset Mode	Behavior
Level hold	Reset when the reset signal is nonzero at the current time step

Programmatic Use**Block Parameter:** ExternalReset**Type:** character vector**Values:** 'None' | 'Rising' | 'Falling' | 'Either' | 'Level' | 'Level hold'**Default:** 'None'**Input processing — Sample- or frame-based processing**

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing.

- Elements as channels (sample based) — Process each element of the input as an independent channel.
- Columns as channels (frame based) — Process each column of the input as an independent channel.

Dependencies

Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use**Block Parameter:** InputProcessing**Type:** character vector**Values:** 'Columns as channels (frame based)' | 'Elements as channels (sample based)'**Default:** 'Elements as channels (sample based)'**Optimize by skipping divide by leading denominator coefficient (a_0) — Skip divide by a_0**

off (default) | on

Select when the leading denominator coefficient, a_0 , equals one. This parameter optimizes your code.When you select this check box, the block does not perform a divide-by- a_0 either in simulation or in the generated code. An error occurs if a_0 is not equal to one.When you clear this check box, the block is fully tunable during simulation. It performs a divide-by- a_0 in both simulation and code generation.**Programmatic Use****Block Parameter:** a0EqualsOne**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Sample time (-1 for inherited) — Interval between samples**

-1 (default) | scalar | vector

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

Data Types

State — State data type

Inherit: Same as input (default) | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the state data type. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Same as input
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: StateDataTypeStr

Type: character vector

Values: 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Same as input'

Numerator coefficients — Numerator coefficient data type

Inherit: Inherit via internal rule (default) | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the numerator coefficient data type. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in signed integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: NumCoeffDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>
Default: 'Inherit: Inherit via internal rule'

Numerator coefficient minimum — Minimum value of numerator coefficients

[] (default) | scalar

Specify the minimum value that a numerator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: NumCoeffMin

Type: character vector

Values: scalar

Default: '[]'

Numerator coefficient maximum — Maximum value of numerator coefficients

[] (default) | scalar

Specify the maximum value that a numerator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: NumCoeffMax

Type: character vector

Values: scalar

Default: '[]'

Numerator product output — Numerator product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the product output data type for the numerator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: NumProductDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Numerator accumulator — Numerator accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the accumulator data type for the numerator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: NumAccumDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Denominator coefficients — Denominator coefficient data type

Inherit: Inherit via internal rule (default) | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the denominator coefficient data type. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: DenCoeffDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Denominator coefficient minimum — Minimum value of denominator coefficients

[] (default) | scalar

Specify the minimum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** DenCoeffMin**Type:** character vector**Values:** scalar**Default:** ' [] '**Denominator coefficient maximum — Maximum value of denominator coefficients**

[] (default) | scalar

Specify the maximum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** DenCoeffMax**Type:** character vector**Values:** scalar**Default:** ' [] '**Denominator product output — Denominator product output data type**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the product output data type for the denominator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** DenProductDataTypeStr**Type:** character vector**Values:** 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'**Default:** 'Inherit: Inherit via internal rule'

Denominator accumulator — Denominator accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the accumulator data type for the denominator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: DenAccumDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Output — Output data type

Inherit: Inherit via internal rule (default) | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the output data type. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Output minimum — Minimum value of output

[] (default) | scalar

Specify the minimum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** scalar**Default:** ' [] '**Output maximum — Maximum value of output**

[] (default) | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** scalar**Default:** ' [] '**Multiplicand data type — Multiplicand data type**

Inherit: Same as input (default) | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the multiplicand data type. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Same as input
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set the **Filter structure** to Direct form I transposed

Programmatic Use**Block Parameter:** MultiplicandDataTypeStr**Type:** character vector**Values:** 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'**Default:** 'Inherit: Same as input'**Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types**

off (default) | on

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (off).	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

State Attributes

State name — Assign unique name to each state

' ' (default) | 'position' | {'a', 'b', 'c'} | a | ...

Assign a unique name to each state. If this field is blank (' '), no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, 'position'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

Limitations

- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

Dependencies

To enable this parameter, set **Filter structure** to `Direct form II`.

Programmatic Use**Block Parameter:** StateName**Type:** character vector**Values:** ' ' | user-defined**Default:** ' '**State name must resolve to Simulink signal object — Require state name resolve to a signal object**

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, set **Filter structure** to Direct form II and specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

Programmatic Use**Block Parameter:** StateMustResolveToSignalObject**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Signal object class — Signal object class**

Simulink.Signal (default) | object of a class that is derived from Simulink.Signal

Specify the signal object class.

Dependencies

To enable this parameter, set **Filter structure** to Direct form II and specify a value for **State name**.

Programmatic Use**Block Parameter:** StateSignalObject**Type:** character vector**Values:** object of a class that is derived from Simulink.Signal**Default:** 'Simulink.Signal'**Code generation storage class — State storage class for code generation**

Auto (default) | Model default | ExportedGlobal | ImportedExtern | ImportedExternPointer | BitField (Custom) | Volatile (Custom) | ExportToFile (Custom) | ImportFromFile (Custom) | FileScope (Custom) | Localizable (Custom) | Struct (Custom) | GetSet (Custom) | Reusable (Custom)

Select state storage class for code generation.

- Auto is the appropriate storage class for states that you do not need to interface to external code.
- *StorageClass* applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

Dependencies

To enable this parameter, set **Filter structure** to `Direct form II`, and specify a value for **State name**.

Programmatic Use

Block Parameter: `StateStorageClass`

Type: character vector

Values: `'Auto'` | `'Model default'` | `'ExportedGlobal'` | `'ImportedExtern'` | `'ImportedExternPointer'` | `'Custom'` | ...

Default: `'Auto'`

Code generation storage type qualifier – Storage type qualifier

`''` (default)

Specify a storage type qualifier such as `const` or `volatile`.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Data Objects”.

Dependencies

To enable this parameter, set **Filter structure** to `Direct form II`. This parameter is hidden unless you previously set its value.

Programmatic Use

Block Parameter: `RTWStateStorageTypeQualifier`

Type: character vector

Values: `''` | `'const'` | `'volatile'` | ...

Default: `''`

Block Characteristics

Data Types	<code>double</code> <code>fixed point^a</code> <code>integer^a</code> <code>single</code>
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

a. This block only supports signed fixed-point data types.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block only supports signed fixed-point data types.

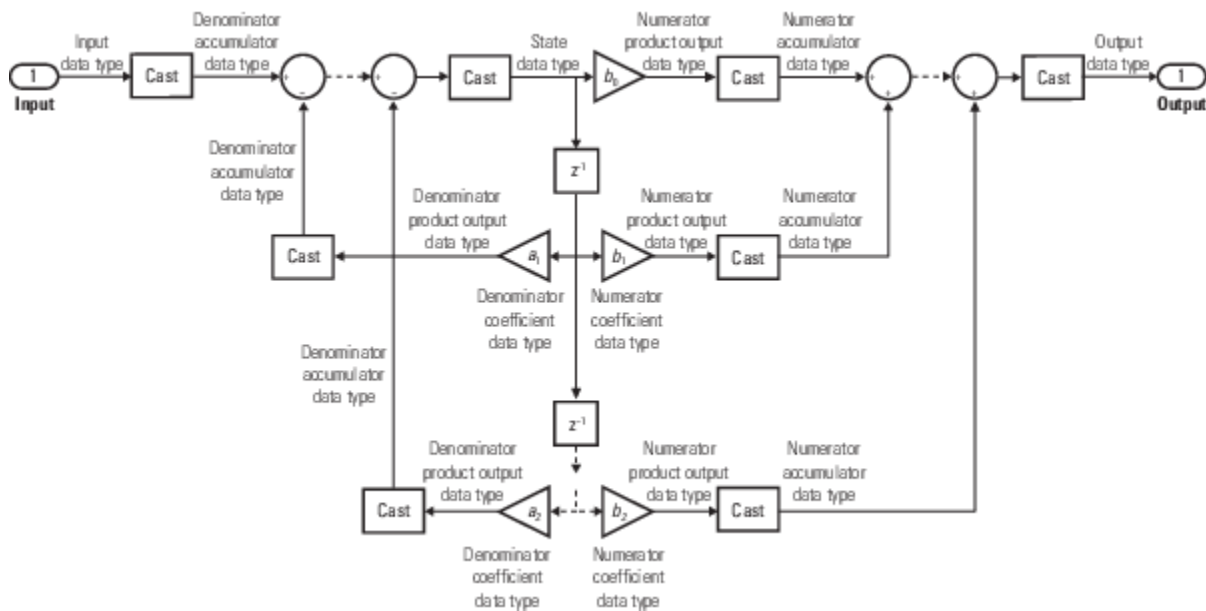

The Discrete Filter block accepts and outputs real and complex signals of any signed numeric data type that Simulink supports. The block supports the same types for the numerator and denominator coefficients.

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

The following diagrams show the filter structure and the data types used within the Discrete Filter block for fixed-point signals.

The block omits the dashed divide when you select the **Optimize by skipping divide by leading denominator coefficient (a0)** parameter.

Introduced before R2006a

Discrete FIR Filter

Model FIR filters

Library: Simulink / Discrete
 HDL Coder / Discrete
 HDL Coder / HDL Floating Point Operations

Description

The Discrete FIR Filter block independently filters each channel of the input signal with the specified digital FIR filter. The block can implement static filters with fixed coefficients, and time-varying filters with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an independent channel (sample-based processing), or each column of the input as an independent channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

The output dimensions equal the input dimensions, except when you specify a matrix of filter taps for the **Coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

This block supports custom state attributes to customize and generate code more efficiently. For an example, see “Custom State Attributes in Discrete FIR Filter block”. Under certain conditions, the block also supports SIMD code generation. For details, see “Code Generation” on page 1-359.

The outputs of this block numerically match the outputs of the DSP System Toolbox Digital Filter Design block.

This block supports the Simulink state logging feature. For more information, see “State”.

Filter Structure Support

You can change the filter structure implemented with the Discrete FIR Filter block by selecting one of the following from the **Filter structure** parameter:

- Direct form
- Direct form symmetric
- Direct form antisymmetric
- Direct form transposed
- Lattice MA

You must have an available DSP System Toolbox license to run a model with any of these filter structures other than **Direct form**.

Specifying Initial States

The Discrete FIR Filter block initializes the internal filter states to zero by default, which has the same effect as assuming that past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial states you must specify and how to specify them, see the table on valid initial states. The **Initial states** parameter can take one of the forms described in the next table.

Valid Initial States

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	<p>Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel:</p> <ul style="list-style-type: none"> The vector length equals the product of the number of input channels and the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code> (or <code>#_of_reflection_coeffs</code> for Lattice MA). The matrix must have the same number of rows as the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code> (<code>#_of_reflection_coeffs</code> for Lattice MA), and must have one column for each channel of the input signal.

Ports

Input

In — Input signal

scalar | vector | matrix

Input signal to filter, specified as a scalar, vector, or matrix.

Dependencies

When you set **Coefficient source** to `Dialog` parameters, the port for the input signal is unlabeled. When you set **Coefficient source** to `Input` port, the port for the input signal is labeled **In**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Num — Filter coefficients

scalar | vector | matrix

Specify the filter coefficients as a scalar, vector, or matrix. When you specify a row vector of filter taps, the block applies a single filter to the input. To apply multiple filters to the same input, specify a matrix of coefficients, where each row represents a different set of filter taps.

Dependencies

To enable this port, set **Coefficient source** to `Input` port.

To implement multiple filters, **Filter structure** must be `Direct` form, and the input must be a scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

External reset — External reset signal

scalar

External reset signal, specified as a scalar. When the specified trigger event occurs, the block resets the states to their initial conditions.

Tip The icon for this port changes based on the value of the **External reset** parameter.

Dependencies

To enable this port, set **External reset** to Rising, Falling, Either, Level, or Level hold.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

□ — Enable signal

scalar

Enable signal, specified as a scalar. This port can control execution of the block. The block is enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

Dependencies

To enable this port, select the **Show enable port** check box.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Filtered output signal

scalar | vector | matrix

Filtered output signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main

Coefficient source — Source of coefficients

Dialog parameters (default) | Input port

Choose to specify the filter coefficients using tunable dialog parameters or through an input port, which is useful for time-varying coefficients.

Programmatic Use

Block Parameter: CoefSource

Type: character vector

Values: 'Dialog parameters' | 'Input port'

Default: 'Dialog parameters'

Filter structure — Filter structure

Direct form (default) | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA

Select the filter structure you want the block to implement.

Dependencies

You must have an available DSP System Toolbox license to run a model with a Discrete FIR Filter block that implements any filter structure other than Direct form.

Programmatic Use

Block Parameter: FilterStructure

Type: character vector

Values: 'Direct form' | 'Direct form symmetric' | 'Direct form antisymmetric' | 'Direct form transposed' | 'Lattice MA'

Default: 'Direct form'

Coefficients — Filter coefficients

[0.5 0.5] (default) | vector | matrix

Specify the coefficient vector for the transfer function. Filter coefficients must be specified as a row vector. When you specify a row vector of filter taps, the block applies a single filter to the input. To apply multiple filters to the same input, specify a matrix of coefficients, where each row represents a different set of filter taps.

Dependencies

To enable this parameter, set **Coefficient source** to Dialog parameters.

To implement multiple filters, **Filter structure** must be Direct form, and the input must be a scalar.

Programmatic Use

Block Parameter: Coefficients

Type: character vector

Values: vector

Default: '[0.5 0.5]'

Input processing — Sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- Elements as channels (sample based) — Treat each element of the input as an independent channel (sample-based processing).
- Columns as channels (frame based) — Treat each column of the input as an independent channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Initial states — Initial conditions of filter states

0 (default) | scalar | vector | matrix

Specify the initial conditions of the filter states. To learn how to specify initial states, see “Specifying Initial States” on page 1-349.

Programmatic Use

Block Parameter: InitialStates

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Show enable port — Create enable port

off (default) | on

Select to control execution of this block with an enable port. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

Programmatic Use

Block Parameter: ShowEnablePort

Type: character vector

Values: 'off' | 'on'

Default: 'off'

External reset — External state reset

None (default) | Rising | Falling | Either | Level | Level hold

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset
Rising	Reset on a rising edge
Falling	Reset on a falling edge
Either	Reset on either a rising or falling edge
Level	Reset in either of these cases: <ul style="list-style-type: none"> When the reset signal is nonzero at the current time step When the reset signal value changes from nonzero at the previous time step to zero at the current time step

Reset Mode	Behavior
Level hold	Reset when the reset signal is nonzero at the current time step

Programmatic Use**Block Parameter:** ExternalReset**Type:** character vector**Values:** 'None' | 'Rising' | 'Falling' | 'Either' | 'Level' | 'Level hold'**Default:** 'None'**Sample time (-1 for inherited) – Time interval between samples**

-1 (default) | scalar | vector

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. For more information, see “Specify Sample Time”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar | vector**Default:** '-1'**Data Types****Tap sum – Tap sum data type**

Inherit: Same as input (default) | Inherit: Inherit via internal rule | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | <data type expression>

Specify the tap sum data type of a direct form symmetric or direct form antisymmetric filter, which is the data type the filter uses when it sums the inputs prior to multiplication by the coefficients. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

This parameter is only visible when you set the **Filter structure** to Direct form symmetric or Direct form antisymmetric.

Programmatic Use**Block Parameter:** TapSumDataTypeStr**Type:** character vector

Values: 'Inherit: Same as input' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Same as input'

Coefficients — Coefficient data type

Inherit: Same wordlength as input (default) | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | <data type expression>

Specify the coefficient data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same word length as input
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: CoeffDataTypeStr

Type: character vector

Values: 'Inherit: Same word length as input' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Same wordlength as input'

Coefficients minimum — Minimum value of coefficients

[] (default) | scalar

Specify the minimum value that a filter coefficient should have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: CoeffMin

Type: character vector

Values: scalar

Default: '[]'

Coefficients maximum — Maximum value of coefficients

[] (default) | scalar

Specify the maximum value that a filter coefficient should have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** CoeffMax**Type:** character vector**Values:** scalar**Default:** '[]'**Product output — Product output data type**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | <data type expression>

Specify the product output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** ProductDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'**Accumulator — Accumulator data type**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | <data type expression>

Specify the accumulator data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** AccumDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

State — State data type

Inherit: Same as accumulator (default) | Inherit: Same as input | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | <data type expression>

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same as accumulator
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Dependencies

To enable this parameter, set the **Filter structure** to Lattice MA.

Programmatic Use

Block Parameter: StateDataTypeStr

Type: character vector

Values: 'Inherit: Same as accumulator' | 'Inherit: Same as input' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Same as accumulator'

Output — Output data type

Inherit: Same as accumulator (default) | Inherit: Same as input | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same as accumulator
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Same as accumulator' | 'Inherit: Same as input' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Same as accumulator'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** ' [] ' | scalar**Default:** ' [] '**Output maximum — Maximum output value for range checking**

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode – Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow – Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (off).	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block supports custom state attributes to customize and generate code more efficiently. To access or set these attributes, open the Model Data Editor. On the **Modeling** tab, click **Model Data Editor**. For an example, see “Custom State Attributes in Discrete FIR Filter block”.

The Discrete FIR Filter block supports SIMD code generation using Intel AVX2 technology when **Filter structure** is set to `Direct` form, and the signal is real-valued with a data type of single or double. The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

For hardware-friendly valid and reset control signals, and to model exact hardware latency behavior in Simulink, use the Discrete FIR Filter HDL Optimized block instead.

To reduce area or increase speed, the Discrete FIR Filter block supports either block-level optimizations or subsystem-level optimizations. For details of available block-level optimization parameters, see “Block Optimizations” on page 1-361. When you enable block optimizations, the block cannot participate in subsystem optimizations. Use block optimizations when your design is a single one-channel filter. Use subsystem optimizations to share resources across multiple channels or multiple filters. For the block to participate in subsystem-level optimizations, set the **Architecture** to **Fully parallel**. See “Subsystem Optimizations for Filters” (HDL Coder).

Multichannel Filter Support

HDL Coder supports the use of vector inputs to Discrete FIR Filter blocks, where each element of the vector represents an independent channel.

- 1 Connect a vector signal to the Discrete FIR Filter block input port.
- 2 Specify **Input processing** as **Elements as channels (sample based)**.
- 3 To reduce area by sharing the filter kernel between channels, set the **ChannelSharing** property to the number of channels.

Programmable Filter Support

HDL Coder supports programmable filters for Discrete FIR Filter blocks.

- 1 On the filter block mask, set **Coefficient source** to **Input port**.
- 2 Connect a vector signal to the Num coefficient port.

Programmable filters are not supported for:

- distributed arithmetic (DA)
- **CoeffMultipliers** set to **csd** or **factored-csd**

Frame-Based Input Support

HDL Coder supports the use of vector inputs to Discrete FIR Filter blocks, where each element of the vector represents a sample in time. You can use an input vector of up to 512 samples. The frame-based implementation supports fixed-point input and output data types, and uses full-precision internal data types. You can use real input signals with real coefficients, complex input signals with real coefficients, or real input signals with complex coefficients. You can also use frame-based input with programmable coefficients.

- 1 Connect a vector signal to the Discrete FIR Filter block input port.
- 2 Specify **Input processing** as **Columns as channels (frame based)**, and set **Filter structure** to **Direct form**.
- 3 Right-click the block and open **HDL Code > HDL Block Properties**. Set the **Architecture** to **Frame Based**. The block implements a direct form parallel HDL architecture. Other

architectures, including fully- or partly-serial, are not supported. See “Frame-Based Architecture” (HDL Coder).

Frame-based input filters are not supported for:

- Optional block-level reset and enable control signals
- Resettable and enabled subsystems
- Complex input signals with complex coefficients. You can use either complex input signals and real coefficients, or complex coefficients and real input signals.
- Multichannel input
- Sharing and streaming optimizations
- distributed arithmetic (DA)

Control Ports

You can generate HDL code for filters with or without the optional enable port, and with or without the optional reset port.

Complex Data Support

You can use any combination of complex input and complex coefficients with fully-parallel filter structures, when you use non-frame-based input data.

Complex coefficients are not supported with serial filter architectures.

When you use frame-based input data you can use either complex input signals and real coefficients, or complex coefficients and real input signals.

You cannot use distributed arithmetic (DA) or **CoeffMultipliers** set to `csd` or `factored-csd` with complex coefficients.

Block Optimizations

Area and Speed Optimizations	
Serial Architecture	<p>To use block-level optimizations to reduce hardware resources, set Architecture to one of the serial options. See “HDL Filter Architectures” (HDL Coder).</p> <p>When you specify SerialPartition and ReuseAccum for a Discrete FIR Filter block, set Filter structure to <code>Direct form</code>, <code>Direct form symmetric</code>, or <code>Direct form antisymmetric</code>. The <code>Direct form transposed</code> structure is not supported with serial architectures.</p>
Distributed Arithmetic	<p>To minimize multipliers by replacing them with LUTs and shift registers, use a distributed arithmetic (DA) filter implementation. See “Distributed Arithmetic for HDL Filters” (HDL Coder).</p> <p>When you select the Distributed Arithmetic (DA) architecture and use the DALUTPartition and DARadix distributed arithmetic properties, set Filter structure to <code>Direct form</code>, <code>Direct form symmetric</code>, or <code>Direct form antisymmetric</code>. The <code>Direct form transposed</code> structure is not supported with distributed arithmetic.</p>

Area and Speed Optimizations	
Multichannel Area Reduction	To share filter logic between channels, set the ChannelSharing property to the number of channels. Using ChannelSharing excludes the filter from other optimizations. You can achieve the same logic sharing across all eligible logic in a subsystem by using the StreamingFactor property. This option also enables the filter to participate in other subsystem optimizations. See the Streaming section of “Subsystem Optimizations for Filters” (HDL Coder).
Pipelining	To improve clock speed, use AddPipelineRegisters to use a pipelined adder tree rather than the default linear adder. You can also specify the number of pipeline stages before and after the multipliers. See “HDL Filter Architectures” (HDL Coder).

HDL Filter Properties	
AddPipelineRegisters	Insert a pipeline register between stages of computation in a filter. See also AddPipelineRegisters (HDL Coder).
ChannelSharing	For a multichannel filter, generate a single filter implementation to be shared between channels. See also ChannelSharing (HDL Coder).
CoeffMultipliers	Specify the use of canonical signed digit (CSD) optimization to decrease filter area by replacing coefficient multipliers with shift-and-add logic. When you choose a fully parallel filter implementation, you can set CoeffMultipliers to <code>csd</code> or <code>factored-csd</code> . The default is <code>multipliers</code> , which retains multipliers in the HDL. See also CoeffMultipliers (HDL Coder).
DALUTPartition	Specify distributed arithmetic partial-product LUT partitions as a vector of the sizes of each partition. The sum of all vector elements must be equal to the filter length. The maximum size for a partition is 12 taps. Set DALUTPartition to a scalar value equal to the filter length to generate DA code without LUT partitions. See also DALUTPartition (HDL Coder).
DARadix	Specify how many distributed arithmetic bit sums are computed in parallel. A DA radix of 8 (2^3) generates a DA implementation that computes three sums at a time. The default value is 2^1 , which generates a fully serial DA implementation. See also DARadix (HDL Coder).
MultiplierInputPipeline	Specify the number of pipeline stages to add at filter multiplier inputs. See also MultiplierInputPipeline (HDL Coder).
MultiplierOutputPipeline	Specify the number of pipeline stages to add at filter multiplier outputs. See also MultiplierOutputPipeline (HDL Coder).
ReuseAccum	Enable or disable accumulator reuse in a serial filter implementation. Set ReuseAccum to <code>on</code> to use a cascade-serial implementation. See also ReuseAccum (HDL Coder).
SerialPartition	Specify partitions for partly serial or cascade-serial filter implementations as a vector of the lengths of each partition. For a fully serial implementation, set this parameter to the length of the filter. See also SerialPartition (HDL Coder).

HDL Block Properties	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restrictions

- HDL code generation is not supported for:
 - Unsigned input data.
 - Nonzero initial states. You must set **Initial states** to 0.
 - **Filter Structure**: Lattice MA.
- **CoeffMultipliers** options are supported only when using a fully parallel architecture. When you select a serial architecture, **CoeffMultipliers** is hidden from the HDL Block Properties dialog box.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The Discrete FIR Filter block accepts and outputs real and complex signals of any numeric data type supported by Simulink. The block supports the same types for the coefficients.

The following diagrams show the filter structure and the data types used within the Discrete FIR Filter block for fixed-point signals.

Direct Form

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

Direct Form Symmetric

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

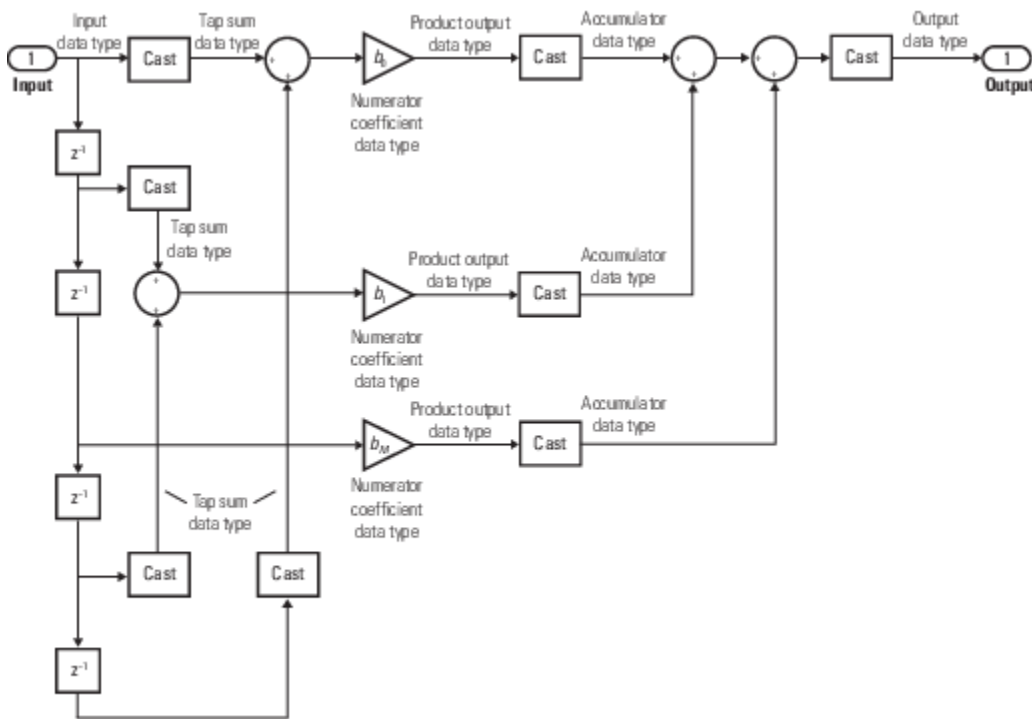

It is assumed that the filter coefficients are symmetric. The block only uses the first half of the coefficients for filtering.

Even Order - Type I

Odd Order - Type II

Even Order - Type I

Odd Order - Type II

Direct Form Antisymmetric

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

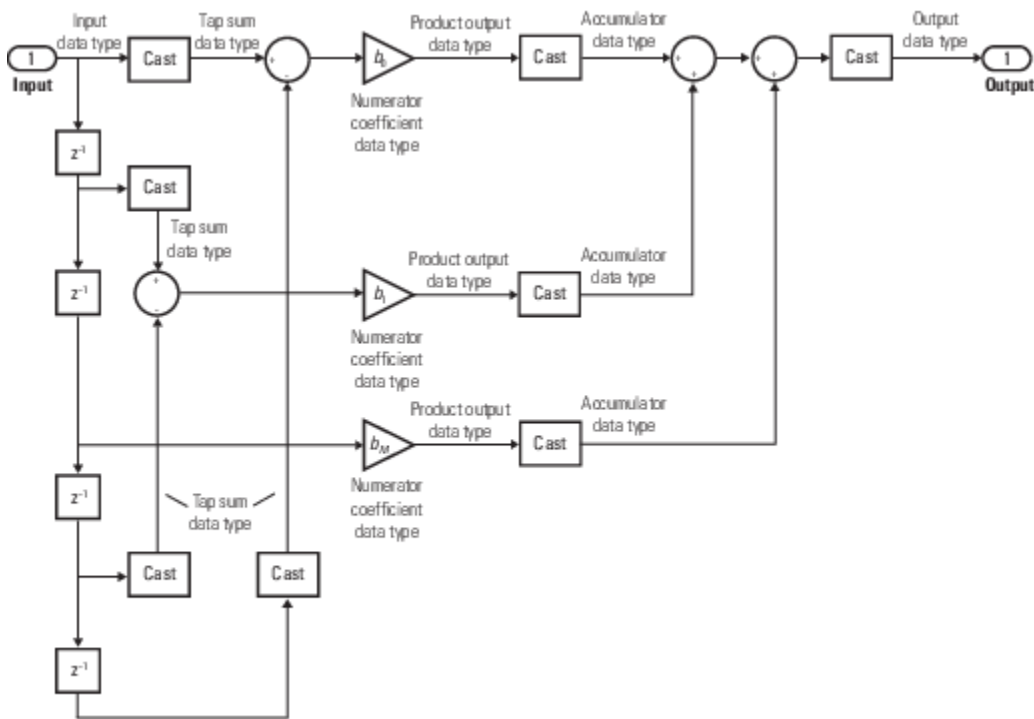

It is assumed that the filter coefficients are antisymmetric. The block only uses the first half of the coefficients for filtering.

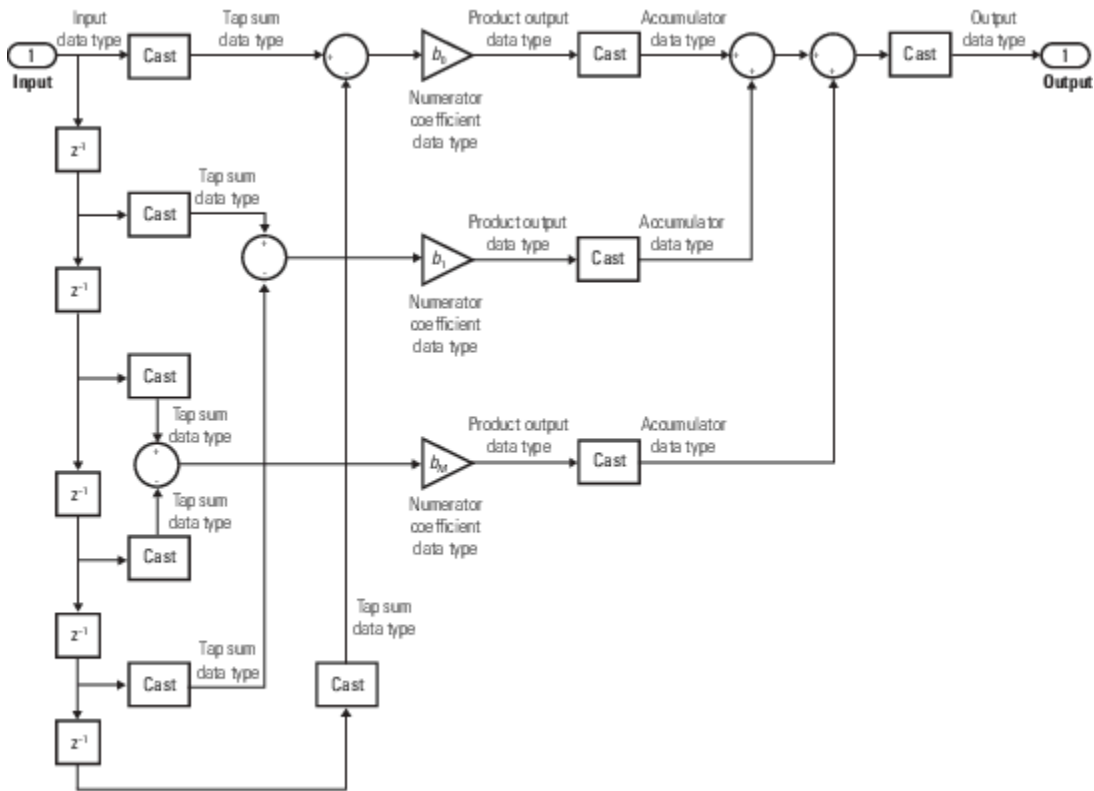

Even Order - Type III

Odd Order - Type IV

Even Order - Type III

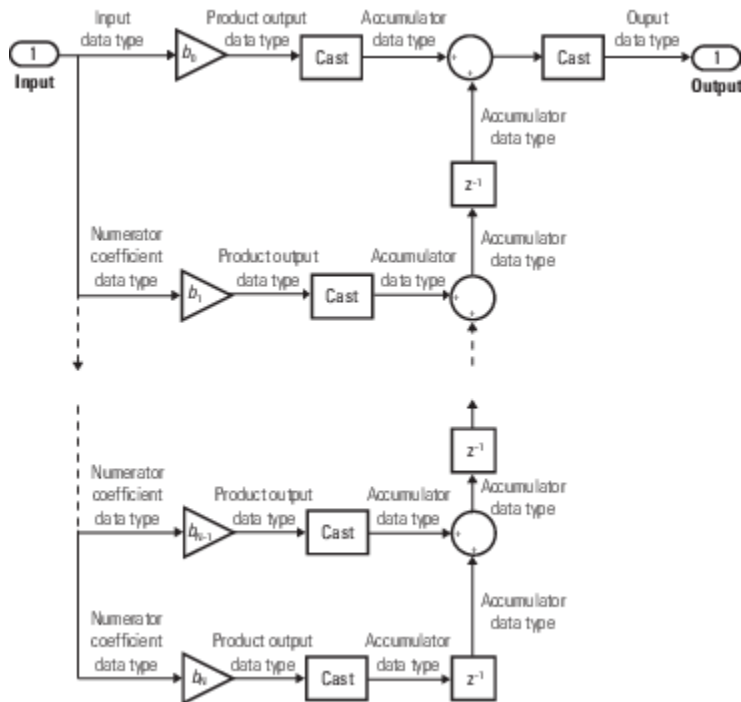

Odd Order - Type IV

Direct Form Transposed

States are complex when either the inputs or the coefficients are complex.

Introduced in R2008a

Discrete PID Controller

Discrete-time or continuous-time PID controller

Library: Simulink / Discrete
HDL Coder / Discrete
HDL Coder / HDL Floating Point Operations

Description

The Discrete PID Controller block implements a PID controller (PID, PI, PD, P only, or I only). The block is identical to the PID Controller block with the **Time domain** parameter set to Discrete-time.

The block output is a weighted sum of the input signal, the integral of the input signal, and the derivative of the input signal. The weights are the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action.

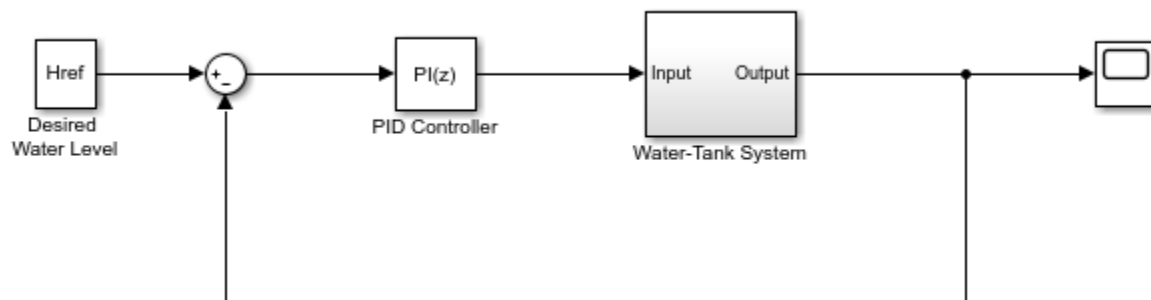

The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, PD, P only, or I only) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (continuous or discrete) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (For more information, see “Variant Subsystems” on page 14-387). To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.

The input of the block is typically an error signal, which is the difference between a reference signal and the system output. For a two-input block that permits setpoint weighting, see Discrete PID Controller (2DOF).

PID Gain Tuning

The PID controller gains are tunable either manually or automatically. Automatic tuning requires Simulink Control Design™ software. For more information about automatic tuning, see the **Select tuning method** parameter.

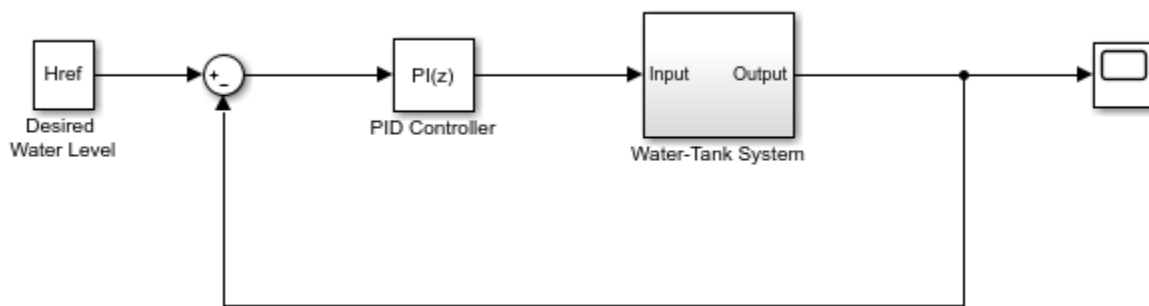

Ports

Input

Port_1(u) — Error signal input

scalar | vector

Difference between a reference signal and the output of the system under control, as shown.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

P — Proportional gain

scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

I — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also

use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

D — Derivative gain

scalar | vector

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

N — Filter coefficient

scalar | vector

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Reset — External reset trigger

scalar

Trigger to reset the integrator and filter to their initial conditions. The value of the **External reset** parameter determines whether reset occurs on a rising signal, a falling signal, or a level signal. The

port icon indicates the selected trigger type. For example, the following illustration shows a continuous-time PID block with **External reset** set to **rising**.

When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the **I₀** and **D₀** ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA®) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than none.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point` | `Boolean`

I₀ – Integrator initial condition

`scalar` | `vector`

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

D₀ – Filter initial condition

`scalar` | `vector`

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

TR – Tracking signal

`scalar` | `vector`

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also

be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

T_{DTI} — Discrete-integrator time

scalar

Discrete-integrator time, provided as a scalar to the block. You can use your own value of discrete-time integrator sample time that defines the rate at which the block is going to be run either in Simulink or on external hardware. The value of the discrete-time integrator time should match the average sampling rate of the external interrupts, when the block is used inside a conditionally-executed subsystem.

In other words, you can specify T_s for any of the integrator methods below such that the value matches the average sampling rate of the external interrupts. In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

$$\alpha(z) = \frac{T_s}{z - 1}.$$

Backward Euler

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

Trapezoidal

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page. For more information on conditionally executed subsystems, see “Conditionally Executed Subsystems Overview”.

Dependencies

To enable this port, set **Time Domain** to Discrete-time and select the **PID Controller is inside a conditionally executed subsystem** option.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Output

Port_1(y) – Controller output

scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as N independent PID controllers, where N is the number of signals in the input vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Controller — Controller type

`PID` (default) | `PI` | `PD` | `P` | `I`

Specify which of the proportional, integral, and derivative terms are in the controller.

PID

Proportional, integral, and derivative action.

PI

Proportional and integral action only.

PD

Proportional and derivative action only.

P

Proportional action only.

I

Integral action only.

Tip The controller transfer function for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: `Controller`

Type: string, character vector

Values: "PID", "PI", "PD", "P", "I"

Default: "PID"

Form — Controller structure

`Parallel` (default) | `Ideal`

Specify whether the controller structure is parallel or ideal.

Parallel

The controller output is the sum of the proportional, integral, and derivative actions, weighted independently by **P**, **I**, and **D**, respectively. For example, for a continuous-time parallel-form PID controller, the transfer function is:

$$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right).$$

For a discrete-time parallel-form controller, the transfer function is:

$$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1+N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Ideal

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time ideal-form PID controller, the transfer function is:

$$C_{id}(s) = P \left[1 + I \left(\frac{1}{s} \right) + D \left(\frac{Ns}{s + N} \right) \right].$$

For a discrete-time ideal-form controller, the transfer function is:

$$C_{id}(z) = P \left[1 + I\alpha(z) + D \frac{N}{1 + N\beta(z)} \right],$$

where the **Integrator method** and **Filter method** parameters determine $a(z)$ and $b(z)$, respectively.

Tip The controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "Parallel", "Ideal"

Default: "Parallel"

Time domain — Specify discrete-time or continuous-time controller

Discrete-time (default) | Continuous-time

When you select **Discrete-time**, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting **Discrete-time** also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select **Continuous-time**.

Note The PID Controller and Discrete PID Controller blocks are identical except for the default value of this parameter.

Programmatic Use

Block Parameter: TimeDomain

Type: string, character vector

Values: "Continuous-time", "Discrete-time"

Default: "Continuous-time"

PID Controller is inside a conditionally executed subsystem – Enable the discrete-integrator time port

off (default) | on

For discrete-time PID controllers, enable the discrete-time integrator port to use your own value of discrete-time integrator sample time. To ensure proper integration, Use the T_{DTI} port to provide a scalar value of Δt for accurate discrete-time integration.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time.

Programmatic Use

Block Parameter: UseExternalTs

Type: string, character vector

Values: "on", "off"

Default: "off"

Sample time (-1 for inherited) – Discrete interval between samples

-1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of -1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to Continuous-time.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to -1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Block Parameter: SampleTime

Type: scalar

Values: -1, positive scalar

Default: -1

Integrator method – Method for computing integral in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the integral term of the controller transfer function is $I\alpha(z)$, where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Note For the BackwardEuler or Trapezoidal methods, you cannot generate HDL code for the block if either:

- **Limit output** is selected and **Anti-Windup Method** is anything other than none.
 - **Enable tracking mode** is selected.
-

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and set **Controller** to a controller type with integral action.

Programmatic Use

Block Parameter: IntegratorMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Filter method — Method for computing derivative in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and enable **Use filtered derivative**.

Programmatic Use

Block Parameter: FilterMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Main

Source — Source for controller gains and filter coefficient

internal (default) | external

Enabling external inputs for the parameters allows you to compute PID gains and filter coefficients externally to the block and provide them to the block as signal inputs.

internal

Specify the controller gains and filter coefficient using the block parameters **P**, **I**, **D**, and **N**.

external

Specify the PID gains and filter coefficient externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the input signal u is multiplied by the externally supplied integrator gain, I , before integration. This implementation yields:

$$y_i = \int uI dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain D to be differentiated.

Programmatic Use

Block Parameter: ControllerParametersSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Proportional (P) — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- **Parallel** — Proportional action is independent of the integral and derivative actions. For instance, for a continuous-time parallel PID controller, the transfer function is:

$$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s + N}\right).$$

For a discrete-time parallel-form controller, the transfer function is:

$$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1 + N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- **Ideal** — The proportional gain multiples the integral and derivative terms. For instance, for a continuous-time ideal PID controller, the transfer function is:

$$C_{id}(s) = P\left[1 + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s + N}\right)\right].$$

For a discrete-time ideal-form controller, the transfer function is:

$$C_{id}(z) = P\left[1 + I\alpha(z) + D\frac{N}{1 + N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal** and set **Controller** to **PID**, **PD**, **PI**, or **P**.

Programmatic Use

Block Parameter: P

Type: scalar, vector

Default: 1

Integral (I) — Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal**, and set **Controller** to a type that has integral action.

Programmatic Use**Block Parameter:** I**Type:** scalar, vector**Default:** 1**Derivative (D) — Derivative gain**

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes**Dependencies**To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to `PID` or `PD`.**Programmatic Use****Block Parameter:** D**Type:** scalar, vector**Default:** 0**Use filtered derivative — Apply filter to derivative term**`on` (default) | `off`

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller transfer function becomes:

$$D \frac{z - 1}{zT_s} \cdot$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time, and set **Controller** to a type that has derivative action.

Programmatic Use

Block Parameter: UseFilter

Type: string, character vector

Values: "on", "off"

Default: "on"

Filter coefficient (N) – Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is Continuous-time, the pole location is $s = -N$.
- When **Time domain** is Discrete-time, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
Forward Euler	$z_{pole} = 1 - NT_s$
Backward Euler	$z_{pole} = \frac{1}{1 + NT_s}$
Trapezoidal	$z_{pole} = \frac{1 - NT_s/2}{1 + NT_s/2}$

The block does not support $N = \text{Inf}$ (ideal unfiltered derivative). When the **Time domain** is Discrete-time, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to internal and set **Controller** to PID or PD.

Programmatic Use

Block Parameter: N

Type: scalar, vector

Default: 100

Select tuning method – Tool for automatic tuning of controller coefficients

Transfer Function Based (PID Tuner App) (default) | Frequency Response Based

If you have Simulink Control Design software, you can automatically tune the PID coefficients. To do so, use this parameter to select a tuning tool, and click **Tune**.

Transfer Function Based (PID Tuner App)

Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. By default, **PID Tuner** works with a linearization of

your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see “Introduction to Model-Based PID Tuning in Simulink” (Simulink Control Design).

Frequency Response Based

Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially useful for plants that are not linearizable or that linearize to zero. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

Enable zero-crossing detection — Detect zero crossings on reset and on entering or leaving a saturation state

on (default) | off

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: ZeroCross

Type: string, character vector

Values: "on", "off"

Default: "on"

Initialization

Source — Source for integrator and derivative initial conditions

internal (default) | external

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

internal

Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator** parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

external

Specify the initial conditions externally using block inputs. Additional input ports I_0 and D_0 appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at D_0 instead of a filter initial condition.

Programmatic Use

Block Parameter: InitialConditionSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Integrator — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: InitialConditionForIntegrator

Type: scalar, vector

Default: 0

Filter — Filter initial condition

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use

Block Parameter: InitialConditionForFilter

Type: scalar, vector

Default: 0

Differentiator — Initial condition for unfiltered derivative

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, set **Time domain** to Discrete-time, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to internal.

Programmatic Use

Block Parameter: DifferentiatorICPrevScaledInput

Type: scalar, vector

Default: 0

Initial condition setting — Location at which initial condition is applied

State (most efficient) (default) | Output

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

State (most efficient)

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use

Block Parameter: InitialConditionSetting

Type: string, character vector

Values: "state", "output"

Default: "state"

External reset — Trigger for resetting integrator and filter values

none (default) | rising | falling | either | level

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and differentiator to initial conditions.) Selecting any option other than **none** enables the **Reset** port on the block for the external reset signal.

none

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

rising

Reset the outputs when the reset signal has a rising edge.

falling

Reset the outputs when the reset signal has a falling edge.

either

Reset the outputs when the reset signal either rises or falls.

level

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use

Block Parameter: ExternalReset

Type: string, character vector

Values: "none", "rising", "falling", "either", "level"

Default: "none"

Ignore reset when linearizing — Force linearization to ignore reset

off (default) | on

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use

Block Parameter: IgnoreLimit

Type: string, character vector

Values: "off", "on"

Default: "off"

Enable tracking mode — Activate signal tracking

off (default) | on

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain K_t , specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

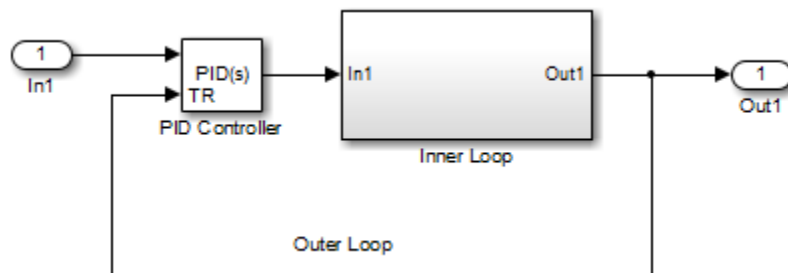

Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.

For more information, see “Bumpless Control Transfer” on page 13-102.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches, as in the following model.

The Inner Loop subsystem contains the blocks shown in the following diagram.

Because the PID controller tracks the output of the inner loop, its output never exceeds the saturated inner-loop output. For more details, see “Prevent Block Windup in Multiloop Control” on page 13-101.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: TrackingMode

Type: string, character vector

Values: "off", "on"

Default: "off"

Tracking coefficient (Kt) — Gain of signal-tracking feedback loop

1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain Kt. Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use

Block Parameter: Kt

Type: scalar

Default: 1

Output saturation

Limit Output — Limit block output to specified saturation values

off (default) | on

Activating this option limits the block output internally to the block, so that you do not need a separate Saturation on page 1-1255 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the saturation limits using the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use

Block Parameter: LimitOutput

Type: string, character vector

Values: "off", "on"

Default: "off"

Upper limit — Upper saturation limit for block output

Inf (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: UpperSaturationLimit

Type: scalar

Default: Inf

Lower limit — Lower saturation limit for block output

-Inf (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: LowerSaturationLimit

Type: scalar

Default: -Inf

Ignore saturation when linearizing — Force linearization to ignore output limits

off (default) | on

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: LinearizeAsGain

Type: string, character vector

Values: "off", "on"

Default: "off"

Anti-windup method — Integrator anti-windup method

none (default) | back-calculation | clamping

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the input signal never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the input signal changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

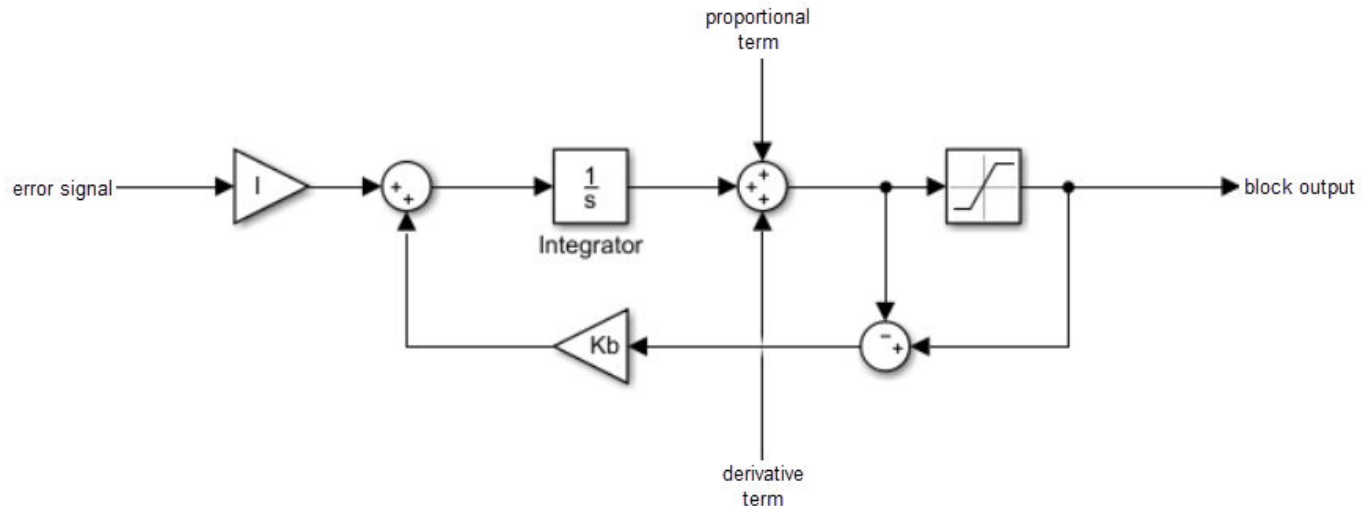

none

Do not use an anti-windup mechanism.

back-calculation

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram

represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.

Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set $K_b = I$, or for controllers with derivative action, $K_b = \sqrt{I \cdot D}$. Back-calculation can be effective for plants with relatively large dead time [1].

clamping

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: AntiWindupMode

Type: string, character vector

Values: "none", "back-calculation", "clamping"

Default: "none"

Back-calculation coefficient (Kb) — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The back-calculation anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to back-calculation.

Programmatic Use

Block Parameter: Kb

Type: scalar

Default: 1

Data Types

The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click  to open the Data Type Assistant for the corresponding quantity. For more information, see “Specify Data Types Using Data Type Assistant”.

Main		Initialization		Output saturation		Data Types		State Attributes

Integer rounding mode:		Floor							
<input type="checkbox"/>		Saturate on integer overflow							
<input type="checkbox"/>		Lock data type settings against changes by the fixed-point tools							
								Open Fixed-Point Tool...	
Data Type			Minimum		Maximum				
P product output:	Inherit: Inherit via internal rule	>>		:		:		:	
I product output:	Inherit: Inherit via internal rule	>>		:		:		:	
D product output:	Inherit: Inherit via internal rule	>>		:		:		:	
N product output:	Inherit: Inherit via internal rule	>>		:		:		:	
b product output:	Inherit: Inherit via internal rule	>>		:		:		:	
c product output:	Inherit: Inherit via internal rule	>>		:		:		:	
Sum output:	Inherit: Inherit via internal rule	>>		:		:		:	
▶ Additional data types									

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.
- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as SumI2. (See **Model Explorer**.)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.
For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**State Attributes**

The parameters in this tab are primarily of use in code generation.

State name (e.g., 'position') – Name for continuous-time filter and integrator states

' ' (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to Continuous-time.

Programmatic Use**Parameter:** IntegratorContinuousStateAttributes, FilterContinuousStateAttributes**Type:** character vector**Default:** ' '**State name – Names for discrete-time filter and integrator states**

empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Parameter: IntegratorStateIdentifier, FilterStateIdentifier

Type: string, character vector

Default: ""

State name must resolve to Simulink signal object — Require that state name resolve to a signal object

off (default) | on

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class** for the corresponding integrator or filter state.

Programmatic Use

Block Parameter: IntegratorStateMustResolveToSignalObject, FilterStateMustResolveToSignalObject

Type: string, character vector

Values: "off", "on"

Default: "off"

Code generation storage class — Storage class for code generation

Auto (default) | ExportedGlobal | ImportedExtern | ImportedExternPointer

Select state storage class for code generation. If you do not need to interface to external code, select Auto.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use

Block Parameter: IntegratorRTWStateStorageClass, FilterRTWStateStorageClass

Type: string, character vector

Values: "Auto", "ExportedGlobal", "ImportedExtern" | "ImportedExternPointer"

Default: "Auto"

Code generation storage type qualifier — Storage type qualifier

empty string (default) | character vector | "const" | "volatile" | ...

Specify a storage type qualifier such as const or volatile.

Note This parameter will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Dependencies

To enable this parameter, set **Code generation storage class** to any value other than Auto.

Programmatic Use

Block Parameter:

IntegratorRTWStateStorageTypeQualifier, FilterRTWStateStorageTypeQualifier

Type: string, character vector

Values: "", "const", "volatile"

Default: ""

Block Characteristics

Data Types	double fixed point integer single

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to **Continuous-time**):

- Consider using "Model Discretizer" to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, from your model, in the **Apps** tab, under **Control Systems**, click **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to **Discrete-time**):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on memcpy or memset functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Restrictions

- HDL code generation is supported for discrete-time PID controllers only (**Time domain** set to **Discrete-time**).
- If the **Integrator method** is set to **BackwardEuler** or **Trapezoidal**, you cannot generate HDL code for the block under either of the following conditions:

- **Limit output** is selected and the **Anti-Windup Method** is anything other than none.
- **Enable tracking mode** is selected.
- To generate HDL code:
 - Use a discrete-time PID controller. On the **Time domain** section, specify **Discrete-time**.
 - Leave the **Use filtered derivative** check box selected.
 - Specify the initial conditions of the filter and integrator internally. On the **Initialization** tab, specify **Source** as `internal`.

You can specify the filter coefficients internally and externally for HDL code generation. On the **Main** tab, for **Source**, you can use `internal` or `external`.

- Set **External reset** to none.
- When you use double inputs, do not set **Anti-windup Method** to clamping.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Fixed-point code generation is supported for discrete-time PID controllers only (**Time domain** set to `Discrete-time`).

Introduced in R2009b

Discrete PID Controller (2DOF)

Discrete-time or continuous-time two-degree-of-freedom PID controller

Library: Simulink / Discrete

Description

The Discrete PID Controller (2DOF) block implements a two-degree-of-freedom PID controller (PID, PI, or PD). The block is identical to the PID Controller (2DOF) block with the **Time domain** parameter set to **Discrete-time**.

The block generates an output signal based on the difference between a reference signal and a measured system output. The block computes a weighted difference signal for the proportional and derivative actions according to the setpoint weights (**b** and **c**) that you specify. The block output is the sum of the proportional, integral, and derivative actions on the respective difference signals, where each action is weighted according to the gain parameters **P**, **I**, and **D**. A first-order pole filters the derivative action.

The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, or PD) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (discrete or continuous) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (See “Variant Subsystems” on page 14-387.) To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.

For a single-input block that accepts an error signal (a difference between a setpoint and a system output), see Discrete PID Controller.

PID Gain Tuning

The PID controller coefficients and the setpoint weights are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software. For more information about automatic tuning, see the **Select tuning method** parameter.

Ports

Input

Ref — Reference signal

scalar | vector

Reference signal for plant to follow, as shown.

When the reference signal is a vector, the block acts separately on each signal, vectorizing the PID coefficients and producing a vector output signal of the same dimensions. You can specify the PID coefficients and some other parameters as vectors of the same dimensions as the input signal. Doing so is equivalent to specifying a separate PID controller for each entry in the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_1(y) — Measured system output

scalar | vector

Feedback signal for the controller, from the plant output.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

P — Proportional gain

scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

I — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to external, and set **Controller** to a controller type that has integral action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

D — Derivative gain

scalar | vector

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to external, and set **Controller** to a controller type that has derivative action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

N – Filter coefficient

scalar | vector

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

b – Proportional setpoint weight

scalar | vector

Proportional setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

c – Derivative setpoint weight

scalar | vector

Derivative setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Reset – External reset trigger

scalar

Trigger to reset the integrator and filter to their initial conditions. Use the **External reset** parameter to specify what kind of signal triggers a reset. The port icon indicates the trigger type specified in that parameter. For example, the following illustration shows a continuous-time PID Controller (2DOF) block with **External reset** set to `rising`.

When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the I_0 and D_0 ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than none.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | Boolean

I_0 — Integrator initial condition

scalar | vector

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to external, and set **Controller** to a controller type that has integral action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

D_0 — Filter initial condition

scalar | vector

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to external, and set **Controller** to a controller type that has derivative action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

TR — Tracking signal

scalar | vector

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also

be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

T_{DTI} — Discrete-integrator time

scalar

Discrete-integrator time, provided as a scalar to the block. You can use your own value of discrete-time integrator sample time that defines the rate at which the block is going to be run either in Simulink or on external hardware. The value of the discrete-time integrator time should match the average sampling rate of the external interrupts, when the block is used inside a conditionally-executed subsystem.

In other words, you can specify T_s for any of the integrator methods below such that the value matches the average sampling rate of the external interrupts. In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

$$\alpha(z) = \frac{T_s}{z - 1}.$$

Backward Euler

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

Trapezoidal

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page. For more information on conditionally executed subsystems, see “Conditionally Executed Subsystems Overview”.

Dependencies

To enable this port, set **Time Domain** to Discrete-time and select the **PID Controller is inside a conditionally executed subsystem** option.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Output

Port_1(u) – Controller output

scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the setpoint weights and by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as N independent PID controllers, where N is the number of signals in the input vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Controller — Controller type

PID (default) | PI | PD

Specify which of the proportional, integral, and derivative terms are in the controller.

PID

Proportional, integral, and derivative action.

PI

Proportional and integral action only.

PD

Proportional and derivative action only.

Tip The controller output for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "PID", "PI", "PD"

Default: "PID"

Form — Controller structure

Parallel (default) | Ideal

Specify whether the controller structure is parallel or ideal.

Parallel

The proportional, integral, and derivative gains **P**, **I**, and **D**, are applied independently. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output u is:

$$u = P(br - y) + I \frac{1}{s}(r - y) + D \frac{N}{1 + N \frac{1}{s}}(cr - y),$$

where r is the reference signal, y is the measured plant output signal, and b and c are the setpoint weights.

For a discrete-time 2-DOF controller in parallel form, the controller output is:

$$u = P(br - y) + I\alpha(z)(r - y) + D \frac{N}{1 + N\beta(z)}(cr - y),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Ideal

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P \left[(br - y) + I \frac{1}{s} (r - y) + D \frac{N}{1 + N \frac{1}{s}} (cr - y) \right].$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P \left[(br - y) + I\alpha(z)(r - y) + D \frac{N}{1 + N\beta(z)} (cr - y) \right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tip The controller output for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "Parallel", "Ideal"

Default: "Parallel"

Time domain — Specify discrete-time or continuous-time controller

Discrete-time (default) | Continuous-time

When you select **Discrete-time**, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting **Discrete-time** also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select **Continuous-time**.

Note The PID Controller (2DOF) and Discrete PID Controller (2DOF) blocks are identical except for the default value of this parameter.

Programmatic Use

Block Parameter: TimeDomain

Type: string, character vector

Values: "Continuous-time", "Discrete-time"

Default: "Discrete-time"

PID Controller is inside a conditionally executed subsystem — Enable the discrete-integrator time port

off (default) | on

For discrete-time PID controllers, enable the discrete-time integrator port to use your own value of discrete-time integrator sample time. To ensure proper integration, Use the T_{DTI} port to provide a scalar value of Δt for accurate discrete-time integration.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time.

Programmatic Use

Block Parameter: UseExternalTs

Type: string, character vector

Values: "on", "off"

Default: "off"

Sample time (-1 for inherited) – Discrete interval between samples

-1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of -1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to Continuous-time.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to -1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Block Parameter: SampleTime

Type: scalar

Values: -1, positive scalar

Default: -1

Integrator method – Method for computing integral in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the integral term of the controller transfer function is $Ia(z)$, where $a(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1}.$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and set **Controller** to a controller type with integral action.

Programmatic Use

Block Parameter: IntegratorMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Filter method — Method for computing derivative in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and enable **Use filtered derivative**.

Programmatic Use

Block Parameter: FilterMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Main

Source — Source for controller gains and filter coefficient

internal (default) | external

internal

Specify the controller gains, filter coefficient, and setpoint weights using the block parameters **P**, **I**, **D**, **N**, **b**, and **c** respectively.

external

Specify the PID gains, filter coefficient, and setpoint weights externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

Enabling external inputs for the parameters allows you to compute their values externally to the block and provide them to the block as signal inputs.

External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control.

In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. The derivative setpoint weight c is also differentiated. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the input signal u is multiplied by the externally supplied integrator gain, I , before integration. This implementation yields:

$$u_i = \int (r - y)I dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain D and the derivative setpoint weight c to be differentiated.

Programmatic Use

Block Parameter: ControllerParametersSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Proportional (P) — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- **Parallel** — Proportional action is independent of the integral and derivative actions. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output u is:

$$u = P(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y),$$

where r is the reference signal, y is the measured plant output signal, and b and c are the setpoint weights.

For a discrete-time 2-DOF controller in parallel form, the controller output is:

$$u = P(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- **Ideal** — The proportional gain multiplies the integral and derivative terms. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P \left[(br - y) + I \frac{1}{s} (r - y) + D \frac{N}{1 + N \frac{1}{s}} (cr - y) \right].$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P \left[(br - y) + I \alpha(z) (r - y) + D \frac{N}{1 + N \beta(z)} (cr - y) \right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, set the Controller parameters **Source** to `internal`.

Programmatic Use

Block Parameter: P

Type: scalar, vector

Default: 1

Integral (I) – Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: I

Type: scalar, vector

Default: 1

Derivative (D) – Derivative gain

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to `PID` or `PD`.

Programmatic Use

Block Parameter: D

Type: scalar, vector

Default: 0

Use filtered derivative – Apply filter to derivative term

on (default) | off

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller output becomes:

$$D \frac{z - 1}{z T_s} (cr - y) .$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time, and set **Controller** to a type that has a derivative term.

Programmatic Use

Block Parameter: UseFilter

Type: string, character vector

Values: "on", "off"

Default: "on"

Filter coefficient (N) – Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is Continuous-time, the pole location is $s = -N$.
- When **Time domain** is Discrete-time, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
Forward Euler	$z_{pole} = 1 - NT_s$
Backward Euler	$z_{pole} = \frac{1}{1 + NT_s}$
Trapezoidal	$z_{pole} = \frac{1 - NT_s/2}{1 + NT_s/2}$

The block does not support $N = \text{Inf}$ (ideal unfiltered derivative). When the **Time domain** is Discrete-time, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to `PID` or `PD`.

Programmatic Use

Block Parameter: `N`

Type: scalar, vector

Default: 100

Setpoint weight (b) — Proportional setpoint weight

1 (default) | scalar | vector

Setpoint weight on the proportional term of the controller. The proportional term of a 2-DOF controller output is $P(br-y)$, where r is the reference signal and y is the measured plant output. Setting b to 0 eliminates proportional action on the reference signal, which can reduce overshoot in the system response to step changes in the setpoint. Changing the relative values of b and c changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`.

Programmatic Use

Block Parameter: `b`

Type: scalar, vector

Default: 1

Setpoint weight (c) — Derivative setpoint weight

1 (default) | scalar | vector

Setpoint weight on the derivative term of the controller. The derivative term of a 2-DOF controller acts on $cr-y$, where r is the reference signal and y is the measured plant output. Thus, setting c to 0 eliminates derivative action on the reference signal, which can reduce transient response to step changes in the setpoint. Setting c to 0 can yield a controller that achieves both effective disturbance rejection and smooth setpoint tracking without excessive transient response. Changing the relative values of b and c changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to a type that has derivative action.

Programmatic Use

Block Parameter: `c`

Type: scalar, vector

Default: 1

Select tuning method — Tool for automatic tuning of controller coefficients

Transfer Function Based (PID Tuner App) (default) | Frequency Response Based

If you have Simulink Control Design software, you can automatically tune the PID coefficients when they are internal to the block. To do so, use this parameter to select a tuning tool, and click **Tune**.

Transfer Function Based (PID Tuner App)

Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. **PID Tuner** can tune all the coefficients **P**, **I**, **D**, and **N**, and the setpoint coefficients **b** and **c**. By default, **PID Tuner** works with a linearization of your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see “Design Two-Degree-of-Freedom PID Controllers” (Simulink Control Design).

Frequency Response Based

Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially useful for plants that are not linearizable or that linearize to zero. **Frequency Response Based PID Tuner** tunes the coefficients **P**, **I**, **D**, and **N**, but does not tune the setpoint coefficients **b** and **c**. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`.

Enable zero-crossing detection — Detect zero crossings on reset and on entering or leaving a saturation state

`on` (default) | `off`

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: `ZeroCross`

Type: string, character vector

Values: "on", "off"

Default: "on"

Initialization

Source — Source for integrator and derivative initial conditions

`internal` (default) | `external`

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

internal

Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator** parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

external

Specify the initial conditions externally using block inputs. Additional input ports **I₀** and **D₀** appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at **D₀** instead of a filter initial condition.

Programmatic Use

Block Parameter: InitialConditionSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Integrator — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: InitialConditionForIntegrator

Type: scalar, vector

Default: 0

Filter — Filter initial condition

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use**Block Parameter:** InitialConditionForFilter**Type:** scalar, vector**Default:** 0**Differentiator — Initial condition for unfiltered derivative**

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, set **Time domain** to Discrete-time, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to internal.

Programmatic Use**Block Parameter:** DifferentiatorICPrevScaledInput**Type:** scalar, vector**Default:** 0**Initial condition setting — Location at which initial condition is applied**

State (most efficient) (default) | Output

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

State (most efficient)

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use**Block Parameter:** InitialConditionSetting**Type:** string, character vector**Values:** "state", "output"**Default:** "state"**External reset — Trigger for resetting integrator and filter values**

none (default) | rising | falling | either | level

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and

differentiator to initial conditions.) Selecting any option other than **none** enables the **Reset** port on the block for the external reset signal.

none

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

rising

Reset the outputs when the reset signal has a rising edge.

falling

Reset the outputs when the reset signal has a falling edge.

either

Reset the outputs when the reset signal either rises or falls.

level

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use

Block Parameter: ExternalReset

Type: string, character vector

Values: "none", "rising", "falling", "either", "level"

Default: "none"

Ignore reset when linearizing — Force linearization to ignore reset

off (default) | on

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use

Block Parameter: IgnoreLimit

Type: string, character vector

Values: "off", "on"

Default: "off"

Enable tracking mode — Activate signal tracking

off (default) | on

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain K_t , specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.

For more information, see “Bumpless Control Transfer with a Two-Degree-of-Freedom PID Controller” on page 13-103.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches. For an example illustrating this approach with a 1DOF PID controller, see “Prevent Block Windup in Multiloop Control” on page 13-101.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: TrackingMode

Type: string, character vector

Values: "off", "on"

Default: "off"

Tracking coefficient (Kt) — Gain of signal-tracking feedback loop

1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain K_t . Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use**Block Parameter:** Kt**Type:** scalar**Default:** 1**Output saturation****Limit Output — Limit block output to specified saturation values**

off (default) | on

Activating this option limits the block output internally to the block, so that you do not need a separate Saturation on page 1-1255 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the saturation limits using the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use**Block Parameter:** LimitOutput**Type:** string, character vector**Values:** "off", "on"**Default:** "off"**Upper limit — Upper saturation limit for block output**

Inf (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use**Block Parameter:** UpperSaturationLimit**Type:** scalar**Default:** Inf**Lower limit — Lower saturation limit for block output**

-Inf (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use**Block Parameter:** LowerSaturationLimit**Type:** scalar**Default:** -Inf**Ignore saturation when linearizing — Force linearization to ignore output limits**

off (default) | on

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to

linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: LinearizeAsGain

Type: string, character vector

Values: "off", "on"

Default: "off"

Anti-windup method — Integrator anti-windup method

`none` (default) | `back-calculation` | `clamping`

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the signal entering the integrator never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the signal entering the integrator changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

`none`

Do not use an anti-windup mechanism.

`back-calculation`

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.

Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set $Kb = I$, or for controllers with derivative action, $Kb = \sqrt{I \cdot D}$. Back-calculation can be effective for plants with relatively large dead time [1].

clamping

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: AntiWindupMode

Type: string, character vector

Values: "none", "back-calculation", "clamping"

Default: "none"

Back-calculation coefficient (Kb) — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The **back-calculation** anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to back-calculation.

Programmatic Use

Block Parameter: Kb

Type: scalar

Default: 1

Data Types

The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click  to open the Data Type Assistant for the corresponding quantity. For more information, see “Specify Data Types Using Data Type Assistant”.

Main		Initialization		Output saturation		Data Types		State Attributes	
Fixed-point operational parameters									
Integer rounding mode:		Floor

<input type="checkbox"/>		Lock data type settings against changes by the fixed-point tools							
								Open Fixed-Point Tool...	
Data Type			Minimum		Maximum				
P product output:	Inherit: Inherit via internal rule	>>		:		:		:	
I product output:	Inherit: Inherit via internal rule	>>		:		:		:	
D product output:	Inherit: Inherit via internal rule	>>		:		:		:	
N product output:	Inherit: Inherit via internal rule	>>		:		:		:	
b product output:	Inherit: Inherit via internal rule	>>		:		:		:	
c product output:	Inherit: Inherit via internal rule	>>		:		:		:	
Sum output:	Inherit: Inherit via internal rule	>>		:		:		:	
▶ Additional data types									

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.
- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as SumI2. (See **Model Explorer**.)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.
For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**State Attributes**

The parameters in this tab are primarily of use in code generation.

State name (e.g., 'position') – Name for continuous-time filter and integrator states

' ' (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to Continuous-time.

Programmatic Use**Parameter:** IntegratorContinuousStateAttributes, FilterContinuousStateAttributes**Type:** character vector**Default:** ' '**State name – Names for discrete-time filter and integrator states**

empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Parameter: IntegratorStateIdentifier, FilterStateIdentifier

Type: string, character vector

Default: ""

State name must resolve to Simulink signal object — Require that state name resolve to a signal object

off (default) | on

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class** for the corresponding integrator or filter state.

Programmatic Use

Block Parameter: IntegratorStateMustResolveToSignalObject, FilterStateMustResolveToSignalObject

Type: string, character vector

Values: "off", "on"

Default: "off"

Code generation storage class — Storage class for code generation

Auto (default) | ExportedGlobal | ImportedExtern | ImportedExternPointer

Select state storage class for code generation. If you do not need to interface to external code, select Auto.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use

Block Parameter: IntegratorRTWStateStorageClass, FilterRTWStateStorageClass

Type: string, character vector

Values: "Auto", "ExportedGlobal", "ImportedExtern" | "ImportedExternPointer"

Default: "Auto"

Code generation storage type qualifier — Storage type qualifier

empty string (default) | character vector | "const" | "volatile" | ...

Specify a storage type qualifier such as const or volatile.

Note This parameter will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Dependencies

To enable this parameter, set **Code generation storage class** to any value other than Auto.

Programmatic Use

Block Parameter:

IntegratorRTWStateStorageTypeQualifier, FilterRTWStateStorageTypeQualifier

Type: string, character vector

Values: "", "const", "volatile"

Default: ""

Block Characteristics

Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Decomposition of 2-DOF PID Controllers

A 2-DOF PID controller can be interpreted as a PID controller with a prefilter, or a PID controller with a feedforward element.

Prefilter Decomposition

In parallel form, a two-degree-of-freedom PID controller can be equivalently modeled by the following block diagram, where C is a single degree-of-freedom PID controller and F is a prefilter on the reference signal.

Ref is the reference signal, y is the feedback from the measured system output, and u is the controller output. For a continuous-time 2-DOF PID controller in parallel form, the transfer functions for F and C are

$$F_{par}(s) = \frac{(bP + cDN)s^2 + (bPN + I)s + IN}{(P + DN)s^2 + (PN + I)s + IN},$$

$$C_{par}(s) = \frac{(P + DN)s^2 + (PN + I)s + IN}{s(s + N)},$$

where b and c are the setpoint weights.

For a 2-DOF PID controller in ideal form, the transfer functions are

$$F_{id}(s) = \frac{(b + cDN)s^2 + (bN + I)s + IN}{(1 + DN)s^2 + (N + I)s + IN},$$

$$C_{id}(s) = P \frac{(1 + DN)s^2 + (N + I)s + IN}{s(s + N)}.$$

A similar decomposition applies for a discrete-time 2-DOF controller.

Feedforward Decomposition

Alternatively, the parallel two-degree-of-freedom PID controller can be modeled by the following block diagram.

In this realization, Q acts as feed-forward conditioning on the reference signal. For a continuous-time 2-DOF PID controller in parallel form, the transfer function for Q is

$$Q_{par}(s) = \frac{((b-1)P + (c-1)DN)s + (b-1)PN}{s + N}.$$

For a 2-DOF PID controller in ideal form, the transfer function is

$$Q_{id}(s) = P \frac{((b-1) + (c-1)DN)s + (b-1)N}{s + N}.$$

The transfer functions for C are the same as in the filter decomposition.

A similar decomposition applies for a discrete-time 2-DOF controller.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to Continuous-time):

- Consider using "Model Discretizer" to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, in the **Apps** tab, under **Control Systems**, click **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to Discrete-time):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on memcopy or memset functions (`string.h`) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Fixed-point code generation is supported for discrete-time PID controllers only (**Time domain** set to **Discrete-time**).

Introduced in R2009b

Discrete State-Space

Implement discrete state-space system
Library: Simulink / Discrete

$$\begin{aligned} x_{n+1} &= Ax_n + Bu_n \\ y_n &= Cx_n + Du_n \end{aligned}$$

Description

Block Behavior for Non-Empty Matrices

The Discrete State-Space block implements the system described by

$$\begin{aligned} x(n+1) &= Ax(n) + Bu(n) \\ y(n) &= Cx(n) + Du(n), \end{aligned}$$

where u is the input, x is the state, and y is the output. The matrix coefficients must have these characteristics, as illustrated in the following diagram:

- **A** must be an n -by- n matrix, where n is the number of states.
- **B** must be an n -by- m matrix, where m is the number of inputs.
- **C** must be an r -by- n matrix, where r is the number of outputs.
- **D** must be an r -by- m matrix.

The block accepts one input and generates one output. The width of the input vector is the number of columns in the **B** and **D** matrices. The width of the output vector is the number of rows in the **C** and **D** matrices. To define the initial state vector, use the **Initial conditions** parameter.

To specify a vector or matrix of zeros for **A**, **B**, **C**, **D**, or **Initial conditions**, use the zeros function.

Block Behavior for Empty Matrices

When the matrices **A**, **B**, and **C** are empty (for example, `[]`), the functionality of the block becomes $y(n) = Du(n)$. If the **Initial conditions** vector is also empty, the block uses an initial state vector of zeros.

Ports

Input

Port_1 – Input signal

scalar | vector

Input vector, where the width equals the number of columns in the **B** and **D** matrices. For more information, see “Description” on page 1-439.

Tip For integer and fixed-point input signals, use the Fixed-Point State-Space block.

Data Types: `single` | `double`

Output

Port_1 — Output vector

scalar | vector

Output vector, with width equal to the number of rows in the **C** and **D** matrices. For more information, see “Description” on page 1-439.

Data Types: `single` | `double`

Parameters

Main

A — Matrix coefficient A

1 (default) | scalar | vector | matrix

Specify the matrix coefficient A, as a real-valued n -by- n matrix, where n is the number of states. For more information on the matrix coefficients, see “Description” on page 1-439.

Programmatic Use

Block Parameter: A

Type: character vector

Values: scalar | vector | matrix

Default: '1'

B — Matrix coefficient B

1 (default) | scalar | vector | matrix

Specify the matrix coefficient B, as a real-valued n -by- m matrix, where n is the number of states, and m is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-439.

Programmatic Use

Block Parameter: B

Type: character vector

Values: scalar | vector | matrix

Default: '1'

C — Matrix coefficient, C

1 (default) | scalar | vector | matrix

Specify the matrix coefficient C, as a real-valued r -by- n matrix, where r is the number of outputs, and n is the number of states. For more information on the matrix coefficients, see “Description” on page 1-439.

Programmatic Use

Block Parameter: C

Type: character vector

Values: scalar | vector | matrix

Default: '1'

D — Matrix coefficient, D

1 (default) | scalar | vector | matrix

Specify the matrix coefficient **D**, as a real-valued r -by- m matrix, where r is the number of outputs, and m is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-439.

Programmatic Use

Block Parameter: D

Type: character vector

Values: scalar | vector | matrix

Default: '1'

Initial conditions — Initial state vector

0 (default) | scalar | vector

Specify the initial state vector as a scalar or vector. The initial state vector cannot include `inf` or `NaN` values.

Programmatic Use

Block Parameter: InitialCondition

Type: character vector

Values: scalar | vector

Default: '0'

Sample time (-1 for inherited) — Interval between samples

-1 (default) | scalar | vector

Specify the time interval between samples. See “Specify Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

State Attributes

State name — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use**Block Parameter:** StateName**Type:** character vector**Values:** unique name**Default:** ''**State name must resolve to Simulink signal object — Require state name resolve to a signal object**

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

Programmatic Use**Block Parameter:** StateMustResolveToSignalObject**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Signal object class — Custom storage class package name**

Simulink.Signal (default) | <StorageClass.PackageName>

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Programmatic Use**Block Parameter:** StateSignalObject**Type:** character vector**Values:** 'Simulink.Signal' | '<StorageClass.PackageName>'**Default:** 'Simulink.Signal'**Code generation storage class — State storage class for code generation**

Auto (default) | Model default | ExportedGlobal | ImportedExtern | ImportedExternPointer | BitField (Custom) | Model default | ExportToFile (Custom) | ImportFromFile (Custom) | FileScope (Custom) | AutoScope (Custom) | Struct (Custom) | GetSet (Custom) | Reusable (Custom)

Select state storage class for code generation.

- Auto is the appropriate storage class for states that you do not need to interface to external code.

- *StorageClass* applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

Dependencies

To enable this parameter, specify a value for **State name**.

Programmatic Use

Block Parameter: StateStorageClass

Type: character vector

Values: 'Auto' | 'Model default' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...

Default: 'Auto'

TypeQualifier — Storage type qualifier

'' (default) | const | volatile | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Minimum and Maximum values of the signal object

For more information, see “Data Objects”.

Dependencies

To enable this parameter, set **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `Model default`. This parameter is hidden unless you previously set its value.

Programmatic Use

Block Parameter: RTWStateStorageTypeQualifier

Type: character vector

Values: '' | 'const' | 'volatile' | ...

Default: ''

Discrete-Time Integrator

Perform discrete-time integration or accumulation of signal

Library: Simulink / Commonly Used Blocks
 Simulink / Discrete
 HDL Coder / Discrete
 HDL Coder / HDL Floating Point Operations

Description

Use the Discrete-Time Integrator block in place of the Integrator block to create a purely discrete model. With the Discrete-Time Integrator block, you can:

- Define initial conditions on the block dialog box or as input to the block
- Define an input gain (K) value
- Output the block state
- Define upper and lower limits on the integral
- Reset the state with an additional reset input

Output Equations

With the first time step, block state $n = 0$, with either initial output $y(0) = IC$ or initial state $x(0) = IC$, depending on the **Initial condition setting** parameter value.

For a given step $n > 0$ with simulation time $t(n)$, Simulink updates output $y(n)$ as follows:

- Forward Euler method:

$$y(n) = y(n-1) + K*[t(n) - t(n-1)]*u(n-1)$$

- Backward Euler method:

$$y(n) = y(n-1) + K*[t(n) - t(n-1)]*u(n)$$

- Trapezoidal method:

$$y(n) = y(n-1) + K*[t(n)-t(n-1)]*[u(n)+u(n-1)]/2$$

Simulink automatically selects a state-space realization of these output equations depending on the block sample time, which can be explicit or triggered. When using explicit sample time, $t(n) - t(n-1)$ reduces to the sample time T for all $n > 0$.

Integration and Accumulation Methods

This block can integrate or accumulate a signal using a forward Euler, backward Euler, or trapezoidal method. Assume that u is the input, y is the output, and x is the state. For a given step n , Simulink updates $y(n)$ and $x(n+1)$. In integration mode, T is the block sample time (ΔT in the case of triggered sample time). In accumulation mode, $T = 1$. The block sample time determines when the output is computed but not the output value. K is the gain value. Values clip according to upper or lower limits.

Forward Euler Method

Forward Euler method (default), also known as forward rectangular, or left-hand approximation

The software approximates $1/s$ as $T/(z-1)$. The expressions for the output of the block at step n are:

$$\begin{aligned}x(n+1) &= x(n) + K*T*u(n) \\y(n) &= x(n)\end{aligned}$$

The block uses these steps to compute the output:

$$\begin{aligned}\text{Step } 0: \quad & y(0) = \text{IC (clip if necessary)} \\ & x(1) = y(0) + K*T*u(0)\end{aligned}$$

$$\begin{aligned}\text{Step } 1: \quad & y(1) = x(1) \\ & x(2) = x(1) + K*T*u(1)\end{aligned}$$

$$\begin{aligned}\text{Step } n: \quad & y(n) = x(n) \\ & x(n+1) = x(n) + K*T*u(n) \text{ (clip if necessary)}\end{aligned}$$

Using this method, input port 1 does not have direct feedthrough.

Backward Euler Method

Backward Euler method, also known as backward rectangular or right-hand approximation

The software approximates $1/s$ as $T*z/(z-1)$. The resulting expression for the output of the block at step n is

$$y(n) = y(n-1) + K*T*u(n).$$

Let $x(n) = y((n) - 1)$. The block uses these steps to compute the output.

- If the parameter **Initial condition setting** is set to Output or Auto for triggered and function-call subsystems:

$$\begin{aligned}\text{Step } 0: \quad & y(0) = \text{IC (clipped if necessary)} \\ & x(1) = y(0)\end{aligned}$$

- If the parameter **Initial condition setting** is set to Auto for non-triggered subsystems:

$$\begin{aligned}\text{Step } 0: \quad & x(0) = \text{IC (clipped if necessary)} \\ & x(1) = y(0) = x(0) + K*T*u(0)\end{aligned}$$

$$\begin{aligned}\text{Step } 1: \quad & y(1) = x(1) + K*T*u(1) \\ & x(2) = y(1)\end{aligned}$$

$$\begin{aligned}\text{Step } n: \quad & y(n) = x(n) + K*T*u(n) \\ & x(n+1) = y(n)\end{aligned}$$

Using this method, input port 1 has direct feedthrough.

Trapezoidal Method

For this method, the software approximates $1/s$ as $T/2*(z+1)/(z-1)$.

When T is fixed (equal to the sampling period), the expressions to compute the output are:

$$x(n) = y(n-1) + K*T/2*u(n-1)$$

$$y(n) = x(n) + K*T/2*u(n)$$

- If the parameter **Initial condition setting** is set to Output or Auto for triggered and function-call subsystems:

$$\text{Step } 0: \quad \begin{aligned} y(0) &= \text{IC (clipped if necessary)} \\ x(1) &= y(0) + K*T/2*u(0) \end{aligned}$$

- If the parameter **Initial condition setting** is set to Auto for non-triggered subsystems:

$$\text{Step } 0: \quad \begin{aligned} x(0) &= \text{IC (clipped if necessary)} \\ y(0) &= x(0) + K*T/2*u(0) \\ x(1) &= y(0) + K*T/2*u(0) \end{aligned}$$

$$\text{Step } 1: \quad \begin{aligned} y(1) &= x(1) + K*T/2*u(1) \\ x(2) &= y(1) + K*T/2*u(1) \end{aligned}$$

$$\text{Step } n: \quad \begin{aligned} y(n) &= x(n) + K*T/2*u(n) \\ x(n+1) &= y(n) + K*T/2*u(n) \end{aligned}$$

Here, $x(n+1)$ is the best estimate of the next output. It is not the same as the state, in that $x(n)$ is not equal to $y(n)$.

Using this method, input port 1 has direct feedthrough.

When T is a Variable

When T is a variable (for example, obtained from the triggering times), the block uses these steps to compute the output.

- If the parameter **Initial condition setting** is set to Output or Auto for triggered and function-call subsystems:

$$\text{Step } 0: \quad \begin{aligned} y(0) &= \text{IC (clipped if necessary)} \\ x(1) &= y(0) \end{aligned}$$

- If the parameter **Initial condition setting** is set to Auto for non-triggered subsystems:

$$\text{Step } 0: \quad \begin{aligned} x(0) &= \text{IC (clipped if necessary)} \\ x(1) &= y(0) = x(0) + K*T/2*u(0) \end{aligned}$$

$$\text{Step } 1: \quad \begin{aligned} y(1) &= x(1) + T/2*(u(1) + u(0)) \\ x(2) &= y(1) \end{aligned}$$

$$\text{Step } n: \quad \begin{aligned} y(n) &= x(n) + T/2*(u(n) + u(n-1)) \\ x(n+1) &= y(n) \end{aligned}$$

Define Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, set the **Initial condition source** parameter to **internal** and enter the value in the **Initial condition** text box.
- To provide the initial conditions from an external source, set the **Initial condition source** parameter to **external**. An additional input port appears on the block.

When to Use the State Port

Use the state port instead of the output port:

- When the output of the block is fed back into the block through the reset port or the initial condition port, causing an algebraic loop. For an example, see the `sldemo_bounce_two_integrators` model.
- When you want to pass the state from one conditionally executed subsystem to another, which can cause timing problems. For an example, see the `sldemo_clutch` model.

You can work around these problems by passing the state through the state port rather than the output port. Simulink generates the state at a slightly different time from the output, which protects your model from these problems. To output the block state, select the **Show state port** check box. The state port appears on the top of the block.

Limit the Integral

To keep the output within certain levels, select the **Limit output** check box and enter the limits in the corresponding text box. Doing so causes the block to function as a limited integrator. When the output reaches the limits, the integral action turns off to prevent integral windup. During a simulation, you can change the limits but you cannot change whether the output is limited. The table shows how the block determines output.

Integral	Output
Less than or equal to the Lower saturation limit and the input is negative	Held at the Lower saturation limit
Between the Lower saturation limit and the Upper saturation limit	The integral
Greater than or equal to the Upper saturation limit and the input is positive	Held at the Upper saturation limit

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A new saturation port appears below the block output port.

The saturation signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- -1 indicates that the lower limit is being applied.

Reset the State

The block resets its state to the specified initial condition, based on an external signal. To cause the block to reset its state, select one of the **External reset** parameter options. A reset port appears that indicates the reset trigger type.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results. To resolve this loop, feed the output of the block state port into the reset port instead. To access the block state, select the **Show state port** check box.

Reset Trigger Types

The **External reset** parameter lets you determine the attribute of the reset signal that triggers the reset. The trigger options include:

- **rising** - Resets the state when the reset signal has a rising edge. For example, this figure shows the effect that a rising reset trigger has on backward Euler integration.

- **falling** — Resets the state when the reset signal has a falling edge. For example, this figure shows the effect that a falling reset trigger has on backward Euler integration.

- **either** — Resets the state when the reset signal rises or falls. For example, the following figure shows the effect that an either reset trigger has on backward Euler integration.

- **level** — Resets and holds the output to the initial condition while the reset signal is nonzero. For example, this figure shows the effect that a level reset trigger has on backward Euler integration.

- **sampled level** — Resets the output to the initial condition when the reset signal is nonzero. For example, this figure shows the effect that a sampled level reset trigger has on backward Euler integration.

The sampled level reset option requires fewer computations, making it more efficient than the level reset option.

Note For the Discrete-Time Integrator block, all trigger detections are based on signals with positive values. For example, a signal changing from -1 to 0 is not considered a rising edge, but a signal changing from 0 to 1 is.

Behavior in Simplified Initialization Mode

Simplified initialization mode is enabled when you set **Underspecified initialization detection** to **Simplified** in the Configuration Parameters dialog box. If you use simplified initialization mode, the behavior of the Discrete-Time Integrator block differs from classic initialization mode. The new initialization behavior is more robust and provides more consistent behavior in these cases:

- In algebraic loops
- On enable and disable
- When comparing results using triggered sample time against explicit sample time, where the block is triggered at the same rate as the explicit sample time

Simplified initialization mode enables easier conversion from Continuous-Time Integrator blocks to Discrete-Time Integrator blocks, because the initial conditions have the same meaning for both blocks.

For more information on classic and simplified initialization modes, see “Underspecified initialization detection”.

Enable and Disable Behavior with Initial Condition Setting set to Output

When you use simplified initialization mode with **Initial condition setting** set to **Output** for triggered and function-call subsystems, the enable and disable behavior of the block is simplified as follows.

At disable time t_d :

$$y(t_d) = y(t_d - 1)$$

At enable time t_e :

- If the parent subsystem control port has **States when enabling** set to **reset**:

$$y(t_e) = IC.$$

- If the parent subsystem control port has **States when enabling** set to held:

$$y(t_e) = y(t_d).$$

The following figure shows this condition.

Iterator Subsystems

When using simplified initialization mode, you cannot place the Discrete-Time Integrator block in an iterator subsystem block.

In simplified initialization mode, Iterator subsystems do not maintain elapsed time. Thus, if a Discrete-Time Integrator block, which needs elapsed time, is placed inside an iterator subsystem block, Simulink reports an error.

Behavior in an Enabled Subsystem Inside a Function-Call Subsystem

Suppose you have a function-call subsystem that includes an enabled subsystem, which contains a Discrete-Time Integrator block. The following behavior applies.

Integrator Method	Sample Time Type of Function-Call Trigger Port	Value of delta T When Function-Call Subsystem Executes for the First Time After Enabled	Reason for Behavior
Forward Euler	Triggered	$t - t_{start}$	When the function-call subsystem executes for the first time, the integrator algorithm uses t_{start} as the previous simulation time.
Backward Euler and Trapezoidal	Triggered	$t - t_{previous}$	When the function-call subsystem executes for the first time, the integrator algorithm uses $t_{previous}$ as the previous simulation time.
Forward Euler, Backward Euler, and Trapezoidal	Periodic	Sample time of the function-call generator	In periodic mode, the Discrete-Time Integrator block uses sample time of the function-call generator for ΔT .

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

IC – Initial conditions of the states

scalar | vector | matrix

Initial conditions of the states, specified as a finite scalar, vector, or matrix.

Dependencies

To enable this port, set **Initial condition source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Discrete-time integration or accumulation of input

scalar | vector | matrix

Discrete-time integration or accumulation of the input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Port_2 – Saturation output

`scalar` | `vector` | `matrix`

Signal indicating when the state is being limited, specified as a scalar, vector, or matrix. The signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- -1 indicates that the lower limit is being applied.

Dependencies

To enable this port, select the **Show saturation port** check box.

Data Types: `single` | `double` | `int8`

Port_3 – State output

`scalar` | `vector` | `matrix`

Block states, output as a scalar, vector, or matrix. By default, the block adds this port to the top of the block icon. Use the state port when:

- The output of the block is fed back into the block through the reset port or the initial condition port, causing an algebraic loop. For an example, see the `sldemo_bounce_two_integrators` model.
- You want to pass the state from one conditionally executed subsystem to another, which can cause timing problems. For an example, see the `sldemo_clutch` model.

For more information, see “When to Use the State Port” on page 1-448.

Dependencies

To enable this port, select the **Show state port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main

Integrator method – Accumulation method

Integration: `Forward Euler (default)` | `Integration: Backward Euler` | `Integration: Trapezoidal` | `Accumulation: Forward Euler` | `Accumulation: Backward Euler` | `Accumulation: Trapezoidal`

Specify the integration or accumulation method. See “Output Equations” on page 1-445 and “Integration and Accumulation Methods” on page 1-445 for more information.

Programmatic Use

Block Parameter: `IntegratorMethod`

Type: character vector

Values: 'Integration: Forward Euler' | 'Integration: Backward Euler' | 'Integration: Trapezoidal' | 'Accumulation: Forward Euler' | 'Accumulation: Backward Euler' | 'Accumulation: Trapezoidal'
Default: 'Integration: Forward Euler'

Gain value — Value to multiply with integrator input

1.0 (default) | scalar | vector

Specify a scalar, vector, or matrix by which to multiply the integrator input. Each element of the gain must be a positive real number.

- Specifying a value other than 1.0 (the default) is semantically equivalent to connecting a Gain block to the input of the integrator.
- Valid entries include:
 - `double(1.0)`
 - `single(1.0)`
 - `[1.1 2.2 3.3 4.4]`
 - `[1.1 2.2; 3.3 4.4]`

Tip Using this parameter to specify the input gain eliminates a multiplication operation in the generated code. However, this parameter must be nontunable to realize this benefit. If you want to tune the input gain, set this parameter to 1.0 and use an external Gain block to specify the input gain.

Programmatic Use

Block Parameter: `gainval`

Type: character vector

Values: scalar | vector

Default: '1.0'

External reset — Select when to reset states to initial conditions

`none` (default) | `rising` | `falling` | `either` | `level` | `sampled level`

Select the type of trigger event that resets the states to their initial conditions:

- `none` — Do not reset the state to initial conditions.
- `rising` — Reset the state when the reset signal has a rising edge.
- `falling` — Reset the state when the reset signal has a falling edge.
- `either` — Reset the state when the reset signal rises or falls.
- `level` — Reset and hold the output to the initial condition while the reset signal is nonzero.
- `sampled level` — Reset the output to the initial condition when the reset signal is nonzero.

For more information, see “Reset the State” on page 1-449 and “Reset Trigger Types” on page 1-449.

Programmatic Use

Block Parameter: `ExternalReset`

Type: character vector

Values: 'none' | 'rising' | 'falling' | 'either' | 'level' | 'sampled level'

Default: 'none'

Initial condition source — Select source of initial condition

internal (default) | external

Select source of initial condition:

- internal — Get the initial conditions of the states from the **Initial condition** block parameter.
- external — Get the initial conditions of the states from an external block, via the **IC** input port.

Dependencies

Selecting `internal` enables the **Initial condition** parameter.

Selecting `external` disables the **Initial condition** parameter and enables the **IC** input port.

Programmatic Use

Block Parameter: InitialConditionSource

Type: character vector, string

Values: 'internal' | 'external'

Default: 'internal'

Initial condition — Initial condition of states

0 (default) | scalar | vector | matrix

Specify initial condition of the block states. The minimum and maximum values are bound by the **Output minimum** and **Output maximum** block parameters.

Tip Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

To enable this parameter, set the **Initial condition source** to `internal`.

Programmatic Use

Block Parameter: InitialCondition

Type: character vector, string

Values: scalar | vector | matrix

Default: '0'

Initial condition setting — Select where to apply the initial condition

Auto (default) | Output | Compatibility

Select whether to apply the value of the **Initial condition** parameter to the block state or block output. The initial condition is also the reset value.

- Auto — Block chooses where to apply the **Initial condition** parameter.
 - If the block is in a non-triggered subsystem and **Integrator method** is set to an integration method, set initial conditions:

$$x(0) = IC$$

At reset:

$$x(n) = IC$$

- If the block is in a triggered or function-call subsystem and **Integrator method** is set to an integration method, set initial conditions as if **output** was selected.
- **Output** — Use this option when the block is in a triggered or a function-call subsystem and **Integrator method** is set to an integration method.

Set initial conditions:

$$y(0) = IC$$

At reset:

$$y(n) = IC$$

- **Compatibility** — This option is present to provide backward compatibility. You cannot select this option for Discrete-Time Integrator blocks in Simulink models but you can select it for Discrete-Time Integrator blocks in a library. Use this option to maintain compatibility with Simulink models created before R2014a.

Prior to R2014a, the option **Auto** was known as **State only (most efficient)**. The option **Output** was known as **State and output**. The behavior of the block with the option **Compatibility** is as follows.

- If **Underspecified initialization detection** is set to **Classic**, the **Initial condition setting** parameter behaves as **Auto**.
- If **Underspecified initialization detection** is set to **Simplified**, the **Initial condition setting** parameter behaves as **Output**.

Note This parameter was named **Use initial condition as initial and reset value for** in Simulink before R2014a.

Programmatic Use

Block Parameter: InitialConditionSetting

Type: character vector

Value: 'Auto' | 'Output' | 'Compatibility'

Default: 'Auto'

Sample time (-1 for inherited) — Interval between samples

-1 (default) | scalar | vector

Enter the discrete time interval between steps.

By default, the block uses a discrete sample time of 1. To set a different sample time, enter another discrete value, such as 0.1.

See “Specify Sample Time” for more information.

Tips

- Do not specify a sample time of 0. This value specifies a continuous sample time, which the Discrete-Time Integrator block does not support.
- Do not specify a sample time of **inf** or **NaN** because these values are not discrete.

- If you specify -1 to inherit the sample time from an upstream block, verify that the upstream block uses a discrete sample time. For example, the Discrete-Time Integrator block cannot inherit a sample time of 0.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar | vector**Default:** '-1'**Limit output — Limit block output values to specified range**

off (default) | on

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

- Selecting this check box limits the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.
- Clearing this check box does not limit the block's output values.

Dependencies

Selecting this parameter enables the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use**Block Parameter:** LimitOutput**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Upper saturation limit — Upper limit for the integral**

inf (default) | scalar | vector | matrix

Specify the upper limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use**Block Parameter:** UpperSaturationLimit**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** 'inf'**Lower saturation limit — Lower limit for the integral**

-inf (default) | scalar | vector | matrix

Specify the lower limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use**Block Parameter:** LowerSaturationLimit**Type:** character vector , string**Values:** scalar | vector | matrix**Default:** '-inf'**Show saturation port — Enable saturation output port**

off (default) | on

Select this check box to add a saturation output port to the block. When you clear this check box, the block does not have a saturation output port.

Dependencies

Selecting this parameter enables a saturation output port.

Programmatic Use**Block Parameter:** ShowSaturationPort**Type:** character vector , string**Values:** 'off' | 'on'**Default:** 'off'**Show state port — Enable state output port**

off (default) | on

Select this check box to add a state output port to the block. When you clear this check box, the block does not have a state output port.

Dependencies

Selecting this parameter enables a state output port.

Programmatic Use**Block Parameter:** ShowStatePort**Type:** character vector , string**Values:** 'off' | 'on'**Default:** 'off'**Ignore limit and reset when linearizing — Treat block as not resettable**

off (default) | on

Select this check box to have Simulink linearization commands treat this block as not resettable and as having no limits on its output, regardless of the settings of the block reset and output limitation options.

Tip Ignoring the limit and resetting allows you to linearize a model around an operating point. This point may cause the integrator to reset or saturate.

Programmatic Use**Block Parameter:** IgnoreLimit**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Data type — Output data type**

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType. For more information, see “Control Signal Data Types”.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, i.e., a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Use data type of the driving block.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'**Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode — Specify the rounding mode for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Floor'**See Also**

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- **off** — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- **on** — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
 - In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.
-

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

State Attributes

State name — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Dependencies

When you specify a value for **State name** and click **Apply**, you enable the **State name must resolve to Simulink signal object** parameter.

Programmatic Use

Parameter: StateName

Type: character vector

Values: unique name

Default: ''

State name must resolve to Simulink signal object — Require state names resolve to signal object

Off (default) | Boolean

Specify if requiring that state name resolve to Simulink signal objects or not. If selected, the software generates an error at run time if you specify a state name that does not match the name of a Simulink signal object.

Dependency

Enabled when you give the parameter **State name** a value and set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

Programmatic Use

Block Parameter: StateMustResolveToSignalObject

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Signal object class — Custom storage class package name

Simulink.Signal (default)

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Programmatic Use

Block Parameter: StateSignalObject

Type: character vector

Values: 'Simulink.Signal' | '<StorageClass.PackageName>'

Default: 'Simulink.Signal'

Code generation storage class — Storage class for code generation

Auto (default) | Model default | ExportedGlobal | ImportedExtern |

ImportedExternPointer | Bitfield (Custom) | Volatile (Custom) | ExportToFile

(Custom) | ImportFromFile (Custom) | FileScope (Custom) | Struct (Custom) | GetSet

(Custom) | Reusable (Custom)

Select state storage class for code generation. If you do not need to interface to external code, select `Auto`.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Programmatic Use**Block Parameter:** StateStorageClass**Type:** character vector**Values:** 'Auto' | 'Model default' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom'**Default:** 'Auto'**TypeQualifier — Storage type qualifier**

'' (default) | const | volatile | ...

Specify a storage type qualifier such as const or volatile.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Dependencies

To enable this parameter, set **Code generation storage class** to ExportedGlobal, ImportedExtern, ImportedExternPointer, or Model default. This parameter is hidden unless you previously set its value.

Programmatic Use**Block Parameter:** RTWStateStorageTypeQualifier**Type:** character vector**Values:** '' | 'const' | 'volatile' | ...**Default:** ''**Block Characteristics**

Data Types	double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Depends on absolute time when used inside a triggered subsystem hierarchy.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is <code>inherit</code> . See also “MantissaMultiplyStrategy” (HDL Coder).

Restrictions

- State ports are not supported for HDL code generation. Clear the **Show state port** option.
- External initial conditions are not supported for HDL code generation. Set **Initial condition source** to `Internal`.
- **External Reset** must be set to `none`, `rising`, or `falling`.
- Width of input and output signals must not exceed 32 bits.
- Continuous sample time is not supported. Use a discrete sample time for the block.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Discrete Transfer Fcn

Implement discrete transfer function

Library: Simulink / Discrete
 HDL Coder / Discrete
 HDL Coder / HDL Floating Point Operations

Description

The Discrete Transfer Fcn block implements the z -transform transfer function as follows:

$$H(z) = \frac{num(z)}{den(z)} = \frac{num_0 z^m + num_1 z^{m-1} + \dots + num_m}{den_0 z^n + den_1 z^{n-1} + \dots + den_n}$$

where $m+1$ and $n+1$ are the number of numerator and denominator coefficients, respectively. num and den contain the coefficients of the numerator and denominator in descending powers of z . num can be a vector or matrix, while den must be a vector. The order of the denominator must be greater than or equal to the order of the numerator.

Specify the coefficients of the numerator and denominator polynomials in descending powers of z . This block lets you use polynomials in z to represent a discrete system, a method that control engineers typically use. Conversely, the Discrete Filter block lets you use polynomials in z^{-1} (the delay operator) to represent a discrete system, a method that signal processing engineers typically use. The two methods are identical when the numerator and denominator polynomials have the same length.

The Discrete Transfer Fcn block applies the z -transform transfer function to each independent channel of the input. The **Input processing** parameter allows you to specify whether the block treats each column of the input as an individual channel (frame-based processing) or each element of the input as an individual channel (sample-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

Specifying Initial States

Use the **Initial states** parameter to specify initial filter states. To determine the number of initial states you must specify and how to specify them, use the following tables.

Frame-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> Column vector (K-by-1) Unoriented vector (K) 	1	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) 	<ul style="list-style-type: none"> Scalar Column vector (M-by-1)
<ul style="list-style-type: none"> Row vector (1-by-N) Matrix (K-by-N) 	N	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-N) 	<ul style="list-style-type: none"> Scalar Matrix (M-by-N)

Sample-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> Scalar 	1	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) 	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M)
<ul style="list-style-type: none"> Row vector (1-by-N) Column vector (N-by-1) Unoriented vector (N) 	N	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-N) 	<ul style="list-style-type: none"> Scalar
<ul style="list-style-type: none"> Matrix (K-by-N) 	$K \times N$	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-$(K \times N)$) 	<ul style="list-style-type: none"> Scalar

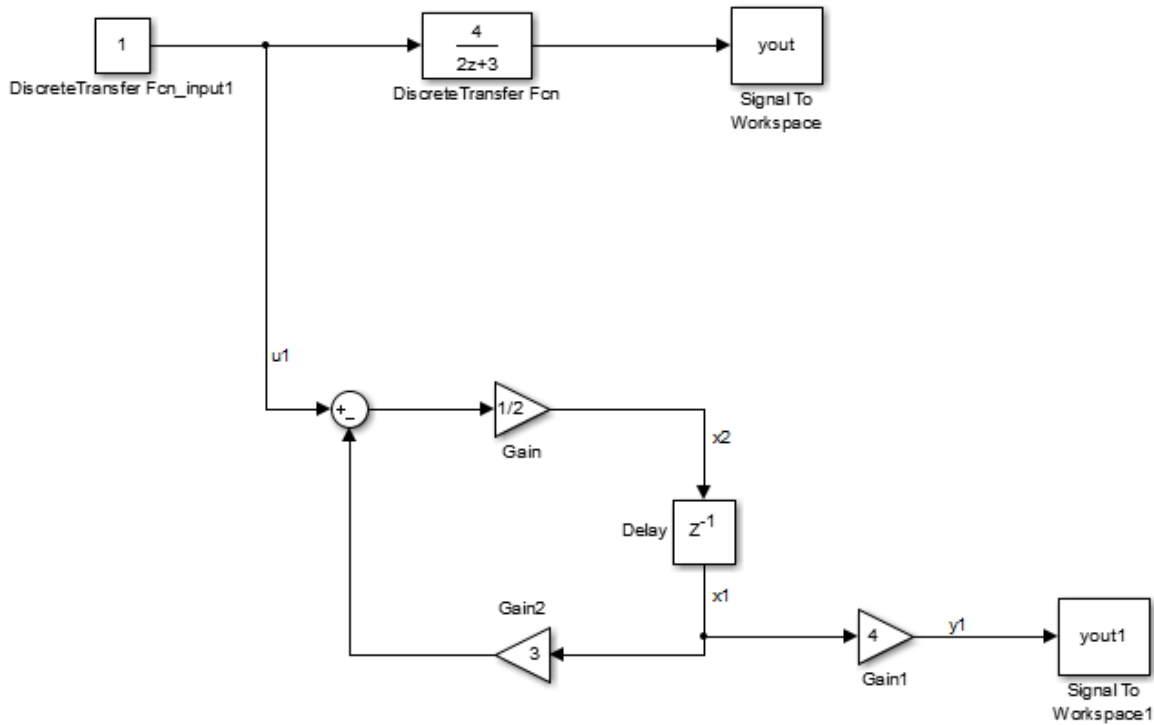

When the **Initial states** is a scalar, the block initializes all filter states to the same scalar value. To initialize all states to zero, enter 0. When the **Initial states** is a vector or a matrix, each vector or matrix element specifies a unique initial state for a corresponding delay element in a corresponding channel:

- The vector length must equal the number of delay elements in the filter, $M = \max(\text{number of zeros, number of poles})$.
- The matrix must have the same number of rows as the number of delay elements in the filter, $M = \max(\text{number of zeros, number of poles})$. The matrix must also have one column for each channel of the input signal.

The following example shows the relationship between the initial filter output and the initial input and state. Given an initial input u_1 , the first output y_1 is related to the initial state $[x_1, x_2]$ and initial input by as follows:

$$y1 = 4x1$$

$$x2 = 1/2(u1 - 3x1)$$

Ports

Input

u – Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | fixed point

Num – Numerator coefficients

scalar | vector | matrix

Coefficients of the numerator polynomial specified as a vector or matrix in descending powers of z . Use a row vector to specify the coefficients for a single numerator polynomial. Use a matrix to specify

coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps. The order of the denominator must be greater than or equal to the order of the numerator.

Dependencies

To enable this port, set **Numerator Source** to Input port.

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Den — Denominator coefficients

scalar | vector | matrix

Coefficients of the denominator polynomial specified as a vector in descending powers of z . Use a row vector to specify the coefficients for a single denominator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps. The order of the denominator must be greater than or equal to the order of the numerator.

Dependencies

To enable this port, set **Denominator Source** to Input port.

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

External reset — External reset signal

scalar

External reset signal, specified as a scalar. When the specified trigger event occurs, the block resets the states to their initial conditions.

Tip The icon for this port changes based on the value of the **External reset** parameter.

Dependencies

To enable this port, set **External reset** to Rising, Falling, Either, Level, or Level hold.

Limitations

The reset signal must be a scalar of type single, double, Boolean, or integer. Fixed-point data types, except for `ufix1`, are not supported.

Data Types: `single` | `double` | `Boolean` | `int8` | `int16` | `int32` | `fixed point`

x0 — Initial states

scalar | vector | matrix

Initial states, specified as a scalar, vector, or matrix. For more information about specifying states, see “Specifying Initial States” on page 1-468. States are complex when either the input or the coefficients are complex.

Dependencies

To enable this port, set **Initial states Source** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Output**Port_1 — Output signal**

`scalar` | `vector` | `matrix`

Output signal specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Parameters**Main****Numerator Source — Source of numerator coefficients**

`Dialog` (default) | `Input port`

Specify the source of the numerator coefficients as `Dialog` or `Input port`.

Programmatic Use

Block Parameter: `NumeratorSource`

Type: character vector

Values: `'Dialog'` | `'Input port'`

Default: `'Dialog'`

Numerator Value — Numerator coefficients

`[1]` (default) | `scalar` | `vector` | `matrix`

Numerator coefficients of the discrete transfer function. To specify the coefficients, set the **Source** to `Dialog`. Then, enter the coefficients in **Value** as descending powers of z . Use a row vector to specify the coefficients for a single numerator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps.

Dependencies

To enable this parameter, set the **Numerator Source** to `Dialog`.

Programmatic Use

Block Parameter: `Numerator`

Type: character vector

Values: `scalar` | `vector` | `matrix`

Default: `'[1]'`

Denominator Source — Source of denominator coefficients

`Dialog` (default) | `Input port`

Specify the source of the denominator coefficients as `Dialog` or `Input port`.

Programmatic Use

Block Parameter: `DenominatorSource`

Type: character vector

Values: 'Dialog' | 'Input port'
Default: 'Dialog'

Denominator Value — Denominator coefficients

[1 0.5] (default) | scalar | vector | matrix

Denominator coefficients of the discrete transfer function. To specify the coefficients, set the **Source** to **Dialog**. Then, enter the coefficients in **Value** as descending powers of z . Use a row vector to specify the coefficients for a single denominator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps.

Dependencies

To enable this parameter, set the **Denominator Source** to **Dialog**.

Programmatic Use

Block Parameter: Denominator

Type: character vector

Values: scalar | vector | matrix

Default: '[1 0.5]'

Initial states Source — Source of initial states

Dialog (default) | Input port

Specify the source of the initial states as **Dialog** or **Input port**.

Programmatic Use

Block Parameter: InitialStatesSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Initial states Value — Initial filter states

0 (default) | scalar | vector | matrix

Specify the initial filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-468.

Dependencies

To enable this parameter, set **Initial states Source** to **Dialog**.

Programmatic Use

Block Parameter: InitialStates

Type: character vector

Values: scalar | vector | matrix

Default: '0'

External reset — External state reset

None (default) | Rising | Falling | Either | Level | Level hold

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset

Reset Mode	Behavior
Rising	Reset on a rising edge
Falling	Reset on a falling edge
Either	Reset on either a rising or falling edge
Level	Reset in either of these cases: <ul style="list-style-type: none"> • When the reset signal is nonzero at the current time step • When the reset signal value changes from nonzero at the previous time step to zero at the current time step
Level hold	Reset when the reset signal is nonzero at the current time step

Programmatic Use**Block Parameter:** ExternalReset**Type:** character vector**Values:** 'None' | 'Rising' | 'Falling' | 'Either' | 'Level' | 'Level hold'**Default:** 'None'**Input processing — Sample- or frame-based processing**

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing.

- Elements as channels (sample based) — Process each element of the input as an independent channel.
- Columns as channels (frame based) — Process each column of the input as an independent channel.

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use**Block Parameter:** InputProcessing**Type:** character vector**Values:** 'Elements as channels (sample based)' | 'Columns as channels (frame based)'**Default:** 'Elements as channels (sample based)'**Optimize by skipping divide by leading denominator coefficient (a0) — Skip divide by a0**

off (default) | on

Select when the leading denominator coefficient, a_0 , equals 1. This parameter optimizes your code.When you select this check box, the block does not perform a divide-by- a_0 either in simulation or in the generated code. An error occurs if a_0 is not equal to one.

When you clear this check box, the block is fully tunable during simulation, and performs a divide-by- a_0 in both simulation and code generation.

Programmatic Use

Block Parameter: `a0EqualsOne`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time (-1 for inherited) – Interval between samples

-1 (default) | scalar | vector

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: `SampleTime`

Type: character vector

Values: scalar | vector

Default: '-1'

Data Types

State – State data type

Inherit: Same as input (default) | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Numerator coefficients – Numerator coefficient data type

Inherit: Inherit via internal rule (default) | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the numerator coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** NumCoeffDataTypeStr**Type:** character vector**Values:** 'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'**Default:** 'Inherit: Inherit via internal rule'**Numerator coefficient minimum — Minimum value of numerator coefficients**

[] (default) | scalar

Specify the minimum value that a numerator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** NumCoeffMin**Type:** character vector**Values:** scalar**Default:** '[]'**Numerator coefficient maximum — Maximum value of numerator coefficients**

[] (default) | scalar

Specify the maximum value that a numerator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** NumCoeffMax**Type:** character vector**Values:** scalar**Default:** '[]'**Numerator product output — Numerator product output data type**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the product output data type for the numerator coefficients. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** NumProductDataTypeStr**Type:** character vector**Values:** 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'**Default:** 'Inherit: Inherit via internal rule'**Numerator accumulator — Numerator accumulator data type**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the accumulator data type for the numerator coefficients. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** NumAccumDataTypeStr**Type:** character vector**Values:** 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'**Default:** 'Inherit: Inherit via internal rule'**Denominator coefficients — Denominator coefficient data type**

Inherit: Inherit via internal rule (default) | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the denominator coefficient data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** DenCoeffDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>
Default: 'Inherit: Same wordlength as input'

Denominator coefficient minimum — Minimum value of denominator coefficients

[] (default) | scalar

Specify the minimum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: DenCoeffMin

Type: character vector

Values: scalar

Default: '[]'

Denominator coefficient maximum — Maximum value of denominator coefficients

[] (default) | scalar

Specify the maximum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: DenCoeffMax

Type: character vector

Values: scalar

Default: '[]'

Denominator product output — Denominator product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the product output data type for the denominator coefficients. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: DenProductDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Denominator accumulator — Denominator accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the accumulator data type for the denominator coefficients. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: DenAccumDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Output — Output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via interal rule'

Output minimum — Minimum value of output

[] (default) | scalar

Specify the minimum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: scalar

Default: '[]'

Output maximum — Maximum value of output

[] (default) | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: scalar

Default: '[]'

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Floor'**Saturate on integer overflow — Method of overflow action**

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

State Attributes

State name — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use

Block Parameter: StateName

Type: character vector

Values: unique name

Default: ' '

State name must resolve to Simulink signal object — Require state name resolve to a signal object

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

Programmatic Use

Block Parameter: StateMustResolveToSignalObject

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Signal object class — Custom storage class package name

Simulink.Signal (default) | <StorageClass.PackageName>

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Programmatic Use

Block Parameter: StateSignalObject

Type: character vector

Values: 'Simulink.Signal' | '<StorageClass.PackageName>'

Default: 'Simulink.Signal'

Code generation storage class — State storage class for code generation

Auto (default) | Model default | ExportedGlobal | ImportedExtern | ImportedExternPointer | BitField (Custom) | Model default | ExportToFile (Custom) | ImportFromFile (Custom) | FileScope (Custom) | AutoScope (Custom) | Struct (Custom) | GetSet (Custom) | Reusable (Custom)

Select state storage class for code generation.

- Auto is the appropriate storage class for states that you do not need to interface to external code.
- *StorageClass* applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

Dependencies

To enable this parameter, specify a value for **State name**.

Programmatic Use

Block Parameter: StateStorageClass

Type: character vector

Values: 'Auto' | 'Model default' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...

Default: 'Auto'

TypeQualifier — Storage type qualifier

'' (default) | const | volatile | ...

Specify a storage type qualifier such as const or volatile.

Note TypeQualifier will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Minimum and Maximum values of the signal object

For more information, see “Data Objects”.

Dependencies

To enable this parameter, set **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `Model` default. This parameter is hidden unless you previously set its value.

Programmatic Use

Block Parameter: `RTWStateStorageTypeQualifier`

Type: character vector

Values: `''` | `'const'` | `'volatile'` | ...

Default: `''`

Block Characteristics

Data Types	<code>double</code> <code>fixed point^a</code> <code>integer^a</code> <code>single</code>
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

a. This block only supports signed fixed-point data types.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
ConstMultiplierOptimization	Canonical signed digit (CSD) or factored CSD optimization. The default is none. See also “ConstMultiplierOptimization” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).

General	
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is <code>inherit</code> . See also “MantissaMultiplyStrategy” (HDL Coder).

Restrictions

- You must use the **Inherit: Inherit via internal rule** option for data type propagation only if the input data type is double.
- Frame, matrix, and vector input data types are not supported.
- The leading denominator coefficient (a0) must be 1 or -1.

The Discrete Transfer Fcn block is excluded from the following optimizations:

- Resource sharing
- Distributed pipelining

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block only supports signed fixed-point data types.

Discrete Zero-Pole

Model system defined by zeros and poles of discrete transfer function

Library: Simulink / Discrete

Description

The Discrete Zero-Pole block models a discrete system defined by the zeros, poles, and gain of a z-domain transfer function. This block assumes that the transfer function has the following form:

$$H(z) = K \frac{Z(z)}{P(z)} = K \frac{(z - Z_1)(z - Z_2)\dots(z - Z_m)}{(z - P_1)(z - P_2)\dots(z - P_n)},$$

where Z represents the zeros vector, P the poles vector, and K the gain. The number of poles must be greater than or equal to the number of zeros ($n \geq m$). If the poles and zeros are complex, they must be complex conjugate pairs.

The block displays the transfer function depending on how the parameters are specified. See Zero-Pole for more information.

Modeling a Single-Output System

For a single-output system, the input and the output of the block are scalar time-domain signals. To model this system:

- 1 Enter a vector for the zeros of the transfer function in the **Zeros** field.
- 2 Enter a vector for the poles of the transfer function in the **Poles** field.
- 3 Enter a 1-by-1 vector for the gain of the transfer function in the **Gain** field.

Modeling a Multiple-Output System

For a multiple-output system, the block input is a scalar and the output is a vector, where each element is an output of the system. To model this system:

- 1 Enter a matrix of zeros in the **Zeros** field.

Each *column* of this matrix contains the zeros of a transfer function that relates the system input to one of the outputs.

- 2 Enter a vector for the poles common to all transfer functions of the system in the **Poles** field.
- 3 Enter a vector of gains in the **Gain** field.

Each element is the gain of the corresponding transfer function in **Zeros**.

Each element of the output vector corresponds to a column in **Zeros**.

Ports

Input

Port_1 — Input signal

scalar

Input signal specified as a real-valued scalar.

Data Types: `single` | `double`

Output

Port_1 — Model of discrete system

scalar | vector

Model of system as defined by zeros, poles, and gain of discrete transfer function. The width of the output is equal to the number of columns in the **Zeros** matrix, or one if **Zeros** is a vector.

Data Types: `single` | `double`

Parameters

Main

Zeros — Matrix of zeros

[1] (default) | vector | matrix

Specify the vector or matrix of zeros. The number of zeros must be less than or equal to the number of poles. If the poles and zeros are complex, they must be complex conjugate pairs.

- For a single-output system, enter a vector for the zeros of the transfer function.
- For a multiple-output system, enter a matrix. Each column of the matrix contains the zeros of a transfer function that relates the system input to one of the outputs.

Programmatic Use

Block Parameter: Zeros

Type: character vector

Values: vector

Default: ' [1] '

Poles — Vector of poles

[0 0.5] (default) | vector

Specify the vector of poles. The number of poles must be greater than or equal to the number of zeros. If the poles and zeros are complex, they must be complex conjugate pairs.

- For a single-output system, enter a vector for the poles of the transfer function.
- For a multiple-output system, enter a vector for the poles common to all transfer functions of the system.

Programmatic Use

Block Parameter: Poles

Type: character vector

Values: vector

Default: '[0 0.5]'

Gain — Gain value

1 (default) | scalar | vector

Specify vector of gain values.

- For a single-output system, enter a scalar or 1-by-1 vector for the gain of the transfer function.
- For a multiple-output system, enter a vector of gains. Each element is the gain of the corresponding transfer function in **Zeros**.

Programmatic Use

Block Parameter: Gain

Type: character vector

Values: scalar | vector

Default: '1'

Sample time (-1 for inherited) — Interval between samples

-1 | scalar | vector

Specify the time interval between samples. For more information, see [Specifying Sample Time](#).

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

State Attributes

State name — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use

Block Parameter: StateName

Type: character vector

Values: unique name

Default: ''

State name must resolve to Simulink signal object — Require state name resolve to a signal object

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

Programmatic Use

Block Parameter: StateMustResolveToSignalObject

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Signal object class — Custom storage class package name

Simulink.Signal (default) | <StorageClass.PackageName>

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Programmatic Use

Block Parameter: StateSignalObject

Type: character vector

Values: 'Simulink.Signal' | '<StorageClass.PackageName>'

Default: 'Simulink.Signal'

Code generation storage class — State storage class for code generation

Auto (default) | Model default | ExportedGlobal | ImportedExtern | ImportedExternPointer | BitField (Custom) | Model default | ExportToFile (Custom) | ImportFromFile (Custom) | FileScope (Custom) | AutoScope (Custom) | Struct (Custom) | GetSet (Custom) | Reusable (Custom)

Select state storage class for code generation.

- Auto is the appropriate storage class for states that you do not need to interface to external code.
- *StorageClass* applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

Dependencies

To enable this parameter, specify a value for **State name**.

Programmatic Use**Block Parameter:** StateStorageClass**Type:** character vector**Values:** 'Auto' | 'Model default' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...**Default:** 'Auto'**TypeQualifier — Storage type qualifier**

'' (default) | const | volatile | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note TypeQualifier will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Minimum and Maximum values of the signal object

For more information, see “Data Objects”.

DependenciesTo enable this parameter, set **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `Model default`. This parameter is hidden unless you previously set its value.**Programmatic Use****Block Parameter:** RTWStateStorageTypeQualifier**Type:** character vector**Values:** '' | 'const' | 'volatile' | ...**Default:** ''**Block Characteristics**

Data Types	double single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

Display

Display signal value during simulation

Library: Simulink / Dashboard

42

Description

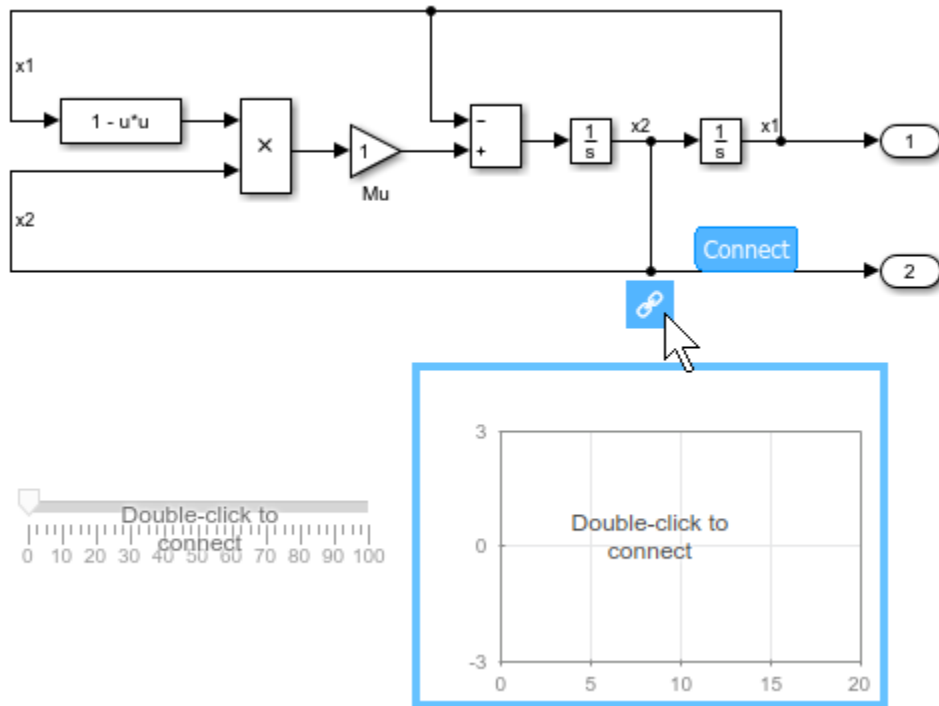

The Display block connects to a signal in your model and displays its value during simulation. You can configure the appearance and format of the Display block to make intuitive sense for the value it displays. You can edit the parameters of the Display block during simulation. The Display block can display complex, vector, and 2-D matrix signals. Use the Display block with other dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Connecting Dashboard Blocks

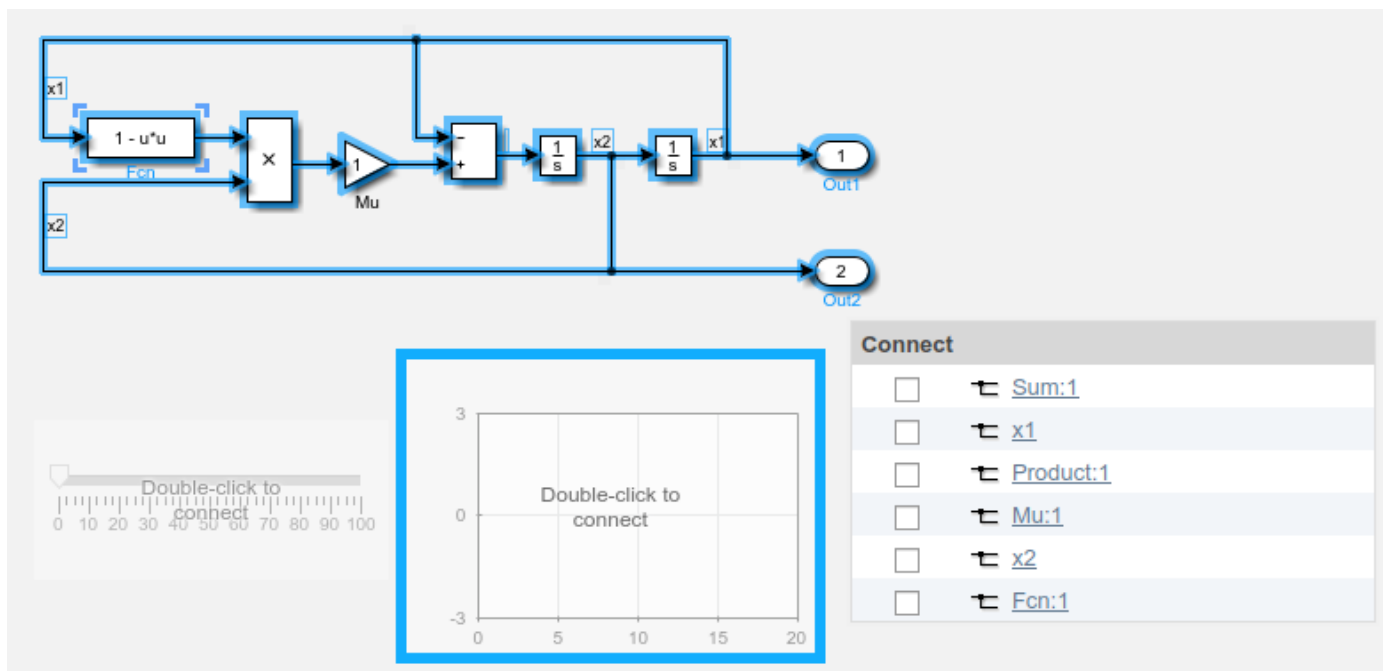

Dashboard blocks do not use ports to connect to signals. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above the block.

In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using connect mode, the Dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, Dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view such signals on a Dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Format — Format for displaying signal values

short (default) | long | shortE | longE | ...

Format for displaying signal values, specified as one of these values:

- `short` — Scaled fixed-decimal format with four digits after the decimal point
- `long` — Scaled fixed-decimal format with fifteen digits after the decimal point for `double` values and seven digits after the decimal point for `single` values
- `shortE` — Scientific notation format with four digits
- `longE` — Scientific notation format with fifteen digits after the decimal point for `double` values and seven digits after the decimal point for `single` values

- `shortG` — Data takes the more compact format between fixed-decimal or scientific notation, with a total of five digits
- `longG` — Data takes the more compact format between fixed-decimal or scientific notation, with a total of fifteen digits for `double` values and seven digits for `single` values
- `shortEng` — Engineering notation where the exponent is a multiple of 3, with 4 digits after the decimal point
- `longEng` — Engineering notation where the exponent is a multiple of 3, with 15 significant digits
- `+` — Positive/negative format. +, -, and blank characters are displayed for positive, negative, and zero values, respectively
- `bank` — Currency format with 2 digits after the decimal point
- `hex` — Hexadecimal representation
- `rat` — Ratio
- `Custom` — Custom string format. Data is displayed in a custom string that you specify using the **Format String** parameter.
- `Integer` — Data rounded to the nearest whole number.

short	3.1416	shortEng	3.1416e+000		
long	3.141592653589793	longEng	3.14159265358979e+000	string	Hello!
shortE	3.1416e+00	bank	3.14		
longE	3.141592653589793e+00	plus	+		
shortG	3.1416	hex	400921FB54442D18	enum	Positive
longG	3.14159265358979	rat	355/113		
Custom	The value of pi is 3.14	Integer	3		

Programmatic Use

Block Parameter: Format

Type: character array | string

Values: 'short' | 'long' | 'shortE' | 'longE' | 'shortG' | 'longG' | 'shortEng' | 'longEng' | 'bank' | '+' | 'hex' | 'rat' | 'Custom' | 'Integer'

Default: 'short'

Format String — Custom string to format data

'%d' (default) | string

Custom string to format displayed signal data, specified as a string. The format string consists of text and format operators, which start with a % sign and end with a conversion character. Use the format operators at the place in the string where you want the signal data to display. For more information about supported formatting operators, see the `formatSpec` input of the `compose` function.

Example: The value of `pi` is `%.2f` displays the value of the connected signal within a sentence.

Example: `$%.2f` displays the value of the connected signal with a dollar sign and two decimal places.

Dependencies

To enable this parameter, set the **Format** parameter to `Custom`.

Programmatic Use**Block Parameter:** `FormatString`**Type:** character array | string**Default:** `'%d'`**Alignment — Text alignment in block**`Center` (default) | `Left` | `Right`

Text alignment in the `Display` block.

Programmatic Use**Block Parameter:** `Alignment`**Type:** character array**Values:** `'Left'` | `'Center'` | `'Right'`**Default:** `'Center'`**Label — Block label position**`Hide` (default) | `Bottom` | `Top`

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** `LabelPosition`**Type:** character vector**Values:** `'Hide'` | `'Bottom'` | `'Top'`**Default:** `'Hide'`**Opacity — Specify block opacity**`1` (default) | scalar

Opacity of the block, specified as a scalar value between 0 and 1.

Example: `0.5`

Programmatic Use**Block Parameter:** `Opacity`**Type:** scalar**Default:** `1`**Layout — How to arrange elements of non-scalar data**`Preserve dimensions` (default) | `Fill available space`

How to arrange elements of non-scalar data, specified as one of these options:

- **Preserve dimensions** — Display elements arranged to match signal dimensions.
- **Fill available space** — Display as many elements as possible within available space.

Programmatic Use

Block Parameter: Layout

Type: character array | string

Values: 'Preserve dimensions' | 'Fill available space'

Default: 'Preserve dimensions'

Show grid for non-scalar signals — Whether to show grid

on (default) | off

Whether to show a grid on the block when the block displays non-scalar data. Specify the color of the grid using the **Grid Color** parameter.

Programmatic Use

Block Parameter: ShowGrid

Type: character array | string

Values: 'on' | 'off'

Default: 'on'

Foreground Color — Block foreground color

[r g b] vector

Block foreground color, including the text. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: ForegroundColor

Type: [r g b] vector

Default: [0 0 0]

Background Color — Block background color

[r g b] vector

Block background color. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: BackgroundColor

Type: [r g b] vector

Default: [0.752940 0.752940 0.752940]

Grid Color — Block grid color

[r g b] vector

Block grid color. The grid shows when the block displays non-scalar data. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the GridColor parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: GridColor

Type: [r g b] vector

Default: [0.502 0.502 0.502]

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Topics

“Tune and Visualize Your Model with Dashboard Blocks”

“Decide How to Visualize Simulation Data”

Introduced in R2017b

Display

Show value of input

Library: Simulink / Sinks

Description

The Display block shows the value of the input data. You can specify the frequency of the display. For numeric input data, you can also specify the format of display.

If the block input is an array, you can resize the block vertically or horizontally to show more than just the first element. If the block input is a vector, the block sequentially adds display fields from left to right and top to bottom. The block displays as many values as possible. A black triangle indicates that the block is not displaying all input array elements.

The Display block shows the first 200 elements of a vector signal and the first 20 rows and 10 columns of a matrix signal.

Note If you specify a numeric display format that is not large enough to display all the digits of a value, the displayed values may lose precision. The result depends on your computer hardware and operating system.

Display Abbreviations

The following abbreviations appear on the Display block to help you identify the format of the value.

When You See...	The Value That Appears Is...
(SI)	The stored integer value
	Note (SI) does not appear when the signal is of an integer data type.
hex	In hexadecimal format
bin	In binary format
oct	In octal format

Displaying Strings

When working with strings, the Display block displays:

- Strings with double quotes.
- Special characters such as newline are shown as escaped sequences, for example '\n'.
- Non-displayable characters as escaped octal number, for example '\201'.

If the incoming signal is of type string, the **Numeric display format** parameter selection does not affect the display of the string.

Ports

Input

Port_1 — Input data

scalar | vector

Input data to display.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

Numeric display format — Format to display numeric input data

short (default) | long | short_e | long_e | bank | hex (Stored Integer) | binary (Stored Integer) | decimal (Stored Integer) | octal (Stored Integer)

Specify the format of the numeric data that appears.

If You Select...	The Block Displays...
short	A 5-digit scaled value with fixed decimal point
long	A 15-digit scaled value with fixed decimal point
short_e	A 5-digit value with a floating decimal point
long_e	A 16-digit value with a floating decimal point
bank	A value in fixed dollars and cents format (but with no \$ or commas)
hex (Stored Integer)	The stored integer value of a fixed-point input in hexadecimal format
binary (Stored Integer)	The stored integer value of a fixed-point input in binary format
decimal (Stored Integer)	The stored integer value of a fixed-point input in decimal format
octal (Stored Integer)	The stored integer value of a fixed-point input in octal format

If the numeric input to a Display block has an enumerated data type (see “Simulink Enumerations” and “Define Simulink Enumerations”):

- The block displays enumerated values, not the values of underlying integers.
- Setting **Numeric display format** to any of the Stored Integer settings causes an error.

If the incoming signal is of type string, the selection of the **Numeric display format** parameter does not affect the display of the string.

Programmatic Use

Block Parameter: Format

Type: character vector

Values: 'short' | 'long' | 'short_e' | 'long_e' | 'bank' | 'hex (Stored Integer)' | 'binary (Stored Integer)' | 'decimal (Stored Integer)' | 'octal (Stored Integer)'

Default: 'short'

Decimation – Display rate

1 (default) | integer

Specify how often to display data.

The amount of data that appears and the time steps at which the data appears depend on the **Decimation** block parameter and the `SampleTime` property.

- The **Decimation** parameter enables you to display data at every n th sample, where n is the decimation factor. The default decimation, 1, displays data at every time step.

Note The Display block updates its display at the initial time, even when the **Decimation** value is greater than one.

- The `SampleTime` property, which you can set with `set_param`, enables you to specify a sampling interval at which to display points. This property is useful when you are using a variable-step solver where the interval between time steps is not the same. The default sample time, -1, causes the block to ignore the sampling interval when determining the points to display.

Note If the block inherits a sample time of `Inf`, the **Decimation** parameter is ignored.

Programmatic Use

Block Parameter: Decimation

Type: character vector

Values: '1' | integer

Default: '1'

Floating display – Floating display

off (default) | on

To use the block as a floating display, select the **Floating display** check box. The block input port disappears and the block displays the value of the signal on a selected line.

If you select **Floating display**:

- Turn off signal storage reuse for your model. See “Signal storage reuse” (Simulink Coder) for more information.
- Do not connect a multidimensional signal to a floating display.

Programmatic Use

Block Parameter: Floating

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	double single Boolean base integer fixed point enumerated string
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Ignored for code generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

Introduced before R2006a

Divide

Divide one input by another

Library: Simulink / Math Operations
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Divide block outputs the result of dividing its first input by its second. The inputs can be scalars, a scalar and a nonscalar, or two nonscalars that have the same dimensions. The Divide block is functionally a Product block that has two block parameter values preset:

- **Multiplication** — Element-wise (.*)
- **Number of Inputs** — */

Setting nondefault values for either of those parameters can change a Divide block to be functionally equivalent to a Product block or a Product of Elements block.

Ports

Input

X — Input signal to multiply

scalar | vector | matrix | N-D array

Input signal to be multiplied with other inputs.

Dependencies

To enable one or more X ports, specify one or more * characters for the **Number of inputs** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

÷ — Input signal to divide or invert

scalar | vector | matrix | N-D array

Input signal for division or inversion operations.

Dependencies

To enable one or more ÷ ports, specify one or more / characters for the **Number of inputs** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_1 — First input to multiply or divide

scalar | vector | matrix | N-D array

First input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Port_N – Nth input to multiply or divide

`scalar` | `vector` | `matrix` | `N-D array`

Nth input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Port_1 – Output computed by multiplying, dividing, or inverting inputs

`scalar` | `vector` | `matrix` | `N-D array`

Output computed by multiplying, dividing, or inverting inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Main

Number of inputs – Control number of inputs and type of operation

`*/` (default) | `positive integer scalar` | `*` or `/` for each input port

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

When you specify:

- **1 or * or /**

The block has one input port. In element-wise mode, the block processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is `1` or `*`, the block outputs the input value. If the value is `/`, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-Wise Mode” on page 1-1122 and “Matrix Mode” on page 1-1123 for more information.

- **Integer value > 1**

The block has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1122 and “Matrix Mode” on page 1-1123 for more information.

- **Unquoted string of two or more * and / characters**

The block has the number of inputs given by the length of the character vector. Each input that corresponds to a `*` character is multiplied into the output. Each input that corresponds to a `/` character is divided into the output. The operations occur in element-wise mode or matrix mode,

as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1122 and “Matrix Mode” on page 1-1123 for more information.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: '2' | '*' | '**' | '*/' | '*/*' | ...

Default: '*/'

Multiplication — Element-wise (.) or Matrix (*) multiplication

Element-wise(.) (default) | Matrix(*)

Specify whether the block performs Element-wise(.) or Matrix(*) multiplication.

Programmatic Use

Block Parameter: Multiplication

Type: character vector

Values: 'Element-wise(.)' | 'Matrix(*)'

Default: 'Element-wise(.)'

Multiply over — All dimensions or specified dimension

All dimensions (default) | Specified dimension

Specify the dimension to multiply over as All dimensions, or Specified dimension. When you select Specified dimension, you can specify the **Dimension** as 1 or 2.

Dependencies

To enable this parameter, set **Number of inputs** to * and **Multiplication** to Element-wise (.).

Programmatic Use

Block Parameter: CollapseMode

Type: character vector

Values: 'All dimensions' | 'Specified dimension'

Default: 'All dimensions'

Dimension — Dimension to multiply over

1 (default) | 2 | ... | N

Specify the dimension to multiply over as an integer less than or equal to the number of dimensions of the input signal.

Dependencies

To enable this parameter, set:

- **Number of inputs** to *
- **Multiplication** to Element-wise (.)
- **Multiply over** to Specified dimension

Programmatic Use

Block Parameter: CollapseDim

Type: character vector

Values: '1' | '2' | ...

Default: '1'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar or vector**Default:** '-1'**Signal Attributes****Require all inputs to have the same data type — Require that all inputs have the same data type**

off (default) | on

Specify if input signals must all have the same data type. If you enable this parameter, then an error occurs during simulation if the input signal types are different.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Output minimum — Minimum output value for range checking**

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output maximum — Maximum output value for range checking**

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type — Specify the output data type**

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | Inherit: Same as first input | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Signal Data Types”.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the

word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of `Inherit: Same as input`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- `Inherit: Inherit via back propagation` — Use data type of the driving block.
- `Inherit: Same as first input` — Use data type of first input signal.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Same as first input'` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'Inherit: Inherit via internal rule'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations. You can select:

Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (off).	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Expected Differences Between Simulation and Code Generation

These conditions may yield different results between simulation and the generated code:

- The Divide block inputs contain a NaN or `inf` value
- The Divide block generates NaN or `inf` during execution

This difference is due to the nonfinite NaN or `inf` values. In such cases, inspect your model configuration and eliminate the conditions that produce NaN or `inf`.

Code Optimizations

The Simulink Coder build process provides efficient code for matrix inverse and division operations. This table describes the benefits and when each benefit is available.

Benefit	Small Matrices (2-by-2 to 5-by-5)	Medium Matrices (6-by-6 to 20-by-20)	Large Matrices (larger than 20-by-20)
Faster code execution time, compared to R2011a and earlier releases	Yes	No	Yes
Reduced ROM and RAM usage, compared to R2011a and earlier releases	Yes, for real values	Yes, for real values	Yes, for real values
Reuse of variables	Yes	Yes	Yes
Dead code elimination	Yes	Yes	Yes
Constant folding	Yes	Yes	Yes
Expression folding	Yes	Yes	Yes
Consistency with MATLAB Coder results	Yes	Yes	Yes

For blocks that have three or more inputs of different dimensions, the code might include an extra buffer to store temporary variables for intermediate results.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Note When you deploy the generated HDL code onto the target hardware, make sure that you set the **signed integer division rounds to** parameter in the **Hardware Implementation** pane of the Configuration Parameters dialog box to **Zero** or **Floor**.

To perform an HDL-optimized divide operation, connect a Product block to a Divide block in reciprocal mode.

HDL Architecture

Default Mode

The Divide block is the same as a Product block with **Number of Inputs** set to */.

Architecture	Parameters	Description
Linear default	None	Generate a divide (/) operator in the HDL code.

Architecture	Parameters	Description
ShiftAdd	UsePipelines	<p>Perform divide operations on fixed-point types by using a non-restoring division algorithm that performs multiple shift and add operations to compute the quotient. This architecture provides improved accuracy compared to the Newton-Raphson approximation method.</p> <p>When you use this architecture, to achieve a higher maximum clock frequency on the target FPGA device, leave the UsePipelines HDL block property to on.</p>

Reciprocal Mode

When **Number of Inputs** is set to /, the Divide block is in reciprocal mode.

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

In reciprocal mode, the Divide block has the HDL block implementations described in the following table.

Architectures	Parameters	Additional cycles of latency	Description
default Linear	None	0	When you compute a reciprocal, use the HDL divide (/) operator to implement the division.
ReciprocalRsqrBasedNewton	Iterations	<p>Signed input: Iterations + 5</p> <p>Unsigned input: Iterations + 3</p>	<p>Use the iterative Newton method. Select this option to optimize area.</p> <p>The default value for Iterations is 3.</p> <p>The recommended value for Iterations is between 2 and 10. If Iterations is outside the recommended range, HDL Coder displays a message.</p>

Architectures	Parameters	Additional cycles of latency	Description
ReciprocalRsqrBasedNewtonSingleRate	Iterations	Signed input: (Iteration s * 4) + 8 Unsigned input: (Iteration s * 4) + 6	Use the single rate pipelined Newton method. Select this option to optimize speed, or if you want a single rate implementation. The default value for Iterations is 3. The recommended value for Iterations is between 2 and 10. If Iterations is outside the recommended range, the coder displays a message.
ShiftAdd	UsePipelines	Signed input: (Input wordlength + 4) Unsigned input: (Input wordlength + 4)	Perform reciprocal operation on a fixed-point input by using a non-restoring division multiple shift and add operations to compute the reciprocal. This architecture provides improved accuracy compared to the Newton-Raphson approximation method. When you use this architecture, to achieve a higher maximum clock frequency on the target FPGA device, leave the UsePipelines HDL block property to on.

The Newton-Raphson iterative method:

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)} = x_i(1.5 - 0.5ax_i^2)$$

ReciprocalRsqrBasedNewton and ReciprocalRsqrBasedNewtonSingleRate implement the Newton-Raphson method with:

$$f(x) = \frac{1}{x^2} - 1$$

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also "DSPStyle" (HDL Coder). Use this property with: <ul style="list-style-type: none"> • Product block • Divide and Reciprocal blocks with Linear architecture
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).
UsePipelines	HDL property that specifies whether to use a pipelined implementation for fixed-point division and reciprocal operations. This implementation provides a higher maximum clock frequency on the target FPGA device. See also "UsePipelines" (HDL Coder).
Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is inherit. See also "HandleDenormals" (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to inherit, Max, Min, Zero, or Custom for the floating-point operator. The default is inherit. See also "LatencyStrategy" (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to Custom. HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also "NFPCustomLatency" (HDL Coder).
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is inherit. See also "MantissaMultiplyStrategy" (HDL Coder).

Native Floating Point	
DivisionAlgorithm	Specify whether to use the Radix-2 or Radix-4 algorithm to perform the floating-point division. The Radix-2 mode offers a trade-off between latency and frequency. The Radix-4 mode offers a trade-off between latency and resource usage. For more information, see "DivisionAlgorithm" (HDL Coder).

Complex Data Support

This block does not support code generation for division with complex signals.

Restrictions

When you use the Divide block in reciprocal mode, the following restrictions apply:

- When you use fixed-point types, the input and output must be scalar. To use vector inputs, specify the `Math` architecture and input a floating-point value.
- Only the `Zero` rounding mode is supported.
- You must select the **Saturate on integer overflow** option on the block.

For the Divide block, only the `Zero` and `Simplest` rounding modes are supported.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

DocBlock

Create text that documents model and save text with model

Library: Simulink / Model-Wide Utilities
HDL Coder / Model-Wide Utilities

Description

The DocBlock allows you to create and edit text that documents a model, and save that text with the model. Double-clicking an instance of the block creates a temporary file containing the text associated with this block and opens the file in an editor. Use the editor to modify the text and save the file. Simulink software stores the contents of the saved file in the model file.

The DocBlock supports HTML, Rich Text Format (RTF), and ASCII text document types. The default editors for these different document types are

- HTML — Microsoft® Word (if available). Otherwise, the DocBlock opens HTML documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.
- RTF — Microsoft Word (if available). Otherwise, the DocBlock opens RTF documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.
- Text — The DocBlock opens text documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.

Use the `docblock` command to change the default editors.

Tip To edit the block parameters of the DocBlock, right-click the block icon and select **Mask > Mask Parameters...**

Parameters

Code generation template symbol — Template symbol for generated code

' ' | Abstract | Description | History | Modified History | Notes

Enter a template symbol name in this field. Embedded Coder software uses this symbol to add comments to the code generated from the model. For more information, see “Add Global Comments in the Generated Code” (Embedded Coder).

Dependencies

For comments to appear in the generated code, you must also set the **Document type** to Text.

Programmatic Use

Block Parameter: ECoderFlag

Type: character vector

Values: Abstract | Description | History | Modified History | Notes

Default: '0'

Document type — Type of document

Text (default) | RTF | HTML

Select the type of document associated with the DocBlock. The options are:

- Text
- RTF
- HTML

Dependencies

If you are using a DocBlock to add comments to your code during code generation, ensure that you set the **Document Type** as Text. If you set the **Document Type** as RTF or HTML, your comments will not appear in the code.

Programmatic Use

Block Parameter: DocumentType

Type: character vector

Values: Text | RTF | HTML

Default: 'Text'

Block Characteristics

Data Types	
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Uses the template symbol you specify for the Embedded Coder Flag block parameter to add comments to generated code. Requires an Embedded Coder license. For more information, see “Use a Simulink DocBlock to Add a Comment” (Embedded Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. See also “Generate Code with Annotations or Comments” (HDL Coder) and “Integrate Custom HDL Code Using DocBlock” (HDL Coder).

HDL Architecture

Architecture	Description
Annotation (default)	Insert text as comment in the generated code.
HDLText	Integrate text as custom HDL code.
No HDL	Do not generate HDL code for this block.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
TargetLanguage	Language of the text, either Verilog [®] or VHDL [®] . The default is VHDL. When Architecture is HDLText, this property is available. To learn more, see “Integrate Custom HDL Code Using DocBlock” (HDL Coder).

Restrictions

- **Document type** must be Text.

HDL Coder does not support the HTML or RTF options.

- You can have a maximum of two DocBlock blocks with **Architecture** set to HDLText in the same subsystem.

If you have two DocBlock blocks, one must have **TargetLanguage** set to VHDL, and the other must have **TargetLanguage** set to Verilog. When generating code, HDL Coder only integrates the custom code from the DocBlock that matches the target language for code generation.

PLC Code Generation

Generate Structured Text code using Simulink[®] PLC Coder[™].

Introduced before R2006a

Dot Product

Generate dot product of two vectors

Library: Simulink / Math Operations
HDL Coder / Math Operations

Description

The Dot Product block generates the dot product of the input vectors. The scalar output, y , is equal to the MATLAB operation

$$y = \text{sum}(\text{conj}(u1) .* u2)$$

where $u1$ and $u2$ represent the input vectors. The inputs can be vectors, column vectors (single-column matrices), or scalars. If both inputs are vectors or column vectors, they must be the same length. If $u1$ and $u2$ are both column vectors, the block outputs the equivalent of the MATLAB expression $u1' * u2$.

The elements of the input vectors can be real- or complex-valued signals. The signal type (complex or real) of the output depends on the signal types of the inputs.

Input 1	Input 2	Output
real	real	real
real	complex	complex
complex	real	complex
complex	complex	complex

Ports

Input

Port_1 – First operand input signal

scalar | vector

Signal representing the first operand to the dot product calculation.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_2 – Second operand input signal

scalar | vector

Signal representing the second operand to the dot product calculation.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Dot product output signal

scalar | vector

Output signal resulting from the dot product calculation of the two input signals.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Require all inputs to have the same data type — Require all inputs to have the same data type

on (default) | off

Clear this check box for all the inputs to have different data types.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Specify the upper value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | Inherit: Same as first input | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Signal Data Types”.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of `Inherit: Same as input`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- `Inherit: Inherit via back propagation` — Use data type of the driving block.
- `Inherit: Same as first input` — Use data type of first input signal.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Same as first input'` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'Inherit: Inherit via internal rule'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- **off** — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- **on** — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

Architecture	Description
Linear (default)	Generates a linear chain of adders to compute the sum of products.
Tree	Generates a tree structure of adders to compute the sum of products.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Edit

Enter new value for parameter

Library: Simulink / Dashboard

42

Description

The Edit block allows you to type in new values for block parameters during simulation. Use the Edit block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Double-clicking the Edit block does not open its dialog box during simulation and when the block is selected. To edit the block parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

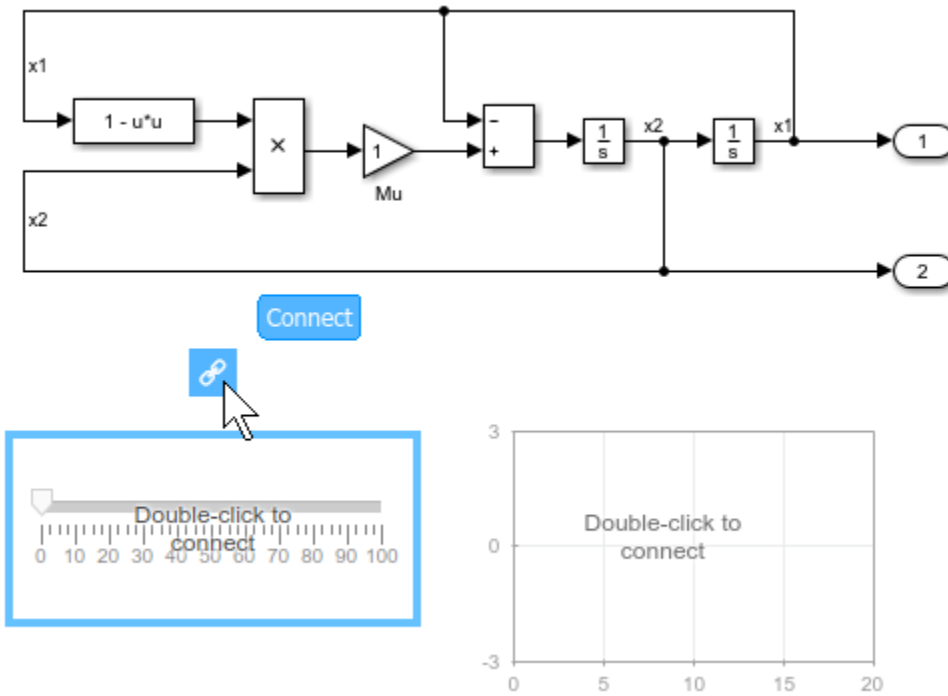

Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to make connections. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

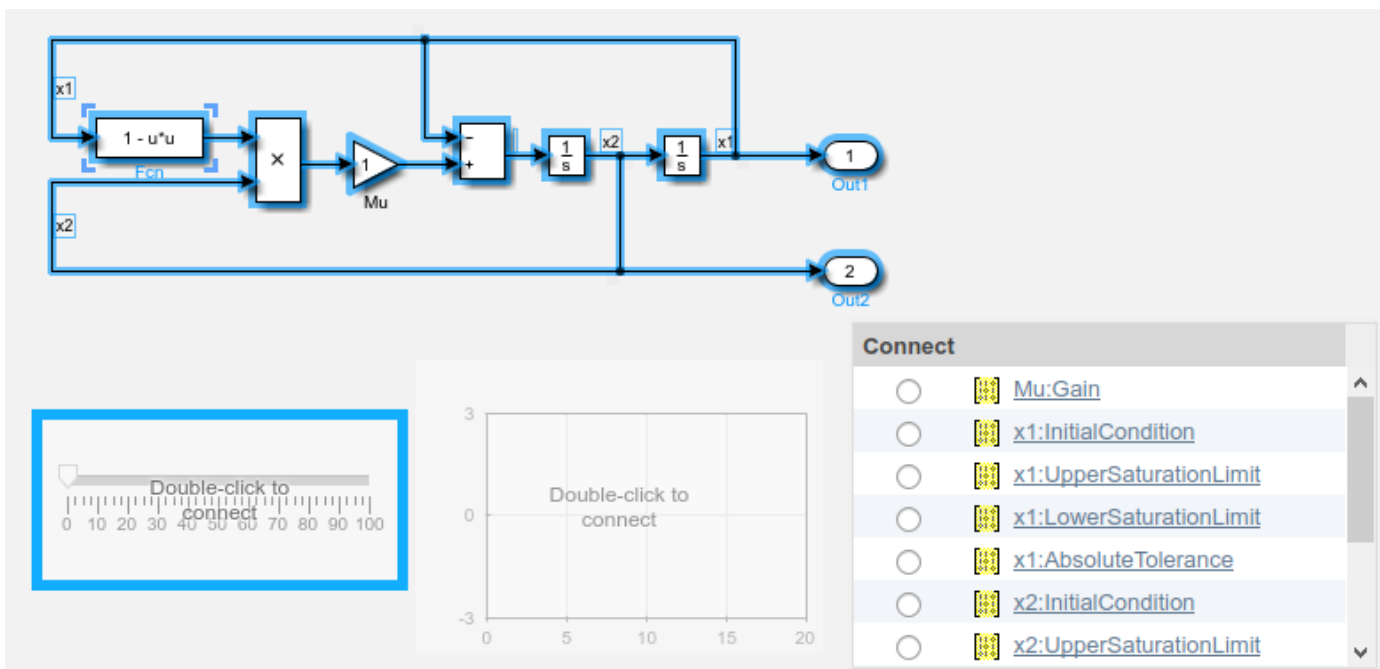

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above it.

In connect mode, when you select one or more signals or blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block. To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a variable or parameter to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.
- When you specify a block parameter value by indexing a variable array, the parameter does not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect
variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.
- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: []

Align — Text alignment

Center (default) | Left | Right

Alignment of the text in the Edit block.

Programmatic Use

Block Parameter: Alignment

Type: string or character vector

Values: 'Center' | 'Left' | 'Right'

Default: 'Center'

Label — Block label position

Hide (default) | Bottom | Top

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Hide' | 'Bottom' | 'Top'

Default: 'Hide'

Block Characteristics

Data Types	double integer single
Direct Feedthrough	no

Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Enable

Add enable port to subsystem or model

Library: Simulink / Ports & Subsystems
HDL Coder / Ports & Subsystems

Description

The Enable block allows an external signal to control execution of a subsystem or a model. To enable this functionality, add the block to a Subsystem block or at the root level of a model that is referenced in a Model block.

If you use an enable port at the root-level of a model:

- For multi-rate models, set the solver to single-tasking.
- For models with a fixed-step size, at least one block in the model must run at the specified fixed-step size rate.

Ports

Output

Enable signal — External enable signal for a subsystem or model

scalar

Enable signal attached externally to the outside of an Enable Subsystem block and passed to the inside of the subsystem. An enable signal port is added to an Enable block when you select the **Show output port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `expression`

Parameters

States when enabling — Select block states when subsystem or model is disabled

`held` (default) | `reset`

When a Subsystem block or Model block is disabled, select what happens to block states for the blocks within the subsystem or model.

`held`

Hold block states at their previous values.

`reset`

Reset block states to their initial conditions (zero if not defined).

Programmatic Use

Block parameter: `StatesWhenEnabling`

Type: character vector
Values: 'held' | 'reset'
Default: 'held'

Propagate sizes of variable-size signals — Select when to propagate a variable-size signal

Only when enabling (default) | During execution

Select when to propagate a variable-size signal.

Only when enabling

Propagate a variable-size signal when reenabling a Subsystem block or Model block containing an Enable port block. When you select this option, sample time must be periodic.

During execution

Propagate variable-size signals at each time step.

Programmatic Use

Block parameter: PropagateVarSize

Type: character vector

Values: 'Only when enabling' | 'During execution'

Default: 'Only when enabling'

Show output port — Control display of output port for enable signal

off (default) | on

The output port passes the enable signal attached externally to the outside of an Enable Subsystem block or enabled Model block to the inside.

off

Remove the output port on the Enable port block.

on

Display an output port on the Enable port block. Selecting this option allows the subsystem or model to process the enable signal.

Programmatic Use

Block parameter: ShowOutputPort

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Enable zero-crossing detection — Control zero-crossing detection

on (default) | off

Control zero-crossing detection for a model.

on

Detect zero crossings.

off

Do not detect zero crossings.

Programmatic Use**Block parameter:** ZeroCross**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Port dimensions — Specify dimensions for the enable signal**

1 (default) | [n] | [m n]

Specify dimensions for the enable signal attached externally to a Model block and passed to the inside of the block.

1

Scalar signal.

[n]

Vector signal of width n.

[m n]

Matrix signal having m rows and n columns.

Programmatic Use**Block parameter:** PortDimensions**Type:** character vector**Values:** '1' | '[n]' | '[m n]'**Default:** '1'**Sample time — Specify time interval**

-1 (default) | Ts | [Ts, To]

Specify time interval between block method execution. See “Specify Sample Time”.

-1

Sample time inherited from the model.

Ts

Scalar where Ts is the time interval.

[Ts, To]

Vector where Ts is the time interval and To is the initial time offset.

Programmatic Use**Block parameter:** SampleTime**Type:** character vector**Values:** '-1' | 'Ts' | '[Ts, To]'**Default:** '-1'**Minimum — Specify minimum output value for the enable signal**

[] (default) | real scalar

Specify minimum value for the enable signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See “Optimize using the specified minimum and maximum values” (Embedded Coder).

[]

Unspecified minimum value.

real scalar

Real double scalar value.

Programmatic Use

Block parameter: OutMin

Type: character vector

Values: '[]' | '<real scalar>'

Default: '[]'

Maximum — Specify maximum output value for the enable signal

[] (default) | real scalar

Specify maximum value for the enable signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See “Optimize using the specified minimum and maximum values” (Embedded Coder).

[]

Unspecified maximum value.

real scalar

Real double scalar value.

Programmatic Use

Block parameter: OutMax

Type: character vector

Values: '[]' | '<real scalar>'

Default: '[]'

Data type — Specify output data type for the enable signal

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^,0) | <data type expression>

Specify data type for the enable signal attached externally to a Model block and passed to the inside of the block.

double

Double-precision floating point.

`single`

Single-precision floating point.

`int8`

Signed 8-bit integer.

`uint8`

Unsigned 8-bit integer.

`int16`

Signed 16-bit integer.

`uint16`

Unsigned 16-bit integer.

`int32`

Signed 32-bit integer.

`uint32`

Unsigned 32-bit integer.

`int64`

Signed 64-bit integer.

`uint64`

Unsigned 64-bit integer.

`boolean`

Boolean with a value of `true` or `false`.

`fixdt(1,16)`

Signed 16-bit fixed point number with binary point undefined.

`fixdt(1,16,0)`

Signed 16-bit fixed point number with binary point set to zero.

`fixdt(1,16,2^0,0)`

Signed 16-bit fixed point number with slope set to 2^0 and bias set to 0.

`<data type expression>`

Data type object, for example `Simulink.NumericType`. Do not specify a bus object as the expression.

Programmatic Use

`b`

Block parameter: `OutDataTypeStr`

Type: character vector

Values: `'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | '<fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`

Default: `'double'`

Mode — Select data type category

Build in (default) | Fixed point | Expression

Select data type category and display drop-down lists to help you define the data type.

Build in

Display drop-down lists for data type and Data type override.

Fixed point

Display drop-down lists for Signedness, Scaling, and Data type override.

Expression

Display text box for entering an expression.

Dependency

To enable this parameter, select the Show data type assistant button.

Programmatic Use

No equivalent command-line parameter.

Interpolate data — Specify value of missing workspace data

on (default) | off

Specify value of missing workspace data when loading data from the workspace.

on

Linearly Interpolate output at time steps for which no corresponding workspace data exists.

off

Do not interpolate output at time steps. The current output equals the output at the most recent time step for which data exists.

Programmatic Use

Block parameter: Interpolate

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	yes

Enabled and Triggered Subsystem

Subsystem whose execution is enabled and triggered by external inputs

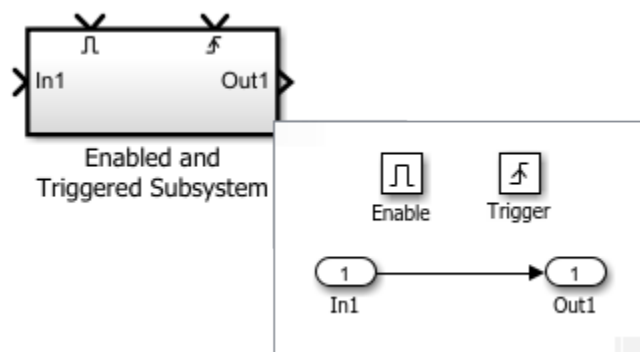

Library: Simulink / Ports & Subsystems

Description

The Enabled and Triggered Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when both of these conditions occur:

- Enable control signal has a positive value.
- Trigger control signal has a trigger value.

Use Enabled and Triggered Subsystem blocks to model:

- Optional functionality.
- Alternative functionality.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Enable — Control signal input to a subsystem block

scalar

Placing an Enable block in a subsystem block adds an external input port to the block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Trigger — Control signal input to a subsystem block

scalar

Placing a Trigger block in a subsystem block adds an external input port to the block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Block Characteristics

Data Types	<code>Boolean^a</code> <code>bus^a</code> <code>double^a</code> <code>enumerated^a</code> <code>fixed point^a</code> <code>integer^a</code> <code>single^a</code> <code>string^a</code>
Direct Feedthrough	no
Multidimensional Signals	limited ^a

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Best Practices

When using enabled subsystems in models targeted for HDL code generation, it is good practice to consider the following:

- For synthesis results to match Simulink results, the Enable port must be driven by registered logic (with a synchronous clock) on the FPGA.
- Put unit delays on Enabled Subsystem output signals. Doing so prevents the code generator from inserting extra bypass registers in the HDL code.

- Enabled subsystems can affect synthesis results in the following ways:
 - In some cases, the system clock speed can drop by a small percentage.
 - Generated code uses more resources, scaling with the number of enabled subsystem instances and the number of output ports per subsystem.

HDL Architecture

Architecture	Description
Module (default)	Generate code for the subsystem and the blocks within the subsystem.
BlackBox	Generate a black box interface. The generated HDL code includes only the input/output port definitions for the subsystem. Therefore, you can use a subsystem in your model to generate an interface to existing, manually written HDL code. The black-box interface generation for subsystems is similar to the Model block interface generation without the clock signals.
No HDL	Remove the subsystem from the generated code. You can use the subsystem in simulation, however, treat it as a “no-op” in the HDL code.

HDL Block Properties

General	
AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . See also “ClockRatePipelining” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is <code>0</code> . For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>off</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is <code>inherit</code> . See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “OutputPipeline” (HDL Coder).

General	
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also “Streaming” (HDL Coder).

Target Specification

This block cannot be the DUT, so the block property settings in the **Target Specification** tab are ignored.

Restrictions

HDL Coder supports HDL code generation for enabled subsystems that meet the following conditions:

- The enabled subsystem is not the DUT.
- The subsystem is not *both* triggered *and* enabled.
- The enable signal is a scalar.
- The data type of the enable signal is either `boolean` or `ufix1`.
- Outputs of the enabled subsystem have an initial value of 0.
- All inputs and outputs of the enabled subsystem (including the enable signal) run at the same rate.
- The **Show output port** parameter of the Enable block is set to `Off`.
- The **States when enabling** parameter of the Enable block is set to `held` (i.e., the Enable block does not reset states when enabled).
- The **Output when disabled** parameter for the enabled subsystem output ports is set to `held` (i.e., the enabled subsystem does not reset output values when disabled).
- If the DUT contains the following blocks, `RAMArchitecture` is set to `WithClockEnable`:
 - Dual Port RAM
 - Simple Dual Port RAM
 - Single Port RAM
- The enabled subsystem does not contain the following blocks:
 - CIC Decimation
 - CIC Interpolation
 - FIR Decimation
 - FIR Interpolation
 - Downsample
 - Upsample
 - HDL FIFO
 - HDL Cosimulation blocks (HDL Verifier™)
 - Rate Transition
 - NR Polar Encoder and NR Polar Decoder (Wireless HDL Toolbox™)

Example

The Automatic Gain Controller example shows how you can use enabled subsystems in HDL code generation. To open the example, enter:

Enumerated Constant

Generate enumerated constant value

Library: Simulink / Sources
HDL Coder / Sources

SLDemoSign.Positive >

Description

The Enumerated Constant block outputs a scalar, array, or matrix of enumerated values. You can also use the Constant block to output enumerated values, but it provides block parameters that do not apply to enumerated types, such as **Output minimum** and **Output maximum**. When you need a block that outputs only constant enumerated values, use Enumerated Constant rather than Constant. For more information, see “Simulink Enumerations”.

Ports

Output

Port_1 — Enumerated constant

scalar | vector | matrix

Enumerated constant value, specified as a scalar, vector, or matrix.

Data Types: enumerated

Parameters

Output data type — Output data type

Enum: SLDemoSign (default) | Enum:<ClassName>

Specify the enumerated type from which you want the block to output one or more values. The initial value, Enum:SLDemoSign, is a dummy enumerated type that prevents a newly cloned block from causing an error. To specify the desired enumerated type, select it from the drop-down list or enter Enum:ClassName in the **Output data type** field, where *ClassName* is the name of the MATLAB class that defines the type.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Enum:<ClassName>'

Default: 'Enum: SLDemoSign'

Mode — Category of data to specify

Enumerated (default)

Select the category of data to specify.

Enumerated

Enumerated data types. Selecting Enumerated enables a second menu/text box to the right, where you can enter the class name.

Value — Enumerated value

`SlDemoSign.Positive` (default) | Enum:<ClassName.Value>

Specify the value or values that the block outputs. The output of the block has the same dimensions and elements as the **Value** parameter. The initial value, `SlDemoSign.Positive`, is a dummy enumerated value that prevents a newly cloned block from causing an error.

To specify the desired enumerated values, select from the drop-down list or enter any MATLAB expression that evaluates to the desired result, including an expression that uses tunable parameters. All specified values must be of the type indicated by the **Output data type**. To specify an array that includes every value in the enumerated type, use the enumeration function.

Programmatic Use

Block Parameter: Value

Type: character vector

Values: 'Enum:<ClassName.Value>'

Default: 'SlDemoSign.Positive'

Sample time — Sample time

`inf` (default) | scalar | vector

Specify the interval between times that the block output can change during simulation (for example, due to tuning the **Value** parameter). The default value of `inf` indicates that the block output can never change. A sample time of `inf` speeds the simulation and generated code by avoiding the need to recompute the block output. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: 'inf'

Block Characteristics

Data Types	enumerated
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Environment Controller

Create branches of block diagram that apply only to simulation or only to code generation

Library: Simulink / Signal Routing

Description

The Environment Controller block outputs the signal at its **Sim** port only if the model that contains it is being simulated. It outputs the signal at its **Coder** port only if code is being generated from the model. This option enables you to create branches of a block diagram that apply only to simulation or code generation. This table describes various scenarios where either the **Sim** or **Coder** port applies.

Scenario	Output
Normal mode simulation	Sim
Accelerator mode simulation	Sim
Rapid accelerator mode simulation	Sim
Simulation of a referenced model in normal or accelerator modes	Sim
Simulation of a referenced model in processor-in-the-loop (PIL) mode	Coder (uses the same code generated for a referenced model)
External mode simulation	Coder
Standard code generation	Coder
Code generation of a referenced model	Coder

Simulink Coder software does not generate code for blocks connected to the **Sim** port if these conditions hold:

- On the **Code Generation > Optimization** pane of the Configuration Parameters dialog box, you set **Default parameter behavior** to **Inlined**.
- The blocks connected to the Sim port do not have external signals.
- The Sim port input path does not contain an S-function or an Interpreted MATLAB Function block.

If you enable block reduction optimization, Simulink eliminates blocks in the branch connected to the Coder port when compiling the model for simulation. For more information, see “Block reduction”.

Note Simulink Coder code generation eliminates the blocks connected to the Sim branch only if the Sim branch has the same signal dimensions as the Coder branch. Regardless of whether it eliminates the Sim branch, Simulink Coder uses the sample times on the Sim branch as well as the Coder branch to determine the fundamental sample time of the generated code and might, in some cases, generate sample-time handling code that applies only to sample times specified on the Sim branch.

Ports

Input

Sim — Simulation input

scalar | vector | matrix

Simulation input values, specified as a scalar, vector, or matrix. Input signal must have the same width as the input to the **Coder** port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Coder — Code generation input

scalar | vector | matrix

Code generation input values, specified as a scalar, vector, or matrix. Input signal must have the same width as the input to the **Sim** port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Out — Values from Sim or Coder input port

scalar | vector | matrix

Values from the **Sim** or **Coder** input port, depending on the current environment. For more information on what the block outputs in various simulation and code generation modes, see “Description” on page 1-549.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and

freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Event Listener

Add event port to a subsystem block

Library: Ports & Subsystems

Description

Add event port to a Subsystem block.

Parameters

Event type — Select event type for subsystem

Initialize (default) | Terminate | Reset

Select event type for subsystem to execute initialize, reset, or terminate algorithms.

Initialize

Select to trigger the execution of an Initialize Function block with an initialize event.

Terminate

Select to trigger the execution of a Terminate Function block with a terminate event.

Reset

Select to trigger the execution of an Initialize Function block reconfigured as a Reset Function block with a reset event.

Programmatic Use

Block Parameter: EventType

Type: character vector

Value: 'Initialize' | 'Terminate' | 'Reset'

Default: 'Initialize'

Event name — Specify event name

Reset (default) | event name

Specify event name for Reset Function block

Reset

Default name on the face of the Reset Function block.

event name

User entered name displayed on the face of the Reset Function block, and the name of the reset event port on the Model block containing the Reset Function block.

When typing the name for a reset function, the auto-completion list provides some suggestions. The list is not complete.

Dependency

To enable this parameter, set the **Event** parameter to **Reset**.

Programmatic Use**Block Parameter:** EventName**Type:** character vector**Value:** 'reset' | '<event name>'**Default:** 'reset'**Enable variant condition – Control activating the variant control (condition)**

off (default) | on

Control activating the variant control (condition) defined with the **Variant Control** parameter. off

Deactivate variant control of subsystem.

 on

Activate variant control of subsystem.

DependencySelecting this parameter, enables the **Variant control** and **Generate preprocessor conditionals** parameters.When you select **Enable variant condition** parameter, the badge indicates the change.**Programmatic Use****Block Parameter:** Variant**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Note**

- The Reset event port of a Model block can be conditional and propagates the net Variant conditions defined on the corresponding Reset Function block(s) in the referenced model.
- Initialize and Terminate event ports are always unconditional because they control both the model default and block-specific initialize and terminate events of the referenced model. If you define an Initialize function block in the referenced model, it corresponds to an explicit initialize event.

Variant control – Specify variant control (condition) expression

Variant (default) | logical expression

Specify variant control (condition) expression that executes a variant Initialize function, Reset function, or Terminate function block when the expression evaluates to true.

Variant

Default name for a logical (Boolean) expression.

logical expression

A logical (Boolean) expression or a Simulink.Variant object representing a boolean expression.

If you want to generate code for your model, define the variables in the expression as Simulink.Parameter objects.

Dependency

To enable this parameter, select the **Enable variant condition** parameter.

Programmatic Use

Block Parameter: VariantControl

Type: character vector

Value: 'Variant' | '<logical expression>'

Default: 'Variant'

Generate preprocessor conditionals — Select if variant choices are enclosed within C preprocessor conditional statements

off (default) | on

Select if variant choices are enclosed within C preprocessor conditional statements.

off

Does not enclose variant choices within C preprocessor conditional statements.

on

When generating code for an ERT target, encloses variant choices within C preprocessor conditional statements (#if).

Dependency

To enable this parameter, select the **Enable variant condition** parameter.

When you select **Generate preprocessor conditionals** parameter, the badge indicates the change.

Programmatic Use

Block Parameter: GeneratePreprocessorConditionals

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Extract Bits

Output selection of contiguous bits from input signal

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Extract Bits block allows you to output a contiguous selection of bits from the stored integer value of the input signal. Use the **Bits to extract** parameter to define the method for selecting the output bits.

- Select **Upper half** to output the half of the input bits that contain the most significant bit. If there is an odd number of bits in the input signal, the number of output bits is given by the equation
$$\text{number of output bits} = \text{ceil}(\text{number of input bits}/2)$$
- Select **Lower half** to output the half of the input bits that contain the least significant bit. If there is an odd number of bits in the input signal, the number of output bits is given by the equation
$$\text{number of output bits} = \text{ceil}(\text{number of input bits}/2)$$
- Select **Range starting with most significant bit** to output a certain number of the most significant bits of the input signal. Specify the number of most significant bits to output in the **Number of bits** parameter.
- Select **Range ending with least significant bit** to output a certain number of the least significant bits of the input signal. Specify the number of least significant bits to output in the **Number of bits** parameter.
- Select **Range of bits** to indicate a series of contiguous bits of the input to output in the **Bit indices** parameter. You indicate the range in `[start end]` format, and the indices of the input bits are labeled contiguously starting at 0 for the least significant bit.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. Floating-point inputs are passed through the block unchanged. `boolean` inputs are treated as `uint8` signals.

Note Performing bit operations on a signed integer is difficult. You can avoid difficulty by converting the data type of your input signals to unsigned integer types.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Port_1 – Extracted bits

scalar | vector | matrix | N-D array

Contiguous selection of extracted bits, specified as a scalar, vector, matrix, or N-D array. Floating-point inputs are passed through the block unchanged.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Bits to extract – Method for extracting bits

Upper half (default) | Lower half | Range starting with most significant bit | Range ending with least significant bit | Range of bits

Select the method for extracting bits from the input signal.

Consider an input signal that is represented in binary by 110111001:

- If you select `Upper half` for the **Bits to extract** parameter, the output is 11011 in binary.
- If you select `Lower half` for the **Bits to extract** parameter, the output is 11001 in binary.
- If you select `Range starting with most significant bit` for the **Bits to extract** parameter, and specify 3 for the **Number of bits** parameter, the output is 110 in binary.
- If you select `Range ending with least significant bit` for the **Bits to extract** parameter, and specify 8 for the **Number of bits** parameter, the output is 10111001 in binary.
- If you select `Range of bits` for the **Bits to extract** parameter, and specify [4 7] for the **Bit indices** parameter, the output is 1011 in binary.

Programmatic Use

Block Parameter: `bitsToExtract`

Type: character vector

Values: `'Upper half'` | `'Lower half'` | `'Range starting with most significant bit'` | `'Range ending with least significant bit'` | `'Range of bits'`

Default: `'Upper half'`

Number of bits – Number of bits to output

8 (default) | positive integer

Select the number of bits to output from the input signal. Signed integer data types must have at least two bits. Unsigned data integer types can be as short as a single bit.

Dependencies

To enable this parameter, set **Bits to extract** to `Range starting with most significant bit` or `Range ending with least significant bit`.

Programmatic Use**Block Parameter:** numBits**Type:** character vector**Values:** positive integer**Default:** '8'**Bit indices — Contiguous range of bits to output**

[0 7] (default) | contiguous range

Specify a contiguous range of bits of the input signal to output. Specify the range in [start end] format. The indices are assigned to the input bits starting with 0 at the least significant bit.

Dependencies

To enable this parameter, set **Bits to extract** to Range of bits.

Programmatic Use**Block Parameter:** bitIdxRange**Type:** character vector**Values:** contiguous range**Default:** '[0 7]'**Output scaling mode — Output scaling mode**

Preserve fixed-point scaling (default) | Treat bit field as an integer

Select the scaling mode to use on the output bit selection:

- When you select `Preserve fixed-point scaling`, the fixed-point scaling of the input is used to determine the output scaling during the data type conversion.
- When you select `Treat bit field as an integer`, the fixed-point scaling of the input is ignored, and only the stored integer is used to compute the output data type.

Programmatic Use**Block Parameter:** outScalingMode**Type:** character vector**Values:** 'Preserve fixed-point scaling' | 'Treat bit field as an integer'**Default:** 'Preserve fixed-point scaling'**Block Characteristics**

Data Types	Boolean double fixed point integer single

Introduced before R2006a

Fcn

(Not recommended) Apply specified expression to input

Note Fcn is not recommended. For more complicated expressions, use the MATLAB Function block. For less complicated expressions, consider replacing with blocks that model the same behavior.

Library: Simulink / User-Defined Functions

Description

The Fcn block applies the specified mathematical expression to its input. The expression can include one or more of these components:

- u — The input to the block. If u is a vector, $u(i)$ represents the i th element of the vector; $u(1)$ or u alone represents the first element.
- Numeric constants.
- Arithmetic operators (+ - * / ^).
- Relational operators (== != > < >= <=) — The expression returns 1 if the relation is true; otherwise, it returns 0.
- Logical operators (&& || !) — The expression returns 1 if the relation is true; otherwise, it returns 0.
- Parentheses.
- Mathematical functions — `abs`, `acos`, `asin`, `atan`, `atan2`, `ceil`, `cos`, `cosh`, `exp`, `floor`, `hypot`, `log`, `log10`, `power`, `rem`, `sgn` (equivalent to `sign` in MATLAB), `sin`, `sinh`, `sqrt`, `tan`, and `tanh`.

Note The Fcn block does not support `round` and `fix`. Use the Rounding Function block to apply these rounding modes.

- Workspace variables — Variable names that are not recognized in the preceding list of items are passed to MATLAB for evaluation. Matrix or vector elements must be specifically referenced (e.g., `A(1,1)` instead of `A` for the first element in the matrix).

The Fcn block observes the following rules of operator precedence:

- 1 ()
- 2 ^
- 3 + - (unary)
- 4 !
- 5 * /
- 6 + -

7 > < <= >=
8 == !=
9 &&
10 ||

The expression differs from a MATLAB expression in that the expression cannot perform matrix computations. Also, this block does not support the colon operator (:).

Block input can be a scalar or vector. The output is always a scalar. For vector output, consider using the Math Function block. If a block input is a vector and the function operates on input elements individually (for example, the `sin` function), the block operates on only the first vector element.

Limitations

- You cannot tune the expression during simulation in Normal or Accelerator mode (see “How Acceleration Modes Work”), or in generated code. To implement tunable expressions, tune the expression outside the Fcn block. For example, use the Relational Operator block to evaluate the expression outside.
- The Fcn block does not support custom storage classes. See “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Ports

Input

In — Input to a Fcn block

scalar | vector

The Fcn block accepts and outputs signals of type `single` or `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Data Types: `single` | `double`

Output

Out — Output from a Fcn block

scalar

The Fcn block accepts and outputs signals of type `single` or `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Data Types: `single` | `double`

Parameters

Expression — Specify the mathematical expression

mathematical expression

Specify the mathematical expression to apply to the input. Expression components are listed above. The expression must be mathematically well-formed (uses matched parentheses, proper number of

function arguments, and so on). The expression has restrictions on tunability (see “Limitations” on page 1-561).

Programmatic Use

Block Parameter: Expr

Type: character vector

Value: mathematical expression

Default: 'sin(u(1)*exp(2.3*(-u(2))))'

Sample time — Specify sample time in the block

scalar

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Block Characteristics

Data Types	double single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

You can generate HDL code for the block with both `single` and `double` data types in native floating-point mode. See “Generate Target-Independent HDL Code with Native Floating-Point” (HDL Coder).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . See also “ClockRatePipelining” (HDL Coder).

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is off. See also “DistributedPipelining” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is inherit. See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Introduced before R2006a

Find Nonzero Elements

Find nonzero elements in array

Library: Simulink / Math Operations

Description

The Find Nonzero Elements block locates all nonzero elements of the input signal and returns the linear indices of those elements. If the input is a multidimensional signal, the Find Nonzero Elements block can also return the subscripts of the nonzero input elements. In both cases, you can show an output port with the nonzero input values.

The Find Nonzero Elements block outputs a variable-size signal. The sample time for any variable-size signal must be discrete. If your model does not already use a fixed-step solver, you may need to select a fixed-step solver in the Configuration Parameters dialog. For more information, see “Compare Solvers” and “Choose a Solver”.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array

Input signal from which the block finds all nonzero elements.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 – Indices of nonzero elements

variable-size signal

The Find Nonzero Elements block outputs the indices of nonzero elements as a variable-size signal. You control the data type of the output using the **Output data type** block parameter.

Dependencies

By default, the block outputs linear indices from the first output port. When you change the **Index output format** to **Subscripts**, the block instead provides the element indices of a two-dimension or larger signal in a subscript form. In this mode, you must specify the **Number of input dimensions**, and the block creates a separate output port for each dimension.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_2 – Values of nonzero elements

variable-size signal

The Find block can optionally output the values of all nonzero elements as a variable-size signal.

Dependencies

To enable this port, select **Show output port for nonzero input values**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters**Main****Index output format — Format for indices of nonzero elements**

Linear indices (default) | Subscripts

Select the output format for the indices of the nonzero input values.

- Selecting **Linear indices** provides the element indices of any dimension signal in a vector form. For one dimension (vector) signals, indices correspond to the position of nonzero values within the vector. For signals with more than one dimension, the conversion of subscripts to indices is along the first dimension. You do not need to know the signal dimension of the input signal.
- Selecting **Subscripts** provides the element indices of a two-dimension or larger signal in a subscript form. Because the block shows an output port for each dimension, this option requires you to specify the **Number of input dimensions**.

Programmatic Use

Block Parameter: IndexOutputFormat

Type: character vector

Values: 'Linear indices' | 'Subscripts'

Default: 'Linear indices'

Number of input dimensions — Number of dimensions for the input signal

1 (default) | scalar

Specify the number of dimensions for the input signal as a positive integer value from 1 to 32.

Dependencies

To enable this parameter, set **Index output format** to **Subscripts**.

Programmatic Use

Block Parameter: NumberOfInputDimensions

Type: character vector

Values: scalar

Default: '1'

Index mode — Specify zero- or one-based indexing

Zero-based (default) | One-based

Specify the indexing mode as Zero-based or One-based.

- For **Zero-based** indexing, an index of 0 specifies the first element of the input vector. An index of 1 specifies the second element, and so on.
- For **One-based** indexing, an index of 1 specifies the first element of the input vector. An index of 2, specifies the second element, and so on.

Programmatic Use**Block Parameter:** IndexMode**Type:** character vector**Values:** 'Zero-based' | 'One-based'**Default:** 'Zero-based'**Show output port for nonzero input values — Enable output port for nonzero values**

off (default) | on

Show or hide the output port for nonzero input values.

- When you clear this check box (off), the block hides the output port for nonzero input values.
- When you select this check box (on), the block displays the output port for nonzero input values. The additional output port provides values of the nonzero input elements.

Programmatic Use**Block Parameter:** ShowOutputPortForNonzeroInputValues**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'**Sample time — Specify sample time as a value other than -1**

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar or vector**Default:** '-1'**Data Types****Output data type — Output data type**

Inherit: Inherit via internal rule (default) | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | <data type expression>

Specify the output data type.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

First Order Hold

Implement linearly extrapolated first order hold on input signal

Library: Simulink / Continuous

Description

The First Order Hold block outputs a continuous piecewise linear approximation of its input signal. Use the First Order Hold block to convert a sampled discrete signal to a continuous signal without triggering a solver reset.

You can also use the First Order Hold block to break algebraic loops in your model.

Ports

Input

Port 1 — Input signal

scalar | vector | matrix

Input signal, specified as a real-valued scalar, vector, or matrix.

Data Types: double

Output

Port 1 — Linearly approximated output signal

scalar | vector | matrix

Piecewise linear approximation of the input signal.

Data Types: double

Parameters

Initial output — Initial output

0 (default) | scalar | vector

Specify the output that the block generates until the simulation time exceeds the first sample hit time of the discrete input.

Dependencies

- The initial output of this block cannot be `inf` or `NaN`.
- A Run-to-run tunable parameter cannot be changed during simulation run time. However, changing it before a simulation begins does not cause Accelerator or Rapid Accelerator to regenerate code.

Programmatic Use**Block Parameter:** InitialOutput**Type:** character vector, string**Values:** scalar | vector**Default:** '0'**Output algorithm — Approximation technique for output signal**

Slow (Avoid Overshoot) (default) | Fast (Minimize Error)

Specify the approximation technique to use to smooth the input signal. The slow, or low pass algorithm aims to avoid overshoots when smoothing the input signal. The fast, or high pass algorithm minimizes error by attempting to predict the next input during the update method of the block. This error reduction in predicted output of the block is traded off against a tendency to overshoot the reference, or input signal.

Programmatic Use**Block Parameter:** OutputAlgorithm**Type:** character vector, string**Values:** Slow (Avoid Overshoot)|Fast (Minimize Error)**Default:** 'Slow (Avoid Overshoot)'**Reset if relative extrapolation error exceeds — Error tolerance for solver reset**

inf (default) | nonnegative real scalar

Specify the tolerance level for the extrapolation error of the Output Algorithm. Extrapolation error greater than this value will cause Simulink to reset the solver for the model.

Tip Enabling the **Allow continuous input** parameter when this parameter is set to inf can lead to numerical inaccuracies in simulation.

Programmatic Use**Block Parameter:** ErrorTolerance**Type:** character vector, string**Values:** scalar**Default:** 'inf'**Allow continuous input — Apply hold on continuous signals**

off (default) | on

Select this parameter to enable the block to accept continuous signals as input. Enabling this parameter creates a delay between the input and output continuous signals.

Note Enable this parameter when using this block to break an algebraic loop.

Programmatic Use**Block Parameter:** AllowContinuousInput**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'off'

Block Characteristics

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

Slow (Avoid overshoot)

The linear extrapolation performed by the slow or low pass algorithm can be described as:

$$y(t) = M_k(t - T_k) + C_k \quad \forall \quad T_k \leq t < t_{k+1}$$

where:

- T_k is the time at k^{th} major step.
- U_k is the input at k^{th} major step.
- C_k and M_k are the linear extrapolation coefficients.
- y_k is the continuous output at time T_k .

The coefficients, or slope M_k and y-intercept C_k , are calculated as follows

$$H_k = T_k - T_{k-1}$$

$$M_{k+1} = \frac{U_k - U_{k-1}}{H_k}$$

$$C_k = y_k$$

Fast (Minimize Error)

The linear extrapolation performed by the fast, or high pass, algorithm can be described as:

$$y(t) = N_k(t - T_k) + C_k \quad \forall \quad T_k \leq t < T_{k+1}$$

where:

- T_k is the time at k^{th} major step.
- U_k is the input at k^{th} major step.
- \hat{U} is the predicted value of the input at $(k+1)^{\text{th}}$ major step.
- (C_k and N_k are the linear extrapolation coefficients.
- y_k is the continuous output at time T_k .

The coefficients, or slope N_k and y-intercept C_k , are calculated as follows

$$H_k = T_k - T_{k-1}$$

$$M_{k+1} = \frac{U_k - U_{k-1}}{H_k}$$

$$\widehat{U} = U_k + M_{k+1}(H_k)$$

$$N_{k+1} = \frac{\widehat{U} - y_k}{H_k}$$

$$C_k = y_k$$

The fast algorithm minimizes error by attempting to predict the next input during the update method of the block. This error reduction in predicted output of the block is traded off against a tendency to overshoot the input signal.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code generation.

Consider discretizing your model.

Memory | Zero-Order Hold

Introduced in R2019b

Fixed-Point State-Space

Implement discrete-time state space

Library: Simulink / Additional Math & Discrete / Additional Discrete

Description

The Fixed-Point State-Space block implements the system described by

$$y(n) = Cx(n) + Du(n)$$

$$x(n + 1) = Ax(n) + Bu(n)$$

where u is the input, x is the state, and y is the output. Both equations have the same data type.

- **A** must be an n -by- n matrix, where n is the number of states.
- **B** must be an n -by- m matrix, where m is the number of inputs.
- **C** must be an r -by- n matrix, where r is the number of outputs.
- **D** must be an r -by- m matrix.

In addition:

- The state x must be an n -by-1 vector.
- The input u must be an m -by-1 vector.
- The output y must be an r -by-1 vector.

The block accepts one input and generates one output. The width of the input vector is the number of columns in the **B** and **D** matrices. The width of the output vector is the number of rows in the **C** and **D** matrices. To define the initial state vector, use the **Initial conditions** parameter.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input vector, where the width equals the number of columns in the **B** and **D** matrices. For more information, see “Description” on page 1-572.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal, with width equal to the number of rows in the **C** and **D** matrices. For more information, see “Description” on page 1-572.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

State Matrix A — Matrix of states

[2.6020 -2.2793 0.6708; 1 0 0; 0 1 0] (default) | scalar | vector | matrix

Specify the matrix of states as an n -by- n matrix of real or complex values, where n is the number of states. For more information on the matrix coefficients, see “Description” on page 1-572.

Programmatic Use

Block Parameter: A

Type: character vector

Values: scalar | vector | matrix

Default: '[2.6020 -2.2793 0.6708; 1 0 0; 0 1 0]'

Input Matrix B — Column vector of inputs

[1; 0; 0] (default) | scalar | vector | matrix

Specify the column vector of inputs as an n -by- m matrix of real or complex values, where n is the number of states, and m is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-572.

Programmatic Use

Block Parameter: B

Type: character vector

Values: scalar | vector | matrix

Default: '[1; 0; 0]'

Output Matrix C — Column vector of outputs

[0.0184 0.0024 0.0055] (default) | scalar | vector | matrix

Specify the column vector of outputs as an r -by- n matrix of real or complex values, where r is the number of outputs, and n is the number of states. For more information on the matrix coefficients, see “Description” on page 1-572.

Programmatic Use

Block Parameter: C

Type: character vector

Values: scalar | vector | matrix

Default: '[0.0184 0.0024 0.0055]'

Direct Feedthrough Matrix D — Matrix for direct feedthrough

[0.0033] (default) | scalar | vector | matrix

Specify the matrix for direct feedthrough as an r -by- m matrix of real or complex values, where r is the number of outputs, and m is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-572.

Programmatic Use**Block Parameter:** D**Type:** character vector**Values:** scalar | vector | matrix**Default:** '[0.0033]'**Initial condition for state — Initial state vector**

0.0 (default) | scalar | vector | matrix

Specify the initial condition for the state.

Limitations

The initial state cannot be `inf` or `NaN`.

Programmatic Use**Block Parameter:** X0**Type:** character vector**Values:** scalar | vector | matrix**Default:** '0.0'**Signal Attributes****Data type for internal calculations — Data type for internal calculations**

fixdt('double') (default) | data type string

Specify the data type the block uses for internal calculations.

Programmatic Use**Block Parameter:** InternalDataType**Type:** character vector**Values:** data type string**Default:** 'fixdt('double')'**Scaling for State Equation $AX+BU$ — Scaling for state equations**2⁰ (default) | scalar

Specify the scaling for the state equation $AX+BU$.

Programmatic Use**Block Parameter:** StateEqScaling**Type:** character vector**Values:** scalar**Default:** '2⁰'**Scaling for Output Equation $CX+DU$ — Scaling for output equations**2⁰ (default) | scalar

Specify the scaling for the output equation $CX+DU$.

Programmatic Use**Block Parameter:** InternalDataType

Type: character vector

Values: scalar

Default: '2^0'

Lock output data type setting against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean ^a double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no

Variable-Size Signals	yes
Zero-Crossing Detection	no

a. This block is not recommended for use with Boolean signals.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Floating Scope and Scope Viewer

Display signals generated during simulation without signal lines

Library: Simulink / Sinks
HDL Coder / Sinks

Description

The Simulink Scope Viewer and Floating Scope block display time domain signals with respect to simulation time. The Scope Viewer and Floating Scope block have the same functionality as the Scope block, but they are not connected to signal lines.

For information on controlling a Floating Scope block from the command line, see “Control Scope Blocks Programmatically” in the Simulink documentation.

Connect Signals

In the Floating Scope window or Scope viewer window, use the  button to connect signals.

To add a viewer with a connected signal, select a signal in the model. Then, on the **Simulation** tab, in the **Prepare** gallery, click **Add Viewer**.

For more details, see “Add Signals to an Existing Floating Scope or Scope Viewer”.

Key Features

- Multiple y-axes (displays) — Display multiple y-axes with multiple input ports. All the y-axes have a common time range on the x-axis.
- Multiple signals — Show multiple signals on the same y-axis (display) from one or more input ports.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Display data after simulation — If a scope is closed at the start of a simulation, scope data is still written to the scope during the simulation. If you open the scope after a simulation, the scope displays simulation results for input signals.

Oscilloscope Measurements

- Triggers — Set triggers on repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics¹ — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder^a — Find maxima, showing the x-axis values at which they occur.
- Bilevel Measurements^a — Measure transitions, overshoots, undershoots, and cycles.

Limitations

When you use model configuration parameters that optimize the simulation, such as **Signal storage reuse** or **Block reduction**, Simulink eliminates storage for some signals during simulation. You are unable to apply a Floating Scope to these eliminated signals. To work around this issue, configure an eliminated signal as a test point. You can then apply a Floating Scope to the signal regardless of optimization settings. To configure test points, see “Configure Signals as Test Points”.

- If you step back the simulation after adding or removing a signal, the Floating Scope clears the existing data. New data does not appear until the simulation steps forward again.
- When connected to a constant signal, the scope plots a single point.
- Simulink messages are not supported for Floating Scope block and Scope Viewer.
- You cannot connect signals from ForEach subsystems.

Ports

Input

Port_1 — Signal or signals to visualize

scalar | vector | matrix | array | bus | nonvirtual bus

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Type** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink”.

1. You must have a Simscape™ or DSP System Toolbox license to use the Peak Finder, Bilevel Measurements, and Signal Statistics.

- **Dimension** — Scalar, one dimensional (vector), two dimensional (matrix), or multidimensional (array). Display multiple channels within one signal depending on the dimension. See “Signal Dimensions” and “Determine Signal Dimensions”.

Input Limitations

- When the input is a constant signal, the scope plots a single point.
- The scope shows gaps in the display when the signal value is NaN.
- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.

Bus Support

You can connect nonvirtual bus and arrays of bus signals to a scope. To display the bus signals, use normal or accelerator simulation mode. The scope displays each bus element signal in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log nonvirtual bus signals with a scope, set the **Save format** parameter to **Dataset**. You can use any **Save format** to log virtual bus signals.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Properties

Configuration Properties

The Configuration Properties dialog box controls various properties about the scope displays. From the scope menu, select **View > Configuration Properties**.

Main

Open at simulation start — Specify when scope window opens

off (default) | on

Select this check box to open the scope window when simulation starts.

Programmatic Use

See `OpenAtSimulationStart`.

Display the full path — Display block path on scope title bar

off (default) | on

Select this check box to display the block path in addition to the block name.

Layout — Number and arrangement of displays

1-by-1 display (default) | an arrangement of *m*-by-*n* displays

Specify number and arrangement of displays. To expand the layout grid beyond 4 by 4, click within the dialog box and drag. The maximum layout is 16 rows by 16 columns.

If the number of displays is equal to the number of ports, signals from each port appear on separate displays. If the number of displays is less than the number of ports, signals from additional ports appear on the last display. For layouts with multiple columns and rows, ports are mapped down and then across.

Programmatic Use

See `LayoutDimensions`.

Input processing — Channel or element signal processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

- Elements as channels (sample based) — Process each element as a unique sample.
- Columns as channels (frame based) — Process signal values in a column as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

Programmatic Use

See `FrameBasedProcessing`.

Maximize axes — Maximize size of plots

Off (default) | Auto | On

- Auto — If “Title” on page 1-0 and “Y-label” on page 1-0 properties are not specified, maximize all plots.
- On — Maximize all plots. Values in **Title** and **Y-label** are hidden.
- Off — Do not maximize plots.

Programmatic Use

See `MaximizeAxes`.

Time

Time span — Length of x-axis to display

Auto (default) | User defined

- Auto — Difference between the simulation start and stop times.

The block calculates the beginning and end times of the time range using the “Time display offset” on page 1-0 and “Time span” on page 1-0 properties. For example, if you set the **Time display offset** to 10 and the **Time span** to 20, the scope sets the time range from 10 to 30.

- User defined — Enter any value less than the total simulation time.

Programmatic Use

See TimeSpan.

Time span overrun action — Display data beyond visible x-axis

Wrap (default) | Scroll

Specify how to display data beyond the visible x-axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

- Wrap — Draw a full screen of data from left to right, clear the screen, and then restart drawing the data from the left.
- Scroll — Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Programmatic Use

See TimeSpanOverrunAction.

Time units — x-axis units

None (default for Scope) | Metric (default for Time Scope) | Seconds

- Metric — Display time units based on the length of “Time span” on page 1-0 .
- Seconds — Display time in seconds.
- None — Do not display time units.

Programmatic Use

See TimeUnits.

Time display offset — x-axis offset

0 (default) | scalar | vector

Offset the x-axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scalar or vector:

- Scalar — Offset all channels of an input signal by the same time value.
- Vector — Independently offset the channels.

Programmatic Use

See TimeDisplayOffset.

Time-axis labels — Display of x-axis labels

Bottom Displays Only (default for Scope) | All (default for Time Scope) | None

Specify how x-axis (time) labels display:

- All — Display x-axis labels on all y-axes.
- None — Do not display labels. Selecting None also clears the **Show time-axis label** check box.
- Bottom displays only — Display x-axis label on the bottom y-axis.

Dependencies

To enable this property, set:

- “Show time-axis label” on page 1-0 to on.
- “Maximize axes” on page 1-0 to off.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See `TimeAxisLabels`.

Show time-axis label — Display or hide x-axis labels

off (default for Scope) | on (default for Time Scope)

Select this check box to show the x-axis label for the active display

Dependencies

To enable this property, set “Time-axis labels” on page 1-0 to All or Bottom Displays Only.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See `ShowTimeAxisLabel`.

Display**Active display — Selected display**

1 (default) | positive integer

Selected display. Use this property to control which display is changed when changing style properties and axes-specific properties.

Specify the desired display using a positive integer that corresponds to the column-wise placement index. For layouts with multiple columns and rows, display numbers are mapped down and then across.

Programmatic Use

See `ActiveDisplay`.

Title — Display name

%<SignalLabel> (default) | string

Title for a display. The default value %<SignalLabel> uses the input signal name for the title.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See Title.

Show Legend — Display signal legend

off (default) | on

Toggle signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names, and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

Note The legend only shows the first 20 signals. Any additional signals cannot be controlled from the legend.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowLegend.

Show grid — Show internal grid lines

on (default) | off

Select this check box to show grid lines.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowGrid.

Plot signals as magnitude and phase — Split display into magnitude and phase plots

off (default) | on

- On — Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.
- Off — Display signal plot. If the signal is complex, plots the real and imaginary parts on the same y-axis.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See `PlotAsMagnitudePhase`.

Y-limits (Minimum) — Minimum y-axis value

-10 (default) | real scalar

Specify the minimum value of the y-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 1-0 `property` determines which display is affected.

Programmatic Use

See `YLimits`.

Y-limits (Maximum) — Maximum y-axis value

10 (default) | real scalar

Specify the maximum value of the y-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 1-0 `property` determines which display is affected.

Programmatic Use

See `YLimits`.

Y-label — Y-axis label

none (default for Scope) | Amplitude (default for Time Scope) | string

Specify the text to display on the y-axis. To display signal units, add (`%<SignalUnits>`) to the label. At the beginning of a simulation, Simulink replaces (`%SignalUnits`) with the units associated with the signals.

Example: For a velocity signal with units of m/s, enter `Velocity (%<SignalUnits>)`.

Dependency

If you select **Plot signals as magnitude and phase**, this property does not apply. The y-axes are labeled Magnitude and Phase.

The “Active display” on page 1-0 `property` determines which display is affected.

Programmatic Use

See `YLabel`.

Logging**Limit data points to last — Limit buffered data values**

off (default) | on

Limit buffered data values before plotting and saving signals. Data values are from the end of a simulation. To use this property, you must also specify the number of data values by entering a positive integer in the text box.

- On — Specify the number of data values saved for each signal (5000 by default). If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

Sometimes, selecting this parameter cause signals to be plotted for less than the entire time range of a simulation. For example, where the sample time is small. If a scope plots a portion of your signals, consider increasing the number of data values the simulation saves.

- Off — Save and plot all data values. Clearing **Limit data points to last** can cause an out-of-memory error for simulations that generate a large amount of data or for systems without enough available memory.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See `DataLoggingLimitDataPoints` and `DataLoggingMaxPoints`.

Decimation — Reduce amount of scope data to display and save

off (default) | on

- On — Plot and log (save) scope data every N^{th} data point, where N is the decimation factor entered in the text box. The default decimation factor is 2. A value of 1 buffers all data values.
- Off — Save all scope data values.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See `DataLoggingDecimateData` and `DataLoggingDecimation`.

Log/Unlog Viewed Signals to Workspace — Toggle logging

on | off

For signals selected with the Signal Selector, clicking this button toggles the state of the **Log signal data** check boxes in the Signals Properties dialog boxes.

Axes Scaling Properties

The Axes Scaling Properties dialog controls the axes limits of the scope. To open the Axes Scaling properties, in the scope menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

Axes scaling — Y-axis scaling mode

Manual (default) | Auto | After N Updates

- **Manual** — Manually scale the y-axis range with the **Scale Y-axis Limits** toolbar button.
- **Auto** — Scale the y-axis range during and after simulation. Selecting this option displays the “Do not allow Y-axis limits to shrink” on page 1-0 check box. If you want the y-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to Auto and clear the **Do not allow Y-axis limits to shrink** check box.
- **After N Updates** — Scale y-axis after the number of time steps specified in the “Number of updates” on page 1-0 text box (10 by default). Scaling occurs only once during each run.

Programmatic Use

See AxesScaling.

Do not allow Y-axis limits to shrink — When y-axis limits can change

on (default) | off

Allow y-axis range limits to increase but not decrease during a simulation.

Dependency

To use this property, set “Axes scaling” on page 1-0 to Auto.

Number of updates — Number of updates before scaling

10 (default) | integer

Set this property to delay auto scaling the y-axis.

Dependency

To use this property, set “Axes scaling” on page 1-0 to After N Updates.

Programmatic Use

See AxesScalingNumUpdates.

Scale axes limits at stop — When y-axis limits can change

on (default) | off

- **On** — Scale axes when simulation stops.
- **Off** — Scale axes continually.

Dependency

To use this property, set “Axes scaling” on page 1-0 to Auto.

Y-axis Data range (%) — Percent of y-axis to use for plotting

80 (default) | integer between [1, 100]

Specify the percentage of the y-axis range used for plotting data. If you set this property to 100, the plotted data uses the entire y-axis range.

Y-axis Align — Alignment along y-axis

Center (default) | Top | Bottom

Specify where to align plotted data along the y-axis data range when **Y-axis Data range** is set to less than 100 percent.

- Top — Align signals with the maximum values of the y-axis range.
- Center — Center signals between the minimum and maximum values.
- Bottom — Align signals with the minimum values of the y-axis range.

Autoscale X-axis limits — Scale x-axis range limits

off (default) | on

Scale x-axis range to fit all signal values. If **Axes scaling** is set to Auto, the data currently within the axes is scaled, not the entire signal in the data buffer.

X-axis Data range (%) — Percent of x-axis to use for plotting

100 (default) | integer in the range [1, 100]

Specify the percentage of the x-axis range to plot data on. For example, if you set this property to 100, plotted data uses the entire x-axis range.

X-axis Align — Alignment along x-axis

Center (default) | Top | Bottom

Specify where to align plotted data along the x-axis data range when **X-axis Data range** is set to less than 100 percent.

- Top — Align signals with the maximum values of the x-axis range.
- Center — Center signals between the minimum and maximum values.
- Bottom — Align signals with the minimum values of the x-axis range.

Style Properties

To open the Style dialog box, from the scope menu, select **View > Style**.

Figure color — Background color for window

black (default) | color

Background color for the scope.

Plot type — How to plot signal

Auto (default for Scope) | Line (default for Time Scope) | Stairs | Stem

When you select Auto, the plot type is a line graph for continuous signals, a stair-step graph for discrete signals, and a stem graph for Simulink message signals.

Axes colors — Background and axes color for individual displays

black (default) | color

Select the background color for axes (displays) with the first color palette. Select the grid and label color with the second color palette.

Preserve colors for copy to clipboard — Copy scope without changing colors

off (default) | on

Specify whether to use the displayed color of the scope when copying.

When you select **File > Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

Properties for line – Line to change

Channel 1 (default)

Select active line for setting line style properties.

Visible – Line visibility

on (default) | off

Show or hide a signal on the plot.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Line – Line style

solid line (default style) | 0.75 (default width) | yellow (default color)

Select line style, width, and color.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Marker – Data point marker style

None (default) | marker shape

Select marker shape.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

For Each

Process elements or subarrays of a mask parameter or input signal independently

Library: Ports & Subsystems

Description

The For Each block serves as a control block for the For Each Subsystem block. Specifically, the For Each block enables the blocks inside the For Each Subsystem to process the elements of input signals or mask parameters independently. Each block inside this subsystem that has states maintains a separate set of states for each element or subarray that it processes. As the set of blocks in the subsystem processes the elements or subarrays, the subsystem concatenates the results to form output signals.

You can use a For Each subsystem to iteratively compute output after changing inputs or mask parameters. To do so, you configure the partitioning of input signals or mask parameters in the For Each block dialog box.

Partition Input Signals to the Subsystem

In a For Each subsystem, you can specify which input signals to partition for each iteration using the **Input Partition** tab in the dialog box of the For Each block. When specifying a signal to be partitioned, you also have to specify the **Partition Dimension**, **Partition Width**, and **Partition Offset** parameters.

Partition Parameters in the For Each block

You can partition the mask parameters of a For Each Subsystem block. Partitioning is useful for systems that have identical structures in each iteration but different parameter values. In this case, changing the model to partition extra input signals for each parameter is cumbersome. Instead, add a mask parameter to a For Each subsystem. For more information, see "Create a Simple Mask". To select the mask parameter for partitioning, use the Parameter Partition tab on the For Each block dialog box. For more information, see "Select Partition Parameters" on page 1-591

Concatenate Output

You define the dimension along which to concatenate the results by specifying the **Concatenation Dimension** in the Output Concatenation tab.

The results generated by the block for each subarray stack along the concatenation dimension, d_1 (y -axis). Whereas, if you specify d_2 by setting the concatenation dimension to 2, the results concatenate along the d_2 direction (x -axis). Thus if the process generates row vectors, then the concatenated result is a row vector.

Select Partition Parameters

When selecting an input signal or subsystem mask parameter for partitioning, you need to specify how to decompose it into elements or subarrays for each iteration. Do this by setting integer values for the **Partition Dimension**, **Partition Width**, and **Partition Offset** parameters.

As an illustration, consider an input signal matrix A of the form:

The labels d_1 and d_2 , respectively, define dimensions 1 and 2. If you retain the default setting of 1 for both the partition dimension and the partition width, and 0 for the partition offset, then Simulink slices perpendicular to partition dimension d_1 at a width equal to the partition width, that is one element.

Matrix A decomposes into these three row vectors.

$$\begin{bmatrix} A_{11} & A_{12} & A_{13} \end{bmatrix}$$

$$\begin{bmatrix} A_{21} & A_{22} & A_{23} \end{bmatrix}$$

$$\begin{bmatrix} A_{31} & A_{32} & A_{33} \end{bmatrix}$$

If instead you specify d_2 as the partition dimension by entering the value 2, Simulink slices perpendicular to d_2 to form three column vectors.

$$\begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} \quad \begin{bmatrix} A_{12} \\ A_{22} \\ A_{32} \end{bmatrix} \quad \begin{bmatrix} A_{13} \\ A_{23} \\ A_{33} \end{bmatrix}$$

In addition to setting the **Partition Dimension** to 2, if you set the **Partition Width** to 2 and the **Partition Offset** to -1, Simulink uses two overlapping 3x2 partitions for processing.

For an example using the **Partition Offset** parameter, open the Simulink model `slexForEachOverlapExample`.

Note Only signals are considered one-dimensional in Simulink. Mask parameters are row or column vectors, according to their orientation. To partition a row vector, specify the partition dimension as 2 (along the columns). To partition a column vector, specify the partition dimension as 1 (along the rows).

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Input Partition Tab

Select each input signal you want to partition and to specify the corresponding **Partition Dimension** and **Partition Width** parameters. See the Inport block reference page for more information.

Port — List of input ports

no default (default) | input port name

List of input ports connected to the For Each Subsystem block.

Partition — Select input port signals to partition

off (default) | on

Select input ports signals connected to the For Each Subsystem block to partition into subarrays or elements.

off

Clear input port signals.

on

Select input port signals to partition.

Dependency

Selecting this parameter enables the **Partition Dimension** and **Partition Width** parameters for the selected input port signal.

Programmatic Use**Block Parameter:** InputPartition**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Partition Dimension — Specify dimension**

1 (default) | integer

Specify the dimension through which to slice the input signal array. The resulting slices are perpendicular to the dimension that you specify. The slices also partition the array into subarrays or elements, as appropriate.

1

Specify a dimension of 1.

integer

Specify dimension. Minimum value 1.

Programmatic Use**Block Parameter:** InputPartitionDimension**Type:** character vector**Values:** '1' | '<integer>'**Default:** '1'**Partition Width — Specify width**

1 (default) | integer

Specify the width of each partition slice of the input signal.

1

Width of one element.

integer

Specify width. Minimum value 1.

Programmatic Use

Block Parameter: InputPartitionWidth

Type: character vector

Values: '1' | '<integer>'

Default: '1'

Partition Offset – Specify partition offset

0 (default) | integer

Specify the offset for each partition slice of the input signal.

0

No offset between partition slices.

integer

Specify partition offset where the sum of the partition width and the partition offset is a positive integer.

For example, a **Partition Width** of 3 and a **Partition Offset** of -2 indicates that each 3 element slice overlaps its neighboring slices by 2 elements.

Programmatic Use

Block Parameter: SubsysMaskParameterOffset

Type: character vector

Values: '0' | '<integer>'

Default: '0'

Show partition index output port (zero-based indexing) – Control display of output port

off (default) | on

Control display of output port for partition index.

off

Hide output port.

on

Display output port on block.

Dependency

Selecting this parameter enables the **Partition index output data type** parameter.

Programmatic Use

Block Parameter: ShowIterationIndex

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Partition index output data type – Specify partition index data type

0 (default) | integer

Specify partition index data type for output port

int32

Select signed 32-bit integer.

double

Select double real.

Programmatic Use

Block Parameter: IterationIndexDataType

Type: character vector

Values: 'int32' | 'double'

Default: 'int32'

Output Concatenation Tab

For each output port, specify the dimension along which to stack (concatenate) the For Each Subsystem block results. See the Outport block reference page for more information.

Port — List of output ports

none (default) | output port name

List of output ports connected to the For Each Subsystem block.

Concatenation Dimension — Specify dimension

1 (default) | integer

Specify the dimension along which to stack the results of the For Each Subsystem block.

1

The results stack in the d_1 direction. If the block generates column vectors, the concatenation process results in a single column vector.

integer

The results stack in the d_2 direction. If the block generates row vectors, the concatenation process results in a single row vector. Minimum value 1

Programmatic Use

Block Parameter: OutputConcatenationDimension

Type: character vector

Values: '1' | '<integer>'

Default: '1'

Parameter Partition Tab

Select each mask parameter to partition and to specify the corresponding **Partition Dimension** and **Partition Width** parameters. Parameters appear in the list only if you have added an editable parameter to the mask of the parent For Each subsystem.

Parameter — List of mask parameters

parameter name

List of mask parameters for the For Each Subsystem block.

Partition — Select mask parameters to partition

off (default) | on

Select mask parameters for the For Each Subsystem block to partition into subarrays or elements.

off

Clear mask parameters.

on

Select mask parameters to partition.

Dependency

Selecting this parameter enables the **Partition Dimension** and **Partition Width** parameters for the selected mask parameter.

Programmatic Use

Block Parameter: SubsysMaskParameterPartition

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Partition Dimension — Specify dimension

1 (default) | integer

Specify the dimension through which to slice the input signal array as an integer greater than or equal to one. The resulting slices are perpendicular to the dimension that you specify. The slices also partition the array into subarrays or elements, as appropriate.

Programmatic Use

Block Parameter: SubsysMaskParameterPartitionDimension

Type: character vector

Values: '1' | '<integer>'

Default: '1'

Partition Width — Specify partition width

1 (default) | integer

Specify the width of each partition slice of the input signal as an integer greater than or equal to one.

Programmatic Use

Block Parameter: SubsysMaskParameterPartitionWidth

Type: character vector

Values: '1' | '<integer>'

Default: '1'

For Each Subsystem

Subsystem that repeats execution on each element or subarray of input signal and concatenates results

Library: Simulink / Ports & Subsystems
HDL Coder / Ports & Subsystems

Description

The For Each Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats execution during a simulation time step on each element or subarray of an input signal.

The set of blocks within the subsystem represents the algorithm applied to a single element or subarray of the original signal. The For Each block inside the subsystem allows you to configure the decomposition of the subsystem inputs into elements or subarrays, and to configure the concatenation of the individual results into output signals. The block parameters **Partition Dimension** and **Partition Width** specify the dimension through which to slice the input signal and the width of each slice respectively. To partition a row vector, specify the **Partition Dimension** as 2. To partition a column vector, specify the **Partition Dimension** as 1. To learn more about the block parameters, see For Each.

Inside this subsystem, each block that has states maintains separate sets of states for each element or subarray that it processes. Consequently, the operation of this subsystem is similar in behavior to copying the contents of the subsystem for each element in the original input signal and then processing each element using its respective copy of the subsystem.

An additional benefit of the For Each Subsystem block is that, for certain models, it improves the code reuse in SimulinkCoder generated code. Consider a model containing two reusable Atomic Subsystem blocks with the same scalar algorithm applied to each element of the signal. If the input signal dimensions of these subsystems are different, Simulink Coder generated code includes two distinct functions. You can replace these two subsystems with two identical For Each Subsystem blocks that are configured to process each element of their respective inputs using the same algorithm. For this case, Simulink Coder generated code consists of a single function parameterized by the number of input signal elements. This function is invoked twice — once for each unique instance of the For Each Subsystem block in the model. For each of these cases, the input signal elements have different values.

S-Function Support

The For Each Subsystem block supports both C-MEX S-functions and Level-2 MATLAB S-functions, provided that the S-function supports multiple execution instances using one of the following techniques:

- A C-MEX S-function must declare `ssSupportsMultipleExecInstances(S, true)` in the `mdlSetWorkWidths` method.
- A Level-2 MATLAB S-function must declare `block.SupportsMultipleExecInstances = true` in the `setup` method.

If you use the above specifications:

- Do not cache run-time data, such as `DWork` and Block I/O, using global or persistent variables or within the user data of the S-function.
- Every S-function execution method from `mdlStart` up to `mdlTerminate` is called once for each element processed by the S-function, when it is in a For Each Subsystem block. Consequently, you need to be careful not to free the same memory on repeated calls to `mdlTerminate`. For example, consider a C-MEX S-function that allocates memory for a run-time parameter within `mdlSetWorkWidths`. The memory only needs to be freed once in `mdlTerminate`. As a solution, set the pointer to be empty after the first call to `mdlTerminate`.

Limitations

The For Each Subsystem block has these limitations, and these are the workarounds.

Limitation	Workaround
You cannot log bus or an array of bus signals directly in the For Each subsystem.	Use one of these approaches: <ul style="list-style-type: none"> • Use a Bus Selector block to select the signals you want to log and mark those signals for signal logging. • Attach the signal to an Outport block and log the signal outside the For Each subsystem.
You cannot log a signal inside a referenced model that is inside a For Each subsystem if either of these conditions exists: <ul style="list-style-type: none"> • The For Each subsystem is in a model simulating in Rapid Accelerator mode. • The For Each subsystem itself is in a model referenced by a Model block in Accelerator mode. 	For the first condition, use Accelerator mode. For the second condition, use Normal or Rapid Accelerator mode.
You cannot log the states of the blocks in a For Each subsystem .	Save and restore the simulation state.
You cannot use Normal mode to simulate a Model block inside a For Each subsystem.	Use Accelerator or Rapid Accelerator mode.

Limitation	Workaround
Reusable code is generated for two For Each Subsystems with identical contents if their input and output signals are vectors (1-D or 2-D row or column vector). For n-D input and output signals, reusable code is generated only when the dimension along which the signal is partitioned is the highest dimension.	Permute the signal dimensions to transform the partition dimension and the concatenation dimension to the highest nonsingleton dimension for n-D signals.

The For Each Subsystem block does not support these features:

- You cannot include these blocks or S-functions inside a For Each Subsystem:
 - Data Store Memory, Data Store Read, or Data Store Write blocks inside the subsystem
 - The From Workspace block if the input is a `Structure` with `Time` that has an empty time field
 - The To Workspace and To File data saving blocks
 - Goto and From blocks that cross the subsystem boundary
 - Referenced model with simulation mode set to Normal
 - Shadow Inports
 - ERT S-functions

For a complete list of the blocks that support the For Each Subsystem, type `showblockdatayetable` at the MATLAB command line.

- You cannot use these types of signals:
 - Signals with an external storage class inside the system
 - Frame signals on subsystem input and output boundaries
 - Variable-size signals
 - Function-call signals crossing the boundaries of the subsystem
- Creation of a linearization point inside the subsystem
- Propagating the Jacobian flag for the blocks inside the subsystem. You can check this condition in MATLAB using `J.Mi.BlockAnalyticFlags.jacobian`, where `J` is the Jacobian object. To verify the correctness of the Jacobian of the For Each Subsystem block, perform these steps:
 - Look at the tag of the For Each Subsystem Jacobian. If it is `"not_supported"`, then the Jacobian is incorrect.
 - Move each block out of the For Each Subsystem and calculate its Jacobian. If any block is `"not_supported"` or has a warning tag, the For Each Subsystem Jacobian is incorrect.
- You cannot perform these types of code generation:
 - Generation of a Simulink Coder S-function target
 - Simulink Coder code generation under both of the following conditions:
 - A Stateflow or MATLAB Function block resides in the subsystem.
 - This block tries to access global data outside the subsystem, such as Data Store Memory blocks or Simulink.Signal objects of ExportedGlobal storage class.

- PLC code generation

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a integer ^a single ^a
Direct Feedthrough	no
Multidimensional Signals	limited ^a
Variable-Size Signals	no
Zero-Crossing Detection	no

a. Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

When you generate HDL code for the For Each Subsystem, the code generator uses a **for-generate** loop that iterates through elements of the input and output signals. The for-generate loop improves readability and reduces the number of lines of code, which can otherwise result in hundreds of lines of code for large vector signals.

You can use a nonzero partition offset for HDL code generation. The code generator supports partitioning of mask parameters inside a For Each Subsystem. Inside the For Each Subsystem, use the mask parameter as the **Constant value** in Constant blocks or as the **Gain** parameter in Gain blocks.

Limitations

- You cannot use the For Each Subsystem block as the DUT.
- You must clear the **Show partition index output port (zero-based indexing)** check box on the For Each block for HDL code generation.

HDL Architecture

Architecture	Description
Module (default)	Generate code for the subsystem and the blocks within the subsystem.
BlackBox	Generate a black box interface. The generated HDL code includes only the input/output port definitions for the subsystem. Therefore, you can use a subsystem in your model to generate an interface to existing, manually written HDL code. The black-box interface generation for subsystems is similar to the Model block interface generation without the clock signals.
No HDL	Remove the subsystem from the generated code. You can use the subsystem in simulation, however, treat it as a “no-op” in the HDL code.

Black Box Interface Customization

For the BlackBox architecture, you can customize port names and set attributes of the external component interface. See “Customize Black Box or HDL Cosimulation Interface” (HDL Coder).

HDL Block Properties

General	
AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <i>inherit</i> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <i>inherit</i> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <i>inherit</i> . See also “ClockRatePipelining” (HDL Coder).

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is off. See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is inherit. See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also “Streaming” (HDL Coder).

Target Specification

This block cannot be the DUT, so the block property settings in the **Target Specification** tab are ignored.

Complex Data Support

The block does not support complex data signals for HDL code generation. To input complex signals, you can convert this signal to an array of signals, and then input to the block. To learn more, see “Generate HDL Code for Blocks Inside For Each Subsystem” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

For Iterator

Repeat execution of a subsystem during a time step for a specified number of iterations

Library: Ports & Subsystems

Description

The For Iterator block, when placed in a Subsystem block, repeats the execution of a subsystem during the current time step until an iteration variable exceeds the specified iteration limit. You can use this block to implement the block diagram equivalent of a `for` loop in a programming language.

The output of a For Iterator Subsystem block cannot be a function-call signal. Simulink displays an error message when the model updates.

Ports

Input

Number of Iterations — External value for iterator variable

scalar | vector, size 1 | matrix, size 1x1

- The input port accepts data of mixed numeric types.
- If the input port value is non-integer, it is first truncated to an integer.
- Internally, the input value is cast to an integer of the type specified for the iteration variable output port.
- If no output port is specified, the input port value is cast to type `int32`.
- If the input port value exceeds the maximum value of the output port type, the overflow wraps around.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Iterator value — Value of iterator variable during time step

scalar | vector, size 1 | matrix, size 1-by-1

Selecting the **Show iteration variable** parameter check box adds an output port to this block.

Data Types: `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Parameters

States when starting — Select block states between time steps

`held` (default) | `reset`

Select how to handle block states between time steps.

held

Hold block states between time steps. Block state values persist across time steps.

reset

Reset block states to their initial values at the beginning of each time step and before the first iteration loop.

Programmatic Use

Block Parameter: ResetStates

Type: character vector

Values: 'held' | 'reset'

Default: 'held'

Iteration limit source — Select source for number of iterations

internal (default) | external

Select source for number of iterations.

internal

Value of the **Iteration limit** parameter determines the number of iterations.

external

Value of the signal at the **N** port determines the number of iterations. The signal source must reside outside the For Iterator Subsystem block.

Dependencies

Selecting `internal` displays and enables the **Iteration limit** parameter. Selecting `external` adds an input port labeled **N**.

Programmatic Use

Block Parameter: IterationSource

Type: character vector

Values: 'internal' | 'external'

Default: 'internal'

Iteration limit — Specify number of iterations

5 (default) | integer

Specify the number of iterations. This parameter supports storage classes. You can define the named constant in the base workspace of the Model Explorer as a `Simulink.Parameter` object of the built-in storage class `Define (custom)` type.

5

Iterate blocks in the For Iterator Subsystem block 5 times.

integer

Specify an integer or a named constant variable.

Dependencies

To enable this parameter, select `internal` from the **Iteration limit source** drop-down list.

Programmatic Use

Block Parameter: IterationLimit

Type: character vector
Values: '5' | '<integer>'
Default: '5'

Set Next i (iteration variable) externally – Control display of input port

off (default) | on

Control display of an input port.

off

Remove input port.

on

Add input port labeled **Next_i** for connecting to an external iteration variable source. The value of the input at the current iteration is used as the value of the iteration variable at the next iteration.

Dependencies

To enable this parameter, select the **Show iteration variable** parameter which also displays an output port labeled **1:N**.

Programmatic Use

Block Parameter: ExternalIncrement

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Show iteration variable – Control display of output port

on (default) | off

Control the display of an output port with the current iterator value for a loop.

on

Add output port labeled **1:N** to the For Iterator block.

off

Remove output port.

Dependencies

Selecting this parameter enables the **Set next i (iteration variable) externally** parameter.

Programmatic Use

Block Parameter: ShowIterationPort

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Index mode – Select initial iteration number

One-based (default) | Zero-based

Select an initial iteration number of 0 or 1.

One-based

Iteration number starts at one.

Zero-based

Iteration number starts at zero.

Programmatic Use

Block Parameter: IndexMode

Type: character vector

Values: 'One-based' | 'Zero-based'

Default: 'One-based'

Iteration variable data type — Select data type

int32 (default) | uint32 | int16 | uint16 | int8 | uint8 | double

Set the data type for the iteration value output from the iteration number port.

int32

Set data type to int32.

uint32

Set data type to uint32.

int16

Set data type to int16.

uint16

Set data type to uint16.

int8

Set data type to int8.

uint8

Set data type to uint8.

double

Set data type to double.

Programmatic Use

Block Parameter: IterationVariableDataType

Type: character vector

Value: 'int32' | 'uint32' | 'int16' | 'uint16' | 'int8' | 'uint8' | 'double'

Default: 'int32'

Blocks

For Iterator Subsystem | Subsystem

Topics

Iterator Subsystem Execution

Introduced before R2006a

For Iterator Subsystem

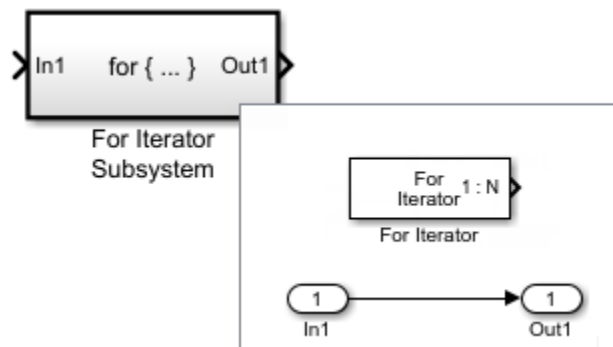

Subsystem that repeats execution during a simulation time step

Library: Simulink / Ports & Subsystems

Description

The For Iterator Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats the execution during a simulation time step for a specified number of iterations. The number of iterations is controlled by a For Iterator block. `Open model`.

When using simplified initialization mode, if you place a block that needs elapsed time (such as a Discrete-Time Integrator block) in a For Iterator Subsystem block, Simulink displays an error.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a Subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a Subsystem block adds an output port from the block. The port label on the Subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed_point` | `enumerated` | `bus`

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed_point ^a integer ^a single ^a string ^a
Direct Feedthrough	no
Multidimensional Signals	limited ^a
Variable-Size Signals	limited ^a
Zero-Crossing Detection	no

a. Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

Iterator Subsystem Execution

Introduced before R2006a

From

Accept input from Goto block

Library: Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The From block accepts a signal from a corresponding Goto block, then passes it as output. The data type of the output is the same as that of the input from the Goto block. From and Goto blocks allow you to pass a signal from one block to another without actually connecting them. To associate a Goto block with a From block, enter the Goto block's tag in the **Goto Tag** parameter.

A From block can receive its signal from only one Goto block, although a Goto block can pass its signal to more than one From block.

This figure shows that using a Goto block and a From block is equivalent to connecting the blocks to which those blocks are connected. In the model at the left, Block1 passes a signal to Block2. That model is equivalent to the model at the right, which connects Block1 to the Goto block, passes that signal to the From block, then on to Block2.

The visibility of a Goto block tag determines the From blocks that can receive its signal. For more information, see Goto and Goto Tag Visibility. The block indicates the visibility of the Goto block tag:

- A local tag name is enclosed in brackets ([]).
- A scoped tag name is enclosed in braces ({ }).
- A global tag name appears without additional characters.

The From block supports signal label propagation.

Ports

Output

Port_1 — Signal from connected Goto block

scalar | vector | matrix | N-D array

Signal from connected Goto block, output with the same dimensions and data type as the input to the Goto block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Goto Tag — Tag of the Goto block that forwards its signal to this block

A (default) | <More Tags...> | ...

Specify the tag of the Goto block that forwards its signal to this From block. To change the tag, select a new tag from the drop-down list.

The drop-down list displays the Goto tags that the From block can currently see. An item labeled <More Tags...> appears at the end of the list the first time you display the list in a Simulink session. Selecting this item causes the block to update the tags list to include the tags of Goto blocks residing in library subsystems referenced by the model containing this From block. Simulink software displays a progress bar while building the list of library tags. Simulink saves the updated tags list for the duration of the Simulink session or until the next time you select the adjacent **Update Tags** button. You need to update the tags list again in the current session only if the libraries referenced by the model have changed since the last time you updated the list.

Tip If you use multiple From and Goto Tag Visibility blocks to refer to the same Goto tag, you can simultaneously rename the tag in all of the blocks. To do so, use the **Rename All** button in the Goto block dialog box.

To find the relevant Goto block, use the **Goto Source** hyperlink in the From block dialog box.

Programmatic Use

Block Parameter: GotoTag

Type: character vector

Values: 'A' | ...

Default: 'A'

Update Tags — Update list of visible tags

Updates the list of tags visible to this From block, including tags residing in libraries referenced by the model containing this From block. Update the tags list again in the current session only if the libraries referenced by the model have changed since the last time you updated the list.

Goto Source — Path to connected Goto block

block path

Path of the Goto block connected to this From block. Clicking the path displays and highlights the Goto block in your model.

Icon Display — Text to display on block icon

Tag | Tag and signal name | Signal name

Specifies the text to display on the From block icon. The options are the block tag, the name of the signal that the block represents, or both the tag and the signal name.

Programmatic Use

Block Parameter: IconDisplay

Type: character vector

Values: 'Signal name' | 'Tag' | 'Tag and signal name'

Default: 'Tag'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

Search for Goto Tags

To search for Goto tags in libraries referenced by the model when opening the From block dialog box, use the `FollowLinksWhenOpeningFromGotoBlocks` model parameter with the `set_param` function.

- 'off' — Do not search for Goto tags (default).
- 'on' — Search for Goto tags.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. See also “Required HDL Settings for Goto and From Blocks” (HDL Coder).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Introduced before R2006a

From File

Load data from MAT-file

Library: Simulink / Sources

Description

The From File block loads data from a MAT-file to a model and outputs the data as a signal. The data is a sequence of samples. Each sample consists of a time stamp and an associated data value. The data can be in array format or MATLAB `timeseries` format.

The From File block icon shows the name of the MAT-file that supplies the data to the block.

You can have multiple From File blocks that load from the same MAT-file.

The supported MAT-file versions are Version 7.0 or earlier and Version 7.3. The From File block incrementally loads data from Version 7.3 files.

You can specify how the data is loaded, including:

- Sample time
- How to handle data for missing data points
- Whether to use zero-crossing detection

For more information, see “Load Data Using the From File Block”.

Ports

Output

Port_1 – File data

scalar | vector | matrix | N-D array

MAT-file data, specified as a sequence of samples. Each sample consists of a time stamp and an associated data value. The data can be in array format or MATLAB `timeseries` format.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

File name – Path or file name

`untitled.mat` (default) | path, or MAT-file name

Path or file name of the MAT-file that contains the input data. Specify a path or file name in one of these ways:

- Browse to a folder that contains a valid MAT-file.

On UNIX® systems, the path name can start with a tilde (~) character, which means your home folder.

- Enter the path for the file in the text box.

The default file name is `untitled.mat`. If you specify a file name without path information, Simulink loads the file in the current folder or on the MATLAB path. (To determine the current folder, at the MATLAB command prompt enter `pwd`.)

After you specify the **File name**, you can use the view button () to preview the signal from the MAT-file. For more information, see “Preview Signal Data”.

Dependencies

Code generation for RSim target provides identical support as Simulink; all other code generation targets support only double, one-dimensional, real signals in array with time format.

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, the MAT-file must contain a nonempty, finite, real matrix with at least two rows.

For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-622.

Programmatic Use

Block Parameter: FileName

Type: character vector

Values: MAT-file name

Default: 'untitled.mat'

Output data type — Output data type

Inherit: auto (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class_name> | Bus: <bus_object> | <data type expression>

The data type for the data that the From File block outputs. For nonbus types, you can use `Inherit: auto` to skip any data type verification. If you specify an output data type, then the From File block verifies that the data in the file matches the specified data type. For more information, see “Control Signal Data Types”.

If you set **Output data type** as a bus object, the bus object must be available when you compile the model. For each signal in bus data, the From File block verifies that data type, dimensions, and complexity are the same for the data and for the bus object.

Click the **Show data type assistant** button () to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>' | '<data type expression>'

Default: 'Inherit: auto'

Sample time — Sampling period and offset

0 | scalar | vector

Specify the sample period and offset.

The From File block loads data from a MAT-file, using a sample time that either:

- You specify for the From File block.
- The From File block inherits from the blocks into which the From File block feeds data.

The default sample time is 0, which specifies a continuous sample time. The MAT-file is loaded at the base (fastest) rate of the model. For details, see “Specify Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '0'

Data extrapolation before first data point — Extrapolation method for simulation times before initial time stamp in MAT-file

Linear extrapolation (default) | Hold first value | Ground value

Extrapolation method for a simulation time hit that occurs before the initial time stamp in the MAT-file. Choose one of the following extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the MAT-file contains only one sample, then the From File block outputs the corresponding data value.</p> <p>If the MAT-file contains more than one sample, then the From File block linearly extrapolates using the first two samples:</p> <ul style="list-style-type: none"> • For <code>double</code> data, linearly extrapolates the value using the first two samples • For <code>Boolean</code> data, outputs the first data value • For a built-in data type other than <code>double</code> or <code>Boolean</code>, the From File block: <ul style="list-style-type: none"> • Upcasts the data to <code>double</code> • Performs linear extrapolation (as described for <code>double</code> data) • Downcasts the extrapolated data value to the original data type <p>You cannot use the <code>Linear extrapolation</code> option with enumerated (<code>enum</code>) data. All signals in a bus use the same extrapolation setting. If any signal in a bus uses <code>enum</code> data, then you cannot use the <code>Linear extrapolation</code> option.</p>

Method	Description
Hold first value	Uses the first data value in the file
Ground value	Uses a value that depends on the data type of MAT-file sample data values: <ul style="list-style-type: none"> • Fixed-point data types — Uses the ground value • Numeric types other than fixed point —Uses 0 • Boolean — Uses false • Enumerated data types — Uses default value

Dependencies

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, you must set this parameter to `Linear extrapolation`. For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-622.

Programmatic Use

Block Parameter: `ExtrapolationBeforeFirstDataPoint`

Type: character vector

Values: 'Linear extrapolation' | 'Hold first value' | 'Ground value'

Default: 'Linear extrapolation'

Data interpolation within time range — Interpolation method for simulation times that fall between two time stamps in the MAT-file

`Linear interpolation (default)` | `Zero order hold`

The interpolation method that Simulink uses for a simulation time hit between two time stamps in the MAT-file. Choose one of these interpolation methods.

Method	Description
Linear interpolation	(Default) The From File block interpolates using the two corresponding MAT-file samples: <ul style="list-style-type: none"> • For <code>double</code> data, linearly interpolates the value using the two corresponding samples • For <code>Boolean</code> data, uses <code>false</code> for the first half of the sample and <code>true</code> for the second half. • For a built-in data type other than <code>double</code> or <code>Boolean</code>, the From File block: <ul style="list-style-type: none"> • Upcasts the data to <code>double</code> • Performs linear interpolation, as described for <code>double</code> data • Downcasts the interpolated value to the original data type
Zero order hold	Uses the data from the first of the two samples

Limitations

You cannot use the `Linear interpolation` option with enumerated (enum) data. All signals in a bus use the same interpolation setting. If any signal in a bus uses enum data, then you cannot use the `Linear interpolation` option.

Dependencies

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, you must set this parameter to `Linear interpolation`. For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-622.

Programmatic Use

Block Parameter: `InterpolationWithinTimeRange`

Type: character vector

Values: 'Linear interpolation' | 'Zero order hold'

Default: 'Linear interpolation'

Data extrapolation after last data point — Extrapolation method for simulation times after last time stamp in MAT-file

`Linear extrapolation (default)` | `Hold last value` | `Ground value`

The extrapolation method for a simulation time hit that occurs after the last time stamp in the MAT-file. Choose one of these extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the MAT-file contains only one sample, then the From File block outputs the corresponding data value.</p> <p>If the MAT-file contains more than one sample, then the From File block linearly extrapolates using data values of the last two samples:</p> <ul style="list-style-type: none"> • For <code>double</code> data, extrapolates the value using the last two samples. • For <code>Boolean</code> data, outputs the first data value. • For built-in data types other than <code>double</code> or <code>Boolean</code>: <ul style="list-style-type: none"> • Upcasts the data to <code>double</code> • Performs linear extrapolation, as described for <code>double</code> data • Downcasts the extrapolated value to the original data type
Hold last value	Uses the last data value in the file
Ground value	<p>Uses a value that depends on the data type of MAT-file sample data values:</p> <ul style="list-style-type: none"> • Fixed-point data types — Uses the ground value • Numeric types other than fixed point — Uses 0 • <code>Boolean</code> — Uses <code>false</code> • Enumerated data types — Uses default value

Limitations

You cannot use the `Linear extrapolation` option with enumerated (enum) data. All signals in a bus use the same extrapolation setting. If any signal in a bus uses enum data, then you cannot use the `Linear extrapolation` option.

Dependencies

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, you must set this parameter to `Linear extrapolation`. For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-622.

Programmatic Use

Block Parameter: `ExtrapolationAfterLastDataPoint`

Type: character vector

Values: 'Linear extrapolation' | 'Hold last value' | 'Ground value'

Default: 'Linear extrapolation'

Enable zero-crossing detection — Enable zero-crossing detection

off (default) | on

Enables zero-crossing detection.

The “Zero-Crossing Detection” parameter applies only if the **Sample time** parameter is set to 0 (continuous).

Simulink uses a technique known as zero-crossing detection to locate a discontinuity in time stamps, without resorting to excessively small time steps. “Zero-crossing” represents a discontinuity.

For the From File block, zero-crossing detection occurs only at time stamps in the file. Simulink examines only the time stamps, not the data values.

For bus signals, Simulink detects zero-crossings across all leaf bus elements.

If the input array contains duplicate time stamps (more than one entry with the same time stamp), Simulink detects a zero crossing at those time stamps. For example, suppose that the input array has this data.

```
time:    0 1 2 2 3
signal:  2 3 4 5 6
```

At time 2, there is a zero crossing from the input signal discontinuity.

For nonduplicate time stamps, zero-crossing detection depends on the settings of these parameters:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

The From File block determination of when zero-crossing occurs depends on the time stamp.

Time Stamp	Setting
First	Data extrapolation before first data point is set to <code>Ground value</code> .
Between first and last	Data interpolation within time range is set to <code>Zero-order hold</code> .

Time Stamp	Setting
Last	One or both of these settings apply: <ul style="list-style-type: none"> • Data extrapolation after last data point is set to Ground value. • Data interpolation within time range is set to Zero-order hold.

This figure illustrates zero-crossing detection for data accessed by a From File block that has these settings:

- **Data extrapolation before first data point** – Linear extrapolation
- **Data interpolation within time range** (for internal points) – Zero order hold
- **Data extrapolation after last data point** – Linear extrapolation

This figure is another illustration of zero-crossing detection for data accessed by a From File block. The block has the following settings for the time stamps (points):

- **Data extrapolation before first data point** – Hold first value
- **Data interpolation within time range** – Zero order hold
- **Data extrapolation after last data point** – Hold last value

Dependencies

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, clear this check box. For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-622.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point ^a integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	yes

a. Supports up to 32-bit fixed-point data types.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- Not recommended for production code.
- Code generation for RSim target provides identical support as Simulink; all other code generation targets support only double, one-dimensional, real signals in array with time format.
- For a From File block, generating code that builds ERT or GRT targets or uses SIL or PIL simulation modes requires that:
 - The MAT-file contains a nonempty, finite, real matrix with at least two rows.
 - Use a data type of `double` for the matrix.
 - Do not include any NaN, Inf, or -Inf elements in the matrix.
 - In the From File block parameters dialog box:
 - Set the **Data extrapolation before first data point** and **Data extrapolation after last data point** parameters to `Linear` extrapolation.
 - Set the **Data interpolation within time range** parameter to `Linear` interpolation.
 - Clear the **Enable zero-crossing detection** parameter.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Supports up to 32-bit fixed-point data types.

From Spreadsheet

Read data from spreadsheet

Library: Simulink / Sources

Description

The From Spreadsheet block reads data from Microsoft Excel® (all platforms) or CSV (MicrosoftWindows® platform with Microsoft Office installed only) spreadsheets and outputs the data as a signal. The From Spreadsheet block does not support Microsoft Excel spreadsheet charts.

The From Spreadsheet icon displays the spreadsheet file name and sheet name specified in the block **File name** and **Sheet name** parameters.

Storage Formats

The data that the From Spreadsheet block reads from a spreadsheet must be appropriately formatted.

For Microsoft Excel spreadsheets:

- The From Spreadsheet block interprets the first row as a signal name. If you do not specify a signal name, the From Spreadsheet block assigns a default one with the format Signal #, where # increments with each additional unnamed signal.
- The From Spreadsheet block interprets the first column as time. In this column, the time values must monotonically increase.
- The From Spreadsheet block interprets the remaining columns as signals.

This example shows an acceptably formatted Microsoft Excel spreadsheet. The first column is Time and the first row contains signal names. Each worksheet contains a signal group.

1	Time	DC In	Trigger	AC In	
2	0	1	2	3	
3	1	2	3	4	
4	2	3	4	5	
5	3	4	5	6	
6	4	5	6	7	
7	5	6	7	8	
8	6	7	8	9	
9	7	8	9	10	
10	8	9	10	11	
11	9	10	11	12	
12	10	11	12	13	
13	11	12	13	14	
14	12	13	14	15	
15	13	14	15	16	
16	14	15	16	17	
17	15	16	17	18	
18					

Navigation: < > Group1 Group2 Group3

For CSV text files (Microsoft platform with Microsoft Office installed only):

- The From Spreadsheet block interprets the first column as time. In this column, the time values must increase.
- The From Spreadsheet block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The From Spreadsheet block interprets each file as one signal group.

This example shows an acceptably formatted CSV file. The contents represent one signal group.

```
0,0,0,5,0
1,0,1,5,0
2,0,1,5,0
3,0,1,5,0
4,5,1,5,0
5,5,1,5,0
6,5,1,5,0
7,0,1,5,0
8,0,1,5,1
9,0,1,5,1
10,0,1,5,0
```

Block Behavior During Simulation

The From Spreadsheet block incrementally reads data from the spreadsheet during simulation.

The **Sample time** parameter specifies the sample time that the From Spreadsheet block uses to read data from the spreadsheet. For details, see “Parameters” on page 1-626. The time stamps in the file must be monotonically nondecreasing.

For each simulation time hit for which the spreadsheet contains no matching time stamp, Simulink software interpolates or extrapolates to obtain the needed data using the selected method. For details, see “Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps” on page 1-625.

Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps

If the simulation time hit does not have a corresponding spreadsheet time stamp, the From Spreadsheet block output depends on:

- Whether the simulation time hit occurs before the first time stamp, within the range of time stamps, or after the last time stamp
- The interpolation or extrapolation methods that you select
- The data type of the spreadsheet data

For details about interpolation and extrapolation options, see the descriptions of these parameters:

- “Data extrapolation before first data point” on page 1-0
- “Data interpolation within time range” on page 1-0
- “Data extrapolation after last data point” on page 1-0

Sometimes the spreadsheet includes two or more data values that have the same time stamp. In such cases, the From Spreadsheet block action depends on when the simulation time hit occurs, relative to the duplicate time stamps in the spreadsheet.

For example, suppose that the spreadsheet contains this data. Three data values have a time stamp value of 2.

```
time stamps:    0 1 2 2 2 3 4
data values:   2 3 6 4 9 1 5
```

The table describes the From Spreadsheet block output.

Simulation Time, Relative to Duplicate Time Stamp Values in Spreadsheet	From Spreadsheet Block Action
Before the duplicate time stamps	Performs the same actions as when the time stamps are distinct, using the first of the duplicate time stamp values as the basis for interpolation. (In this example, the time stamp value is 6.)
At or after the duplicate time stamps	Performs the same actions as when the times stamps are distinct, using the last of the duplicate time stamp values as the basis for interpolation. (In this example, that time stamp value is 9.)

Ports

Output

Port_1 — Data from spreadsheet

scalar | vector | matrix

Incremental data from the specified spreadsheet.

The **Sample time** parameter specifies the sample time that the From Spreadsheet block uses to read data from the spreadsheet. For details, see “Parameters” on page 1-626. The time stamps in the file must be monotonically nondecreasing.

For each simulation time hit for which the spreadsheet contains no matching time stamp, Simulink software interpolates or extrapolates to obtain the needed data using the selected method. For details, see “Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps” on page 1-625.

The From Spreadsheet block accepts data type specifications at a block level. If you want to specify different data types for each signal, consider selecting **Output Data Type > Inherit: Auto**. This option resolves back signal data types using back propagation. For example, assume that there are two signals in the From Spreadsheet block, In1 and In2, which the block sends to ports that have int8 and Boolean data types. With back propagation, the block recasts In1 as int8 and In2 as Boolean.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Parameters

File name — Full path and file name

`untitled.xlsx` (default) | full path and file name

Enter full path and file name of a spreadsheet file.

This block supports non-English full paths and file names only on Microsoft platforms.

Programmatic Use

Block Parameter: FileName

Type: character vector

Value: full path and file name

Default: 'untitled.xlsx'

Sheet name — Name of sheet in spreadsheet

`Sheet1` (default) | sheet name

Enter the name of the sheet in the spreadsheet. You can type the sheet name in this edit box or select the sheet name after you open the sheet.

If your spreadsheet is the CSV format, the block populates this parameter with the name of the CSV file without the extension. Do not change this value.

To open the sheet, click . In the sheet, you can select the range of data by dragging over the desired range of values.

Alternatively, you can select the range of data by specifying the range of values in the **Range** parameter.

Programmatic Use

Block Parameter: SheetName

Type: character vector

Value: Sheet name

Default: 'Sheet1'

Range — Cell range

entire range of used cells in sheet (default) | A1:B3,D1:D3,A7:B9,D7:D9 | comma-separated list of *column:row*

To specify the range, use the format *column:row*, with multiple specifications separated by commas. For example, A1:B3,D1:D3,A7:B9,D7:D9. If unspecified, or empty, the block automatically detects the used range, which is all the data in the sheet.

A	B	C	D	E	F	G	H	I	J	K
Time	Signal1	Signal2	Signal3	Signal4	Signal5	Signal6	Signal7	Signal8	Signal9	Signal10
0	1.1008	1.5774	2.5733	3.6900	5.1900	5.8712	6.6145	7.6217	8.9888	9.7016
2.7778	0.9025	1.5715	3.0779	4.1831	4.5617	5.9126	6.8203	7.5290	9.3648	9.7325
5.5556	1.4038	1.9424	3.0091	4.4612	4.9577	6.1982	6.9004	8.1338	8.6296	10.2585
8.3333	0.5669	1.5482	3.0697	4.0333	4.5459	5.6497	7.1820	7.7123	8.8344	9.5369
11.1111	0.8831	2.4625	2.8027	4.0957	5.4559	5.6548	6.5501	7.6782	9.3752	9.8517
13.8889	1.4181	1.7568	2.5790	3.5821	4.5151	5.7424	7.2375	7.5058	9.4361	10.3232
16.6667	1.4352	1.6601	3.2009	3.5572	5.2831	6.4310	7.1034	7.7896	9.0152	9.7239
19.4444	0.5845	2.0186	3.0550	4.3965	4.6682	6.0019	7.1016	7.5480	9.0634	9.6670
22.2222	0.8893	2.0304	2.8024	3.6859	4.9812	5.8476	6.9719	8.1404	9.2989	10.4111
25	1.0712	2.0016	2.9639	3.7118	4.5929	5.9932	7.0083	7.9710	8.7347	9.6780

If the selections overlap, the block resolves the selection information as appropriate. For example, if you specify multiple ranges that overlap, such as A1:B4,B1:E7, the block resolves the selection to A1 to E7, inclusive.

An alternate to using the **Range** parameter is to open the sheet, by clicking . In the sheet, you can select the range of data by dragging over the desired range of values.

Programmatic Use

Block Parameter: Range

Type: character vector

Value: Cell range

Default: ''

Output data type — Output data type

Inherit: auto (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class_name> | <data type expression>

The data type for the From Spreadsheet block output. The From Spreadsheet block accepts spreadsheets that contain many data types. However, the block reads the spreadsheet data type as doubles. It then outputs the data type according to the value of **Output data type**.

If you want to specify different data types for each signal, consider selecting **Output Data Type > Inherit: auto**. This option resolves back signal data types using back propagation. For example, assume that there are two signals in the From Spreadsheet block, In1 and In2, which the block sends to ports that have int8 and Boolean data types. With back propagation, the block recasts In1 as int8 and In2 as boolean.

To allow the block to cast the output data type to match that of the receiving block, use **Inherit: auto**.

For more information, see “Control Signal Data Types”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | '<data type expression>'

Default: 'Inherit: auto'

Treat first column as — Time or data

Time (default) | Data

Select how the block should treat the first column of the spreadsheet:

- Time — Treat first column as time.
- Data — Treat first column as data.

Dependencies

When you select Data, the block disables:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

And enables:

- **Output after last data point**

Programmatic Use

Block Parameter: TreatFirstColumnAs

Type: character vector

Value: 'Time' | 'Data'

Default: 'Time'

Sample time — Sampling period and offset

0 (default) | scalar | vector

The sample period and offset.

The From Spreadsheet block reads data from a spreadsheet using a sample time that either:

- You specify for the From Spreadsheet block
- The From Spreadsheet block inherits from the blocks into which the From Spreadsheet block feeds data

The default is 0, which specifies a continuous sample time. The spreadsheet is read at the base (fastest) rate of the model. For details, see “Specify Sample Time”.

Programmatic Use

Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '0'

Data extrapolation before first data point — Extrapolation method for simulation times before initial time stamp in MAT-file

Linear extrapolation (default) | Hold first value | Ground value

Extrapolation method that Simulink uses for a simulation time hit that is before the first time stamp in the spreadsheet. Choose one of these extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the spreadsheet contains only one sample, the From Spreadsheet block outputs the corresponding data value.</p> <p>If the spreadsheet contains more than one sample, the From Spreadsheet block linearly extrapolates using the first two samples:</p> <ul style="list-style-type: none"> • For double data, linearly extrapolates the value using the first two samples • For Boolean data, outputs the first data value • For a built-in data type other than double or Boolean: <ul style="list-style-type: none"> • Upcasts the data to double • Performs linear extrapolation (as described above for double data) • Downcasts the extrapolated data value to the original data type <p>You cannot use the Linear extrapolation option with enumerated (enum) data.</p>
Hold first value	Uses the first data value in the file
Ground value	<p>Uses a value that depends on the data type of spreadsheet sample data values:</p> <ul style="list-style-type: none"> • Fixed-point data types — Uses the ground value • Numeric types other than fixed-point — Uses 0 • Boolean — Uses false • Enumerated data types — Uses default value

Dependencies

To enable this parameter, set **Treat first column as** to **Time**.

Programmatic Use

Parameter: ExtrapolationBeforeFirstDataPoint

Type: character vector

Values: 'Linear extrapolation' | 'Hold first value' | 'Ground value'

Default: 'Linear extrapolation'

Data interpolation within time range — Interpolation method for simulation times that fall between two time stamps in the MAT-file

Linear interpolation (default) | Zero order hold

The interpolation method that Simulink uses for a simulation time hit between two time stamps in the spreadsheet. Choose one of the following interpolation methods.

Method	Description
Linear interpolation	<p>(Default)</p> <p>The From Spreadsheet block interpolates using the two corresponding spreadsheet samples:</p> <ul style="list-style-type: none"> • For <code>double</code> data, linearly interpolates the value using the two corresponding samples • For <code>Boolean</code> data, uses <code>false</code> for the first half of the sample and <code>true</code> for the second half • For a built-in data type other than <code>double</code> or <code>Boolean</code>: <ul style="list-style-type: none"> • Upcasts the data to <code>double</code> • Performs linear interpolation (as described above for <code>double</code> data) • Downcasts the interpolated value to the original data type <p>You cannot use the <code>Linear interpolation</code> option with enumerated (<code>enum</code>) data.</p>
Zero order hold	Uses the data from the first of the two samples

Dependencies

To enable this parameter, set **Treat first column as** to `Time`.

Programmatic Use

Parameter: `InterpolationWithinTimeRange`

Type: character vector

Values: `'Linear interpolation'` | `'Zero order hold'`

Default: `'Linear interpolation'`

Data extrapolation after last data point – Extrapolation method for simulation times after last time stamp in MAT-file

`Linear extrapolation (default)` | `Hold last value` | `Ground value`

The extrapolation method that Simulink uses for a simulation time hit that is after the last time stamp in the spreadsheet. Choose one of the following extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the spreadsheet contains only one sample, the From Spreadsheet block outputs the corresponding data value.</p> <p>If the spreadsheet contains more than one sample, the From Spreadsheet block linearly extrapolates using data values of the last two samples:</p> <ul style="list-style-type: none"> • For <code>double</code> data, extrapolates the value using the last two samples • For <code>Boolean</code> data, outputs the last data value • For a built-in data type other than <code>double</code> or <code>Boolean</code>: <ul style="list-style-type: none"> • Upcasts the data to <code>double</code>. • Performs linear extrapolation (as described above for <code>double</code> data). • Downcasts the extrapolated value to the original data type. <p>You cannot use the <code>Linear extrapolation</code> option with enumerated (<code>enum</code>) data.</p>
Hold last value	Uses the last data value in the file
Ground value	<p>Uses a value that depends on the data type of spreadsheet sample data values:</p> <ul style="list-style-type: none"> • Fixed-point data types — Uses the ground value • Numeric types other than fixed-point — uses 0 • <code>Boolean</code> — Uses <code>false</code> • Enumerated data types — Uses default value

Dependencies

To enable this parameter, set **Treat first column as** to `Time`.

Programmatic Use

Parameter: `ExtrapolationAfterLastDataPoint`

Type: character vector

Values: `'Linear extrapolation'` | `'Hold last value'` | `'Ground value'`

Default: `'Linear extrapolation'`

Output after last data point — Action after last data point

`Repeating sequence (default)` | `Hold final value` | `Ground value`

Select action after last data point:

- `Repeating sequence` — Repeat the sequence by reading the data from the first row of the range specified in **Range**
- `Hold final value` — Output the last defined value for the remainder of the simulation.
- `Ground value` — Output a ground value depending on the data type value specified in **Output data type**.

Dependencies

To enable this parameter, set **Treat first column as** to Data.

Programmatic Use

Parameter: OutputAfterLastPoint

Type: character vector

Values: 'Repeating sequence' | 'Hold final value' | 'Ground value'

Default: 'Repeating sequence'

Enable zero-crossing detection — Enable zero-crossing detection

off (default) | on

Select to enable zero-crossing detection.

The “Zero-Crossing Detection” parameter applies only if the **Sample time** parameter is set to 0 (continuous).

Simulink uses a technique known as zero-crossing detection to locate accurately a discontinuity, without resorting to excessively small time steps. In this context, zero-crossing is used to represent discontinuities.

For the From Spreadsheet block, zero-crossing detection can only occur at time stamps in the file. Simulink examines only the time stamps, not the data values.

If the input array contains duplicate time stamps (more than one entry with the same time stamp), Simulink detects a zero crossing at that time stamp. For example, suppose that the input array has this data.

```
time:    0 1 2 2 3
signal:  2 3 4 5 6
```

At time 2, there is a zero crossing from the input signal discontinuity.

For data with nonduplicate time stamps, zero-crossing detection depends on the settings of the following parameters:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

The block applies the following rules when determining when:

- Zero-crossing occurs for the first time stamp
- For time stamps between the first and last time stamp
- For the last time stamp

Time Stamp	When Zero-Crossing Detection Occurs
First	Data extrapolation before first data point is set to Ground value.
Between first and last	Data interpolation within time range is set to Zero-order hold.

Time Stamp	When Zero-Crossing Detection Occurs
Last	One or both of these settings occur: <ul style="list-style-type: none"> • Data extrapolation after last data point is set to Ground value. • Data interpolation within time range is set to Zero-order hold.

The following figure illustrates zero-crossing detection for data accessed by a From Spreadsheet block that has these settings:

- **Data extrapolation before first data point** – Linear extrapolation
- **Data interpolation within time range** (for internal points) – Zero order hold
- **Data extrapolation after last data point** – Linear extrapolation

The following figure is another illustration of zero-crossing detection for data accessed by a From Spreadsheet block. The block has these settings for the time stamps (points):

- **Data extrapolation before first data point** – Hold first value
- **Data interpolation within time range** – Zero order hold
- **Data extrapolation after last data point** – Hold last value

**Programmatic Use****Block Parameter:** ZeroCross**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	Boolean double enumerated fixed point ^a integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

a. Supports up to 32-bit fixed-point data types.

Algorithms

When the From Spreadsheet block reads data from a spreadsheet, it reads all signals with double precision and then casts them to the data type specified in the **Output data type** parameter for the output signal. During casting, the block uses rounding mode and saturation on integer overflow as follows.

Rounding Mode

The From Spreadsheet block rounds positive and negative numbers toward negative infinity. This mode is equivalent to the MATLAB `floor` function.

Saturation on Integer Overflow

For data type conversion, the From Spreadsheet block deals with saturation overflow by wrapping to the appropriate value that the data type can represent. For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- Not recommended for production code.
- Code generation for RSim target provides identical support as Simulink; all other code generation targets support only double, one-dimensional, real signals in array with time format.
- Simulating in accelerator, rapid accelerator, model reference accelerator mode, or model reference rapid accelerator mode behaves the same way, and has the same requirements, as simulating in normal mode.
- The From Spreadsheet block does not support generating code that involves building ERT or GRT targets, or using SIL or PIL simulation modes.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Supports up to 32-bit fixed-point data types.

Introduced in R2015b

From Workspace

Load signal data from workspace

Library: Simulink / Sources

Description

The From Workspace block reads signal data from a workspace and provides the data at its output as a signal.

The block displays the expression specified in the **Data** parameter. For details about how the expression gets evaluated, see “Symbol Resolution”.

You can specify how the data is loaded, including sample time, how to handle data for missing data points, and whether to use zero-crossing detection. For more information, see “Load Data Using the From Workspace Block”.

Note Simulink Coder software does not generate code for this block when connected to the **Sim** port under the conditions listed in Environment Controller.

Specifying Workspace Data

In the From Workspace block dialog box, use the **Data** parameter to specify the workspace data to load. You can specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of these options:

- A `timeseries` object
- A structure of `timeseries` objects
- A `timetable` object
- A structure of `timetable` objects
- A structure, with or without time
- A two-dimensional matrix

For additional information, see “Load Data Using the From Workspace Block”.

Note When you specify `timetable` data to load, each `timetable` object can contain data for only one signal.

Use with Data Dictionary

When you link a model to a data dictionary, you:

- Store design data, which contributes to the fundamental design of the model in the Design Data section of the dictionary. Design data includes numeric variables and `Simulink.Parameter` objects that you use to set block parameter values.

- Store simulation input data, which you use to stimulate and experiment with the model, in the base workspace. Typically, you create simulation input data as MATLAB `timeseries` objects.

For more information about storing variables, objects, and other data that a model uses, see “Determine Where to Store Variables and Objects for Simulink Models”.

- To access design data by using a From Workspace block, store the target variable in the Design Data section of the dictionary and set the **Data** parameter of the block to the name of the variable.
- To access simulation input data, store the target variable in the base workspace and set the **Data** parameter by using a call to the `evalin` function. In the call to `evalin`, specify the `ws` argument as `'base'` so that the block seeks the variable in the base workspace instead of the data dictionary. For example, if the name of the variable is `myTimeseriesObject`, set **Data** to `evalin('base','myTimeseriesObject')`.

Ports

Output

Port_1 — Workspace data

scalar | vector | matrix

Signal created from workspace data. The block can generate real or complex signals of any type that Simulink supports, including fixed-point and enumerated data types.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Data — Workspace data to load

`simin` (default) | `timeseries` object | structure of `timeseries` objects | `timetable` object | structure of `timetable` objects | structure | 2-D matrix

In the **Data** parameter, specify the workspace data to load. Specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of the following:

- A `timeseries` object
- A structure of `timeseries` objects
- A `timetable` object
- A structure of `timetable` objects
- A structure, with or without time
- A two-dimensional matrix

The From Workspace block also accepts a bus object as a data type. To load bus data, use a structure of `timeseries` or `timetable` objects. For details, see “Load Bus Data to Root-Level Input Ports”.

Real signals of type `double` can be in any data format that the From Workspace block supports. For complex signals and real signals of a data type other than `double`, use any format except `Array`.

For additional information, see “Specify the Workspace Data”.

Note When you specify timetable data to load, each timetable object can contain data for only one signal.

Programmatic Use**Block Parameter:** VariableName**Type:** character vector**Values:** timeseries object | structure of timeseries objects | structure | 2-D matrix**Default:** 'simin'**Output data type — Output data type**

Inherit: auto (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class_name> | Bus: <bus_object> | <data type expression>

Required data type for the workspace data that the From Workspace block loads. For non-bus types, to skip any data type verification, you can use Inherit: auto. For more information, see “Control Signal Data Types”.

To load bus data, use a structure of timeseries or timetable objects. For details, see “Load Bus Data to Root-Level Input Ports”.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>' | '<data type expression>'

Default: 'Inherit: auto'**Sample time — Sample rate of loaded data**

0 (default) | scalar | vector

Sample rate of loaded workspace data. For details, see “Specify Sample Time”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar | vector**Default:** '0'**Interpolate data — Interpolate or use last known data point**

on (default) | off

When you select this option, the block performs linear interpolation at time hits for which no corresponding workspace data exist. Otherwise, the current output equals the output at the most recent time for which data exists.

The From Workspace block interpolates by using the two corresponding workspace samples:

- For double data, linearly interpolates the value by using the two corresponding samples
- For Boolean data, uses false for the first half of the time between two time values and true for the second half

- For a built-in data type other than `double` or `Boolean`:
 - Upcasts the data to `double`
 - Performs linear interpolation (as described for `double` data)
 - Downcasts the interpolated value to the original data type

You cannot use linear interpolation with enumerated (`enum`) data.

The block uses the value of the last known data point as the value of time hits that occur after the last known data point.

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

For details, see the **Form output after final data value by** parameter.

Programmatic Use

Block Parameter: `Interpolate`

Type: character vector

Values: `'off'` | `'on'`

Default: `'on'`

Enable zero-crossing detection — Enable zero-crossing detection

`on` (default) | `off`

When you select **Enable zero-crossing detection**, and the input array contains multiple entries for the same time hit, Simulink detects a zero crossing. For example, suppose that the input array has this data.

```
time:    0 1 2 2 3
signal:  2 3 4 5 6
```

At time 2, there is a zero crossing from input signal discontinuity. For more information, see “Zero-Crossing Detection”.

For bus signals, Simulink detects zero crossings across all leaf bus elements.

Programmatic Use

Block Parameter: `ZeroCross`

Type: character vector

Values: `'off'` | `'on'`

Default: `'on'`

Form output after final data value by — Determine block output after final data point

`Extrapolation` (default) | `Setting to zero` | `Holding final value` | `Cyclic repetition`

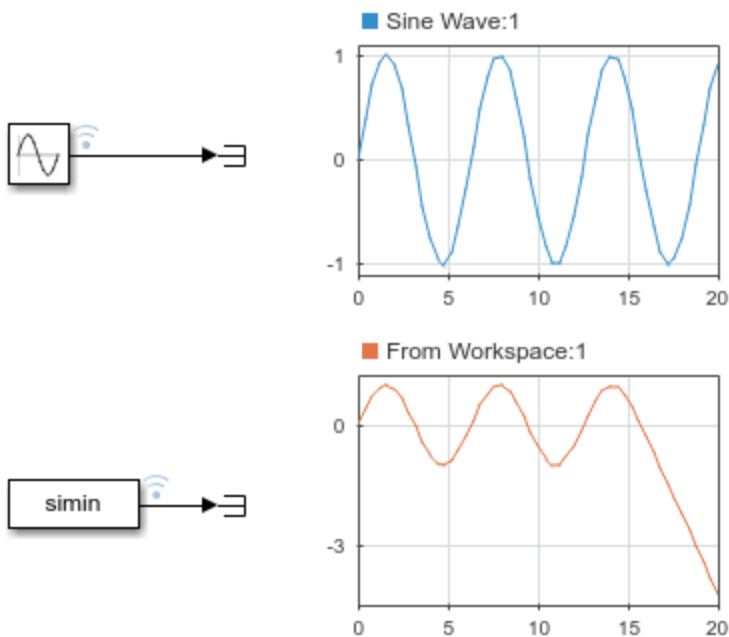

The From Workspace block uses the **Interpolate data** and **Form output after final data value by** settings to determine the block output after the last sample available in the workspace data.

This table lists the block output, based on the values of the two options.

Setting for Form Output After Final Data Value By	Setting for Interpolate Data	Block Output After Final Data
Extrapolation	On	Extrapolated from final data value
	Off	Error
Setting to zero	On	Zero
	Off	
Holding final value	On	Final value from workspace
	Off	
Cyclic repetition	On	Error
	Off	Repeated from workspace if the workspace data is in structure-without-time format. Error otherwise.

For example, when you enable **Interpolate data** and set **Form output after final data value by** to **Extrapolation**, the block uses the last two data points in the workspace data to extrapolate values for subsequent data points.

For example, consider this model. The From Workspace block reads workspace data that was created by logging the output of the Sine Wave block for a 16-second simulation. The Dashboard Scope blocks display the Sine Wave block output and From Workspace block output for a 20-second simulation. After the simulation reaches 16 seconds, the From Workspace block output diverges from the Sine Wave block output as the From Workspace block linearly extrapolates values for the remainder of the simulation.

Programmatic Use**Block Parameter:** OutputAfterFinalValue**Type:** character vector**Values:** 'Extrapolation' | 'Setting to zero' | 'Holding final value' | 'Cyclic repetition'**Default:** 'Extrapolation'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point ^a integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	yes

a. Supports input via `fi` objects created using Fixed-Point Designer.

Extended Capabilities**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

Supports input via `fi` objects created using Fixed-Point Designer.

Function-Call Feedback Latch

Break feedback loop involving data signals between function-call blocks

Library: Simulink / Ports & Subsystems

Description

Use the Function-Call Feedback Latch block to break a feedback loop of data signals between one or more function-call blocks. Specifically, break a feedback loop formed in one of the following ways.

- **When function-call blocks connect to branches of the same function-call signal**

Place the Function-Call Feedback Latch block on the feedback signal between the branched blocks. As a result, the latch block delays the signal at the input of the destination function-call block, and the destination function-call block executes prior to the source function-call block of the latch block.

To run this model, see “Function-Call Blocks Connected to Branches of the Same Function-Call Signal” on page 13-160.

- **When the loop involves parent and child function-call blocks, where the child initiator is inside the parent**

Place the Function-Call Feedback Latch block on the feedback signal between the child and the parent. This arrangement prevents the signal value, read by the parent (FCSS1), from changing during execution of the child. In other words, the parent reads the value from the previous execution of the child (FCSS2).

To run this model, see “Function-Call Feedback Latch on Feedback Signal Between Child and Parent” on page 13-161.

Using the latch block is equivalent to selecting the **Latch input for function-call feedback signals** check box on the Inport block in the destination function-call subsystem or model. However, an advantage of the latch block over using the dialog parameter is that one can design the destination function-call subsystem or model in a modular fashion and then use it either in or out of the context of loops.

The Function-Call Feedback Latch block is better suited than Unit Delay or Memory blocks in breaking function-call feedback loops for the following reasons:

- The latch block delays the feedback signal for exactly one execution of the source function-call block. This behavior is different from the Unit Delay or Memory blocks for cases where the function-call subsystem blocks may execute multiple times in a given simulation step.
- Unlike the Unit Delay or Memory blocks, the latch block may be used to break loops involving asynchronous function-call subsystems.
- The latch block can result in better performance, in terms of memory optimization, for generated code.

Ports

Input

In — Signal from a function-call subsystem block

Introduced in R2011a

Function-Call Generator

Provide function-call events to control execution of a subsystem or model

Library: Simulink / Ports & Subsystems

Description

The Function-Call Generator block provides function-call events that execute a function-call subsystem or function-call model at the rate that you specify with the **Sample time** parameter. To iteratively execute each function-call block multiple times at each time step, use the **Number of Iterations** parameter.

To execute multiple function-call subsystems or models in a specified order, use the Function-Call Generator block with a Function-Call Split block. For an example, see the Function-Call Split block documentation.

Ports

Output

Function Call — Sends function-call events to the function-call input port of a function-call subsystem or function-call model

scalar

Parameters

Sample time — Specify time interval

-1 (default) | T_s | [T_s , T_o]

Specify the time interval between function call events to a subsystem or model containing a Trigger block with **Trigger type** set to `function-call`. If the actual calling rate for the subsystem or model differs from the time interval this parameter specifies, Simulink displays an error.

Settings

-1

Inherit time interval from the model.

T_s

Scalar where T_s is the time interval.

[T_s , T_o]

Vector where T_s is the time interval and T_o is the initial time offset.

Programmatic Use

Block Parameter: `sample_time`

Type: character vector

Values: '-1' | 'Ts' | '[Ts, To]'

Default: '-1'

Number of iterations — Specify number of times to provide a function-call at each time step

1 (default) | integer

The value of this parameter can be a vector where each element of the vector specifies a number of times to execute a function-call subsystem. The total number of times that a function-call subsystem executes per time step is equal to the sum of vector element values.

Suppose that you specify the number of iterations to be [2 2] and connect the output of this block to the control port of a function-call subsystem. In this case, the function-call subsystem executes four times at each time step.

Settings

1

Provide function-call once during each time step.

integer

Signed or unsigned integer number. Provide the specified number of function calls at each time step.

Programmatic Use

Block Parameter: numberOfIterations

Type: character vector

Values: '1' | '<integer>'

Default: '1'

Block Characteristics

Data Types	
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Function-Call Split

Provide junction for splitting function-call line

Library: Simulink / Ports & Subsystems

Description

The Function-Call Split block allows a function-call line to branch and connect to several function-call subsystems or function-call models.

The function-call subsystem or function-call model connected to the output port of the Function-Call Split block that is marked with a dot execute before the subsystems or models connected to other output ports. If data dependencies between subsystems or models do not support the specified execution order, the Function-Call Split block returns an error. To eliminate this error, consider selecting the **Latch input for feedback signals of function-call subsystem outputs** parameter on one or more Inport blocks of the function-call subsystems models involved in a data-dependency loop. Selecting this option delays the corresponding function-call, thereby eliminating the data-dependency loop.

If you select the model menu option **Display > Blocks > Sorted Execution Order**, then the execution order of function-call subsystems connected to branches of a given function-call signal appears on the blocks. Each subsystem has an execution order of the form $s : [B\#]$ where $\#$ is a number that ranges from 0 to one less than the total number of subsystems or models connected to branches of a given signal. The subsystems execute in ascending order based on this number.

The Function-Call Split block supports "Signal Label Propagation".

The following model shows how to apply the **Latch input for feedback signals of function-call subsystem outputs** parameter to work around a data-dependency error caused by using a Function-Call Split block. By turning this parameter on in the f1 subsystem Inport block, the Function-Call Split block ignores the data dependency of signal b. The block breaks the loop of data dependencies between subsystems f1 and g1. The model achieves the behavior of consistently calling f1 to execute before g1. For a given execution step, subsystem f1 uses the g1 output computed at the previous execution step.

Limitations

The Function-Call Split block has these limitations:

- All function-call subsystems and models connected to a given function-call signal must reside within the same nonvirtual layer of the model hierarchy.
- You cannot connect branched function-call subsystems or models and their children directly back to the function-call initiator.
- Function-call subsystems and models connected to branches of a function-call signal cannot have multiple (muxed) initiators.
- A Function-Call Split block cannot have its input from a signal with multiple function-call elements.

Ports

Input

Function Call – Function-call line

scalar

A Function-Call Generator block or a Stateflowchart can provide function-call events.

Output

Function Call – Function-call signal

scalar

Function-call line connected to a function-call subsystem or function-call model.

Parameters

Icon shape — Select block icon shape

`distinctive` (default) | `round`

Select block icon shape.

Settings

`distinctive`

Rectangular block icon.

`round`

Circular block icon.

Programmatic Use

Block Parameter: `IconShape`

Type: character vector

Values: `'distinctive'` | `'round'`

Default: `'distinctive'`

Number of output ports — Specify number of output ports

`2` (default) | `integer`

Specify number of function-call signal output ports.

Settings

`2`

Two function-call output ports.

`integer`

Integer number

Programmatic Use

Block Parameter: `NumOutputPorts`

Type: character vector

Values: `'2'` | `'<integer>'`

Default: `'2'`

Output port layout — Select order of output ports

`default` (default) | `reverse`

Select the order of function-call output ports with respect to which port provides a function-call first.

Settings

`default`

Top port provides function-call first.

`reverse`

Bottom port provides function-call first.

Programmatic Use

Block Parameter: `OutputPortLayout`

Type: character vector

Values: 'default' | 'reverse'

Default: 'default'

Block Characteristics

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

Topics

“Using Function-Call Subsystems”

Introduced in R2010a

Function-Call Subsystem

Subsystem whose execution is controlled by an external function-call input

Library: Simulink / Ports & Subsystems

Description

The Function-Call Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when a function-call input port receives a function-call event. A Stateflow chart, Function-Call Generator block, or an S-function block can provide function-call events. See “Using Function-Call Subsystems”.

Use Function-Call Subsystem blocks to:

- Schedule the execution order of model components.
- Control the rate of model component execution.

Simulink ignores a priority set on a Function-Call Subsystem block. Instead, set the priority on a Inport block connected to the control port. The Inport block can receive a function-call event from a Stateflow chart, Function-Call Generator block, or an S-function block.

For an explanation of Function-Call Subsystem block parameters, see Subsystem, Atomic Subsystem, Nonvirtual Subsystem, CodeReuse Subsystem.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Function Call – Function-call input port to a subsystem block

scalar

Placing a Trigger block in a subsystem block adds an external input port to the block. Selecting function-call from the **Trigger type** list, changes the block to a Function-Call port block that accepts function-call events.

Output

Out – Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a integer ^a single ^a string ^a
Direct Feedthrough	no
Multidimensional Signals	limited ^a
Variable-Size Signals	limited ^a
Zero-Crossing Detection	no

a. Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

“Using Function-Call Subsystems”

Introduced before R2006a

Function Caller

Call Simulink or exported Stateflow function

Library: Simulink / User-Defined Functions

Description

A Function Caller block calls and executes a function defined with a Simulink Function block or an exported Stateflow function. Using Function Caller blocks, you can call a function from anywhere in a model or chart hierarchy.

Ports

Input

Input argument — Input signal for an input argument

scalar | vector | matrix

Input signal for an input argument that is sent to the function.

The function prototype determines the number and name of input ports that appear on the Function Caller block. Connect signal lines to the input ports to send data to a function through the function input arguments.

For example, `y = myfunction(u)` creates one input port (`u`) on the Function Caller block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

Output argument — Output signal for an output argument

scalar | vector | matrix

Output signal for an output argument that the function returns.

The function prototype determines the number and name of output ports that appear on the Function Caller block. Connect signal lines to the output ports to receive data from a function through the function output arguments.

For example, `y = myfunction(u)` creates one output port (`y`) on the Function Caller block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Function prototype — Specify function interface

`y=f(u)` (default) | `<function prototype>`

Specify the function interface between a Function Caller block and a Simulink function. A Simulink function can be a Simulink Function block, an exported Stateflow graphical function, or an exported Stateflow MATLAB function. For a call to a Simulink Function block:

- Function call argument names must match the function arguments.
- Function names, input arguments, and output arguments must be valid MATLAB identifiers.

Programmatic Use

Block Parameter: `FunctionPrototype`

Type: character vector

Values: `'y=f(u)'` | `'<function prototype>'`

Default: `'y=f(u)'`

Input argument specifications — Specify input argument data type, dimensions, and complexity

`<Enter example>` (default) | `<MATLAB expression>`

Specify a comma-separated list of MATLAB expressions that combine data type, dimensions, and complexity (real or imaginary) for each input argument. For examples, see “Argument Specification for Simulink Function Blocks”.

This specification must match the Simulink Function block data type specified with the **Data type** parameter of the Argument Inport block.

Programmatic Use

Block Parameter: `'InputArgumentSpecifications'`

Type: character vector

Values: `''` | `'<MATLAB expression>'`

Default: `''`

Output argument specifications — Specify output argument data type, dimensions, and complexity

`<Enter example>` (default) | `<MATLAB Expression>`

Specify a comma-separated list of MATLAB expressions that combine data type, dimensions, and complexity (real or imaginary) for each output argument. For examples, see “Argument Specification for Simulink Function Blocks”.

This specification must match the Simulink Function block data type specified with the **Data type** parameter of the Argument Outport Block.

Programmatic Use

Block Parameter: `'OutputArgumentSpecifications'`

Type: character vector

Values: `''` | `'<MATLAB expression>'`

Default: `''`

Sample time — Time interval between function calls

`-1` (default) | `Ts` | `[Ts, To]`

Specify the time interval between function calls to a subsystem or model containing this Trigger block. If the actual calling rate for the subsystem or model differs from the time interval this parameter specifies, Simulink displays an error.

Settings

-1

Inherit time interval from the trigger signal.

Ts

Scalar where Ts is the time interval.

[Ts, To]

Vector where Ts is the time interval and To is the initial time offset.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: '-1' | 'Ts' | '[Ts, To]'

Default: '-1'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Gain

Multiply input by constant

Library: Simulink / Commonly Used Blocks
 Simulink / Math Operations
 HDL Coder / Commonly Used Blocks
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Gain block multiplies the input by a constant value (gain). The input and the gain can each be a scalar, vector, or matrix.

You specify the value of gain in the **Gain** parameter. The **Multiplication** parameter lets you specify element-wise or matrix multiplication. For matrix multiplication, this parameter also lets you indicate the order of the multiplicands.

Gain is converted from doubles to the data type specified in the block mask offline using round-to-nearest and saturation. The input and gain are then multiplied, and the result is converted to the output data type using the specified rounding and overflow modes.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

The Gain block accepts real or complex-valued scalar, vector, or matrix input. The Gain block supports fixed-point data types. If the input of the Gain block is real and gain is complex, the output is complex.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Input multiplied by gain

scalar | vector | matrix

The Gain block outputs the input multiplied by a constant gain value. When the input to the Gain block is real and gain is complex, the output is complex.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Gain — Value by which to multiply the input

1 (default) | real or complex-valued scalar, vector, or matrix

Specify the value by which to multiply the input. Gain can be a real or complex-valued scalar, vector, or matrix.

Programmatic Use

Block Parameter: Gain

Type: character vector

Values: '1' | real- or complex-valued scalar, vector, or matrix

Default: '1'

Multiplication — Specify the multiplication mode

Element-wise(K.*u) (default) | Matrix(K*u) | Matrix(u*K) | Matrix(K*u) (u vector)

Specify one of these multiplication modes:

- **Element-wise(K.*u)** — Each element of the input is multiplied by each element of the gain. The block performs expansions, if necessary, so that the input and gain have the same dimensions.
- **Matrix(K*u)** — The input and gain are matrix-multiplied with the input as the second operand.
- **Matrix(u*K)** — The input and gain are matrix-multiplied with the input as the first operand.
- **Matrix(K*u) (u vector)** — The input and gain are matrix multiplied with the input as the second operand. This mode is identical to **Matrix(K*u)**, except for how dimensions are determined.

Suppose that K is an m-by-n matrix. **Matrix(K*u) (u vector)** sets the input to a vector of length n and the output to a vector of length m. In contrast, **Matrix(K*u)** uses propagation to determine dimensions for the input and output. For an m-by-n gain matrix, the input can propagate to an n-by-q matrix, and the output becomes an m-by-q matrix.

Programmatic Use

Parameter: Multiplication

Type: character vector

Value: 'Element-wise(K.*u)' | 'Matrix(K*u)' | 'Matrix(u*K)' | 'Matrix(K*u) (u vector)'

Default: 'Element-wise(K.*u)'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type — Specify the output data type**

Inherit: Inherit via internal rule (default) | Inherit: Keep MSB | Inherit: Match scaling | Inherit: Inherit via back propagation | Inherit: Same as input | double | single | int8 | uint8 | int16 | uint16 | int32 | int64 | uint64 | uint32 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select an inherited option, the block exhibits these behaviors:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.
- **Inherit: Keep MSB**— Simulink chooses a data type that maintains the full range of the operation, then reduces the precision of the output to a size appropriate for the embedded target hardware.

Tip For more efficient generated code, deselect the **Saturate on integer overflow** parameter.

This rule never produces overflows.

- **Inherit: Match scaling**— Simulink chooses a data type whose scaling matches the scaling of the input types. If the full range of the type does not fit on the embedded target hardware, the range is reduced yielding a type appropriate for the embedded target hardware. This rule can produce overflows.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If these internal rules do not meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Use data type of the driving block.

- **Inherit:** Same as input — Use data type of input signal.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule'|'Inherit: Keep MSB'|'Inherit: Match scaling'|'Inherit: Same as input'|'Inherit: Inherit via back propagation'|'single'|'int8'|'uint8'|'int16'|'uint16', 'int32'|'uint32'|'int64'|'uint64'|'fixdt(1,16)'|'fixdt(1,16,0)'|'fixdt(1,16,2^0,0)'| '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Parameter Attributes

Parameter `minimum` — Specify the minimum value of gain

[] (default) | scalar

Specify the minimum value of gain. The default value is [] (unspecified). Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** ParamMin**Type:** character vector**Value:** scalar**Default:** '[]'**Parameter maximum — Specify the maximum value of gain**

[] (default) | scalar

Specify the maximum value of gain. The default value is [] (unspecified). Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** ParamMax**Type:** character vector**Value:** scalar**Default:** '[]'**Parameter data type — Specify the data type of the Gain parameter**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Inherit from 'Gain' | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the data type of the **Gain** parameter.

Programmatic Use**Block Parameter:** ParamDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Inherit via back propagation' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16', 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'**Block Characteristics**

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Tunable Parameters

You can use a tunable parameter in a Gain block intended for HDL code generation. For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder).

HDL Architecture

ConstMultiplierOptimization	Description
<code>none</code> (Default)	By default, HDL Coder does not perform CSD or FCSD optimizations. Code generated for the Gain block retains multiplier operations.
<code>csd</code>	When you specify this option, the generated code decreases the area used by the model while maintaining or increasing clock speed, using canonical signed digit (CSD) techniques. CSD replaces multiplier operations with add and subtract operations. CSD minimizes the number of addition operations required for constant multiplication by representing binary numbers with a minimum count of nonzero digits.
<code>fcsd</code>	This option uses factored CSD (FCSD) techniques, which replace multiplier operations with shift and add/subtract operations on certain factors of the operands. These factors are generally prime but can also be a number close to a power of 2, which favors area reduction. You can achieve a greater area reduction with FCSD at the cost of decreasing clock speed.
<code>auto</code>	When you specify this option, the coder chooses between the CSD or FCSD optimizations. The coder chooses the optimization that yields the most area-efficient implementation, based on the number of adders required. When you specify <code>auto</code> , the coder does not use multipliers, unless conditions are such that CSD or FCSD optimizations are not possible (for example, if the design uses floating-point arithmetic).

HDL Block Properties

General	
ConstMultiplierOptimization	Canonical signed digit (CSD) or factored CSD optimization. The default is <code>none</code> . See also “ConstMultiplierOptimization” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . See also “DSPStyle” (HDL Coder).

General	
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Note For certain values of the **Gain** parameter, native floating point implements the algorithm differently instead of using multipliers. For example, if you set the **Gain** parameter to 1, the generated model uses a wire to pass the input to the output. If you set the **Gain** parameter to -1, the generated model shows a Unary Minus block that inverts the polarity of the input signal. This implementation reduces the latency and resource usage on the target platform.

Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , <code>Zero</code> , or <code>Custom</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <code>Custom</code> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is <code>inherit</code> . See also “MantissaMultiplyStrategy” (HDL Coder).

Gauge

Display signal value on circular scale

Library: Simulink / Dashboard

Description

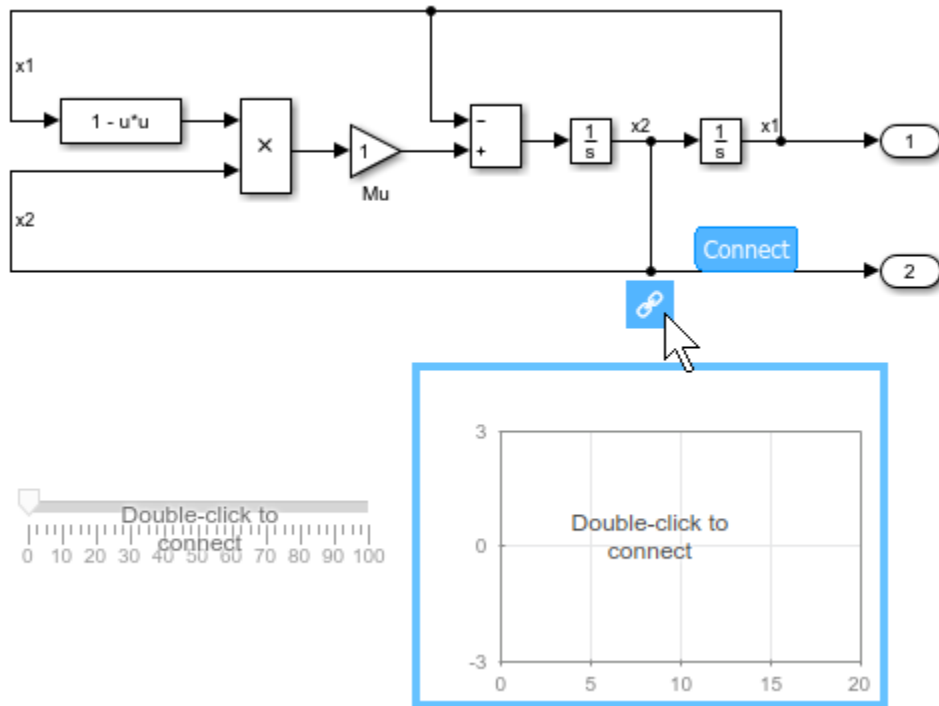

The Gauge block displays the connected signal on a circular scale during simulation. You can use the Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Gauge block to fit your data. You can also change the appearance of the dial to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connecting Dashboard Blocks

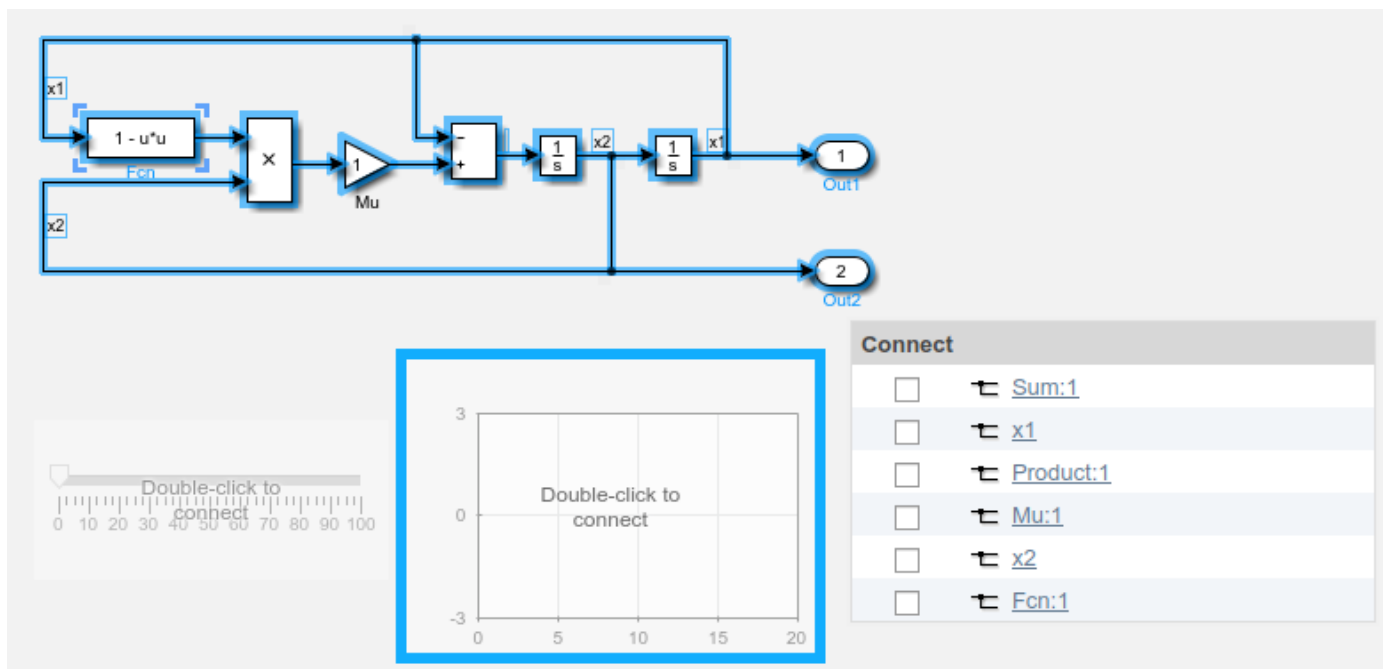

Dashboard blocks do not use ports to connect to signals. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above the block.

In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify `-1`.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Maximum — Maximum tick mark value**

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the **Maximum** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Tick Interval — Interval between major tick marks**

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to **auto**, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the **Tick Interval** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Scale Colors — Color indications on gauge scale**

colors for scale ranges

Color specifications for value ranges on the scale. Press the **+** button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the **Scale Colors** parameter, use an array of structures with the fields:

- **Min** — Minimum value for the color range on the scale
- **Max** — Maximum value for the color range on the scale
- **Color** — 1-by-3 vector of double values between 0 and 1 that specify the color for the range in the form [r g b]

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;  
range1.Max = 10;
```

```
range1.Color = [0 0 1];
range2.Min = 10;
range2.Max = 15;
range2.Color = [0 1 0];
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors**Type:** structure array**Default:** 0x1 struct array**Label — Block label position**

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Top' | 'Bottom' | 'Hide'**Default:** 'Top'**Block Characteristics**

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no

Goto

Pass block input to From blocks

Library: Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The Goto block passes its input to its corresponding From blocks. The input can be a real- or complex-valued signal or vector of any data type. From and Goto blocks allow you to pass a signal from one block to another without actually connecting them.

A Goto block can pass its input signal to more than one From block, although a From block can receive a signal from only one Goto block. The input to that Goto block is passed to the From blocks associated with it as though the blocks were physically connected. Goto blocks and From blocks are matched by the use of Goto tags.

The **Tag Visibility** parameter determines whether the location of From blocks that access the signal is limited:

- `local` (default) — From and Goto blocks that use the same tag must be in the same subsystem. A local tag name is enclosed in brackets ([]).
- `scoped` — From and Goto blocks that use the same tag must be in the same subsystem or at any level in the model hierarchy below the Goto Tag Visibility block that does not entail crossing a nonvirtual subsystem boundary, in other words, the boundary of an atomic, conditionally executed, or function-call subsystem or a model reference. A scoped tag name is enclosed in braces ({ }).
- `global` — From and Goto blocks using the same tag can be anywhere in the model except in locations that span nonvirtual subsystem boundaries.

The rule that From-Goto block connections cannot cross nonvirtual subsystem boundaries has the following exception. A Goto block connected to a state port in one conditionally executed subsystem is visible to a From block inside another conditionally executed subsystem.

Note A `scoped` Goto block in a masked system is visible only in that subsystem and in the nonvirtual subsystems it contains. Simulink generates an error if you run or update a diagram that has a Goto Tag Visibility block at a higher level in the block diagram than the corresponding `scoped` Goto block in the masked subsystem.

Use local tags when the Goto and From blocks using the same tag name reside in the same subsystem. You must use global or scoped tags when the Goto and From blocks using the same tag name reside in different subsystems. When you define a tag as global, all uses of that tag access the same signal. A tag defined as scoped can be used in more than one place in the model.

The Goto block supports signal label propagation.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal to be passed to the corresponding From block, specified as a scalar, vector, matrix, or N-D array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Goto tag — Block identifier

A (default) | ...

The Goto block identifier. This parameter identifies the Goto block whose scope is defined in this block.

Programmatic Use

Block Parameter: GotoTag

Type: character vector

Values: 'A' | ...

Default: 'A'

Tag visibility — Scope of the Goto block tag

local (default) | scoped | global

The scope of the Goto block tag, specified as `local`, `scoped`, or `global`. When you set this parameter to `scoped`, you must use a Goto Tag Visibility block to define the scope of tag visibility.

Programmatic Use

Block Parameter: TagVisibility

Type: character vector

Values: 'local' | 'scoped' | 'global'

Default: 'local'

Icon display — Text to display on block icon

Tag (default) | Signal name | Tag and signal name

Specifies the text to display on the block icon. The options are the block tag, the name of the signal that the block represents, or both the tag and the signal name.

Programmatic Use

Block Parameter: IconDisplay

Type: character vector

Values: 'Signal name' | 'Tag' | 'Tag and signal name'

Default: 'Tag'

Rename All — Propagate name throughout model

button

Rename the Goto tag. The new name propagates to all From and Goto Tag Visibility blocks that are listed in the **Corresponding blocks** box.

Corresponding blocks — Blocks connected to this Goto block

block path | ...

List of the From blocks and Goto Tag Visibility blocks connected to this Goto block. Click an entry in the list to display and highlight the corresponding From or Goto Tag Visibility block.

Goto Tag Visibility

Define scope of Goto block tag

Library: Simulink / Signal Routing

Description

The Goto Tag Visibility block defines the accessibility of Goto block tags that have **scoped** visibility. The value you specify for the **Goto tag** block parameter is accessible by From blocks in the same subsystem that contains the Goto Tag Visibility block and in subsystems below it in the model hierarchy.

A Goto Tag Visibility block is required for Goto blocks whose **Tag Visibility** parameter value is **scoped**. No Goto Tag Visibility block is needed if the tag visibility is either **local** or **global**. The block shows the tag name enclosed in braces (`{}`).

Note A **scoped** Goto block in a masked system is visible only in that subsystem and in the nonvirtual subsystems it contains. Simulink generates an error if you run or update a diagram that has a Goto Tag Visibility block at a lower level in the block diagram than the corresponding **scoped** Goto block in the masked subsystem.

Parameters

Goto tag — Goto block tag whose visibility is defined by the location of this block

A (default) | ...

The Goto block tag whose visibility is defined by the location of this block. From and Goto blocks using the specified tag must be in the same subsystem or at any level in the model hierarchy below the Goto Tag Visibility block that does not entail crossing a nonvirtual subsystem boundary, in other words, the boundary of an atomic, conditionally executed, or function-call subsystem or a model reference. A **scoped** tag name is enclosed in braces (`{}`).

Tip If you use multiple From and Goto Tag Visibility blocks to refer to the same Goto tag, you can simultaneously rename the tag in all of the blocks. Use the **Rename All** button in the Goto block dialog box.

Ground

Ground unconnected input port

Library: Simulink / Commonly Used Blocks
 Simulink / Sources
 HDL Coder / Sources

Description

The Ground block connects to blocks whose input ports do not connect to other blocks. If you run a simulation with blocks that have unconnected input ports, Simulink issues warnings. Using a Ground block to ground those unconnected blocks can prevent these warnings.

Working with Fixed-Point Data Types

When working with fixed-point data types, there may be instances where the fixed-point data type cannot represent zero exactly. In these cases, the Ground block outputs a nonzero value that is the closest possible value to zero. This behavior applies only to fixed-point data types with nonzero bias. These expressions are examples of fixed-point data types that cannot represent zero:

- `fixdt(0, 8, 1, 1)` — an unsigned 8-bit type with slope of 1 and bias of 1
- `fixdt(1, 8, 6, 3)` — a signed 8-bit type with slope of 6 and bias of 3

Working with Enumerated Data Types

When working with enumerated data types, the Ground block outputs the default value of the enumeration. This behavior applies whether:

- The enumeration can represent zero
- The default value of the enumeration is zero

If the enumerated type does not have a default value, the Ground block outputs the first enumeration value in the type definition.

Ports

Output

Port_1 — Ground signal

scalar

The Ground block outputs a scalar signal with zero value, and the same data type as the port to which it connects.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Half Gauge

Display input value on semicircular scale

Library: Simulink / Dashboard

Description

The Half Gauge block displays the connected signal on a semicircular scale during simulation. You can use the Half Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Half Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Half Gauge block to fit your data. You can also customize the appearance of the Half Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above the block.

In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify `-1`.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Maximum — Maximum tick mark value**

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the `Maximum` parameter, use a 1-by-3 vector containing values for the `Minimum`, `Tick Interval`, and `Maximum` parameters, in that order. To use the `auto` value for the `Tick Interval`, leave the `Tick Interval` position in the vector empty or specify `-1`.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Tick Interval — Interval between major tick marks**

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the `Tick Interval` parameter, use a 1-by-3 vector containing values for the `Minimum`, `Tick Interval`, and `Maximum` parameters, in that order. To use the `auto` value for the `Tick Interval`, leave the `Tick Interval` position in the vector empty or specify `-1`.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Scale Colors — Color indications on gauge scale**

colors for scale ranges

Color specifications for value ranges on the scale. Press the **+** button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the `Scale Colors` parameter, use an array of structures with the fields:

- `Min` — Minimum value for the color range on the scale
- `Max` — Maximum value for the color range on the scale
- `Color` — 1-by-3 vector of double values between 0 and 1 that specify the color for the range in the form [r g b]

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;  
range1.Max = 10;
```

```
range1.Color = [0 0 1];
range2.Min = 10;
range2.Max = 15;
range2.Color = [0 1 0];
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors

Type: structure array

Default: 0x1 struct array

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Hit Crossing

Detect crossing point

Library: Simulink / Discontinuities
 Simulink / Messages & Events
 HDL Coder / Discontinuities
 SimEvents

Description

The Hit Crossing block detects when the input reaches the **Hit crossing offset** parameter value in the direction specified by the **Hit crossing direction** property.

You can configure the block to output a 1 or 0 signal, a SimEvents® message, or a function-call event. See “Output” on page 1-688 for more information.

Ports

Input

Port_1 – Input signal

scalar | vector

Input signal that the block detects when it reaches the offset in the specified direction.

Data Types: double

Output

Port_1 – Output signal

scalar | vector | SimEvents message | function-call event

Output indicating if the input signal crossed the hit offset. This port is visible only when you select the **Show output port** parameter check box.

Signal Output

If you select the **Show output port** check box and set the **Output type** parameter to Signal, the block output indicates when the crossing occurs.

- If the input signal is exactly the value of the offset value after the hit crossing is detected in the specified direction, the block continues to output a value of 1.
- If the input signals at two adjacent points brackets the offset value, the block outputs a value of 1 at the second time step.
- If the **Show output port** check box is *not* selected, the block ensures that the simulation finds the crossing point but does not generate output.
- If the initial signal is equal to the offset value, the block outputs 1 only if the **Hit crossing direction** property is set to either.
- If Boolean logic signals are enabled, then the output is a Boolean.

SimEvents Message Output

The Hit Crossing block can also output a SimEvents message when the **Output type** parameter is set to **Message**.

- If the input signal crosses the offset value in the specified direction, the block outputs a message.
- If the input signal reaches the offset value in the specified direction and remains there, block outputs one message at the hit time and one message when the signal leaves the offset value.
- If the initial input signal is equal to the offset value, the block outputs a message with **Crossing Type** value **None** only if the **Hit crossing direction** is set to either.

The SimEvents message output signal is a `struct` with four fields.

Function-Call Output

The Hit Crossing block can also output a function-call event when the **Output type** parameter is set to **Function-Call**.

- Each time the input signal crosses the offset value in the specified direction, the block outputs a single function-call event.
- The function-call event can be sent to the function-call input port of a function-call subsystem or function-call model.
- The output is equivalent to the output of a Function-Call Generator block at each time step with the **Number of iterations** parameter of that block set to 1.

CrossingType — Direction of zero-crossing

None | NegativeToPositive | NegativeToZero | ZeroToPositive | PositiveToNegative | PositiveToZero | ZeroToNegative

This field shows the direction in which the signal crosses the **Hit crossing offset** value. Negative, Zero, and Positive are defined relative to the offset value. The data type is `slHitCrossingType` which is an enumerated data type. See “Use Enumerated Data in Simulink Models” for more information. For example, if `HitCrossingOffset` is set to 2, a rising signal crossing this offset value would be recorded as a `NegativeToPositive` hit crossing.

Note A hit crossing is recorded based on the **Hit crossing direction** setting. In other words, if you set **Hit crossing direction** to detect a falling hit crossing, a `NegativeToPositive` hit is not recorded.

Note In a SimEvents block, if the `Crossing Type` of an entity is a `NegativeToPositive` hitcrossing then `entity.CrossingType == slHitCrossingType.NegativeToPositive` returns logical 1 (`true`).

If the signal reaches the `HitCrossingOffset` value and holds it, a single `NegativeToZero` or `PositiveToZero`, depending on the direction, hit is registered at the time of the hit crossing.

Data Types: `slHitCrossingType`

Index — Index of the input signal at which the hit crossing event occurs

nonnegative integer

For n signals being passed to the Hit Crossing block, this field denotes which signal had a hit crossing event. For a matrix input, this field follows MATLAB linear indexing. See “Array Indexing” (MATLAB).

Data Types: uint32

Time — Time of hit crossing event

real, finite

Time T of the hit crossing event.

Data Types: double

Offset — Hit crossing value for detection

0 (default) | real values

Hit crossing offset value as specified by the “Hit crossing offset” on page 1-0 parameter.

Data Types: double

Data Types: double | Boolean | struct

Note If the SimEvents message output signal crosses model reference boundaries or is used as an input to a Stateflow chart, you need to create a bus object for the message. See “Tips” on page 1-691.

Parameters

Hit crossing offset — Hit crossing value for detection

0 (default) | real values

Specify the value the block detects when the input crosses in the direction specified by **Hit crossing direction**.

Programmatic Use

Block Parameter: HitCrossingOffset

Type: character vector

Values: real values

Default: '0'

Hit crossing direction — Input signal direction to hit crossing

either (default) | falling | rising

Direction from which the input signal approaches the hit crossing offset for a crossing to be detected.

When set to `either`, the block serves as an *almost equal* block, useful in working around limitations in finite mathematics and computer precision. Used for these reasons, this block might be more convenient than adding logic to your model to detect this condition.

When the **Hit crossing direction** property is set to `either` and the model uses a fixed-step solver, the block has the following behavior. If the output signal is 1, the block sets the output signal to 0 at the next time step, unless the input signal equals the offset value.

Programmatic Use

Block Parameter: HitCrossingDirection

Type: character vector

Values: 'either' | 'rising' | 'falling'

Default: 'either'

Show output port — Display an output port

off (default) | on

If selected, create an output port on the block icon.

Programmatic Use**Block Parameter:** ShowOutputPort**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Output type — Choose signal, message, or function-call output**

Signal (default for Simulink) | Message (default for SimEvents) | Function-Call

When **Output type** is set to Signal, the output signal is set to one whenever the input signal crosses the **Hit crossing offset** value in the **Hit crossing direction** and is zero at other times.

When the **Output type** is set to Message, the output signal becomes a SimEvents message.

When **Output type** is set to Function-Call, the output signal becomes a function-call event.

Programmatic Use**Block Parameter:** HitCrossingOutputType**Type:** character vector**Values:** 'Signal' | 'Message' | 'Function-Call'**Default:** 'Signal'**Enable zero-crossing detection — Enable zero-crossing detection**

on (default) | off

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use**Parameter:** ZeroCross**Type:** character vector, string**Values:** 'on' | 'off'**Default:** 'on'**Block Characteristics**

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

Tips

If the Hit Crossing block is configured to output a SimEvents message and the output signal:

- Crosses into or out of a referenced model
- Is fed to the input of a Stateflow chart

then you need to create a bus object for the message signal. In the MATLAB Command Window, run `Simulink.createHitCrossMessage` to check for and, if needed, create a hit crossing message bus object in the base workspace.

Set the data type of the corresponding port to `Bus: HitCrossMessage`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code.

Does not support non-floating data type for ert targets.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restriction

The Hit crossing direction must be `rising` or `falling`.

HDL code generation is not supported when the `Output Type` is set to `Message`.

Introduced before R2006a

Horizontal Gauge

Display signal value on horizontal, customizable gauge during simulation

Library: Simulink / Dashboard

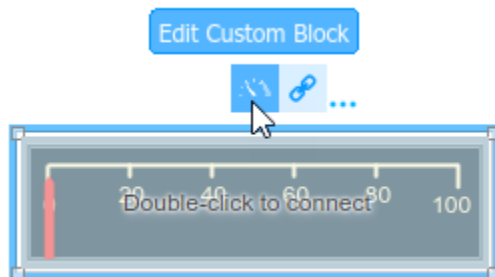

Description

The Horizontal Gauge block displays the value of the connected signal on a linear gauge that you can customize to look like a gauge in a real system.

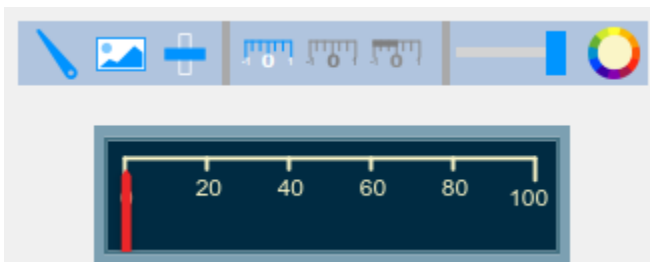

The Horizontal Gauge block displays the instantaneous value of the connected signal throughout simulation. You can modify the range and tick values on the Horizontal Gauge block to fit your data. Use the Horizontal Gauge block with other dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Customize the Horizontal Gauge Block

When you add a Horizontal Gauge block to your model, the block is preconfigured with a default design. You can use the block with the default design, or you can customize the appearance of the block. To customize the block, pause on the block and click the **Edit Custom Block** button that appears above the block.

In the custom block edit mode, a toolbar that you can use to customize the block appears above the selected custom block. In the left section of the toolbar, you can specify a custom image to use for the background and needle, and you can modify the orientation of the block. In the middle section, you select a component of the scale. You can independently modify the color and transparency for the scale, the tick labels, and the value bar. Use the right section of the toolbar to specify the transparency and color for the selected scale component.

While in the custom block edit mode, you can also resize and reposition the scale and needle as desired.

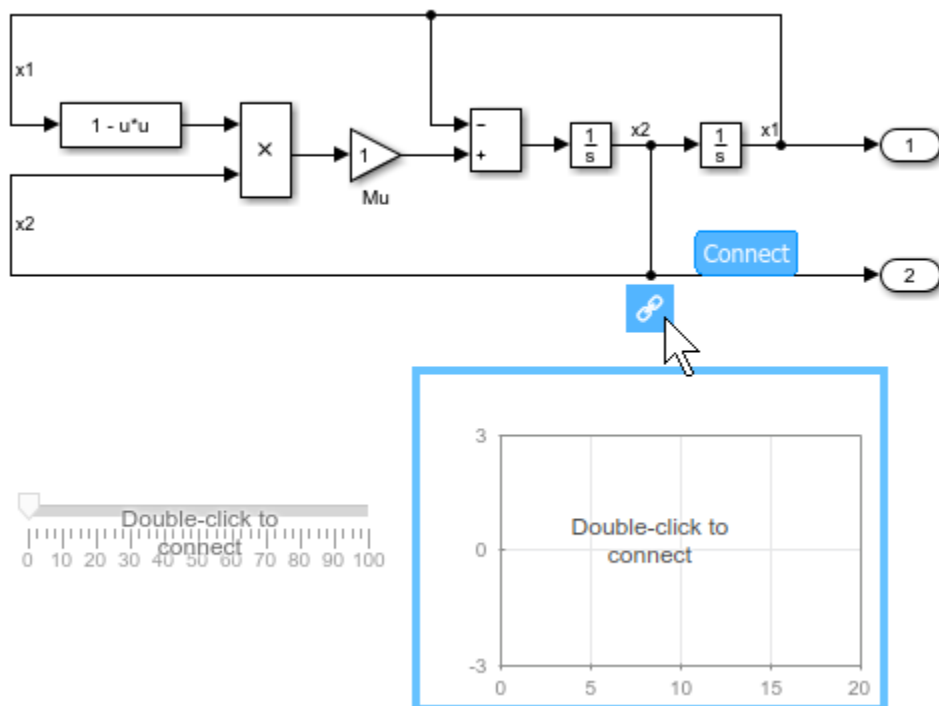

When you finish editing the gauge, click the **Exit** button in the upper-right of the canvas to exit the custom block edit mode.

Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above the block.

In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.

- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the Tick Interval parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Scale Colors — Color indications on gauge scale

colors for scale ranges

Color specifications for value ranges on the scale. Press the + button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the Scale Colors parameter, use an array of structures with the fields:

- **Min** — Minimum value for the color range on the scale
- **Max** — Maximum value for the color range on the scale
- **Color** — 1-by-3 vector of double values between 0 and 1 that specify the color for the range in the form [r g b]

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;
range1.Max = 10;
range1.Color = [0 0 1];
range2.Min = 10;
range2.Max = 15;
range2.Color = [0 1 0];
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors

Type: structure array

Default: 0x1 struct array

Lock Aspect Ratio — Whether to maintain block aspect ratio

on (default) | off

Whether to maintain the block aspect ratio when resizing the block and when you specify a new background image.

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
-------------------	----------------------------------------------------------------

Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

IC

Set initial value of signal

Library: Simulink / Signal Attributes

Description

The IC block sets the initial condition of the signal at its input port, for example, the value of the signal at the simulation start time (t_{start}). To do so, the block outputs the specified initial condition when you start the simulation, regardless of the actual value of the input signal. Thereafter, the block outputs the actual value of the input signal.

The IC block is useful for providing an initial guess for the algebraic state variables in a loop. For more information, see “Algebraic Loop Concepts”.

Behavior for Nonzero Sample Time Offset

If an IC block has a nonzero sample time offset (t_{offset}), the IC block outputs its initial value at time t ,

$$t = n * t_{period} + t_{offset}$$

where n is the smallest integer such that $t \geq t_{start}$.

That is, the IC block outputs its initial value the first-time blocks with sample time $[t_{period}, t_{offset}]$ execute, which can be after t_{start} .

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. The block sets the initial condition of this signal to the **Initial value** you specify.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 – Output signal

scalar | vector | matrix | N-D array

Output signal provided as the **Initial value** you specify, followed by the actual values of the input signal. See “Behavior for Nonzero Sample Time Offset” on page 1-700 for more information.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Initial value — Initial value

1 (default) | real, finite scalar, vector, matrix, or N-D array

Specify the initial value of the input signal as a finite, real-valued scalar, vector, matrix, or N-D array. The value must be a scalar, or have the same dimensions as the input signal.

Programmatic Use

Block Parameter: `Value`

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: `'1'`

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: `SampleTime`

Type: character vector

Values: scalar or vector

Default: `'-1'`

Block Characteristics

Data Types	<code>Boolean</code> <code>double</code> <code>enumerated</code> <code>fixed point</code> <code>integer</code> <code>single</code>
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely varying execution times. While

the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If

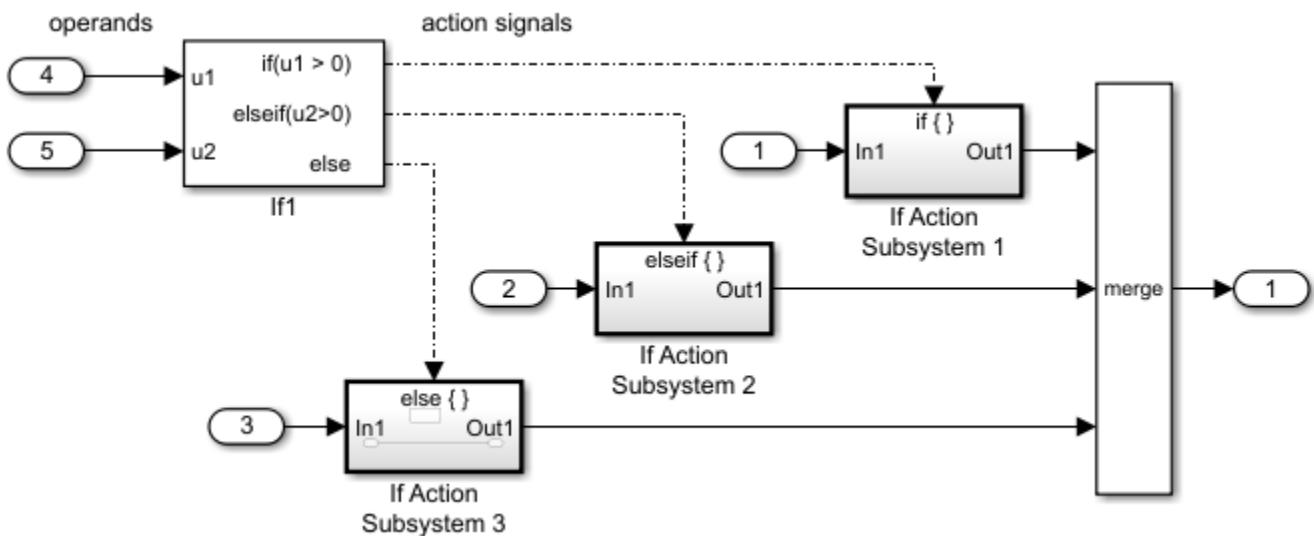

Select subsystem execution using logic similar to if-else statement

Library: Simulink / Ports & Subsystems

Description

The If block, along with If Action Subsystem blocks containing an Action Port block, implements if-else logic to control subsystem execution. For an example using the If block, see If Action Subsystems.

Limitations

The If block has the following limitations:

- It does not support tunable parameters. Values for an `if` or `elseif` expression cannot be tuned during a simulation in normal or accelerator mode, or when running generated code.

To implement tunable if-else expressions, tune the expression outside the If block. For example, use the Relational Operator block to evaluate the expression outside of the If block or add the tunable parameter as an input to the If block.

- It does not support custom storage classes. See “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).
- The **If expression** and **Elseif expressions** cannot accept certain operators, such as `+`, `-`, `*`, and `/`.

Ports

Input

Logical operands — Values for evaluating logical expressions

scalar | vector

Inputs u_1, u_2, \dots, u_n must have the same data type. The inputs cannot be of any user-defined type, such as an enumerated type.

The If block does not directly support fixed-point data types. However, you can use the Compare To Constant block to work around this limitation. See Support for Fixed-Point Data Type in If Action Subsystems.

The If block does not support a boolean data type. If you want to input a boolean signal to an If block, convert the signal to an integer type using the Data Type Conversion block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Action — Action signal for an If Action Subsystem block

scalar

Outputs from the `if`, `else`, and `elseif` ports are action signals to If Action Subsystem blocks.

Support for Fixed-Point Data Type

Parameters

Number of inputs — Specify number of input ports

1 (default) | integer

1

Specify one input port.

integer

Specify the number of input ports. Block ports are labeled with a 'u' character followed by a number, $1, 2, \dots, n$, where n equals the number of inputs that you specify.

Programmatic Use

Block Parameter: NumInputs

Type: character vector

Values: '1' | '<integer>'

Default: '1'

if expression — Specify logical expression

$u_1 > 0$ (default) | logical expression

The If Action Subsystem attached to the `if` port executes when its associated expression evaluates to true.

$u_1 > 0$

Specify sending an action signal on the output port when the input u_1 is greater than 0.

logical expression

Specify logical expression. This expression appears on the If block adjacent to the **if** output port.

The expression can include only the operators `<`, `<=`, `==`, `~=`, `>`, `>=`, `&`, `|`, `~`, `()`, unary-minus. Operators such as `+`, `-`, `*`, `/`, and `^` are not allowed. The expression must not contain data type expressions, for example, `int8(6)`, and must not reference workspace variables whose data type is other than `double` or `single`.

Programmatic Use

Block Parameter: IfExpression

Type: character vector

Values: `'u1 > 0'` | `'<logical expression>'`

Default: `'u1 > 0'`

Elseif expressions — Specify logical expression

empty (default) | list of logical expressions

The If Action Subsystem attached to an **elseif** port executes when its expression evaluates to `true` and all `if` and `elseif` expressions are false.

empty

Logical expressions not specified.

list of logical expressions

Specify a list of logical expressions delimited by commas. The expressions appear on the If block below the **if** port and above the **else** port when you select the **Show else condition** check box.

Expressions can include only the operators `<`, `<=`, `==`, `~=`, `>`, `>=`, `&`, `|`, `~`, `()`, unary-minus. Operators such as `+`, `-`, `*`, `/`, and `^` are not allowed. The expressions must not contain data type expressions, for example, `int8(6)`, and must not reference workspace variables whose data type is other than `double` or `single`.

Programmatic Use

Block Parameter: ElseIfExpressions

Type: character vector

Values: `''` | `'<list of logical expressions>'`

Default: `''`

Show else condition — Control display of else port

on (default) | off

When the **if** port and all **elseif** port expressions are false, the **else** port sends an action signal to execute the attached If Action Subsystem block.

on

Display **else** port.

off

Hide **else** port.

Programmatic Use

Block Parameter: ShowElse

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Enable zero-crossing detection — Control zero-crossing detection

on (default) | off

Control zero-crossing detection.

on

Detect zero crossings.

off

Do not detect zero crossings.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	Boolean double integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

Extended Capabilities

Blocks

Action Port | If Action Subsystem | Subsystem

Topics

Select Subsystem Execution

Introduced before R2006a

If Action Subsystem

Subsystem whose execution is enabled by an If block

Library: Simulink / Ports & Subsystems

Description

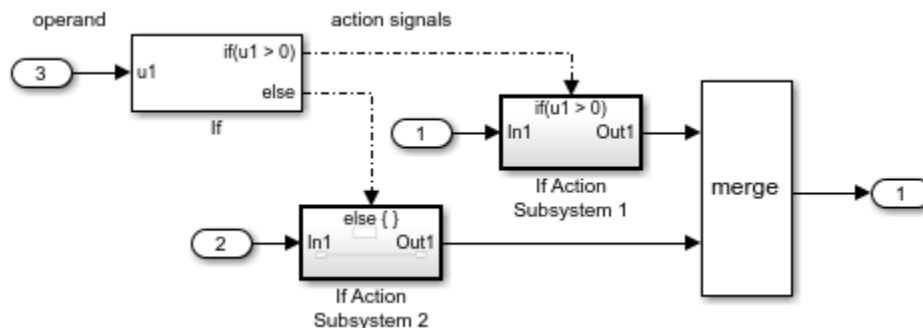

The If Action Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem whose execution is controlled by an If block. The If block evaluates a logical expression and then, depending on the result of the evaluation, outputs an action signal.

Simulink ignores a priority set on an If Action Subsystem block. Instead, set the priority on the If block that initiates execution of the subsystem.

Merge signals from If Action Subsystem blocks

This example shows how to merge signals controlled by an If block. The If block selects the execution of an If Action Subsystem block from a set of subsystems. Regardless of which subsystem the If block selects, you can create a single signal with a Merge block. `Open model.`

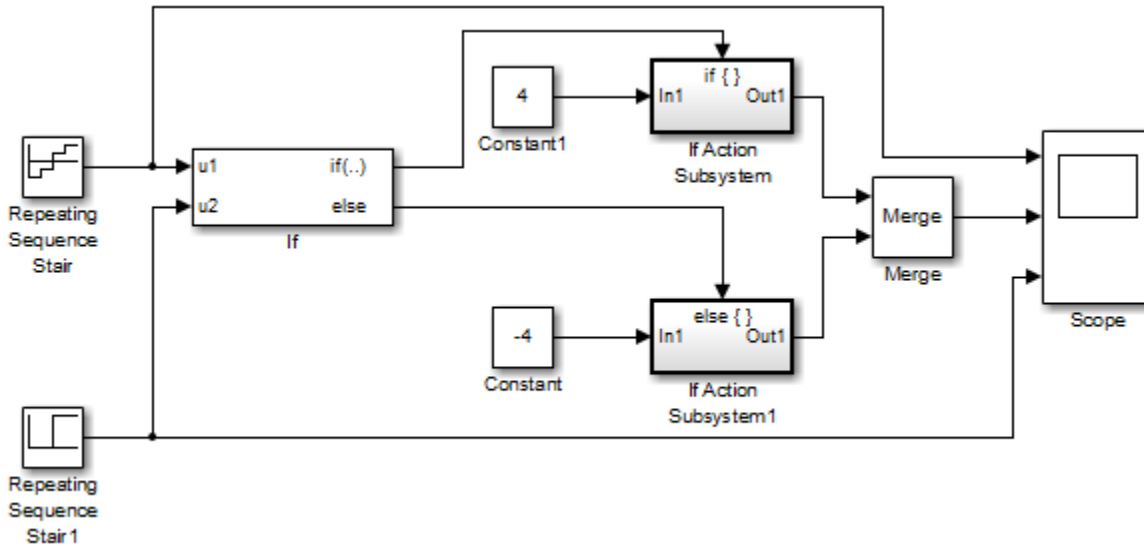

All blocks in an If Action Subsystem block must execute at the same rate as the driving If block. You can satisfy this requirement by setting the sample time parameter for each block to either inherited (-1) or the same value as the If block sample time.

Support for Fixed-Point Data Type

The If block does not directly support fixed-point data types. However, you can use the Compare To Constant block to work around this limitation.

Consider the following floating-point model without fixed-point data types:

In this model, the If Action Subsystem blocks use their default configurations. The simulation parameters are set to their default values except for the parameters listed in the following table.

Configuration Parameter Pane	Parameter	Setting
Solver	Start time	0.0
	Stop time	1.0
	Type	Fixed-step
	Solver	discrete (no continuous states)
	Fixed-step size	0.1

The block parameters are set to their default values except for the parameters listed in the following table.

Block	Parameter	Setting
Repeating Sequence Stair	Vector of output values	[-2 -1 1 2].'
Repeating Sequence Stair1	Vector of output values	[0 0 0 0 1 1 1 1].'
If	Number of inputs	2
	If expression	(u1 > 0) (u2 > 0.5)
	Show else condition	Selected
Constant	Constant value	-4

Block	Parameter	Setting
Constant1	Constant value	4
Scope	Number of axes	3
	Time range	1

For this model, when input u_1 is greater than 0 or input u_2 is greater than 0.5, the output is 4. Otherwise, the output is -4. The Scope block displays the output from the Merge block with inputs u_1 , and u_2 .

You can implement this block diagram as a model with fixed-point data types:

The Repeating Sequence Stair blocks output fixed-point data types.

The Compare To Constant blocks implement two parts of the **If expression** that is used in the If block in the floating-point version of the model, ($u1 > 0$) and ($u2 > 0.5$). The OR operation, ($u1 | u2$), can still be implemented inside the If block. For a fixed-point model, the expression must be partially implemented outside of the If block as it is in this model.

The block and simulation parameters for the fixed-point model are the same as for the floating-point model with the following exceptions and additions:

Block	Parameter	Setting
Compare To Constant	Operator	>
	Constant value	0
	Output data type mode	Boolean
	Enable zero-crossing detection	off
Compare To Constant1	Operator	>
	Constant value	0.5
	Output data type mode	Boolean
	Enable zero-crossing detection	off
If	Number of inputs	2
	If expression	$u1 u2$

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Action — Control signal input to a subsystem block

`scalar` | `vector` | `matrix`

Placing an Action Port block in a subsystem block adds an external input port to the block and changes the block to an If Action Subsystem.

Dot-dash lines from a Switch Case block to an Switch Case Action Subsystem block represent *action* signals. An action signal is a control signal connected to the action port of a Switch Case Action Subsystem block. A message on the action signal initiates execution of the subsystem.

Data Types: `action`

Output

Out — Signal output from a subsystem

`scalar` | `vector` | `matrix`

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Block Characteristics

Data Types	<code>Boolean^a</code> <code>bus^a</code> <code>double^a</code> <code>enumerated^a</code> <code>fixed point^a</code> <code>integer^a</code> <code>single^a</code> <code>string^a</code>
Direct Feedthrough	no
Multidimensional Signals	limited ^a
Variable-Size Signals	limited ^a
Zero-Crossing Detection	no

a. Actual data type or capability support depends on block implementation.

In Bus Element, Bus Element In

Select signal that connects to input port

Library: Simulink / Ports & Subsystems
 Simulink / Sources
 HDL Coder / Ports & Subsystems
 HDL Coder / Sources

InBus.signal1 

Description

The In Bus Element block, also known as the Bus Element In block, combines the functionality of an Inport block and a Bus Selector block. This block is of the Inport block type and all In Bus Element blocks that use the same port share a Block Parameters dialog box.

You can use an In Bus Element block to select a virtual bus element, virtual bus, or nonbus signal associated with the port. To select multiple signals from a bus, use multiple In Bus Element blocks.

Create Port and Related Blocks

When you insert an In Bus Element block, the block label populates with default values. The label consists of two interactive text fields: the port name and the bus element. To change the name of the port associated with the block, edit the first text field in the label by clicking in it.

InBus. signal1 

To create related In Bus Element blocks, in the Block Parameters dialog box, you can select the **Add blocks for selected signals**  button.

If multiple blocks are associated with the same port and you change the name of the port, all blocks that share the port update to reflect the new port name.

You can create additional ports by holding **Ctrl** while you drag an existing In Bus Element block to a new location. Upon releasing the mouse, you have the option to create a port or use the existing port associated with the block being copied.

Examine Port Input

You can view the signals associated with a port in the Block Parameters dialog box for any of the related In Bus Element blocks.

▼ InBus

a

b

c

d

Black element names are already associated with an In Bus Element block. Grey element names are available, but are not being used. Red element names are not available in the input bus, despite being specified by an In Bus Element block.

You can create In Bus Element blocks for each selected signal by clicking the **Add blocks for selected signals** button .

To remove blocks associated with selected elements, such as elements which are unavailable in the input bus, click the **Remove blocks of selected signals** button .

Select a Signal

To change the bus element associated with the block, edit the second text field in the label by clicking in it.

If a bus is connected to the port, you can select an element of the bus from the list that appears. To see all elements of the bus along with the previously specified signal, clear the text. The list of elements is filtered to include only the elements that contain the existing text.

Each dot in the part of the label that describes the bus element indicates a new level of bus hierarchy. To reduce the size of the label, you can display only the signal name by selecting the block, pausing over the ellipsis, and selecting **Compact Notation** from the action bar. To show the signal hierarchy again, select **Expanded Notation** from the action bar.

You can pass through the entire signal connected to the port by leaving the second text field empty. The signal connected to the port can be a nonbus signal.

Load Input Data

You can use an In Bus Element block to load external input data for a bus. An In Bus Element block can load data for an element of a bus or for an entire bus. When you use an In Bus Element block to load data for an entire bus, you must specify the data type for the block using a `Simulink.Bus` object. For more information about loading input data for bus elements, see “Load Input Data for a Bus Using In Bus Element Blocks”.

You can load simulation input data for a group of root-level In Bus Element blocks by using a structure of `timeseries`, `timetable`, or `SimulationDatastore` objects. In Bus Element blocks interpolate loaded data for all data types except `string`, `enumerated`, and `fixed point`.

Ports

Output

Port_1 — Selected input signal

signal

Selected input bus or bus element that is associated with an external subsystem or model port.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Port name — Name of input port

InBus (default) | port name

Specify a port name that is not already in use by another block or port. The name appears on the parent Subsystem or Model block. The name also appears next to the block. Multiple blocks can access the same port.

Programmatic Use

Block Parameter: PortName

Type: character vector

Values: 'InBus' | '<port name>'

Default: 'InBus'

Port number — Position of port on parent block

1 (default) | real integer

Specify the order in which the port that corresponds to the block appears on the parent Subsystem or Model block.

- If you add a block that creates another port, the port number is the next available number.
- Deleting all blocks associated with a port deletes the port. Other ports are renumbered so that they are sequential and do not skip any numbers.
- Specifying a port number that exceeds the number of ports creates a port for that number and for any skipped sequential numbers.

Programmatic Use

Block Parameter: Port

Type: character vector

Values: real integer

Default: '1'

Set color — Specify block background color

Black (default) | White | Red | Green | Blue | ... | ...

Specify the background color for bus element port blocks. This specification sets the color of blocks associated with selected bus elements, or of all blocks associated with the port if you do not select any bus elements.

You can specify Black, White, Red, Green, Blue, Cyan, Magenta, Yellow, Gray, Light Blue, Orange, Dark Green, and More Colors.

Programmatic Use

Block Parameter: BackgroundColor

Type: character vector

Values: 'black' | 'white' | 'red' | 'green' | 'blue' | 'cyan' | 'magenta' | 'yellow' | 'gray' | 'lightBlue' | 'orange' | 'darkGreen' | '[r,g,b]' where r, g, and b, are the red, green, blue values of the color in the range 0.0 to 1.0

Default: 'black'

Filter — Filter set of displayed signals

text

Specify a search term to use for filtering a long list of bus elements. Do not enclose the search term in quotation marks. The filter does a partial string search and supports regular expressions. To use a regular expression character as a literal, include an escape character (\). For example, to use a question mark, type sig\?1.

Signal Attributes

To specify signal attributes, click the pencil button or the specified attributes next to a signal name.

Data Type — Data type

Inherit: auto (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | Bus: <object name> | <data type expression>

Specify the data type. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType. Do not specify a bus object as the expression.

Dimensions — Signal dimensions

-1 (default) | integer | [integer, integer]

Specify the dimensions of a signal.

-1	The signal can have any dimensions.
N	The signal must be a vector of size N.
[R C]	The signal must be a matrix having R rows and C columns.

Programmatic Use

Block Parameter: PortDimensions

Type: character vector

Values: '-1' | integer | [integer, integer]
Default: '-1'

Dims Mode — Allow variable-size signals

Inherit (default) | Fixed | Variable

Specify the type of signals allowed. To allow variable-size and fixed-size signals, select `Inherit`. To allow only variable-size signals, select `Variable`. To not allow variable-size signals, select `Fixed`.

Dependencies

When the signal is variable-sized, the **Dimensions** parameter specifies the maximum dimensions of the signal.

Command-Line Information

Parameter: VarSizeSig

Type: character vector

Value: 'Inherit' | 'No' | 'Yes'

Default: 'Inherit'

Unit — Physical unit of the signal

inherit (default) | <Enter unit>

Specify the physical unit of the signal. For a list of supported units, see Allowed Unit Systems.

Programmatic Use

Block Parameter: Unit

Type: character vector

Values: 'inherit' | '<Enter unit>'

Default: 'inherit'

Sample time — Specify sample time

-1 (default) | scalar

Specify the discrete interval between sample time hits or specify another appropriate sample time such as continuous or inherited.

By default, the signal inherits its sample time. To set a different sample time, enter a valid sample time based on the table in “Types of Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar

Default: '-1'

Complexity — Signal type

auto (default) | real | complex

Specify the numeric type of the signal. To choose the numeric type of the signal, select `auto`. Otherwise, choose a real or complex signal type.

Programmatic Use

Block Parameter: SignalType

Type: character vector

Values: 'auto' | 'real' | 'complex'

Default: 'auto'

Minimum — Minimum value

[] (default) | scalar

Lower value of the range that Simulink checks.

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Maximum — Maximum value

[] (default) | scalar

Upper value of the range that Simulink checks.

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no

Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used to simplify the Subsystem bus interfaces when you use the block in subsystems that generate HDL code, but is not included in the hardware implementation.

To learn more about using buses for HDL code generation, see “Buses” (HDL Coder) and “Use Bus Signals to Improve Readability of Model and Generate HDL Code” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Increment Real World

Increase real-world value of signal by one

Library: Simulink / Additional Math & Discrete / Additional Math:
Increment - Decrement
HDL Coder / Math Operations

Description

The Increment Real World block increases the real-world value of the signal by one.

Overflows always wrap.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output is the real-world value of the input signal increased by one. Overflows always wrap. The output has the same data type and dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Increment Stored Integer

Increase stored integer value of signal by one

Library: Simulink / Additional Math & Discrete / Additional Math:
Increment - Decrement
HDL Coder / Math Operations

Description

The Increment Stored Integer block increases the stored integer value of a signal by one.

Floating-point signals also increase by one, and overflows always wrap.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output is the stored integer value of the input signal increased by one. Floating-point signals also increase by one, and overflows always wrap. The output has the same data type and dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Block Characteristics

Data Types	double fixed point integer single

Index Vector

Switch output between different inputs based on value of first input

Library: Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The Index Vector block is a special configuration of the Multiport Switch block in which you specify one data input and the control input is zero-based. The block output is the element of the input vector whose index matches the control input. For example, if the input vector is [18 15 17 10] and the control input is 3, the element that matches the index of 3 (zero-based) is 10, and that becomes the output value.

To configure a Multiport Switch block to work as an Index Vector block set **Number of data ports** to 1 and **Data port order** to Zero-based contiguous.

For more information about the Multiport Switch block, see the Multiport Switch block reference page.

Ports

Input

Port_1 — Control signal

scalar

Control signal, specified as a scalar. When the control input is not an integer value, the block truncates the value to an integer by rounding to zero.

For information on control signals of enumerated type, see “Guidelines on Setting Parameters for Enumerated Control Port” on page 1-984 on the Multiport Switch block ref page.

Limitations

- If the control signal is numeric, the control signal cannot be complex.
- If the control signal is an enumerated signal, the block uses the value of the underlying integer to select a data port.
- If the underlying integer does not correspond to a data input, an error occurs.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

0 or 1 — First data input

scalar | vector

First data input, specified as a scalar or vector. The port is labeled **0** when you set **Data port order** to **Zero-based contiguous**, and labeled **1** when you set **Data port order** to **One-based contiguous**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `bus` | `enumerated` | `string`

Output

Port_1 — Selected data input, based on control signal value

scalar

The block outputs the selected value from the input data vector, according to the control signal value. The output is a scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

Data port order — Type of ordering for data input ports

`Zero-based contiguous` (default) | `One-based contiguous` | `Specify indices`

Specify the type of ordering for your data input ports.

- **Zero-based contiguous** — Block uses zero-based indexing for ordering contiguous data ports. This is the default value of the Index Vector block.
- **One-based contiguous** — Block uses one-based indexing for ordering contiguous data ports. This is the default value of the Multiport Switch block.
- **Specify indices** — Block uses noncontiguous indexing for ordering data ports. This value is supported only for configurations with two or more input data ports.

Tips

- When the control port is of enumerated type, select `Specify indices`.
- If you select `Zero-based contiguous` or `One-based contiguous`, verify that the control port is not of enumerated type. This configuration is deprecated and produces an error. You can run the Upgrade Advisor on your model to replace each Multiport Switch block of this configuration with a block that explicitly specifies data port indices. See “Model Upgrades”.
- Avoid situations where the block contains unused data ports for simulation or code generation. When the control port is of fixed-point or built-in data type, verify that all data port indices are representable with that type. Otherwise, the following block behavior occurs:

If the block has unused data ports and data port order is:	The block produces:
<code>Zero-based contiguous</code> or <code>One-based contiguous</code>	A warning
<code>Specify indices</code>	An error

Dependencies

Selecting Zero-based contiguous or One-based contiguous enables the **Number of data ports** parameter.

Selecting Specify indices enables the **Data port indices** parameter.

Programmatic Use

Block Parameter: DataPortOrder

Type: character vector

Values: 'Zero-based contiguous' | 'One-based contiguous' | 'Specify indices'

Default: 'Zero-based contiguous'

Number of data ports — Number of data input ports

1 (default) | integer between 1 and 65536

Specify the number of data input ports to the block.

Dependencies

To enable this parameter, set **Data port order** to Zero-based contiguous or One-based contiguous.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: integer between 1 and 65536

Default: '1'

Signal Attributes**Require all data port inputs to have the same data type — Require all inputs to have the same data type**

off (default) | on

Select this check box to require that all data input ports have the same data type. When you clear this check box, the block allows data port inputs to have different data types.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).

- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule**—Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:
 - Specify the output data type explicitly.
 - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
 - To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Uses the data type of the driving block.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

Integer rounding mode — Specify the rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

See Also

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Allow different data input sizes (Results in variable-size output signal) — Allow input signals with different sizes**

off (default) | on

Select this check box to allow input signals with different sizes.

- On — Allows input signals with different sizes, and propagate the input signal size to the output signal. In this mode, the block produces a variable-size output signal.
- Off — Requires that all nonscalar data input signals be the same size.

Programmatic Use**Parameter:** AllowDiffInputSizes**Type:** character vector**Value:** 'on' | 'off'**Default:** 'off'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point integer single

Initialize Function

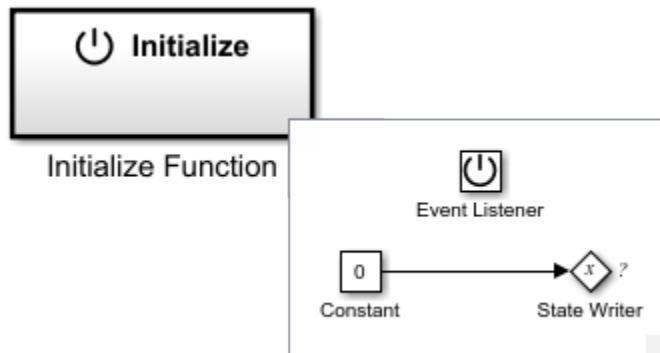

Executes contents on a model initialize event

Library: Simulink / User-Defined Functions

Description

The Initialize Function block is a pre-configured subsystem block that executes on a model initialize event. By default, the Initialize Function block includes an Event Listener block with **Event** set to Initialize, a Constant block with **Constant value** set to 0, and a State Writer block.

Replace the Constant block with blocks that generate the state value for the State Writer block.

Conditionally executed subsystem blocks with output ports fully supported within Terminate Function blocks

For a list of unsupported blocks and features, see “Initialize, Reset, and Terminate Function Limitations”.

The input and output ports of a component containing Initialize Function and Terminate Function blocks must connect to input and output port blocks.

The code generated from this block is part of the `model_initialize` function that is called once at the beginning of model execution.

Block Characteristics

Inport

Create input port for subsystem or external input

Library: Simulink / Commonly Used Blocks
 Simulink / Ports & Subsystems
 Simulink / Sources
 HDL Coder / Commonly Used Blocks
 HDL Coder / Ports & Subsystems
 HDL Coder / Sources

Description

Inport blocks link signals from outside a system into the system.

Simulink software assigns Inport block port numbers according to these rules:

- It automatically numbers the Inport blocks within a top-level system or subsystem sequentially, starting with 1.
- If you add an Inport block, the label is the next available number.
- If you delete an Inport block, other port numbers are automatically renumbered to ensure that the Inport blocks are in sequence and that no numbers are omitted.
- If you copy an Inport block into a system, its port number is *not* renumbered unless its current number conflicts with an inport already in the system. If the copied Inport block port number is not in sequence, renumber the block. Otherwise, you get an error message when you run the simulation or update the block diagram.

Inport Blocks in a Top-Level System

You can use an Inport block in a top-level system to:

- Supply external inputs from the workspace using one of these approaches. If no external outputs are supplied, then the default output is the ground value.
 - Use the **Configuration Parameters > Data Import/Export > Input** parameter. See “Load Data to Root-Level Input Ports”.

Tip To import many signals to root-level input ports, consider using the Root Inport Mapper tool. For more information, see “Map Data Using Root Inport Mapper Tool”.

- Use the `ut` argument of the `sim` command to specify the inputs.
- Provide a means for perturbation of the model by the `linmod` and `trim` analysis functions.
 - Use Inport blocks to inject inputs into the system. See “Linearizing Models”.
- To load logged signal data using root Inport blocks, use the `createInputDataset` function to create a `Dataset` object that contains elements corresponding to root-level Inport blocks.

Inport Blocks in a Subsystem

Inport blocks in a subsystem represent inputs to the subsystem. A signal arriving at an input port on a Subsystem block flows out of the associated Inport block in that subsystem. The Inport block

associated with an input port on a Subsystem block is the block whose **Port number** parameter matches the relative position of the input port on the Subsystem block. For example, the Inport block whose **Port number** parameter is 1 gets its signal from the block connected to the topmost port on the Subsystem block.

If you renumber the **Port number** of an Inport block, the block becomes connected to a different input port. The block continues to receive its signal from the same block outside the subsystem.

Inport blocks inside a subsystem support signal label propagation, but root-level Inport blocks do not.

Tip For models that include bus signals composed of many bus elements, consider using In Bus Element and Out Bus Element blocks. These blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

The In Bus Element block is of block type Inport and the Out Bus Element block is of block type Output.

Creating Duplicate Inports

You can create any number of duplicates of an Inport block. The duplicates are graphical representations of the original intended to simplify block diagrams by eliminating unnecessary lines. The duplicate has the same port number, properties, and output as the original.

To create a duplicate of an Inport block:

- 1 In the block diagram, select the unconnected Inport block that you want to duplicate.
- 2 Press and hold the **Ctrl** key and drag the block.
- 3 Release the mouse and then select **Duplicate** from the context menu.

Connecting Buses to Root-Level Inports

If you want a root-level Inport of a model to produce a bus signal, set the **Data type** parameter to the name of a bus object that defines the bus that the Inport produces. For more information, see “Specify Bus Properties with Simulink.Bus Objects”.

Ports

Output

Port_1 — Inport signal

scalar | vector

Input signal that flows through the inport into the system.

You can use a subsystem inport to supply fixed-point data in a structure or any other format.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Main

Port number — Position of port on parent block

1 (default) | real integer

Specify the order in which the port that corresponds to the block appears on the parent Subsystem or Model block.

- If you add a block that creates another port, the port number is the next available number.
- Deleting all blocks associated with a port deletes the port. Other ports are renumbered so that they are sequential and do not skip any numbers.
- Specifying a port number that exceeds the number of ports creates a port for that number and for any skipped sequential numbers.

Programmatic Use

Block Parameter: Port

Type: character vector

Values: real integer

Default: '1'

Icon display — Icon display

Port number (default) | Signal name | Port number and signal name

Specify the information displayed on the block icon.

Programmatic Use

Block Parameter: IconDisplay

Type: character vector

Values: 'Signal name' | 'Port number' | 'Port number and signal name'

Default: 'Port number'

Latch input by delaying outside signal — Latch signal by delay

off (default) | on

Select to specify the block outputs the value of the input signal at the previous time step.

Selecting this check box enables Simulink to resolve data dependencies among triggered subsystems that are part of a loop.

The Inport block indicates that this option is selected by displaying <Lo>.

Dependency

Enabled in a triggered subsystem.

Programmatic Use

Block Parameter: LatchByDelaying OutsideSignal

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Latch input for feedback signals of function-call subsystem outputs — Latch signal from changing

off (default) | on

Select to specify the block latches the value of the input to this subsystem and prevents this value from changing during the execution of the subsystem. For a single function call that is branched to invoke multiple function-call subsystems, this option breaks a loop formed by a signal fed back from one of these function-call subsystems into the other. This option prevents any change to the values of a feedback signal from a function-call subsystem that is invoked during the execution of this subsystem.

The Inport block indicates that this option is selected by displaying .

**Dependency**

Enabled when Inport block is in a function-call subsystem.

Programmatic Use

Block Parameter: LatchInputFor FeedbackSignals

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Interpolate data — Interpolate output data

on (default) | off

When loading data from the workspace to a root-level Inport block, specify whether the block linearly interpolates and extrapolates output at time steps for which no corresponding data exists.

To load discrete signal data from the workspace, in the Inport block dialog box:

- 1 Set the **Sample time** parameter to a discrete value, such as 2.
- 2 Clear the **Interpolate data** parameter.

Specifying the discrete sample time causes the simulation to have hit times exactly at those instances when the discrete data is sampled. You specify the data values, not time values.

Turning interpolation off avoids unexpected data values at other simulation time points as a result of double precision arithmetic processing. For more information, see “Load Data to Test a Discrete Algorithm”.

Simulink uses the following interpolation and extrapolation:

- For time steps between the first specified data point and the last specified data point — zero-order hold
- For time steps before the first specified data point and after the last specified data point — ground value
- For variable-size signals for time steps before the first specified data point — a NaN is logged for single or double data types and ground for other data types. For time steps after the last specified data point, uses ground values.

Programmatic Use

Block Parameter: Interpolate

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Connect Input — Tool to help map signals to inports

button

To import, visualize, and map signal and bus data to root-level inports, click this button. The Root Inport Mapper tool displays.

Dependency

This button appears only if this block is a root inport block.

Signal Attributes

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Output function call — Output function-call trigger signal

off (default) | on

Specify that the input signal outputs a function-call trigger signal.

Select this option if it is necessary for a current model to accept a function-call trigger signal when referenced in the top model.

Dependency

Enabled in an asynchronous function call.

Minimum — Minimum output value

[] (default) | scalar

Lower value of the output range that Simulink checks.

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Maximum — Maximum output value

[] (default) | scalar

Upper value of the output range that Simulink checks.

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Data type – Output data type

Inherit: auto (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | Bus: <object name> | <data type expression>

Specify the output data type of the external input. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. Do not specify a bus object as the expression.

Lock output data type setting against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output as nonvirtual bus – Specify virtual or nonvirtual bus output

off (default) | on

Specify whether the output for a top-level Inport block used to load bus data is virtual or nonvirtual.

- Select this parameter to specify a nonvirtual bus output.
- Clear this parameter to specify a virtual bus output.

Tips

- All signals in a nonvirtual bus must have the same sample time, even if the associated bus object specifies inherited sample time for some elements. Any operation that would result in a nonvirtual bus containing signals with different sample rates generates an error. You cannot load multirate data for a nonvirtual bus. See “Rate Transitions for Nonvirtual Buses” for details on how to pass signals with different sample rates into a referenced model as a nonvirtual bus.

To load multirate data for a bus, clear the **Output as nonvirtual bus** parameter, and set the **Sample time** parameter to inherited (-1).

- For the top model in a model reference hierarchy, code generation creates a C structure to represent the nonvirtual bus output.
- For referenced models, select this option to create a C structure in generated code. Otherwise, code generation creates an argument for each leaf element of the bus.

Dependency

This parameter is only available for top-level Inport blocks with Bus: <object name> selected for the **Data type** parameter.

Programmatic Use

Block Parameter: BusOutputAsStruct

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Unit (e.g., m, m/s², N*m) — Physical unit of the input signal to the block

inherit (default) | <Enter unit>

Specify the physical unit of the input signal to the block. To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

Programmatic Use

Block Parameter: Unit

Type: character vector

Values: 'inherit' | '<Enter unit>'

Default: 'inherit'

Port dimensions (-1 for inherited) — Port dimensions

-1 (default) | integer | [integer integer]

Specify the dimensions of the output signal for this Inport block.

-1	The port can load data for a signal with any dimensions. The port inherits dimensions from the connected signal.
N	The port can load data for a signal that is a vector of size N.
[R C]	The port can load data for a matrix signal having R rows and C columns.

Programmatic Use

Block Parameter: PortDimensions

Type: character vector

Values: '-1' | integer | [integer integer]

Default: '-1'

Variable-size signal — Allow variable-size signals

Inherit (default) | No | Yes

Specify the type of signals allowed out of this port. To allow variable-size and fixed-size signals, select Inherit. To allow only variable-size signals, select Yes. To allow only fixed-size signals, select No.

Dependencies

When the signal at this port is a variable-size signal, the **Port dimensions** parameter specifies the maximum dimensions of the signal.

Command-Line Information

Parameter: VarSizeSig

Type: character vector

Value: 'Inherit' | 'No' | 'Yes'

Default: 'Inherit'

Sample time (-1 for inherited) — Specify sample time

-1 (default) | scalar

Specify the discrete interval between sample time hits or specify another appropriate sample time such as continuous or inherited.

By default, the block inherits its sample time based upon the context of the block within the model. To set a different sample time, enter a valid sample time based upon the table in “Types of Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar

Default: '-1'

Signal type — Output signal type

auto (default) | real | complex

Specify the numeric type of the signal output. To choose the numeric type of the signal that is connected to its input, select auto. Otherwise, choose a real or complex signal type.

Programmatic Use

Block Parameter: SignalType

Type: character vector

Values: 'auto' | 'real' | 'complex'

Default: 'auto'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General		
BidirectionalPort	BidirectionalPort Setting	Description
	on	Specify the port as bidirectional. The following requirements apply: <ul style="list-style-type: none"> The port must be in a Subsystem block with black box implementation. There must also be no logic between the bidirectional port and the corresponding top-level DUT subsystem port. For more information, see “Specify Bidirectional Ports” (HDL Coder).
	off (default)	Do not specify the port as bidirectional.
Target Specification		
IOInterface	<p>Target platform interface type for DUT ports, specified as a character vector. The IOInterface block property is ignored for Inport and Outputport blocks that are not DUT ports.</p> <p>To specify valid IOInterface settings, use the HDL Workflow Advisor:</p> <ol style="list-style-type: none"> In the HDL Workflow Advisor, in the Set Target > Set Target Interface step, in the Target platform interface table, in the Target Platform Interfaces column, use the drop-down list to set the target platform interface type. Save the model. <p>The IOInterface value is saved as an HDL block property of the port.</p> <p>For example, to view the IOInterface value, if the full path to your DUT port is hdlcoder_led_blinking/led_counter/LED, enter:</p> <pre>hdlget_param('hdlcoder_led_blinking/led_counter/LED', 'IOInterface')</pre>	

Target Specification	
IOInterfaceMapping	<p>Target platform interface port mapping for DUT ports, specified as a character vector. The <code>IOInterfaceMapping</code> block property is ignored for Inport and Outport blocks that are not DUT ports.</p> <p>To specify valid <code>IOInterfaceMapping</code> settings, use the HDL Workflow Advisor:</p> <ol style="list-style-type: none"> 1 In the HDL Workflow Advisor, in the Set Target > Set Target Interface step, in the Target platform interface table, in the Target Platform Interfaces column, use the drop-down list to set the target platform interface type. 2 In the Bit Range / Address / FPGA Pin column, if you want to change the default value, enter a target platform interface mapping. 3 Save the model. <p>The <code>IOInterfaceMapping</code> value is saved as an HDL block property of the port.</p> <p>For example, to view the <code>IOInterfaceMapping</code> value, if the full path to your DUT port is <code>hdlcoder_led_blinking/led_counter/LED</code>, enter:</p> <pre>hdlget_param('hdlcoder_led_blinking/led_counter/LED',... 'IOInterfaceMapping')</pre>

Integrator

Integrate signal

Library: Simulink / Commonly Used Blocks
Simulink / Continuous

Description

The Integrator block outputs the value of the integral of its input signal with respect to time.

Simulink treats the Integrator block as a dynamic system with one state. The block dynamics are given by:

$$\begin{cases} \dot{x}(t) = u(t) \\ y(t) = x(t) \end{cases} \quad x(t_0) = x_0$$

where:

- u is the block input.
- y is the block output.
- x is the block state.
- x_0 is the initial condition of x .

While these equations define an exact relationship in continuous time, Simulink uses numerical approximation methods to evaluate them with finite precision. Simulink can use several different numerical integration methods to compute the output of the block, each with advantages in particular applications. Use the **Solver** pane of the Configuration Parameters dialog box (see “Solver Pane”) to select the technique best suited to your application.

The selected solver computes the output of the Integrator block at the current time step, using the current input value and the value of the state at the previous time step. To support this computational model, the Integrator block saves its output at the current time step for use by the solver to compute its output at the next time step. The block also provides the solver with an initial condition for use in computing the block's initial state at the beginning of a simulation. The default value of the initial condition is 0. Use the block parameter dialog box to specify another value for the initial condition or create an initial value input port on the block.

Use the parameter dialog box to:

- Define upper and lower limits on the integral
- Create an input that resets the block's output (state) to its initial value, depending on how the input changes
- Create an optional state output so that the value of the block's output can trigger a block reset

Use the Discrete-Time Integrator block to create a purely discrete system.

Defining Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, specify the **Initial condition source** parameter as `internal` and enter the value in the **Initial condition** field.
- To provide the initial conditions from an external source, specify the **Initial condition source** parameter as `external`. An additional input port appears under the block input.

Note If the integrator limits its output (see “Limiting the Integral” on page 1-746), the initial condition must fall inside the integrator's saturation limits. If the initial condition is outside the block saturation limits, the block displays an error message.

Limiting the Integral

To prevent the output from exceeding specifiable levels, select the **Limit output** check box and enter the limits in the appropriate parameter fields. This action causes the block to function as a limited integrator. When the output reaches the limits, the integral action is turned off to prevent integral wind up. During a simulation, you can change the limits but you cannot change whether the output is limited. The block determines output as follows:

- When the integral is less than or equal to the **Lower saturation limit**, the output is held at the **Lower saturation limit**.
- When the integral is between the **Lower saturation limit** and the **Upper saturation limit**, the output is the integral.
- When the integral is greater than or equal to the **Upper saturation limit**, the output is held at the **Upper saturation limit**.

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A saturation port appears below the block output port.

The signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- -1 indicates that the lower limit is being applied.

When you select this check box, the block has three zero crossings: one to detect when it enters the upper saturation limit, one to detect when it enters the lower saturation limit, and one to detect when it leaves saturation.

Note For the Integrator Limited block, by default, **Limit output** is selected, **Upper saturation limit** is set to 1, and **Lower saturation limit** is set to 0.

Wrapping Cyclic States

Several physical phenomena are cyclic, periodic, or rotary in nature. Objects or machinery that exhibit rotational movement and oscillators are examples of such phenomena.

Modeling these phenomena in Simulink involves integrating the rate of change of the periodic or cyclic signals to obtain the state of the movement.

The drawback with this approach, however, is that over long simulation time spans, the states representing periodic or cyclic signals integrate to large values. Further, computing the sine or cosine of these signals takes an increasingly large amount of time because of angle reduction. The large signals values also negatively impact solver performance and accuracy.

One approach for overcoming this drawback is to reset the angular state to 0 when it reaches 2π (or to $-\pi$ when it reaches π , for numerical symmetry). This approach improves the accuracy of sine and cosine computations and reduces angle reduction time. But it also requires zero-crossing detection and introduces solver resets, which slow down the simulation for variable step solvers, particularly in large models.

To eliminate solver resets at wrap points, the Integrator block supports wrapped states that you can enable by checking **Wrap state** on the block parameter dialog box. When you enable **Wrap state**, the block icon changes to indicate that the block has wrapping states.

Simulink allows wrapping states that are bounded by upper and lower values parameters of the wrapped state. The algorithm for determining wrapping states is given by:

$$y = \begin{cases} x & x \in [x_l, x_u) \\ x - (x_u - x_l) \left\lfloor \frac{x - x_l}{x_u - x_l} \right\rfloor & \text{otherwise} \end{cases}$$

where:

- x_l is the lower value of the wrapped state.
- x_u is the upper value of the wrapped state.
- y is the output.

The support for wrapping states provides these advantages.

- It eliminates simulation instability when your model approaches large angles and large state values.
- It reduces the number of solver resets during simulation and eliminates the need for zero-crossing detection, improving simulation time.
- It eliminates large angle values, speeding up computation of trigonometric functions on angular states.
- It improves solver accuracy and performance and enables unlimited simulation time.

Resetting the State

The block can reset its state to the specified initial condition based on an external signal. To cause the block to reset its state, select one of the **External reset** choices. A trigger port appears below the block's input port and indicates the trigger type.

- Select **rising** to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select **falling** to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select **either** to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select **level** to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select **level hold** to reset the state when the reset signal is nonzero at the current time step.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see "Algebraic Loop Concepts"). Use the Integrator block's state port to feed back the block's output without creating an algebraic loop.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of Integrator blocks.

About the State Port

Selecting the **Show state port** check box on the Integrator block's parameter dialog box causes an additional output port, the state port, to appear at the top of the Integrator block.

The output of the state port is the same as the output of the block's standard output port except for the following case. If the block is reset in the current time step, the output of the state port is the

value that would have appeared at the block's standard output if the block had not been reset. The state port's output appears earlier in the time step than the output of the Integrator block's output port. Use the state port to avoid creating algebraic loops in these modeling scenarios:

- Self-resetting integrators (see “Creating Self-Resetting Integrators” on page 1-749)
- Handing off a state from one enabled subsystem to another (see “Handing Off States Between Enabled Subsystems” on page 1-750)

Note When updating a model, Simulink checks that the state port applies to one of these two scenarios. If not, an error message appears. Also, you cannot log the output of this port in a referenced model that executes in Accelerator mode. If logging is enabled for the port, Simulink generates a "signal not found" warning during execution of the referenced model.

Creating Self-Resetting Integrators

The Integrator block's state port helps you avoid an algebraic loop when creating an integrator that resets itself based on the value of its output. Consider, for example, the following model.

This model tries to create a self-resetting integrator by feeding the integrator's output, subtracted from 1, back into the integrator's reset port. However, the model creates an algebraic loop. To compute the integrator block's output, Simulink software needs to know the value of the block's reset signal, and vice versa. Because the two values are mutually dependent, Simulink software cannot determine either. Therefore, an error message appears if you try to simulate or update this model.

The following model uses the integrator's state port to avoid the algebraic loop.

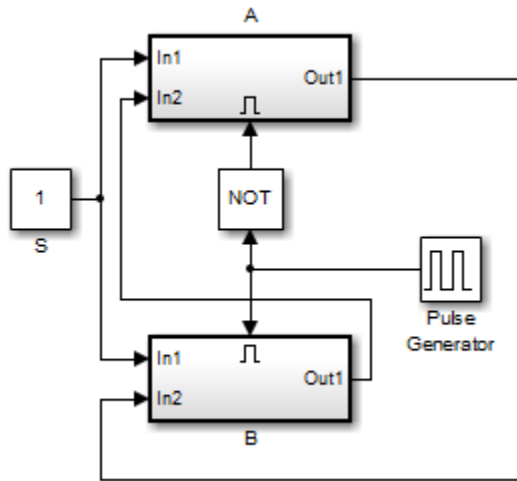

In this version, the value of the reset signal depends on the value of the state port. The value of the state port is available earlier in the current time step than the value of the integrator block's output

port. Therefore, Simulink can determine whether the block needs to be reset before computing the block's output, thereby avoiding the algebraic loop.

Handing Off States Between Enabled Subsystems

The state port helps you avoid an algebraic loop when passing a state between two enabled subsystems. Consider, for example, the following model.

The enabled subsystems, A and B, contain the following blocks:

Subsystem A	Subsystem B

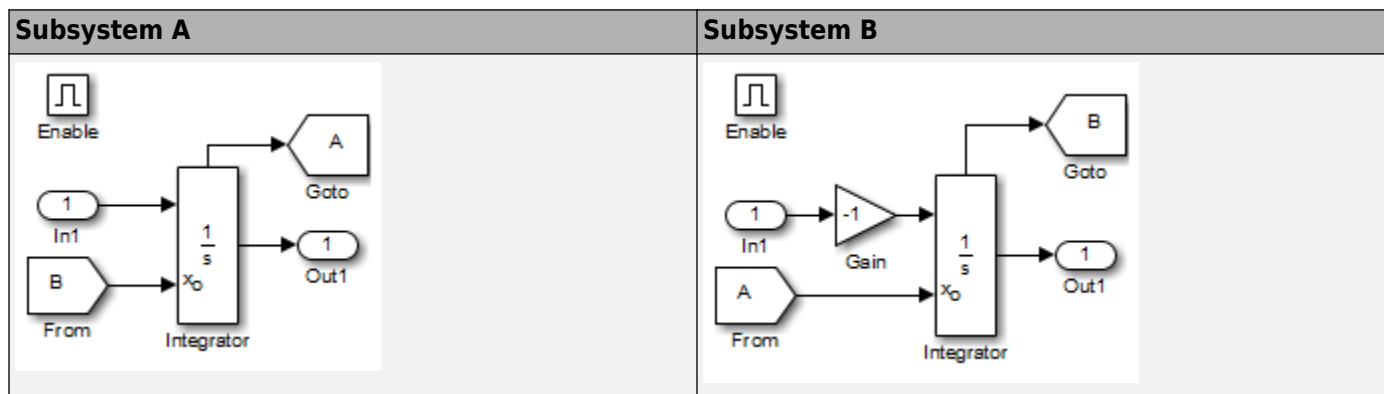

In this model, a constant input signal drives two enabled subsystems that integrate the signal. A pulse generator generates an enabling signal that causes execution to alternate between the two subsystems. The enable port of each subsystem is set to reset, which causes the subsystem to reset its integrator when it becomes active. Resetting the integrator causes the integrator to read the value of its initial condition port. The initial condition port of the integrator in each subsystem is connected to the output port of the integrator in the other subsystem.

This connection is intended to enable continuous integration of the input signal as execution alternates between two subsystems. However, the connection creates an algebraic loop. To compute the output of A, Simulink needs to know the output of B, and vice versa. Because the outputs are mutually dependent, Simulink cannot compute the output values. Therefore, an error message appears if you try to simulate or update this model.

The following version of the same model uses the integrator state port to avoid creating an algebraic loop when handing off the state.

The enabled subsystems, A and B, contain the following blocks:

In this model, the initial condition of the integrator in A depends on the value of the state port of the integrator in B, and vice versa. The values of the state ports are updated earlier in the simulation time step than the values of the integrator output ports. Therefore, Simulink can compute the initial condition of either integrator without knowing the final output value of the other integrator. For another example of using the state port to hand off states between conditionally executed subsystems, see the `sldemo_clutch` model.

Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the Integrator block. If this value does not provide sufficient error control, specify a more appropriate value in the **Absolute tolerance** field of the Integrator block dialog box. The value that you specify is used to compute all the block outputs.

Selecting All Options

When you select all options, the block icon looks like this.

Ports

The Integrator block accepts and outputs signals of type `double` on its data ports. The external reset port accepts signals of type `double` or `Boolean`.

Input

Port_1 — Integrand signal

real scalar or array

Signal that needs to be integrated.

Data Types: `double`

External Reset — Reset state to initial conditions

real scalar or array

Reset the state to the specified initial conditions based on an external signal. See “Resetting the State” on page 1-748.

Dependencies

To enable this port, enable the **External Reset** parameter.

Data Types: `Boolean`

x_0 — Initial condition

real scalar or array

Set the initial condition of the block's state from an external signal.

Dependencies

To enable this port, set the **Initial Conditions** parameter to `external`.

Data Types: `double`

Output

Port_1 — Output signal

real scalar or array

Output the integrated state.

Data Types: `double`

Port_2 — Show output saturation

-1 | 0 | 1

Indicate when the state is being limited. The signal has a value of 1 when the integral is limited by the specified **Upper saturation limit**. When the signal is limited by the **Lower saturation limit**, the

signal value is -1. When the integral is between the saturation limits, the signal value is 0. See “Limiting the Integral” on page 1-746.

Data Types: double

Port_3 – State

real scalar or array

Output the state of the block. See “About the State Port” on page 1-748.

Dependencies

Enable this port by enabling the **Show state port** parameter.

Data Types: double

Parameters

External reset – Reset states to their initial conditions

none (default) | rising | falling | either | level | level hold

Specify the type of trigger to use for the external reset signal.

- Select **rising** to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select **falling** to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select **either** to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select **level** to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select **level hold** to reset the state when the reset signal is nonzero at the current time step.

Programmatic Use

Block Parameter: ExternalReset

Type: character vector , string

Values: 'none' | 'rising' | 'falling' | 'either' | 'level' | 'level hold'

Default: 'none'

Initial condition source – Select source of initial condition

internal (default) | external

Select source of initial condition:

- **internal** — Get the initial conditions of the states from the **Initial condition** block parameter.
- **external** — Get the initial conditions of the states from an external block, via the **IC** input port.

Dependencies

Selecting **internal** enables the **Initial condition** parameter.

Selecting **external** disables the **Initial condition** parameter and enables the **IC** input port.

Programmatic Use**Block Parameter:** InitialConditionSource**Type:** character vector, string**Values:** 'internal' | 'external'**Default:** 'internal'**Initial condition — Initial state**

0 (default) | real scalar or array

Set the initial state of the Integrator block.

TipsSimulink software does not allow the initial condition of this block to be `inf` or `NaN`.**Dependencies**Setting **Initial condition source** to `internal` enables this parameter.Setting **Initial condition source** to `external` disables this parameter.**Programmatic Use****Block Parameter:** InitialCondition**Type:** scalar or vector**Default:** '0'**Limit output — Limit block output values to specified range**`off` (default for Integrator) | `on` (default for Integrator Limited)Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

- Selecting this check box limits the block output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.
- Clearing this check box does not limit the block output values.

DependenciesSelecting this parameter enables the **Lower saturation limit** and **Upper saturation limit** parameters.**Programmatic Use****Block Parameter:** LimitOutput**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'off'**Upper saturation limit — Upper limit for the integral**`inf` (default) | scalar | vector | matrixSpecify the upper limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.**Dependencies**To enable this parameter, select the **Limit output** check box.

Programmatic Use**Block Parameter:** UpperSaturationLimit**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** 'inf'**Lower saturation limit — Lower limit for the integral**

-inf (default) | scalar | vector | matrix

Specify the lower limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use**Block Parameter:** LowerSaturationLimit**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** '-inf'**Wrap state — Enable wrapping of states**

off (default) | on

Enable wrapping of states between the **Wrapped state upper value** and **Wrapped state lower value** parameters. Enabling wrap states eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

If you specify **Wrapped state upper value** as inf and **Wrapped state lower value** as -inf, wrapping does not occur.

Dependencies

Selecting this parameter enables **Wrapped state upper value** and **Wrapped state lower value** parameters.

Programmatic Use**Block Parameter:** WrapState**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'off'**Wrapped state upper value — Specify upper value for wrapped state**

pi (default) | scalar or vector

Upper limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use**Block Parameter:** WrappedStateUpperValue**Type:** scalar or vector

Values: '2*pi'

Default: 'pi'

Wrapped state lower value — Specify lower value for wrap state

-pi (default) | scalar or vector

Lower limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use

Block Parameter: WrappedStateLowerValue

Type: scalar or vector

Values: '0'

Default: '-pi'

Show saturation port — Enable saturation output port

off (default) | on

Select this check box to add a saturation output port to the block. When you clear this check box, the block does not have a saturation output port.

Dependencies

Selecting this parameter enables a saturation output port.

Programmatic Use

Block Parameter: ShowSaturationPort

Type: character vector , string

Values: 'off' | 'on'

Default: 'off'

Show state port — Enable state output port

off (default) | on

Select this check box to add a state output port to the block. When you clear this check box, the block does not have a state output port.

Dependencies

Selecting this parameter enables a state output port.

Programmatic Use

Block Parameter: ShowStatePort

Type: character vector , string

Values: 'off' | 'on'

Default: 'off'

Absolute tolerance — Absolute tolerance for block states

auto (default) | real scalar or vector

- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.

- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use**Block Parameter:** AbsoluteTolerance**Type:** character vector, string, scalar, or vector**Values:** 'auto' | '-1' | any positive real scalar or vector**Default:** 'auto'**Ignore limit and reset when linearizing — Treat block as unresettable and output unlimited**

off (default) | on

Cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the reset and output limitation options of the block.

Tip

Use this check box to linearize a model around an operating point that causes the integrator to reset or saturate.

Programmatic Use**Block Parameter:** IgnoreLimit**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'off'**Enable zero-crossing detection — Enable zero-crossing detection**

on (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use**Block Parameter:** ZeroCross**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'on'**State Name (e.g., 'position') — Assign unique name to each state**

' ' (default) | character vector | string

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Discrete-Time Integrator | Second-Order Integrator

Introduced before R2006a

Integrator Limited

Integrate signal

Library: Simulink / Continuous

Description

The Integrator Limited block is identical to the Integrator block with the exception that the output of the block is limited based on the upper and lower saturation limits. See “Limiting the Integral” on page 1-761 for details.

Simulink treats the Integrator block as a dynamic system with one state. The block dynamics are given by:

$$\begin{cases} \dot{x}(t) = u(t) \\ y(t) = x(t) \end{cases} \quad x(t_0) = x_0$$

where:

- u is the block input.
- y is the block output.
- x is the block state.
- x_0 is the initial condition of x .

While these equations define an exact relationship in continuous time, Simulink uses numerical approximation methods to evaluate them with finite precision. Simulink can use several different numerical integration methods to compute the output of the block, each with advantages in particular applications. Use the **Solver** pane of the Configuration Parameters dialog box (see “Solver Pane”) to select the technique best suited to your application.

The selected solver computes the output of the Integrator block at the current time step, using the current input value and the value of the state at the previous time step. To support this computational model, the Integrator block saves its output at the current time step for use by the solver to compute its output at the next time step. The block also provides the solver with an initial condition for use in computing the block's initial state at the beginning of a simulation. The default value of the initial condition is 0. Use the block parameter dialog box to specify another value for the initial condition or create an initial value input port on the block.

Use the parameter dialog box to:

- Define upper and lower limits on the integral
- Create an input that resets the block's output (state) to its initial value, depending on how the input changes
- Create an optional state output so that the value of the block's output can trigger a block reset

Use the Discrete-Time Integrator block to create a purely discrete system.

Defining Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, specify the **Initial condition source** parameter as `internal` and enter the value in the **Initial condition** field.
- To provide the initial conditions from an external source, specify the **Initial condition source** parameter as `external`. An additional input port appears under the block input.

Note If the integrator limits its output (see “Limiting the Integral” on page 1-761), the initial condition must fall inside the integrator’s saturation limits. If the initial condition is outside the block saturation limits, the block displays an error message.

Wrapping Cyclic States

Several physical phenomena are cyclic, periodic, or rotary in nature. Objects or machinery that exhibit rotational movement and oscillators are examples of such phenomena.

Modeling these phenomena in Simulink involves integrating the rate of change of the periodic or cyclic signals to obtain the state of the movement.

The drawback with this approach, however, is that over long simulation time spans, the states representing periodic or cyclic signals integrate to large values. Further, computing the sine or cosine of these signals takes an increasingly large amount of time because of angle reduction. The large signals values also negatively impact solver performance and accuracy.

One approach for overcoming this drawback is to reset the angular state to 0 when it reaches 2π (or to $-\pi$ when it reaches π , for numerical symmetry). This approach improves the accuracy of sine and cosine computations and reduces angle reduction time. But it also requires zero-crossing detection and introduces solver resets, which slow down the simulation for variable step solvers, particularly in large models.

To eliminate solver resets at wrap points, the Integrator block supports wrapped states that you can enable by checking **Wrap state** on the block parameter dialog box. When you enable **Wrap state**, the block icon changes to indicate that the block has wrapping states.

Simulink allows wrapping states that are bounded by upper and lower values parameters of the wrapped state. The algorithm for determining wrapping states is given by:

$$y = \begin{cases} x & x \in [x_l, x_u) \\ x - (x_u - x_l) \left\lfloor \frac{x - x_l}{x_u - x_l} \right\rfloor & \text{otherwise} \end{cases}$$

where:

- x_l is the lower value of the wrapped state.
- x_u is the upper value of the wrapped state.
- y is the output.

The support for wrapping states provides these advantages.

- It eliminates simulation instability when your model approaches large angles and large state values.
- It reduces the number of solver resets during simulation and eliminates the need for zero-crossing detection, improving simulation time.
- It eliminates large angle values, speeding up computation of trigonometric functions on angular states.
- It improves solver accuracy and performance and enables unlimited simulation time.

Limiting the Integral

To prevent the output from exceeding specifiable levels, select the **Limit output** check box and enter the limits in the appropriate parameter fields. This action causes the block to function as a limited integrator. When the output reaches the limits, the integral action is turned off to prevent integral wind up. During a simulation, you can change the limits but you cannot change whether the output is limited. The block determines output as follows:

- When the integral is less than or equal to the **Lower saturation limit**, the output is held at the **Lower saturation limit**.
- When the integral is between the **Lower saturation limit** and the **Upper saturation limit**, the output is the integral.
- When the integral is greater than or equal to the **Upper saturation limit**, the output is held at the **Upper saturation limit**.

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A saturation port appears below the block output port.

The signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.

- -1 indicates that the lower limit is being applied.

When you select this check box, the block has three zero crossings: one to detect when it enters the upper saturation limit, one to detect when it enters the lower saturation limit, and one to detect when it leaves saturation.

Note For the Integrator Limited block, by default, **Limit output** is selected, **Upper saturation limit** is set to 1, and **Lower saturation limit** is set to 0.

Resetting the State

The block can reset its state to the specified initial condition based on an external signal. To cause the block to reset its state, select one of the **External reset** choices. A trigger port appears below the block's input port and indicates the trigger type.

- Select **rising** to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select **falling** to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select **either** to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select **level** to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select **level hold** to reset the state when the reset signal is nonzero at the current time step.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see "Algebraic Loop Concepts"). Use the Integrator block's state port to feed back the block's output without creating an algebraic loop.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of Integrator blocks.

About the State Port

Selecting the **Show state port** check box on the Integrator block's parameter dialog box causes an additional output port, the state port, to appear at the top of the Integrator block.

The output of the state port is the same as the output of the block's standard output port except for the following case. If the block is reset in the current time step, the output of the state port is the

value that would have appeared at the block's standard output if the block had not been reset. The state port's output appears earlier in the time step than the output of the Integrator block's output port. Use the state port to avoid creating algebraic loops in these modeling scenarios:

- Self-resetting integrators (see “Creating Self-Resetting Integrators” on page 1-763)
- Handing off a state from one enabled subsystem to another (see “Handing Off States Between Enabled Subsystems” on page 1-764)

Note When updating a model, Simulink checks that the state port applies to one of these two scenarios. If not, an error message appears. Also, you cannot log the output of this port in a referenced model that executes in Accelerator mode. If logging is enabled for the port, Simulink generates a "signal not found" warning during execution of the referenced model.

Creating Self-Resetting Integrators

The Integrator block's state port helps you avoid an algebraic loop when creating an integrator that resets itself based on the value of its output. Consider, for example, the following model.

This model tries to create a self-resetting integrator by feeding the integrator's output, subtracted from 1, back into the integrator's reset port. However, the model creates an algebraic loop. To compute the integrator block's output, Simulink software needs to know the value of the block's reset signal, and vice versa. Because the two values are mutually dependent, Simulink software cannot determine either. Therefore, an error message appears if you try to simulate or update this model.

The following model uses the integrator's state port to avoid the algebraic loop.

In this version, the value of the reset signal depends on the value of the state port. The value of the state port is available earlier in the current time step than the value of the integrator block's output

port. Therefore, Simulink can determine whether the block needs to be reset before computing the block's output, thereby avoiding the algebraic loop.

Handing Off States Between Enabled Subsystems

The state port helps you avoid an algebraic loop when passing a state between two enabled subsystems. Consider, for example, the following model.

The enabled subsystems, A and B, contain the following blocks:

In this model, a constant input signal drives two enabled subsystems that integrate the signal. A pulse generator generates an enabling signal that causes execution to alternate between the two subsystems. The enable port of each subsystem is set to reset, which causes the subsystem to reset its integrator when it becomes active. Resetting the integrator causes the integrator to read the value of its initial condition port. The initial condition port of the integrator in each subsystem is connected to the output port of the integrator in the other subsystem.

This connection is intended to enable continuous integration of the input signal as execution alternates between two subsystems. However, the connection creates an algebraic loop. To compute the output of A, Simulink needs to know the output of B, and vice versa. Because the outputs are mutually dependent, Simulink cannot compute the output values. Therefore, an error message appears if you try to simulate or update this model.

The following version of the same model uses the integrator state port to avoid creating an algebraic loop when handing off the state.

The enabled subsystems, A and B, contain the following blocks:

In this model, the initial condition of the integrator in A depends on the value of the state port of the integrator in B, and vice versa. The values of the state ports are updated earlier in the simulation time step than the values of the integrator output ports. Therefore, Simulink can compute the initial condition of either integrator without knowing the final output value of the other integrator. For another example of using the state port to hand off states between conditionally executed subsystems, see the `sldemo_clutch` model.

Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the Integrator block. If this value does not provide sufficient error control, specify a more appropriate value in the **Absolute tolerance** field of the Integrator block dialog box. The value that you specify is used to compute all the block outputs.

Selecting All Options

When you select all options, the block icon looks like this.

Ports

Input

Port_1 — Integrand signal

real scalar or array

Signal that needs to be integrated.

Data Types: double

External Reset — Reset state to initial conditions

real scalar or array

Reset the state to the specified initial conditions based on an external signal. See “Resetting the State” on page 1-762.

Dependencies

To enable this port, enable the **External Reset** parameter.

Data Types: Boolean

x_0 — Initial condition

real scalar or array

Set the initial condition of the block's state from an external signal.

Dependencies

To enable this port, set the **Initial Conditions** parameter to external.

Data Types: double

Output

Port_1 — Output signal

real scalar or array

Output the integrated state.

Data Types: double

Port_2 — Show output saturation

-1 | 0 | 1

Indicate when the state is being limited. The signal has a value of 1 when the integral is limited by the specified **Upper saturation limit**. When the signal is limited by the **Lower saturation limit**, the signal value is -1. When the integral is between the saturation limits, the signal value is 0. See “Limiting the Integral” on page 1-761.

Data Types: double

Port_3 – State

real scalar or array

Output the state of the block. See “About the State Port” on page 1-762.

Dependencies

Enable this port by enabling the **Show state port** parameter.

Data Types: double

Parameters

External reset – Reset states to their initial conditions

none (default) | rising | falling | either | level | level hold

Specify the type of trigger to use for the external reset signal.

- Select **rising** to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select **falling** to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select **either** to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select **level** to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select **level hold** to reset the state when the reset signal is nonzero at the current time step.

Programmatic Use

Block Parameter: ExternalReset

Type: character vector, string

Values: 'none' | 'rising' | 'falling' | 'either' | 'level' | 'level hold'

Default: 'none'

Initial condition source – Select source of initial condition

internal (default) | external

Select source of initial condition:

- **internal** — Get the initial conditions of the states from the **Initial condition** block parameter.
- **external** — Get the initial conditions of the states from an external block, via the **IC** input port.

Dependencies

Selecting **internal** enables the **Initial condition** parameter.

Selecting **external** disables the **Initial condition** parameter and enables the **IC** input port.

Programmatic Use

Block Parameter: InitialConditionSource

Type: character vector, string

Values: 'internal' | 'external'

Default: 'internal'

Initial condition — Initial state

0 (default) | real scalar or array

Set the initial state of the Integrator block.

Tips

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

Setting **Initial condition source** to `internal` enables this parameter.

Setting **Initial condition source** to `external` disables this parameter.

Programmatic Use

Block Parameter: InitialCondition

Type: scalar or vector

Default: '0'

Limit output — Limit block output values to specified range

off (default for Integrator) | on (default for Integrator Limited)

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

- Selecting this check box limits the block output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.
- Clearing this check box does not limit the block output values.

Dependencies

Selecting this parameter enables the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use

Block Parameter: LimitOutput

Type: character vector , string

Values: 'off' | 'on'

Default: 'off'

Upper saturation limit — Upper limit for the integral

inf (default) | scalar | vector | matrix

Specify the upper limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use

Block Parameter: UpperSaturationLimit

Type: character vector, string

Values: scalar | vector | matrix

Default: 'inf'

Lower saturation limit — Lower limit for the integral

-inf (default) | scalar | vector | matrix

Specify the lower limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use

Block Parameter: LowerSaturationLimit

Type: character vector, string

Values: scalar | vector | matrix

Default: '-inf'

Wrap state — Enable wrapping of states

off (default) | on

Enable wrapping of states between the **Wrapped state upper value** and **Wrapped state lower value** parameters. Enabling wrap states eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

If you specify **Wrapped state upper value** as inf and **Wrapped state lower value** as -inf, wrapping does not occur.

Dependencies

Selecting this parameter enables **Wrapped state upper value** and **Wrapped state lower value** parameters.

Programmatic Use

Block Parameter: WrapState

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Wrapped state upper value — Specify upper value for wrapped state

pi (default) | scalar or vector

Upper limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use

Block Parameter: WrappedStateUpperValue

Type: scalar or vector

Values: '2*pi'

Default: 'pi'

Wrapped state lower value — Specify lower value for wrap state

-pi (default) | scalar or vector

Lower limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use

Block Parameter: WrappedStateLowerValue

Type: scalar or vector

Values: '0'

Default: '-pi'

Show saturation port — Enable saturation output port

off (default) | on

Select this check box to add a saturation output port to the block. When you clear this check box, the block does not have a saturation output port.

Dependencies

Selecting this parameter enables a saturation output port.

Programmatic Use

Block Parameter: ShowSaturationPort

Type: character vector , string

Values: 'off' | 'on'

Default: 'off'

Show state port — Enable state output port

off (default) | on

Select this check box to add a state output port to the block. When you clear this check box, the block does not have a state output port.

Dependencies

Selecting this parameter enables a state output port.

Programmatic Use

Block Parameter: ShowStatePort

Type: character vector , string

Values: 'off' | 'on'

Default: 'off'

Absolute tolerance — Absolute tolerance for block states

auto (default) | real scalar or vector

- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use**Block Parameter:** AbsoluteTolerance**Type:** character vector, string, scalar, or vector**Values:** 'auto' | '-1' | any positive real scalar or vector**Default:** 'auto'**Ignore limit and reset when linearizing — Treat block as unresettable and output unlimited**

off (default) | on

Cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the reset and output limitation options of the block.

Tip

Use this check box to linearize a model around an operating point that causes the integrator to reset or saturate.

Programmatic Use**Block Parameter:** IgnoreLimit**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'off'**Enable zero-crossing detection — Enable zero-crossing detection**

on (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use**Block Parameter:** ZeroCross**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'on'**State Name (e.g., 'position') — Assign unique name to each state**

' ' (default) | character vector | string

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Programmatic Use**Block Parameter:** ContinuousStateAttributes

Type: character vector, string

Values: ' ' | user-defined

Default: ' '

Block Characteristics

Interpolation Using Prelookup

Use precalculated index and fraction values to accelerate approximation of N-dimensional function

Library: Simulink / Lookup Tables

Description

The Interpolation Using Prelookup block is most efficient when used with the Prelookup block. The Prelookup block calculates the index and interval fraction that specify how its input value u relates to the breakpoint data set. Feed the resulting index and fraction values into an Interpolation Using Prelookup block to interpolate an n -dimensional table. These two blocks have distributed algorithms. When combined together, they perform the same operation as the integrated algorithm in the n -D Lookup Table block. However, the Prelookup and Interpolation Using Prelookup blocks offer greater flexibility that can provide more efficient simulation and code generation. For more information, see “Efficiency of Performance”.

Supported Block Operations

To use the Interpolation Using Prelookup block, you specify a set of table data values directly on the dialog box or feed values into the **T** input port. Typically, these table values correspond to the breakpoint data sets specified in Prelookup blocks. The Interpolation Using Prelookup block generates output by looking up or estimating table values based on index and interval fraction values fed from Prelookup blocks. Labels for the index and interval fraction appear as k and f on the Interpolation Using Prelookup block icon.

When inputs for index and interval fraction...	The Interpolation Using Prelookup block...
Map to values in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not map to values in breakpoint data sets, but are within range	Interpolates appropriate table values using the Interpolation method you select
Do not map to values in breakpoint data sets, and are out of range	Extrapolates the output value using the Extrapolation method you select

How The Block Interpolates a Subset of Table Data

You can use the **Number of sub-table selection dimensions** parameter to specify that interpolation occur only on a subset of the table data. To activate this interpolation mode, set this parameter to a positive integer. This value defines the number of dimensions to select, starting from the highest dimension of table data for the default column-major algorithm. Therefore, the value must be less than or equal to the **Number of table dimensions**.

For row-major algorithms, the interpolation starts from the first or lowest dimension of the table data.

For nonzero values, the subtable selection behavior is optimized for row-major layout when you select the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter.

Suppose that you have 3-D table data in your Interpolation Using Prelookup block. This behavior applies for the column-major algorithm.

Number of Selection Dimensions	Action by the Block	Block Appearance
0	Interpolates the entire table and does not activate subtable selection	Does not change
1	Interpolates the first two dimensions and selects the third dimension	Displays an input port with the label <code>s3</code> that you use to select and interpolate 2-D tables
2	Interpolates the first dimension and selects the second and third dimensions	Displays two input ports with the labels <code>s2</code> and <code>s3</code> that you use to select and interpolate 1-D tables

Subtable selection uses zero-based indexing. For an example of interpolating a subset of table data, type `sldemo_bpcheck` at the MATLAB command prompt.

For 2-D or n-D interpolation without subtable selection, the column-major and row-major algorithms may differ in the order of output calculations, causing slight different numerical results.

Ports

Input

k1 — Index, k, for the first dimension of the table

scalar | vector | matrix

Zero-based index, `k`, specifying the interval containing the input `u` for the first dimension of the table.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | fixed point

f1 — Fraction, f, for the first dimension of the table

scalar | vector | matrix

Fraction, `f`, representing the normalized position of the input within the interval, `k`, for the first dimension of the table.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | fixed point

kn — Index, k, for the n-th dimension of the table

scalar | vector | matrix

Zero-based index, `k`, specifying the interval containing the input `u` for the n-th dimension of the table.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | fixed point

fn — Fraction, f, for the n-th dimension of the table

scalar | vector | matrix

Fraction, *f*, representing the normalized position of the input within the interval, *k*, for the *n*-th dimension of the table.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

kf1 — Input containing index k and fraction f

bus object

Inputs to the **kf1** port contain index *k* and fraction *f* specified as a bus object.

Dependencies

To enable this port, select the **Require index and fraction as a bus** check box.

The number of available **kf** input ports depends on the value of the **Number of dimensions** and **Number of sub-table selection dimensions** parameters.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | bus

kfn — Input containing index k and fraction f

bus object

Inputs to the **kfn** port contain index *k* and fraction *f* for the *n*-th dimension of the input, specified as a bus object.

Dependencies

To enable this port, select the **Require index and fraction as a bus** check box.

The number of available **kf** input ports depends on the value of the **Number of dimensions** and **Number of sub-table selection dimensions** parameters.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | bus

sm — Select and interpolate a subset of the table data

scalar | vector | matrix

For column-major algorithm, the block uses inputs to the *sm*, *sm*+1, ... *sn* port to perform selection and interpolation within the subtables. *m* maps to the *m*th dimension of the table. *n* equals the **Number of dimensions**.

For row-major algorithm, the block uses inputs to the *s1*, *s2*, ... ,*sm* port to perform selection and interpolation within the subtables. *m* maps to the *m*th dimension of the table. *m* equals the **Number of sub-table selection dimensions**.

Dependencies

To enable this port, the **Number of sub-table selection dimensions** must be a positive integer less than or equal to the **Number of dimensions**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

T — Table data

scalar | vector | matrix | n-d array

Table data values provided as input to port **T**. Typically, these table values correspond to the breakpoint data sets specified in Prelookup blocks. The Interpolation Using Prelookup block generates output by looking up or estimating table values based on index (k) and interval fraction (f) values fed from Prelookup blocks.

Dependencies

To enable this port, set **Source** to Input port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output**Port_1 — Approximation of N-dimensional function**

scalar | vector | matrix

Approximation of N-dimensional function, computed by interpolating (or extrapolating) table data using values from the input index, k, and fraction, f.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters**Main****Table data****Number of dimensions — Number of table data dimensions**

2 (default) | integer between 1 and 30

Specify the number of dimensions that the table data must have. The **Number of dimensions** defines the number of independent variables for the table.

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

Programmatic Use**Block Parameter:** NumberOfTableDimensions**Type:** character vector**Values:** '1' | '2' | '3' | '4' | ... | '30'**Default:** '2'**Require index and fraction as bus — Index and fraction inputs can be combined in a bus**

off (default) | on

Select this check box to combine index and fraction inputs in a bus.

To enable the Prelookup block to supply input to the Interpolation Using Prelookup block, set:

- **Output selection** to Index and fraction as bus
- **Output** to Bus: <object name>, where <object name> must be a valid bus object name accessible to the model

Regardless of this check box setting, the selection port always operates in nonbus mode.

Programmatic Use

Block Parameter: RequireIndexFractionAsBus

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Specification — Choose how to enter table data

Explicit values (default) | Lookup table object

Specify whether to enter table data directly or use a lookup table object. If you set this parameter to:

- Explicit values, the **Source** and **Value** parameters are visible on the dialog box.
- Lookup table object, the **Name** parameter is visible on the dialog box.

Programmatic Use

Block Parameter: TableSpecification

Type: character vector

Values: 'Explicit values' | 'Lookup table object'

Default: 'Explicit values'

Source — Source of table data

Dialog (default) | Input port

Specify whether to enter table data in the dialog box or to inherit the data from an input port. If you set **Source** to:

- Dialog, enter table data in the text box under **Value**
- Input port, verify that an upstream signal supplies table data to the table input port

Dependencies

To enable this parameter, set **Specification** to Explicit values.

Programmatic Use

Block Parameter: TableSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Value — Specify table data values

$\text{sqrt}([1:11]' * [1:11])$ (default) | multidimensional array of table data

Specify table data as an N-D array, where N is the value of the **Number of dimensions** parameter. You can edit the block diagram without specifying a correctly dimensioned matrix by entering an empty matrix ([]) or an undefined workspace variable in the **Value** edit field. For information about how to construct multidimensional arrays in MATLAB, see “Multidimensional Arrays” (MATLAB).

If you set **Source** to Input port, verify that an upstream signal supplies table data to the **T** input port. The size of table data must match the **Number of table dimensions**. For this option, the block inherits table attributes from the **T** input port.

To edit lookup tables using the Lookup Table Editor, click **Edit** (see “Edit Lookup Tables”).

Dependencies

To enable this parameter and explicitly specify table values on the dialog box, you must set **Specification** to Explicit values and **Source** to Dialog.

Programmatic Use

Block Parameter: Table

Type: character vector

Values: scalar, vector, matrix, or N-D array

Default: 'sqrt([1:11]' * [1:11])'

Name — Name of a Simulink.LookupTable object

Simulink.LookupTable object

Specify the name of a Simulink.LookupTable object. A lookup table object references Simulink

breakpoint objects. If a Simulink.LookupTable object does not exist, click the action button  and select **Create**. The corresponding parameters of the new lookup table object are automatically populated with the block information.

Dependencies

To enable this parameter, set **Specification** to Lookup table object.

Programmatic Use

Block Parameter: LookupTableObject

Type: character vector

Value: Simulink.LookupTable object

Default: ''

Algorithm

Interpolation method — Select Linear point-slope, Flat, Nearest, or Linear Lagrange

Linear point-slope (default) | Nearest | Flat | Linear Lagrange

Specify the method the block uses to interpolate table data. You can select Linear point-slope, Flat, Nearest, or Linear Lagrange. See “Interpolation Methods” for more information.

Programmatic Use

Block Parameter: InterpMethod

Type: character vector

Values: 'Flat' | 'Linear point-slope' | 'Nearest' | 'Linear Lagrange'

Default: 'Linear point-slope'

Extrapolation method — Method of handling input that falls outside the range of the breakpoint data set

Linear (default) | Clip

Specify the method the block uses to extrapolate values for all inputs that fall outside the range of the breakpoint data set. You can select **Clip** or **Linear**. See “Extrapolation Methods” for more information.

If the extrapolation method is **Linear**, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is **Linear Lagrange**, the extrapolation method inherits the **Linear Lagrange** equation to compute the extrapolated value.

Dependencies

To enable the **Extrapolation method** parameter, set the **Interpolation method** to **Linear**.

The Interpolation Using Prelookup block does not support **Linear** extrapolation when the input or output signals specify integer or fixed-point data types.

Programmatic Use

Block Parameter: ExtrapMethod

Type: character vector

Values: 'Clip' | 'Linear'

Default: 'Linear'

Valid index input may reach last index — Allow inputs to access the last elements of table data

off (default) | on

Specify how block inputs for index (**k**) and interval fraction (**f**) access the last elements of *n*-dimensional table data. Index values are zero based.

This check box is relevant if the input index is equal to or larger than the table's last index for that dimension. Due to rounding, selecting and clearing this check box may result in differing results for the last index between simulation and code generation.

Check Box	Block Behavior
on	Returns the value of the last element in a dimension of its table when: <ul style="list-style-type: none"> • k indexes the last table element in the corresponding dimension • f is 0
off	Returns the value of the last element in a dimension of its table when: <ul style="list-style-type: none"> • k indexes the next-to-last table element in the corresponding dimension • f is 1

Dependencies

This check box is visible only when:

- **Interpolation method** is **Linear point-slope** or **Linear Lagrange**
- **Extrapolation method** is **Clip**

Tip When you select **Valid index input may reach last index** for an Interpolation Using Prelookup block, you must also select **Use last breakpoint for input at or above upper limit** for all Prelookup blocks that feed it. This action allows the blocks to use the same indexing convention when accessing the last elements of their breakpoint and table data sets.

Programmatic Use**Block Parameter:** ValidIndexMayReachLast**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Diagnostic for out-of-range input — Block action when input is out of range**

None (default) | Warning | Error

Specify whether to produce a warning or error when the input is out of range. Options include:

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use**Block Parameter:** DiagnosticForOutOfRangeInput**Type:** character vector**Values:** 'None' | 'Warning' | 'Error'**Default:** 'None'**Number of sub-table selection dimensions — Number of dimensions of the output computation subtable**

0 (default) | positive integer, less than or equal to the number of table dimensions

Specify the number of dimensions of the subtable that the block uses to compute the output. Follow these rules:

- To enable subtable selection, enter a positive integer.

This integer must be less than or equal to the **Number of table dimensions**.

- To disable subtable selection, enter 0 to interpolate the entire table.

For nonzero values, the subtable selection behavior is optimized for row-major layout when you select the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter.

For more information, see “How The Block Interpolates a Subset of Table Data” on page 1-773.

Programmatic Use**Block Parameter:** NumSelectionDims**Type:** character vector**Values:** '0' | '1' | '2' | '3' | '4' | ... | Number of table dimensions**Default:** '0'**Code generation****Remove protection against out-of-range index in generated code — Remove code that checks for out-of-range index inputs**

off (default) | on

Check Box	Result	When to Use
on	Generated code does not include conditional statements to check for out-of-range index inputs. When the input k or f is out of range, it may cause undefined behavior for generated code.	For code efficiency
off	Generated code includes conditional statements to check for out-of-range index inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input k or f is out of range, the behavior is undefined for generated code.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

This check box has no effect on the generated code when one of the following is true:

- The Prelookup block feeds index values to the Interpolation Using Prelookup block.

Because index values from the Prelookup block are always valid, no check code is necessary.

- The data type of the input k restricts the data to valid index values.

For example, unsigned integer data types guarantee nonnegative index values. Therefore, unsigned input values of k do not require check code for negative values.

Programmatic Use**Block Parameter:** RemoveProtectionIndex**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Sample time — Specify sample time as a value other than -1**`-1 (default) | scalar | vector`

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar or vector**Default:** '-1'**Data Types****Table data — Data type of table values**`Inherit: Same as output (default) | Inherit: Inherit from 'Table data' | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>`

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the table data type.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
 - Sharing of prescaled table data between two Interpolation Using Prelookup blocks with different output data types
 - Sharing of custom storage table data in Simulink Coder generated code for blocks with different output data types
-

Programmatic Use**Block Parameter:** TableDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit from table data' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as input'**Table minimum — Minimum value of table data**

[] (default) | scalar

Specify the minimum value for table data as a finite, real, double, scalar. The default value is [] (unspecified).

Programmatic Use**Block Parameter:** TableMin**Type:** character vector**Values:** scalar**Default:** '[]'**Table maximum — Maximum value of table data**

[] (default) | scalar

Specify the maximum value for table data as a finite, real, double, scalar. The default value is [] (unspecified).

Programmatic Use**Block Parameter:** TableMax**Type:** character vector**Values:** scalar**Default:** '[]'**Intermediate results — Data type of intermediate results**

Inherit: Inherit via internal rule (default) | Inherit: Same as output | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher precision for internal computations than for table data or output data.

Programmatic Use**Block Parameter:** IntermediateResultsDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as input'**Output — Output data type**

Inherit: Inherit from 'Table data' (default) | Inherit: Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via back propagation
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the output data type.

See “Control Signal Data Types” in the *Simulink User's Guide* for more information.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit from table data'**Output minimum — Minimum value the block can output**

[] (default) | scalar

Specify the minimum value that the block should output as a finite, real-valued scalar. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use**Block Parameter:** OutMin

Type: character vector

Values: scalar

Default: ' [] '

Output maximum — Maximum value the block can output

[] (default) | scalar

Specify the maximum value that the block should output as a finite, real-valued scalar. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: scalar

Default: ' [] '

Internal rule priority — Internal rule for intermediate calculations

Speed (default) | Precision

Specify the internal rule for intermediate calculations. Select Speed for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use

Block Parameter: InternalRulePriority

Type: character vector

Values: 'Speed' | 'Precision'

Default: 'Speed'

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Convergent | Ceiling | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function in the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Simulink PLC Coder™ has limited support for lookup table blocks. The coder does not support:

- Number of dimensions greater than 2
- Cubic spline interpolation method
- Begin index search using a previous index mode
- Cubic spline extrapolation method

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Interpreted MATLAB Function

Apply MATLAB function or expression to input

Library: Simulink / User-Defined Functions

Description

The Interpreted MATLAB Function block applies the specified MATLAB function or expression to the input. The output of the function must match the output dimensions of the block.

Some valid expressions for this block are:

```
sin
atan2(u(1), u(2))
u(1)^u(2)
```

Note This block is slow because it calls the MATLAB parser during each integration step. Consider using built-in blocks (such as the Math Function block) instead. Alternatively, you can write the function as a MATLAB S-function or MEX-file S-function, then access it using the S-Function block.

Ports

Input

In — Input of a Interpreted MATLAB function

scalar | vector | matrix

The Interpreted MATLAB Function block accepts one real or complex input of type `double` and generates real or complex output of type `double`, depending on the setting of the **Output signal type** parameter.

Data Types: `double`

Output

Out — Output of a Interpreted MATLAB function

scalar | vector | matrix

The Interpreted MATLAB Function block accepts one real or complex input of type `double` and generates real or complex output of type `double`, depending on the setting of the **Output signal type** parameter.

Data Types: `double`

Parameters

MATLAB Function — Specify the function or expression

function (default)

Specify the function or expression. If you specify a function only, it is not necessary to include the input argument in parentheses.

Output dimensions — Specify the dimensions of the block output signal

scalar | matrix | vector | inherited

Specify the dimensions of the block output signal, for example, 2 for a two-element vector. The output dimensions must match the dimensions of the value returned by the function or expression in the **MATLAB function** field.

Specify -1 to inherit the dimensions from the output of the specified function or expression. To determine the output dimensions, Simulink runs the function or expression once before simulation starts.

Note If you specify -1 for this parameter and your function has persistent variables, then the variables might update before the simulation starts. If you need to use persistent variables, consider setting this parameter to a value other than -1.

Output signal type — Specify the block output signal type

auto (default) | real | complex

Specify the output signal type of the block as real, complex, or auto. A value of auto sets the output type to be the same as the type of the input signal.

Collapse 2-D results to 1-D — Output a 2-D array as a 1-D array

off (default) | on

Select this check box to output a 2-D array as a 1-D array containing the 2-D array's elements in column-major order.

Sample time — Specify sample time in the block

scalar

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no

Zero-Crossing Detection	no

Interval Test

Determine if signal is in specified interval

Library: Simulink / Logic and Bit Operations

Description

The Interval Test block outputs true (1) if the input is between the values specified by the **Lower limit** and **Upper limit** parameters. The block outputs false (0) if the input is outside those values. The output of the block when the input is equal to the **Lower limit** or the **Upper limit** is determined by whether you select the **Interval closed on left** and **Interval closed on right** check boxes.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **Upper limit** and **Lower limit** values must be of the same enumerated type.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 – Output signal

scalar | vector | matrix | N-D array

Output signal indicating whether the input values fall within the specified interval. You can specify the **Output data type** as boolean or uint8.

Data Types: uint8 | Boolean

Parameters

Interval closed on right – Include upper limit value

on (default) | off

When you select this check box, the **Upper limit** is included in the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: IntervalClosedRight

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Upper limit – Upper limit of interval

0.5 (default) | scalar | vector | matrix | N-D array

The upper limit of the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: uplimit

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '0.5'

Interval closed on left – Include lower limit value

on (default) | off

When you select this check box, the **Lower limit** is included in the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: IntervalClosedLeft

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Lower limit – Lower limit of interval

-0.5 (default) | scalar | vector | matrix | N-D array

The lower limit of the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: lowlimit

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '-0.5'

Output data type – Output data type

boolean (default) | uint8

Specify the output data type as boolean or uint8.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes

Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

Interval Test Dynamic

Introduced before R2006a

Interval Test Dynamic

Determine if signal is in specified interval

Library: Simulink / Logic and Bit Operations

Description

The Interval Test Dynamic block outputs true (1) if the input is between the values of the external signals **up** and **lo**. The block outputs false (0) if the input is outside those values. To control how the block handles input values that are equal to the signal **lo** or the signal **up**, use the **Interval closed on left** and **Interval closed on right** check boxes.

Ports

Input

up — Upper limit of interval

scalar | vector | matrix | N-D array

Upper limit of interval, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **up** and **lo** signals must be of the same enumerated type.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **up** and **lo** signals must be of the same enumerated type.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

lo — Lower limit of interval

scalar | vector | matrix | N-D array

Lower limit of interval, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **up** and **lo** signals must be of the same enumerated type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Output

y — Output signal

scalar | vector | matrix | N-D array

Output signal indicating whether the input values fall within the specified interval. You can specify the **Output data type** as `boolean` or `uint8`.

Data Types: `uint8` | `Boolean`

Parameters

Interval closed on right — Include upper limit value

`on` (default) | `off`

When you select this check box, the value of the signal connected to the **up** input port is included in the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: `IntervalClosedRight`

Type: character vector

Values: `'on'` | `'off'`

Default: `'on'`

Interval closed on left — Include lower limit value

`on` (default) | `off`

When you select this check box, the value of the signal connected to the **lo** input port is included in the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: `IntervalClosedLeft`

Type: character vector

Values: `'on'` | `'off'`

Default: `'on'`

Output data type — Output data type

`boolean` (default) | `uint8`

Specify the output data type as `boolean` or `uint8`.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'boolean'` | `'uint8'`

Default: `'boolean'`

Block Characteristics

Data Types	<code>Boolean</code> <code>double</code> <code>enumerated</code> <code>fixed point</code> <code>integer</code> <code>single</code>
Direct Feedthrough	yes

Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Interval Test

Introduced before R2006a

Knob

Tune parameter value with dial

Library: Simulink / Dashboard

Description

The Knob block tunes the value of the connected block parameter to during simulation. For example, you can connect the Knob block to a Gain block in your model and adjust its value during simulation. You can modify the range of the Knob block's scale to fit your data. Use the Knob block with other Dashboard blocks to create an interactive dashboard to control your model.

Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to make connections. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

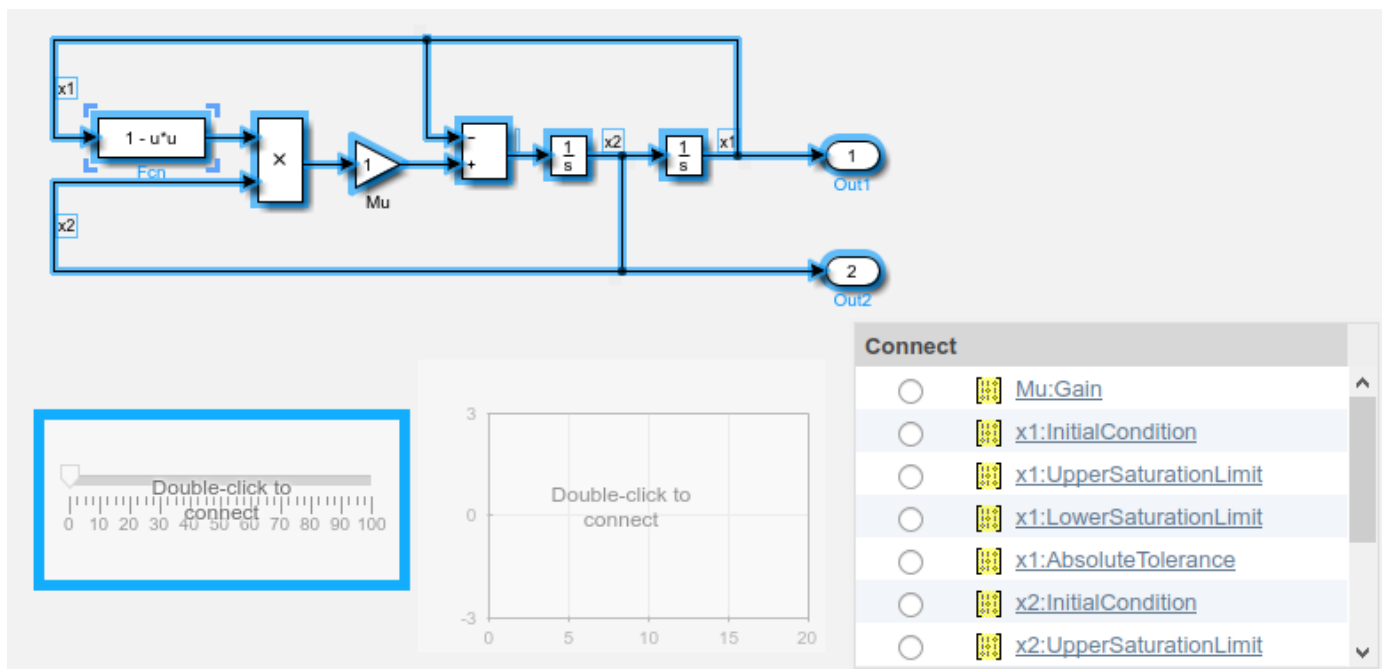

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above it.

In connect mode, when you select one or more signals or blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block. To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a variable or parameter to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.
- When you specify a block parameter value by indexing a variable array, the parameter does not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect
variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.
- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: []

Scale Type — Type of scale

Linear (default) | Log

Type of scale displayed on the block. **Linear** specifies a linear scale, and **Log** specifies a logarithmic scale.

Programmatic Use

Block Parameter: `ScaleType`

Type: string or character vector

Values: 'Linear' | 'Log'

Default: 'Linear'

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: `Limits`

Type: 1×3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the **Maximum** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to **auto**, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the **Tick Interval** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	double integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Lamp

Display color reflecting input value

Library: Simulink / Dashboard

Description

The Lamp block displays a color indicating the value of the input signal. You can use the Lamp block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. You can specify pairs of input values and colors to provide the information you want during simulation.

Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above the block.

In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

States — Match values to colors to display

scalar and RGB vector

States match a display color to the value of the connected variable or parameter. Each state consists of a **State** and a **Color**.

- **State** — Connected variable or parameter value that causes the Lamp block to display the specified color indication.
- **Color** — Lamp color when the connected variable or parameter value matches the corresponding **State** value. You can select from a palette of standard colors or specify a custom color with RGB values.

The [undefined] state specifies the color of the Lamp block when the input value does not match any of the values specified in the **States** table. Click the **+** button to add another state.

Programmatic Use

To programmatically specify the **State** and **Color** parameter values for a Lamp block, use an array of structures containing the fields:

- **Value** — Scalar **double** value corresponding to the state.
- **Color** — 1-by-3 [r g b] vector with values between 0 and 1 specifying the color for the Lamp to display.

```
lampState1.Value = 1;
lampState1.Color = [0 0 1];
lampState2.Value = 2;
lampState2.Color = [1 0 0];
lampStates = [lampState1 lampState2];
```

Block Parameter: StateColors

Type: structure array

Default: structure

The **ColorDefault** parameter specifies the color for the Lamp block when the value of the connected signal does not match any of the specified state values. Specify the **ColorDefault** parameter as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: ColorDefault

Type: [r g b] vector

Default: [0.7529 0.7529 0.7529]

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

Level-2 MATLAB S-Function

Use Level-2 MATLAB S-function in model

Library: Simulink / User-Defined Functions

Description

This block allows you to use a Level-2 MATLAB S-function (see “Write Level-2 MATLAB S-Functions”) in a model. To do this, create an instance of this block in the model. Then enter the name of the Level-2 MATLAB S-function in the **S-function name** field of the block's parameter dialog box.

Note Use the S-Function block to include a Level-1 MATLAB S-function in a block.

If the Level-2 MATLAB S-function defines any additional parameters, you can enter them in the **Parameters** field of the block's parameter dialog box. Enter the parameters as MATLAB expressions that evaluate to their values in the order defined by the MATLAB S-function. Use commas to separate each expression.

If a model includes a Level-2 MATLAB S-Function block, and an error occurs in the S-function, the Level-2 MATLAB S-Function block displays MATLAB stack trace information for the error in a dialog box. Click **OK** to close the dialog box.

Parameters

S-Function Name — Specify S-Function name

matlabfile (default) | S-Function name

Specify the name of a MATLAB function that defines the behavior of this block. The MATLAB function must follow the Level-2 standard for writing MATLAB S-functions (see “Write Level-2 MATLAB S-Functions” for details).

Programmatic Use

Block Parameter: FunctionName

Type: character vector

Values: 'matlabfile' | S-Function name

Default: 'matlabfile'

Parameters — Specify values of parameters for this block

no default (default)

Specify values of parameters for this block.

Programmatic Use

Block Parameter: Parameters

Type: character vector

Values: values of block parameters

Default: ' '

Block Characteristics

Data Types	Boolean ^a double ^a fixed point ^a integer ^a single ^a
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

a. Level-1 MATLAB S-functions support only the double data type. Level-2 MATLAB S-functions support all data types that Simulink supports.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- If a corresponding TLC file is available, the Level-2 MATLAB S-Function block uses the TLC file to generate code, otherwise code generation throws an error.
- Real-time code generation does not support S-functions that call MATLAB.
- Actual data type or capability support depends on block implementation.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Level-1 MATLAB S-functions support only the double data type. Level-2 MATLAB S-functions support all data types that Simulink supports.

Linear Gauge

Display input value on linear scale

Library: Simulink / Dashboard

Description

The Linear Gauge block displays the connected signal on a straight linear scale during simulation. Use the Linear Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Linear Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Linear Gauge block to fit your data. You can also customize the appearance of the Linear Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above the block.

In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify `-1`.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Maximum — Maximum tick mark value**

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the **Maximum** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Tick Interval — Interval between major tick marks**

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to **auto**, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the **Tick Interval** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Scale Colors — Color indications on gauge scale**

colors for scale ranges

Color specifications for value ranges on the scale. Press the **+** button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the **Scale Colors** parameter, use an array of structures with the fields:

- **Min** — Minimum value for the color range on the scale
- **Max** — Maximum value for the color range on the scale
- **Color** — 1-by-3 vector of double values between 0 and 1 that specify the color for the range in the form [r g b]

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;
range1.Max = 10;
```

```
range1.Color = [0 0 1];
range2.Min = 10;
range2.Max = 15;
range2.Color = [0 1 0];
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors

Type: structure array

Default: 0x1 struct array

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

Logical Operator

Perform specified logical operation on input

Library: Simulink / Commonly Used Blocks
 Simulink / Logic and Bit Operations
 HDL Coder / Commonly Used Blocks
 HDL Coder / Logic and Bit Operations

Description

The Logical Operator block performs the specified logical operation on its inputs. An input value is true (1) if it is nonzero and false (0) if it is zero.

You select the Boolean operation connecting the inputs with the **Operator** parameter list. If you select rectangular as the **Icon shape** property, the name of the selected operator displays on the block icon. If you select distinctive as the **Icon shape** property, the name of the selected operator does not display on the block icon. This table shows supported operations:

Operation	Description
AND	TRUE if all inputs are TRUE
OR	TRUE if at least one input is TRUE
NAND	TRUE if at least one input is FALSE
NOR	TRUE when no inputs are TRUE
XOR	TRUE if an odd number of inputs are TRUE
NXOR	TRUE if an even number of inputs are TRUE
NOT	TRUE if the input is FALSE

If you select distinctive as the **Icon shape**, the block appearance indicates its function. Simulink software displays a distinctive shape for the selected operator, conforming to the IEEE Standard Graphic Symbols for Logic Functions.

To specify the number of input ports, use the **Number of input ports** parameter. The output type is specified using the **Output data type** parameter. An output value is 1 if TRUE and 0 if FALSE.

Note The output data type should represent zero exactly. Data types that satisfy this condition include signed and unsigned integers, and any floating-point data type.

The size of the output depends on input vector size and the selected operator:

- If the block has more than one input, any nonscalar inputs must have the same dimensions. For example, if any input is a 2-by-2 array, all other nonscalar inputs must also be 2-by-2 arrays.

Scalar inputs are expanded to have the same dimensions as the nonscalar inputs.

If the block has more than one input, the output has the same dimensions as the inputs (after scalar expansion) and each output element is the result of applying the specified logical operation to the corresponding input elements. For example, if the specified operation is AND and the inputs are 2-by-2 arrays, the output is a 2-by-2 array whose top left element is the result of applying AND to the top left elements of the inputs, and so on.

- For a single vector input, the block applies the operation (except the NOT operator) to all elements of the vector. The output is always a scalar.
- The NOT operator accepts only one input, which can be a scalar or a vector. If the input is a vector, the output is a vector of the same size containing the logical complements of the input vector elements.

When configured as a multi-input XOR gate, this block performs an addition modulo two operation as mandated by the IEEE Standard for Logic Elements.

Ports

Input

Port_1 — First input signal

scalar | vector | matrix

First input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_2 — Second input signal

scalar | vector | matrix

Second input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_N — Nth input signal

scalar | vector | matrix

Nth input signal, specified as a scalar, vector, or matrix.

Dependencies

To enable additional input ports, use the **Number of input ports** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal, consisting of zeros and ones, with the same dimensions as the input. You control the output data type with the **Require all inputs and output to have the same data type** and **Output data type** parameters.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Operator — Logical operator

AND (default) | OR | NAND | NOR | XOR | NXOR | NOT

Select the logical operator to apply to block inputs.

- AND — T if all inputs are TRUE
- OR — TRUE if at least one input is TRUE
- NAND — TRUE if at least one input is FALSE
- NOR — TRUE when no inputs are TRUE
- XOR — TRUE if an odd number of inputs are TRUE
- NXOR — TRUE if an even number of inputs are TRUE
- XOR — TRUE if the input is FALSE

Programmatic Use

Block Parameter: Operator

Type: character vector

Values: 'AND' | 'OR' | 'NAND' | 'NOR' | 'XOR' | 'NXOR' | 'NOT'

Default: 'AND'

Number of input ports — Number of inputs

2 (default) | positive integer

Specify the number of block inputs as a positive integer.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: positive integer

Default: '2'

Dependencies

This parameter is not available when you set the **Operator** to NOT.

Icon shape — Icon shape

rectangular (default) | distinctive

Specify the shape of the block icon.

- `rectangular` — Results in a rectangular block that displays the name of the selected operator.
- `distinctive` — Use the graphic symbol for the selected operator as specified by the IEEE standard.

Programmatic Use**Block Parameter:** `IconShape`**Type:** character vector**Values:** `'rectangular'` | `'distinctive'`**Default:** `'rectangular'`**Sample time — Specify sample time as a value other than -1**`-1` (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** `SampleTime`**Type:** character vector**Values:** scalar or vector**Default:** `'-1'`**Data Type****Require all inputs and output to have the same data type — Require all ports to have same data type**`off` (default) | `on`

To require that all block inputs and the output have the same data type, select this check box. When you clear this check box, the inputs and output can have different data types.

Programmatic Use**Block Parameter:** `AllPortsSameDT`**Type:** character vector**Values:** `'off'` | `'on'`**Default:** `'off'`**Output data type — Output data type**`boolean` (default) | `Inherit: Logical` (see Configuration Parameters: Optimization) | `fixdt(1,16)` | `<data type expression>`

Specify the output data type. When you select:

- `boolean` — The block output has data type `boolean`.
- `Inherit: Logical` (see Configuration Parameters: Optimization) — The block uses the **Implement logic signals as Boolean data** configuration parameter to specify the output data type (see “Implement logic signals as Boolean data (vs. double)”).

Note This option supports models created before the `boolean` option was available. Use one of the other options, preferably `boolean`, for new models.

- `fixdt(1,16)` — The block output has the specified fixed-point data type `fixdt(1,16)`.

Tip Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

- `<data type expression>` — The block output has the data type you specify as a data type expression, for example, `Simulink.NumericType`.

Tip To enter a built-in data type (`double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`), enclose the expression in single quotes. For example, enter `'double'` instead of `double`.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Logical (see Configuration Parameters: Optimization)'` | `'boolean'` | `'fixdt(1,16)'` | `'<data type expression>'`

Default: `'boolean'`

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

1-D Lookup Table

Approximate one-dimensional function

Library: Simulink / Lookup Tables
HDL Coder / Lookup Tables

Description

Supported Block Operations

The 1-D, 2-D, and n-D Lookup Table blocks evaluate a sampled representation of a function in N variables

$$y = F(x_1, x_2, x_3, \dots, x_N)$$

where the function F can be empirical. The block maps inputs to an output value by looking up or interpolating a table of values you define with block parameters. The block supports flat (constant), linear (linear point-slope), Lagrange (linear Lagrange), nearest, cubic-spline, and Akima spline interpolation methods. You can apply these methods to a table of any dimension from 1 through 30.

In the following block, the first input identifies the first dimension (row) breakpoints, the second input identifies the second dimension (column) breakpoints, and so on.

See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the 2-D and n-D Lookup Table block behavior changes from column-major to row-major. For these blocks, the column-major and row-major algorithms may differ in the order of the output calculations, possibly resulting in slightly different numerical values. This capability requires a Simulink Coder or Embedded Coder license. For more information on row-major support, see “Code Generation of Matrices and Arrays” (Simulink Coder).

Specification of Breakpoint and Table Data

These block parameters define the breakpoint and table data.

Block Parameter	Purpose
Number of table dimensions	Specifies the number of dimensions of your lookup table.
Breakpoints	Specifies a breakpoint vector that corresponds to each dimension of your lookup table.
Table data	Defines the associated set of output values.

Tip Evenly spaced breakpoints can make the generated code division-free. For more information, see `fixpt_evenspace_cleanup` and “Identify questionable fixed-point operations” (Embedded Coder).

How the Block Generates Output

The n-D, 1-D and 2-D Lookup Table blocks generate output by looking up or estimating table values based on the input values.

Block Inputs	n-D Lookup Table Block Behavior
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Other Blocks that Perform Equivalent Operations

You can use the Interpolation Using Prelookup block with the Prelookup block to perform the equivalent operation of one n-D Lookup Table block. This combination of blocks offers greater flexibility that can result in more efficient simulation performance for linear interpolations.

When the lookup operation is an array access that does not require interpolation, use the Direct Lookup Table (n-D) block. For example, if you have an integer value k and you want the k th element of a table, $y = \text{table}(k)$, interpolation is unnecessary.

Ports

Input

u1 — First-dimension (row) inputs

scalar | vector | matrix

Real-valued inputs to the **u1** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: `0:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `enumerated` | `fixed point`

Output

Port_1 — Output computed by looking up or estimating table values

scalar | vector | matrix

Output generated by looking up or estimating table values based on the input values.

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Table and Breakpoints

Number of table dimensions — Number of lookup table dimensions

1 (default) | 2 | 3 | 4 | ... | 30

Enter the number of dimensions of the lookup table. This parameter determines:

- The number of independent variables for the table and the number of block inputs
- The number of breakpoint sets to specify

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

For example, a table with a size of $M \times N \times \dots$ means that the size of dimension 1 is M , the size of dimension 2 is N , and so forth. M must match the first breakpoint length, N must match the second breakpoint length, and so forth.

Programmatic Use

Block Parameter: NumberOfTableDimensions

Type: character vector

Values: '1' | '2' | '3' | '4' | ... | 30

Default: '1'

Data specification — Method of table and breakpoint specification

Table and breakpoints (default) | Lookup table object

From the list, select:

- **Table and breakpoints** — Specify the table data and breakpoints. Selecting this option enables these parameters:
 - **Table data**
 - **Breakpoints specification**
 - **Breakpoints 1**
 - **Edit table and breakpoints**
- **Lookup table object** — Use an existing lookup table (`Simulink.LookupTable`) object. Selecting this option enables the **Name** field and **Edit table and breakpoints** button.

Programmatic Use**Block Parameter:** `DataSpecification`**Type:** character vector**Values:** 'Table and breakpoints' | 'Lookup table object'**Default:** 'Table and breakpoints'**Name — Name of the lookup table object**[] (default) | `Simulink.LookupTable` object

Enter the name of the lookup table (`Simulink.LookupTable`) object. If a `Simulink.LookupTable` object does not exist, click the action button  and select **Create**. The corresponding parameters of the new lookup table object are automatically populated with the block information.

Dependencies

To enable this parameter, set **Data specification** to `Lookup table object`.

Programmatic Use**Block Parameter:** `LookupTableObject`**Type:** character vector**Values:** name of a `Simulink.LookupTable` object**Default:** ''**Table data — Define the table of output values**`tanh([-5:5])` (default) | vector of values

Enter the table of output values.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as []) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`.

Programmatic Use**Block Parameter:** `Table`**Type:** character vector**Values:** vector of table values**Default:** 'tanh([-5:5])'

Breakpoints specification — Method of breakpoint specification

Explicit values (default) | Even spacing

Specify whether to enter data as explicit breakpoints or as parameters that generate evenly spaced breakpoints.

- To explicitly specify breakpoint data, set this parameter to `Explicit values` and enter breakpoint data in the text box next to the **Breakpoints** parameters.
- To specify parameters that generate evenly spaced breakpoints, set this parameter to `Even spacing` and enter values for the **First point** and **Spacing** parameters for each dimension of breakpoint data. The block calculates the number of points to generate from the table data.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`.

Programmatic Use**Block Parameter:** BreakpointsSpecification**Type:** character vector**Values:** 'Explicit values' | 'Even spacing'**Default:** 'Explicit values'**Breakpoints — Explicit breakpoint values, or first point and spacing of breakpoints**

[10, 22, 31] (default) | 1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly or as evenly-spaced breakpoints, based on the value of the **Breakpoints specification** parameter.

- If you set **Breakpoints specification** to `Explicit values`, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.
- If you set **Breakpoints specification** to `Even spacing`, enter the parameters **First point** and **Spacing** in each **Breakpoints** row to generate evenly spaced breakpoints in the respective dimension. Your table data determines the number of evenly spaced points.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`.

Programmatic Use**Block Parameter:** BreakpointsForDimension1**Type:** character vector**Values:** 1-by-n or n-by-1 vector of monotonically increasing values**Default:** '[10, 22, 31]'**First point — First point in evenly spaced breakpoint data**

1 (default) | scalar

Specify the first point in your evenly spaced breakpoint data as a real-valued, finite, scalar. This parameter is available when **Breakpoints specification** is set to `Even spacing`.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`, and **Breakpoints specification** to `Even spacing`.

Programmatic Use**Block Parameter:** BreakpointsForDimension1FirstPoint**Type:** character vector**Values:** real-valued, finite, scalar**Default:** '1'**Spacing — Spacing between evenly spaced breakpoints**

1 (default) | scalar

Specify the spacing between points in your evenly spaced breakpoint data.

Dependencies

To enable this parameter, set **Data specification** to Table and breakpoints, and **Breakpoints specification** to Even spacing.

Programmatic Use**Block Parameter:** BreakpointsForDimension1Spacing**Type:** character vector**Values:** positive, real-valued, finite, scalar**Default:** '1'**Edit table and breakpoints — Launch Lookup Table Editor dialog box**

button

Click this button to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

Clicking this button for a lookup table object lets you edit the object and save the new values for the object.

Algorithm**Lookup method****Interpolation method — Method of interpolation between breakpoint values**

Linear point-slope (default) | Flat | Nearest | Linear Lagrange | Cubic spline | Akima spline

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. For more information on interpolation methods, see “Interpolation Methods”.

Dependencies

- If you select Cubic spline, the block supports only scalar signals. The other interpolation methods support nonscalar signals.
- If you select Akima spline, the extrapolation method can only be Akima spline.

When set to the modified Akima interpolation method, this block does not support:

- Row-major array layout and algorithms optimized for row-major array layout
- Scaled double and fixed-point data types
- Simulink.LookupTable objects

- Code generation when the configuration parameter **Code Generation > Interface > Support non-finite numbers** check box is selected

Programmatic Use**Block Parameter:** InterpMethod**Type:** character vector**Values:** 'Linear point-slope' | 'Flat' | 'Nearest' | 'Linear Lagrange' | 'Cubic spline' | 'Akima spline'**Default:** 'Linear point-slope'**Extrapolation method — Method of handling input values that fall outside the range of a breakpoint data set**

Linear (default) | Clip | Cubic spline | Akima spline

Select Clip, Linear, or Cubic spline. See “Extrapolation Methods” for more information.

If the extrapolation method is Linear, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is linear Lagrange, the extrapolation method inherits the linear Lagrange equation to compute the extrapolated value.

Dependencies

- To select Cubic spline for **Extrapolation method**, you must also select Cubic spline for **Interpolation method**.
- To select Akima spline for **Extrapolation method**, you must also select Akima spline for **Interpolation method**.

Programmatic Use**Block Parameter:** ExtrapMethod**Type:** character vector**Values:** 'Linear' | 'Clip' | 'Cubic spline' | 'Akima spline'**Default:** 'Linear'**Index search method — Method of calculating table indices**

Evenly spaced points (default) | Linear search | Binary search

Select Evenly spaced points, Linear search, or Binary search. Each search method has speed advantages in different circumstances:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting Evenly spaced points to calculate table indices.

This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.

Note Set **Index search method** to Evenly spaced points when using the Simulink.LookupTable object to specify table data and the **Breakpoints Specification** parameter of the referenced Simulink.LookupTable object is set to Even spacing.

- For unevenly spaced breakpoint sets, follow these guidelines:
 - If input signals do not vary much between time steps, selecting Linear search with **Begin index search using previous index result** produces the best performance.
 - If input signals jump more than one or two table intervals per time step, selecting Binary search produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
 - The index search method is `Evenly spaced points`.
-

Programmatic Use

Block Parameter: `IndexSearchMethod`

Type: character vector

Values: `'Binary search'` | `'Evenly spaced points'` | `'Linear search'`

Default: `'Binary search'`

Begin index search using previous index result — Start using the index from the previous time step

`off (default)` | `on`

Select this check box when you want the block to start its search using the index found at the previous time step. For inputs that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Dependencies

To enable this parameter, set **Index search method** to `Linear search` or `Binary search`.

Programmatic Use

Block Parameter: `BeginIndexSearchUsing PreviousIndexResult`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Diagnostic for out-of-range input — Block action when input is out of range

`None (default)` | `Warning` | `Error`

Specify whether to produce a warning or error when the input is out of range. Options include:

- `None` — Produce no response.
- `Warning` — Display a warning and continue the simulation.
- `Error` — Terminate the simulation and display an error.

Programmatic Use

Block Parameter: `DiagnosticForOutOfRangeInput`

Type: character vector

Values: `'None'` | `'Warning'` | `'Error'`

Default: `'None'`

Use last table value for inputs at or above last breakpoint — Method for computing output for inputs at or above last breakpoint

`off (default)` | `on`

Using this check box, specify the indexing convention that the block uses to address the last element of a breakpoint set and its corresponding table value. This check box is relevant if the input is equal to or larger than the last element of the breakpoint data. Due to rounding, selecting and clearing this check box may result in differing results for the last breakpoint between simulation and code generation.

Check Box	Index Used by Block	Interval Fraction
Selected	Last element of breakpoint data on the Table and Breakpoints tab	0
Cleared	Next-to-last element of breakpoint data on the Table and Breakpoints tab	1

Given an input u within range of a breakpoint set bp , the interval fraction f , in the range $0 \leq f < 1$, is computed as shown below.

Suppose the breakpoint set is [1 4 5] and input u is 5.5. If you select this check box, the index is that of the last element (5) and the interval fraction is 0. If you clear this check box, the index is that of the next-to-last element (4) and the interval fraction is 1.

Dependencies

To enable this parameter, set:

- **Interpolation method** to Linear.
- **Extrapolation method** to Clip.

Programmatic Use

Block Parameter: UseLastTableValue

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Input settings

Use one input port for all input data — Use only one input port

off (default) | on

Select this check box to use only one input port that expects a signal that is n elements wide for an n -dimensional table. This option is useful for removing line clutter on a block diagram with many lookup tables.

Note When you select this check box, one input port with the label u appears on the block.

Programmatic Use

Block Parameter: UseOneInputPortForAllInputData

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Code generation

Remove protection against out-of-range input in generated code — Remove code that checks for out-of-range input values

off (default) | on

Specify whether or not to include code that checks for out-of-range input values.

Check Box	Result	When to Use
on	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code.	For code efficiency
off	Generated code includes conditional statements to check for out-of-range inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input is out of range, the behavior is undefined for generated code.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

Programmatic Use

Block Parameter: RemoveProtectionInput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Support tunable table size in code generation — Enable tunable table size in the generated code

off (default) | on

Select this check box to enable tunable table size in the generated code. This option enables you to change the size and values of the lookup table and breakpoint data in the generated code without regenerating or recompiling the code. You can only decrease the size of the lookup table and breakpoint data.

Dependencies

If you set **Interpolation method** to Cubic spline, this check box is not available.

Programmatic Use

Block Parameter: SupportTunableTableSize

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Maximum indices for each dimension — Maximum index value for each table dimension

[] (default) | scalar or vector of positive integer values

Example: [4 6] for a 5-by-7 table

Specify the maximum index values for each table dimension using zero-based indexing. You can specify a scalar or vector of positive integer values using the following data types:

- Built-in floating-point types: `double` and `single`
- Built-in integer types: `int8`, `int16`, `int32`, `uint8`, `uint16`, and `uint32`

Examples of valid specifications include:

- [4 6] for a 5-by-7 table
- [`int8(2)` `int16(5)` `int32(9)`] for a 3-by-6-by-10 table
- A `Simulink.Parameter` whose value on generating code is one less than the dimensions of the table data. For more information, see “Tunable Table Size in the Generated Code” on page 1-839.

Dependencies

To enable this parameter, select **Support tunable table size in code generation**. On tuning this parameter in the generated code, provide the new table data and breakpoints along with the tuned parameter value.

Programmatic Use

Block Parameter: `MaximumIndicesForEachDimension`

Type: character vector

Values: scalar or vector of positive integer values

Default: '[]'

Data Types

Table data — Data type of table data

Inherit: `Same as output (default)` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | <data type expression>

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
- Sharing of prescaled table data between two n-D Lookup Table blocks with different output data types

- Sharing of custom storage table data in the generated code for blocks with different output data types

Programmatic Use**Block Parameter:** TableDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit from 'Table data'' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as output'**Table data Minimum — Minimum value of the table data**

[] | scalar

Specify the minimum value for table data. The default value is [] (unspecified).

Programmatic Use**Block Parameter:** TableMin**Type:** character vector**Values:** scalar**Default:** '[]'**Table data Maximum — Maximum value of the table data**

[] | scalar

Specify the maximum value for table data. The default value is [] (unspecified).

Programmatic Use**Block Parameter:** TableMax**Type:** character vector**Values:** scalar**Default:** '[]'**Breakpoints — Breakpoint data type**

Inherit: Same as corresponding input (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the data type for a set of breakpoint data. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as corresponding input`
- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Tip

- Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.

- If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
- For enumerated data, **Extrapolation method** must be **Clip**.
- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

This is a limitation for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a breakpoint data type different from the corresponding input data type for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal
- Sharing of prescaled breakpoint data between two n-D Lookup Table blocks with different input data types
- Sharing of custom storage breakpoint data in the generated code for blocks with different input data types

Programmatic Use

Block Parameter: BreakpointsForDimension1DataTypeStr |
BreakpointsForDimension2DataTypeStr | ... |
BreakpointsForDimension30DataTypeStr

Type: character vector

Values: 'Inherit: Same as corresponding input' | 'Inherit: Inherit from
'Breakpoint data' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' |
'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' |
'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as corresponding input'

Breakpoints Minimum — Minimum value breakpoint data can have

[] | scalar

Specify the minimum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Min | BreakpointsForDimension2Min
| ... | BreakpointsForDimension30Min

Type: character vector

Values: scalar

Default: '[]'

Breakpoints Maximum — Maximum value breakpoint data can have

[] | scalar

Specify the maximum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Max | BreakpointsForDimension2Max
| ... | BreakpointsForDimension30Max

Type: character vector

Values: scalar

Default: '[]'

Fraction — Fraction data type

Inherit: Inherit via internal rule (default) | double | single | fixdt(1,16,0) | <data type expression>

Specify the fraction data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: FractionDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'double' | 'single' |
'fixdt(1,16,0)' | <data type expression>

Default: 'Inherit: Inherit via internal rule'

Intermediate results — Intermediate results data type

Inherit: Same as output (default) | double | single | int8 | uint8 | int16 | uint16 | int32
| uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type
expression>

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher (or lower) precision for internal computations than for table data or output data.

Programmatic Use

Block Parameter: IntermediateResultsDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as output'

Output — Output data type

Inherit: Same as input (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via back propagation
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'Inherit: Same as first input' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as first input'

Output Minimum — Minimum value the block can output

[] | scalar

Specify the minimum value that the block outputs. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).

- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** scalar**Default:** ' [] '**Output Maximum — Maximum value the block can output**

[] | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** scalar**Default:** ' [] '**Internal rule priority — Internal rule for intermediate calculations**

Speed (default) | Precision

Specify the internal rule for intermediate calculations. Select Speed for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use**Block Parameter:** InternalRulePriority**Type:** character vector**Values:** 'Speed' | 'Precision'**Default:** 'Speed'**Require all inputs to have the same data type — Require all inputs to have the same data type**

on (default) | off

Select to require all inputs to have the same data type.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'

Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode – Rounding mode for fixed-point operations**

Simplest (default) | Ceiling | Convergent | Floor | Nearest | Round | Zero

Specify the rounding mode for fixed-point lookup table calculations that occur during simulation or execution of code generated from the model. For more information, see “Rounding” (Fixed-Point Designer).

This option does not affect rounding of values of block parameters. Simulink rounds such values to the nearest representable integer value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the edit field on the block dialog box.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Simplest'**Saturate on integer overflow – Method of overflow action**

off (default) | on

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box (on).	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tip If you save your model as version R2009a or earlier, this check box setting has no effect and no saturation code appears. This behavior preserves backward compatibility.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Tunable Table Size in the Generated Code

Suppose that you have a lookup table and want to make the size tunable in the generated code. When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to configure lookup table data for calibration in the generated code, use the `SupportTunableSize` property of the objects to enable a tunable table size. When you do not use these classes, use the **Support tunable table size in code generation** parameter in an n-D Lookup Table block to enable a tunable table size.

Assume that:

- You define a `Simulink.Parameter` structure in the preload function of your model:

```
p = Simulink.Parameter;
p.Value.MaxIdx = [2 2];
p.Value.BP1 = [1 2 3];
p.Value.BP2 = [1 4 16];
p.Value.Table = [4 5 6; 16 19 20; 10 18 23];
p.DataType = 'Bus: slLookupTable';
p.CoderInfo.StorageClass = 'ExportedGlobal';

% Create bus object slBus1 from MATLAB structure
Simulink.Bus.createObject(p.Value);
slLookupTable = slBus1;
slLookupTable.Elements(1).DataType = 'uint32';
```

- These block parameters apply in the n-D Lookup Table block.

Parameter	Value
Number of table dimensions	2

Parameter	Value
Table data	p.Table
Breakpoints 1	p.BP1
Breakpoints 2	p.BP2
Support tunable table size in code generation	on
Maximum indices for each dimension	p.MaxIdx

The generated `model_types.h` header file contains a type definition that looks something like this.

```
typedef struct {
    uint32_T MaxIdx[2];
    real_T BP1[3];
    real_T BP2[3];
    real_T Table[9];
} sLookupTable;
```

The generated `model.c` file contains code that looks something like this.

```
/* Exported block parameters */
sLookupTable p = {
    { 2U, 2U },

    { 1.0, 2.0, 3.0 },

    { 1.0, 4.0, 16.0 },

    { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
};

/* More code */

/* Model output function */
static void ex_lut_nd_tunable_table_output(int_T tid)
{
    /* Lookup_n-D: '<Root>/n-D Lookup Table' incorporates:
     * Inport: '<Root>/In1'
     * Inport: '<Root>/In2'
     */
    Y = look2_binlcpw(U1, U2, p.BP1, p.BP2, p.Table, ...
p.MaxIdx, p.MaxIdx[0] + 1U);

    /* Outport: '<Root>/Out1' */
    ex_lut_nd_tunable_table_Y.Out1 = Y;

    /* tid is required for a uniform function interface.
     * Argument tid is not used in the function. */
    UNUSED_PARAMETER(tid);
}
```

The highlighted line of code specifies a tunable table size for the lookup table. You can change the size and values of the lookup table and breakpoint data without regenerating or recompiling the code.

Enumerated Values in Lookup Tables

Suppose that you have a lookup table with an enumerated class like this defined:

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(-1),
        NEUTRAL(0)
    end
end
```

n-D Lookup block has these settings:

- **Number of dimensions** to 1.
- **Table data** value is [5 10 20 40 80 -5 0].
- **Breakpoints 1** value is enumeration('Gears').
- Interpolation method is Flat.
- For an unordered search, set **Index search method** to Linear search and clear the **Begin index search using previous index result** check box.

Simulation produces a vector [10 -5 80], which correspond to GEAR2, REVERSE, and SPORTS.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For information about HDL code generation support for 1-D Lookup Table blocks, see “HDL Code Generation” on page 1-886 .

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

2-D Lookup Table

Approximate two-dimensional function

Library: Simulink / Lookup Tables
HDL Coder / Lookup Tables

Description

Supported Block Operations

The 1-D, 2-D, and n-D Lookup Table blocks evaluate a sampled representation of a function in N variables

$$y = F(x_1, x_2, x_3, \dots, x_N)$$

where the function F can be empirical. The block maps inputs to an output value by looking up or interpolating a table of values you define with block parameters. The block supports flat (constant), linear (linear point-slope), Lagrange (linear Lagrange), nearest, cubic-spline, and Akima spline interpolation methods. You can apply these methods to a table of any dimension from 1 through 30.

In the following block, the first input identifies the first dimension (row) breakpoints, the second input identifies the second dimension (column) breakpoints, and so on.

See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the 2-D and n-D Lookup Table block behavior changes from column-major to row-major. For these blocks, the column-major and row-major algorithms may differ in the order of the output calculations, possibly resulting in slightly different numerical values. This capability requires a Simulink Coder or Embedded Coder license. For more information on row-major support, see “Code Generation of Matrices and Arrays” (Simulink Coder).

Specification of Breakpoint and Table Data

These block parameters define the breakpoint and table data.

Block Parameter	Purpose
Number of table dimensions	Specifies the number of dimensions of your lookup table.
Breakpoints	Specifies a breakpoint vector that corresponds to each dimension of your lookup table.
Table data	Defines the associated set of output values.

Tip Evenly spaced breakpoints can make the generated code division-free. For more information, see `fixpt_evenspace_cleanup` and “Identify questionable fixed-point operations” (Embedded Coder).

How the Block Generates Output

The n-D, 1-D and 2-D Lookup Table blocks generate output by looking up or estimating table values based on the input values.

Block Inputs	n-D Lookup Table Block Behavior
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Other Blocks that Perform Equivalent Operations

You can use the Interpolation Using Prelookup block with the Prelookup block to perform the equivalent operation of one n-D Lookup Table block. This combination of blocks offers greater flexibility that can result in more efficient simulation performance for linear interpolations.

When the lookup operation is an array access that does not require interpolation, use the Direct Lookup Table (n-D) block. For example, if you have an integer value k and you want the k th element of a table, $y = \text{table}(k)$, interpolation is unnecessary.

Ports

Input

u1 — First-dimension (row) inputs

scalar | vector | matrix

Real-valued inputs to the **u1** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: `0:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `enumerated` | `fixed point`

u2 — Second-dimension (column) inputs

scalar | vector | matrix

Real-valued inputs to the **u2** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: 0:10

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | enumerated | fixed point

Output

Port_1 — Output computed by looking up or estimating table values

scalar | vector | matrix

Output generated by looking up or estimating table values based on the input values.

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Table and Breakpoints

Number of table dimensions — Number of lookup table dimensions

2 (default) | 1 | 3 | 4 | ... | 30

Enter the number of dimensions of the lookup table. This parameter determines:

- The number of independent variables for the table and the number of block inputs
- The number of breakpoint sets to specify

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

For example, a table with a size of $M \times N \times \dots$ means that the size of dimension 1 is M , the size of dimension 2 is N , and so forth. M must match the first breakpoint length, N must match the second breakpoint length, and so forth.

Programmatic Use

Block Parameter: NumberOfTableDimensions

Type: character vector

Values: '1' | '2' | '3' | '4' | ... | 30
Default: '2'

Data specification — Method of table and breakpoint specification

Table and breakpoints (default) | Lookup table object

From the list, select:

- Table and breakpoints — Specify the table data and breakpoints. Selecting this option enables these parameters:
 - Table data
 - Breakpoints specification
 - Breakpoints 1
 - Breakpoints 2
 - Edit table and breakpoints
- Lookup table object — Use an existing lookup table (`Simulink.LookupTable`) object. Selecting this option enables the **Name** field and **Edit table and breakpoints** button.

Programmatic Use

Block Parameter: DataSpecification

Type: character vector

Values: 'Table and breakpoints' | 'Lookup table object'

Default: 'Table and breakpoints'

Name — Name of the lookup table object

[] (default) | `Simulink.LookupTable` object

Enter the name of the lookup table (`Simulink.LookupTable`) object. If a `Simulink.LookupTable` object does not exist, click the action button  and select **Create**. The corresponding parameters of the new lookup table object are automatically populated with the block information.

Dependencies

To enable this parameter, set **Data specification** to Lookup table object.

Programmatic Use

Block Parameter: LookupTableObject

Type: character vector

Values: name of a `Simulink.LookupTable` object

Default: ''

Table data — Define the table of output values

[4 5 6; 16 19 20; 10 18 23] (default) | matrix of values

Enter the table of output values.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as []) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`.

Programmatic Use

Block Parameter: `Table`

Type: character vector

Values: matrix of table values

Default: `'[4 5 6; 16 19 20; 10 18 23]'`

Breakpoints specification — Method of breakpoint specification

`Explicit values (default) | Even spacing`

Specify whether to enter data as explicit breakpoints or as parameters that generate evenly spaced breakpoints.

- To explicitly specify breakpoint data, set this parameter to `Explicit values` and enter breakpoint data in the text box next to the **Breakpoints** parameters.
- To specify parameters that generate evenly spaced breakpoints, set this parameter to `Even spacing` and enter values for the **First point** and **Spacing** parameters for each dimension of breakpoint data. The block calculates the number of points to generate from the table data.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsSpecification`

Type: character vector

Values: `'Explicit values' | 'Even spacing'`

Default: `'Explicit values'`

Breakpoints — Explicit breakpoint values, or first point and spacing of breakpoints

`[1:3] (default) | 1-by-n or n-by-1 vector of monotonically increasing values`

Specify the breakpoint data explicitly or as evenly-spaced breakpoints, based on the value of the **Breakpoints specification** parameter.

- If you set **Breakpoints specification** to `Explicit values`, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.
- If you set **Breakpoints specification** to `Even spacing`, enter the parameters **First point** and **Spacing** in each **Breakpoints** row to generate evenly-spaced breakpoints in the respective dimension. Your table data determines the number of evenly spaced points.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1`

Type: character vector

Values: 1-by-n or n-by-1 vector of monotonically increasing values

Default: `'[1:3]'`

First point — First point in evenly spaced breakpoint data

1 (default) | scalar

Specify the first point in your evenly spaced breakpoint data as a real-valued, finite, scalar. This parameter is available when **Breakpoints specification** is set to Even spacing.

Dependencies

To enable this parameter, set **Data specification** to Table and breakpoints, and **Breakpoints specification** to Even spacing.

Programmatic Use

Block Parameter: BreakpointsForDimension1FirstPoint | BreakpointsForDimension2FirstPoint

Type: character vector

Values: real-valued, finite, scalar

Default: '1'

Spacing — Spacing between evenly spaced breakpoints

1 (default) | scalar

Specify the spacing between points in your evenly-spaced breakpoint data.

Dependencies

To enable this parameter, set **Data specification** to Table and breakpoints, and **Breakpoints specification** to Even spacing.

Programmatic Use

Block Parameter: BreakpointsForDimension1Spacing | BreakpointsForDimension2Spacing

Type: character vector

Values: positive, real-valued, finite, scalar

Default: '1'

Edit table and breakpoints — Launch Lookup Table Editor dialog box

button

Click this button to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

Clicking this button for a lookup table object lets you edit the object and save the new values for the object.

Algorithm**Lookup method****Interpolation method — Method of interpolation between breakpoint values**

Linear point-slope (default) | Flat | Nearest | Linear Lagrange | Cubic spline | Akima spline

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. For more information on interpolation methods, see “Interpolation Methods”.

Dependencies

- If you select `Cubic spline`, the block supports only scalar signals. The other interpolation methods support nonscalar signals.
- If you select `Akima spline`, the extrapolation method can only be `Akima spline`.

When set to the modified Akima interpolation method, this block does not support:

- Row-major array layout and algorithms optimized for row-major array layout
- Scaled double and fixed-point data types
- `Simulink.LookupTable` objects
- Code generation when the configuration parameter **Code Generation > Interface > Support non-finite numbers** check box is selected

Programmatic Use

Block Parameter: `InterpMethod`

Type: character vector

Values: `'Linear point-slope'` | `'Flat'` | `'Nearest'` | `'Linear Lagrange'` | `'Cubic spline'` | `'Akima spline'`

Default: `'Linear point-slope'`

Extrapolation method — Method of handling input values that fall outside the range of a breakpoint data set

`Linear (default)` | `Clip` | `Cubic spline` | `Akima spline`

Select `Clip`, `Linear`, or `Cubic spline`. See “Extrapolation Methods” for more information.

If the extrapolation method is `Linear`, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is linear Lagrange, the extrapolation method inherits the linear Lagrange equation to compute the extrapolated value.

Dependencies

- To select `Cubic spline` for **Extrapolation method**, you must also select `Cubic spline` for **Interpolation method**.
- To select `Akima spline` for **Extrapolation method**, you must also select `Akima spline` for **Interpolation method**.

Programmatic Use

Block Parameter: `ExtrapMethod`

Type: character vector

Values: `'Linear'` | `'Clip'` | `'Cubic spline'` | `'Akima spline'`

Default: `'Linear'`

Index search method — Method of calculating table indices

`Evenly spaced points (default)` | `Linear search` | `Binary search`

Select `Evenly spaced points`, `Linear search`, or `Binary search`. Each search method has speed advantages in different circumstances:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting `Evenly spaced points` to calculate table indices.

This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.

Note Set **Index search method** to **Evenly spaced points** when using the `Simulink.LookupTable` object to specify table data and the **Breakpoints Specification** parameter of the referenced `Simulink.LookupTable` object is set to **Even spacing**.

- For unevenly spaced breakpoint sets, follow these guidelines:
 - If input signals do not vary much between time steps, selecting **Linear search** with **Begin index search using previous index result** produces the best performance.
 - If input signals jump more than one or two table intervals per time step, selecting **Binary search** produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
 - The index search method is **Evenly spaced points**.
-

Programmatic Use

Block Parameter: `IndexSearchMethod`

Type: character vector

Values: 'Binary search' | 'Evenly spaced points' | 'Linear search'

Default: 'Binary search'

Begin index search using previous index result — Start using the index from the previous time step

off (default) | on

Select this check box when you want the block to start its search using the index found at the previous time step. For inputs that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Dependencies

To enable this parameter, set **Index search method** to **Linear search** or **Binary search**.

Programmatic Use

Block Parameter: `BeginIndexSearchUsing PreviousIndexResult`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Diagnostic for out-of-range input — Block action when input is out of range

None (default) | Warning | Error

Specify whether to produce a warning or error when the input is out of range. Options include:

- **None** — Produce no response.
- **Warning** — Display a warning and continue the simulation.

- **Error** — Terminate the simulation and display an error.

Programmatic Use

Block Parameter: DiagnosticForOutOfRangeInput

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'None'

Use last table value for inputs at or above last breakpoint — Method for computing output for inputs at or above last breakpoint

off (default) | on

Using this check box, specify the indexing convention that the block uses to address the last element of a breakpoint set and its corresponding table value. This check box is relevant if the input is equal to or larger than the last element of the breakpoint data. Due to rounding, selecting and clearing this check box may result in differing results for the last breakpoint between simulation and code generation.

Check Box	Index Used by Block	Interval Fraction
Selected	Last element of breakpoint data on the Table and Breakpoints tab	0
Cleared	Next-to-last element of breakpoint data on the Table and Breakpoints tab	1

Given an input u within range of a breakpoint set bp , the interval fraction f , in the range $0 \leq f < 1$, is computed as shown below.

Suppose the breakpoint set is [1 4 5] and input u is 5.5. If you select this check box, the index is that of the last element (5) and the interval fraction is 0. If you clear this check box, the index is that of the next-to-last element (4) and the interval fraction is 1.

Dependencies

To enable this parameter, set:

- **Interpolation method** to Linear.

- **Extrapolation method** to Clip.

Programmatic Use

Block Parameter: UseLastTableValue

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Input settings

Use one input port for all input data – Use only one input port

off (default) | on

Select this check box to use only one input port that expects a signal that is n elements wide for an n-dimensional table. This option is useful for removing line clutter on a block diagram with many lookup tables.

Note When you select this check box, one input port with the label u appears on the block.

Programmatic Use

Block Parameter: UseOneInputPortForAllInputData

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Code generation

Remove protection against out-of-range input in generated code – Remove code that checks for out-of-range input values

off (default) | on

Specify whether or not to include code that checks for out-of-range input values.

Check Box	Result	When to Use
on	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code.	For code efficiency
off	Generated code includes conditional statements to check for out-of-range inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input is out of range, the behavior is undefined for generated code.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

Programmatic Use

Block Parameter: RemoveProtectionInput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Support tunable table size in code generation – Enable tunable table size in the generated code

off (default) | on

Select this check box to enable tunable table size in the generated code. This option enables you to change the size and values of the lookup table and breakpoint data in the generated code without regenerating or recompiling the code. You can only decrease the size of the lookup table and breakpoint data.

Dependencies

If you set **Interpolation method** to Cubic spline, this check box is not available.

Programmatic Use

Block Parameter: SupportTunableTableSize

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time – Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Maximum indices for each dimension — Maximum index value for each table dimension

[] (default) | scalar or vector of positive integer values

Example: [4 6] for a 5-by-7 table

Specify the maximum index values for each table dimension using zero-based indexing. You can specify a scalar or vector of positive integer values using the following data types:

- Built-in floating-point types: `double` and `single`
- Built-in integer types: `int8`, `int16`, `int32`, `uint8`, `uint16`, and `uint32`

Examples of valid specifications include:

- [4 6] for a 5-by-7 table
- [int8(2) int16(5) int32(9)] for a 3-by-6-by-10 table
- A `Simulink.Parameter` whose value on generating code is one less than the dimensions of the table data. For more information, see “Tunable Table Size in the Generated Code” on page 1-861.

Dependencies

To enable this parameter, select **Support tunable table size in code generation**. On tuning this parameter in the generated code, provide the new table data and breakpoints along with the tuned parameter value.

Programmatic Use

Block Parameter: MaximumIndicesForEachDimension

Type: character vector

Values: scalar or vector of positive integer values

Default: '[]'

Data Types**Table data — Data type of table data**

Inherit: Same as output (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | <data type expression>

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
 - Sharing of prescaled table data between two n-D Lookup Table blocks with different output data types
 - Sharing of custom storage table data in the generated code for blocks with different output data types
-

Programmatic Use

Block Parameter: TableDataTypeStr

Type: character vector

Values: 'Inherit: Inherit from 'Table data'' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as output'

Table data Minimum — Minimum value of the table data

[] | scalar

Specify the minimum value for table data. The default value is [] (unspecified).

Programmatic Use

Block Parameter: TableMin

Type: character vector

Values: scalar

Default: '[]'

Table data Maximum — Maximum value of the table data

[] | scalar

Specify the maximum value for table data. The default value is [] (unspecified).

Programmatic Use

Block Parameter: TableMax

Type: character vector

Values: scalar

Default: '[]'

Breakpoints — Breakpoint data type

Inherit: Same as corresponding input (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the data type for a set of breakpoint data. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same as corresponding input

- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Tip

- Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.
 - If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
 - For enumerated data, **Extrapolation method** must be `Clip`.
 - The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.
-

This is a limitation for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a breakpoint data type different from the corresponding input data type for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal
 - Sharing of prescaled breakpoint data between two n-D Lookup Table blocks with different input data types
 - Sharing of custom storage breakpoint data in the generated code for blocks with different input data types
-

Programmatic Use

Block Parameter: `BreakpointsForDimension1DataTypeStr` | `BreakpointsForDimension2DataTypeStr` | ... | `BreakpointsForDimension30DataTypeStr`

Type: character vector

Values: `'Inherit: Same as corresponding input'` | `'Inherit: Inherit from 'Breakpoint data''` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: 'Inherit: Same as corresponding input'

Breakpoints Minimum — Minimum value breakpoint data can have

[] | scalar

Specify the minimum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Min | BreakpointsForDimension2Min
| ... | BreakpointsForDimension30Min

Type: character vector

Values: scalar

Default: '[]'

Breakpoints Maximum — Maximum value breakpoint data can have

[] | scalar

Specify the maximum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Max | BreakpointsForDimension2Max
| ... | BreakpointsForDimension30Max

Type: character vector

Values: scalar

Default: '[]'

Fraction — Fraction data type

Inherit: Inherit via internal rule (default) | double | single | fixdt(1,16,0) | <data type expression>

Specify the fraction data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: FractionDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'double' | 'single' |
'fixdt(1,16,0)' | <data type expression>

Default: 'Inherit: Inherit via internal rule'

Intermediate results — Intermediate results data type

Inherit: Same as output (default) | double | single | int8 | uint8 | int16 | uint16 | int32
| uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type
expression>

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher (or lower) precision for internal computations than for table data or output data.

Programmatic Use

Block Parameter: `IntermediateResultsDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`

Default: `'Inherit: Same as output'`

Output — Output data type

`Inherit: Same as input (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'Inherit: Same as first input' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`

Default: `'Inherit: Same as first input'`

Output Minimum — Minimum value the block can output

[] | scalar

Specify the minimum value that the block outputs. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** scalar**Default:** ' [] '**Output Maximum — Maximum value the block can output**

[] | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** scalar**Default:** ' [] '**Internal rule priority — Internal rule for intermediate calculations**

Speed (default) | Precision

Specify the internal rule for intermediate calculations. Select Speed for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use**Block Parameter:** InternalRulePriority**Type:** character vector**Values:** 'Speed' | 'Precision'**Default:** 'Speed'**Require all inputs to have the same data type — Require all inputs to have the same data type**

on (default) | off

Select to require all inputs to have the same data type.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode — Rounding mode for fixed-point operations**

Simplest (default) | Ceiling | Convergent | Floor | Nearest | Round | Zero

Specify the rounding mode for fixed-point lookup table calculations that occur during simulation or execution of code generated from the model. For more information, see “Rounding” (Fixed-Point Designer).

This option does not affect rounding of values of block parameters. Simulink rounds such values to the nearest representable integer value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the edit field on the block dialog box.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Simplest'**Saturate on integer overflow — Method of overflow action**

off (default) | on

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box (on).	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box (off).	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tip If you save your model as version R2009a or earlier, this check box setting has no effect and no saturation code appears. This behavior preserves backward compatibility.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Tunable Table Size in the Generated Code

Suppose that you have a lookup table and want to make the size tunable in the generated code. When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to configure lookup table data for calibration in the generated code, use the `SupportTunableSize` property of the objects to enable a tunable table size. When you do not use these classes, use the **Support tunable table size in code generation** parameter in an n-D Lookup Table block to enable a tunable table size.

Assume that:

- You define a `Simulink.Parameter` structure in the preload function of your model:

```
p = Simulink.Parameter;
p.Value.MaxIdx = [2 2];
p.Value.BP1 = [1 2 3];
p.Value.BP2 = [1 4 16];
p.Value.Table = [4 5 6; 16 19 20; 10 18 23];
p.DataType = 'Bus: slLookupTable';
p.CoderInfo.StorageClass = 'ExportedGlobal';

% Create bus object slBus1 from MATLAB structure
Simulink.Bus.createObject(p.Value);
slLookupTable = slBus1;
slLookupTable.Elements(1).DataType = 'uint32';
```

- These block parameters apply in the n-D Lookup Table block.

Parameter	Value
Number of table dimensions	2
Table data	p.Table
Breakpoints 1	p.BP1
Breakpoints 2	p.BP2
Support tunable table size in code generation	on
Maximum indices for each dimension	p.MaxIdx

The generated `model_types.h` header file contains a type definition that looks something like this.

```
typedef struct {
    uint32_T MaxIdx[2];
    real_T BP1[3];
    real_T BP2[3];
    real_T Table[9];
} slLookupTable;
```

The generated `model.c` file contains code that looks something like this.

```
/* Exported block parameters */
slLookupTable p = {
    { 2U, 2U },

    { 1.0, 2.0, 3.0 },

    { 1.0, 4.0, 16.0 },

    { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
};

/* More code */

/* Model output function */
static void ex_lut_nd_tunable_table_output(int_T tid)
{
    /* Lookup_n-D: '<Root>/n-D Lookup Table' incorporates:
     * Inport: '<Root>/In1'
     */
}
```

```

    * Inport: '<Root>/In2'
    */
    Y = look2_binlcpw(U1, U2, p.BP1, p.BP2, p.Table, ...
p.MaxIdx, p.MaxIdx[0] + 1U);

    /* Outport: '<Root>/Out1' */
    ex_lut_nd_tunable_table_Y.Out1 = Y;

    /* tid is required for a uniform function interface.
    * Argument tid is not used in the function. */
    UNUSED_PARAMETER(tid);
}

```

The highlighted line of code specifies a tunable table size for the lookup table. You can change the size and values of the lookup table and breakpoint data without regenerating or recompiling the code.

Enumerated Values in Lookup Tables

Suppose that you have a lookup table with an enumerated class like this defined:

```

classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(-1),
        NEUTRAL(0)
    end
end

```

n-D Lookup block has these settings:

- **Number of dimensions** to 1.
- **Table data** value is [5 10 20 40 80 -5 0].
- **Breakpoints 1** value is enumeration('Gears').
- Interpolation method is Flat.
- For an unordered search, set **Index search method** to Linear search and clear the **Begin index search using previous index result** check box.

Simulation produces a vector [10 -5 80], which correspond to GEAR2, REVERSE, and SPORTS.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For information about HDL code generation support for 2-D Lookup Table blocks, see “HDL Code Generation” on page 1-886.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

n-D Lookup Table

Approximate n-dimensional function

Library: Simulink / Lookup Tables
HDL Coder / Lookup Tables

Description

Supported Block Operations

The 1-D, 2-D, and n-D Lookup Table blocks evaluate a sampled representation of a function in N variables

$$y = F(x_1, x_2, x_3, \dots, x_N)$$

where the function F can be empirical. The block maps inputs to an output value by looking up or interpolating a table of values you define with block parameters. The block supports flat (constant), linear (linear point-slope), Lagrange (linear Lagrange), nearest, cubic-spline, and Akima spline interpolation methods. You can apply these methods to a table of any dimension from 1 through 30.

In the following block, the first input identifies the first dimension (row) breakpoints, the second input identifies the second dimension (column) breakpoints, and so on.

See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the 2-D and n-D Lookup Table block behavior changes from column-major to row-major. For these blocks, the column-major and row-major algorithms may differ in the order of the output calculations, possibly resulting in slightly different numerical values. This capability requires a Simulink Coder or Embedded Coder license. For more information on row-major support, see “Code Generation of Matrices and Arrays” (Simulink Coder).

Specification of Breakpoint and Table Data

These block parameters define the breakpoint and table data.

Block Parameter	Purpose
Number of table dimensions	Specifies the number of dimensions of your lookup table.
Breakpoints	Specifies a breakpoint vector that corresponds to each dimension of your lookup table.
Table data	Defines the associated set of output values.

Tip Evenly spaced breakpoints can make the generated code division-free. For more information, see `fixpt_evenspace_cleanup` and “Identify questionable fixed-point operations” (Embedded Coder).

How the Block Generates Output

The n-D, 1-D and 2-D Lookup Table blocks generate output by looking up or estimating table values based on the input values.

Block Inputs	n-D Lookup Table Block Behavior
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Other Blocks that Perform Equivalent Operations

You can use the Interpolation Using Prelookup block with the Prelookup block to perform the equivalent operation of one n-D Lookup Table block. This combination of blocks offers greater flexibility that can result in more efficient simulation performance for linear interpolations.

When the lookup operation is an array access that does not require interpolation, use the Direct Lookup Table (n-D) block. For example, if you have an integer value k and you want the k th element of a table, $y = \text{table}(k)$, interpolation is unnecessary.

Ports

Input

u1 — First-dimension (row) inputs

scalar | vector | matrix

Real-valued inputs to the **u1** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: `0:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `enumerated` | `fixed point`

uN — n-th dimension input values

scalar | vector | matrix

Real-valued inputs to the **uN** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: 0:10

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `enumerated` | `fixed point`

Output

Port_1 — Output computed by looking up or estimating table values

`scalar` | `vector` | `matrix`

Output generated by looking up or estimating table values based on the input values:

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Table and Breakpoints

Number of table dimensions — Number of lookup table dimensions

3 (default) | 1 | 2 | 4 | ... | 30

Enter the number of dimensions of the lookup table. This parameter determines:

- The number of independent variables for the table and the number of block inputs
- The number of breakpoint sets to specify

Value	Setting
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

For example, a table with a size of $M \times N \times \dots$ means that the size of dimension 1 is M , the size of dimension 2 is N , and so forth. M must match the first breakpoint length, N must match the second breakpoint length, and so forth.

Programmatic Use

Block Parameter: `NumberOfTableDimensions`

Type: `character vector`

Values: '1' | '2' | '3' | '4' | ... | 30
Default: '3'

Data specification — Method of table and breakpoint specification

Table and breakpoints (default) | Lookup table object

From the list, select:

- Table and breakpoints — Specify the table data and breakpoints. Selecting this option enables the following parameters:
 - Table data
 - Breakpoints specification
 - Breakpoints 1
 - Breakpoints 2
 - Breakpoints 3
 - Edit table and breakpoints
- Lookup table object — Use an existing lookup table (`Simulink.LookupTable`) object. Selecting this option enables the **Name** field and **Edit table and breakpoints** button.

Programmatic Use

Block Parameter: DataSpecification

Type: character vector

Values: 'Table and breakpoints' | 'Lookup table object'

Default: 'Table and breakpoints'

Name — Name of the lookup table object

[] (default) | `Simulink.LookupTable` object

Enter the name of the lookup table (`Simulink.LookupTable`) object. If a `Simulink.LookupTable`

object does not exist, click the action button  and select **Create**. The corresponding parameters of the new lookup table object are automatically populated with the block information.

Dependencies

To enable this parameter, set **Data specification** to `Lookup table object`.

Programmatic Use

Block Parameter: LookupTableObject

Type: character vector

Values: name of a `Simulink.LookupTable` object

Default: ''

Table data — Define the table of output values

`reshape(repmat([4 5 6;16 19 20;10 18 23],1,2),[3,3,2])` (default) | matrix of values with dimensions that match the **Number of table dimensions**

Enter the table of output values.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as []) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`.

Programmatic Use

Block Parameter: `Table`

Type: character vector

Values: matrix of table values

Default: `'reshape(repmat([4 5 6;16 19 20;10 18 23],1,2),[3,3,2])'`

Breakpoints specification — Method of breakpoint specification

`Explicit values (default) | Even spacing`

Specify whether to enter data as explicit breakpoints or as parameters that generate evenly spaced breakpoints.

- To explicitly specify breakpoint data, set this parameter to `Explicit values` and enter breakpoint data in the text box next to the **Breakpoints** parameters.
- To specify parameters that generate evenly spaced breakpoints, set this parameter to `Even spacing` and enter values for the **First point** and **Spacing** parameters for each dimension of breakpoint data. The block calculates the number of points to generate from the table data.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsSpecification`

Type: character vector

Values: `'Explicit values' | 'Even spacing'`

Default: `'Explicit values'`

Breakpoints — Explicit breakpoint values, or first point and spacing of breakpoints

`[10,22,31] (default) | 1-by-n or n-by-1 vector of monotonically increasing values`

Specify the breakpoint data explicitly or as evenly-spaced breakpoints, based on the value of the **Breakpoints specification** parameter.

- If you set **Breakpoints specification** to `Explicit values`, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.
- If you set **Breakpoints specification** to `Even spacing`, enter the parameters **First point** and **Spacing** in each **Breakpoints** row to generate evenly-spaced breakpoints in the respective dimension. Your table data determines the number of evenly spaced points.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1 | BreakpointsForDimension2 | ... | BreakpointsForDimension30` |

Type: character vector

Values: 1-by-n or n-by-1 vector of monotonically increasing values

Default: '[10, 22, 31]'

First point — First point in evenly spaced breakpoint data

1 (default) | scalar

Specify the first point in your evenly spaced breakpoint data as a real-valued, finite scalar. This parameter is available when **Breakpoints specification** is set to Even spacing.

Dependencies

To enable this parameter, set **Data specification** to Table and breakpoints, and **Breakpoints specification** to Even spacing.

Programmatic Use

Block Parameter: BreakpointsForDimension1FirstPoint |
BreakpointsForDimension2FirstPoint | ... |
BreakpointsForDimension30FirstPoint |

Type: character vector

Values: real-valued, finite, scalar

Default: '1'

Spacing — Spacing between evenly spaced breakpoints

1 (default) | scalar

Specify the spacing between points in your evenly-spaced breakpoint data.

Dependencies

To enable this parameter, set **Data specification** to Table and breakpoints, and **Breakpoints specification** to Even spacing.

Programmatic Use

Block Parameter: BreakpointsForDimension1Spacing |
BreakpointsForDimension2Spacing | ... | BreakpointsForDimension30Spacing |

Type: character vector

Values: positive, real-valued, finite, scalar

Default: '1'

Edit table and breakpoints — Launch Lookup Table Editor dialog box

button

Click this button to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

Clicking this button for a lookup table object lets you edit the object and save the new values for the object.

Algorithm

Lookup method

Interpolation method — Method of interpolation between breakpoint values

Linear point-slope (default) | Flat | Nearest | Linear Lagrange | Cubic spline | Akima spline

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. For more information on interpolation methods, see “Interpolation Methods”.

Dependencies

- If you select `Cubic spline`, the block supports only scalar signals. The other interpolation methods support nonscalar signals.
- If you select `Akima spline`, the extrapolation method can only be `Akima spline`.

When set to the modified Akima interpolation method, this block does not support:

- Row-major array layout and algorithms optimized for row-major array layout
- Scaled double and fixed-point data types
- `Simulink.LookupTable` objects
- Code generation when the configuration parameter **Code Generation > Interface > Support non-finite numbers** check box is selected

Programmatic Use

Block Parameter: `InterpMethod`

Type: character vector

Values: `'Linear point-slope'` | `'Flat'` | `'Nearest'` | `'Linear Lagrange'` | `'Cubic spline'` | `'Akima spline'`

Default: `'Linear point-slope'`

Extrapolation method — Method of handling input values that fall outside the range of a breakpoint data set

`Linear (default)` | `Clip` | `Cubic spline` | `Akima spline`

Select `Clip`, `Linear`, or `Cubic spline`. See “Extrapolation Methods” for more information.

If the extrapolation method is `Linear`, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is linear Lagrange, the extrapolation method inherits the linear Lagrange equation to compute the extrapolated value.

Dependencies

- To select `Cubic spline` for **Extrapolation method**, you must also select `Cubic spline` for **Interpolation method**.
- To select `Akima spline` for **Extrapolation method**, you must also select `Akima spline` for **Interpolation method**.

Programmatic Use

Block Parameter: `ExtrapMethod`

Type: character vector

Values: `'Linear'` | `'Clip'` | `'Cubic spline'` | `'Akima spline'`

Default: `'Linear'`

Index search method — Method of calculating table indices

`Evenly spaced points (default)` | `Linear search` | `Binary search`

Select `Evenly spaced points`, `Linear search`, or `Binary search`. Each search method has speed advantages in different circumstances:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting `Evenly spaced points` to calculate table indices.

This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.

Note Set **Index search method** to `Evenly spaced points` when using the `Simulink.LookupTable` object to specify table data and the **Breakpoints Specification** parameter of the referenced `Simulink.LookupTable` object is set to `Even spacing`.

- For unevenly spaced breakpoint sets, follow these guidelines:
 - If input signals do not vary much between time steps, selecting `Linear search` with **Begin index search using previous index result** produces the best performance.
 - If input signals jump more than one or two table intervals per time step, selecting `Binary search` produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
 - The index search method is `Evenly spaced points`.
-

Programmatic Use

Block Parameter: `IndexSearchMethod`

Type: character vector

Values: `'Binary search'` | `'Evenly spaced points'` | `'Linear search'`

Default: `'Binary search'`

Begin index search using previous index result – Start using the index from the previous time step

`off (default)` | `on`

Select this check box when you want the block to start its search using the index found at the previous time step. For inputs that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Dependencies

To enable this parameter, set **Index search method** to `Linear search` or `Binary search`.

Programmatic Use

Block Parameter: `BeginIndexSearchUsing PreviousIndexResult`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Diagnostic for out-of-range input – Block action when input is out of range

None (default) | Warning | Error

Specify whether to produce a warning or error when the input is out of range. Options include:

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use**Block Parameter:** DiagnosticForOutOfRangeInput**Type:** character vector**Values:** 'None' | 'Warning' | 'Error'**Default:** 'None'**Use last table value for inputs at or above last breakpoint – Method for computing output for inputs at or above last breakpoint**

off (default) | on

Using this check box, specify the indexing convention that the block uses to address the last element of a breakpoint set and its corresponding table value. This check box is relevant if the input is equal to or larger than the last element of the breakpoint data. Due to rounding, selecting and clearing this check box may result in differing results for the last breakpoint between simulation and code generation.

Check Box	Index Used by Block	Interval Fraction
Selected	Last element of breakpoint data on the Table and Breakpoints tab	0
Cleared	Next-to-last element of breakpoint data on the Table and Breakpoints tab	1

Given an input u within range of a breakpoint set bp , the interval fraction f , in the range $0 \leq f < 1$, is computed as shown below.

Suppose the breakpoint set is [1 4 5] and input u is 5.5. If you select this check box, the index is that of the last element (5) and the interval fraction is 0. If you clear this check box, the index is that of the next-to-last element (4) and the interval fraction is 1.

Dependencies

To enable this parameter, set:

- **Interpolation method** to Linear.
- **Extrapolation method** to Clip.

Programmatic Use

Block Parameter: UseLastTableValue

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Input settings

Use one input port for all input data — Use only one input port

off (default) | on

Select this check box to use only one input port that expects a signal that is n elements wide for an n -dimensional table. This option is useful for removing line clutter on a block diagram with many lookup tables.

Note When you select this check box, one input port with the label u appears on the block.

Programmatic Use

Block Parameter: UseOneInputPortForAllInputData

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Code generation

Remove protection against out-of-range input in generated code — Remove code that checks for out-of-range input values

off (default) | on

Specify whether or not to include code that checks for out-of-range input values.

Check Box	Result	When to Use
on	<p>Generated code does not include conditional statements to check for out-of-range breakpoint inputs.</p> <p>When the input is out-of-range, it may cause undefined behavior for generated code.</p>	For code efficiency

Check Box	Result	When to Use
off	Generated code includes conditional statements to check for out-of-range inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input is out of range, the behavior is undefined for generated code.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

Programmatic Use

Block Parameter: RemoveProtectionInput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Support tunable table size in code generation – Enable tunable table size in the generated code

off (default) | on

Select this check box to enable tunable table size in the generated code. This option enables you to change the size and values of the lookup table and breakpoint data in the generated code without regenerating or recompiling the code. You can only decrease the size of the lookup table and breakpoint data.

Dependencies

If you set **Interpolation method** to Cubic spline, this check box is not available.

Programmatic Use**Block Parameter:** SupportTunableTableSize**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Sample time — Specify sample time as a value other than -1**

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar or vector**Default:** '-1'**Maximum indices for each dimension — Maximum index value for each table dimension**

[] (default) | scalar or vector of positive integer values

Example: [4 6] for a 5-by-7 table

Specify the maximum index values for each table dimension using zero-based indexing. You can specify a scalar or vector of positive integer values using the following data types:

- Built-in floating-point types: `double` and `single`
- Built-in integer types: `int8`, `int16`, `int32`, `uint8`, `uint16`, and `uint32`

Examples of valid specifications include:

- [4 6] for a 5-by-7 table
- [int8(2) int16(5) int32(9)] for a 3-by-6-by-10 table
- A `Simulink.Parameter` whose value on generating code is one less than the dimensions of the table data. For more information, see “Tunable Table Size in the Generated Code” on page 1-883.

Dependencies

To enable this parameter, select **Support tunable table size in code generation**. On tuning this parameter in the generated code, provide the new table data and breakpoints along with the tuned parameter value.

Programmatic Use**Block Parameter:** MaximumIndicesForEachDimension**Type:** character vector**Values:** scalar or vector of positive integer values**Default:** '[]'

Data Types

Table data — Data type of table data

Inherit: Same as output (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
 - Sharing of prescaled table data between two n-D Lookup Table blocks with different output data types
 - Sharing of custom storage table data in the generated code for blocks with different output data types
-

Programmatic Use

Block Parameter: `TableDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit from 'Table data''` | `'Inherit: Same as output'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'Inherit: Same as output'`

Table data Minimum — Minimum value of the table data

`[]` | scalar

Specify the minimum value for table data. The default value is `[]` (unspecified).

Programmatic Use

Block Parameter: `TableMin`

Type: character vector

Values: scalar

Default: `'[]'`

Table data Maximum — Maximum value of the table data

`[]` | scalar

Specify the maximum value for table data. The default value is `[]` (unspecified).

Programmatic Use**Block Parameter:** TableMax**Type:** character vector**Values:** scalar**Default:** '[]'**Breakpoints — Breakpoint data type**

Inherit: Same as corresponding input (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the data type for a set of breakpoint data. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as corresponding input`
- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Tip

- Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.
- If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
- For enumerated data, **Extrapolation method** must be `Clip`.
- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

This is a limitation for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a breakpoint data type different from the corresponding input data type for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal
- Sharing of prescaled breakpoint data between two n-D Lookup Table blocks with different input data types

- Sharing of custom storage breakpoint data in the generated code for blocks with different input data types

Programmatic Use

Block Parameter: BreakpointsForDimension1DataTypeStr | BreakpointsForDimension2DataTypeStr | ... | BreakpointsForDimension30DataTypeStr

Type: character vector

Values: 'Inherit: Same as corresponding input' | 'Inherit: Inherit from 'Breakpoint data'' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as corresponding input'

Breakpoints Minimum — Minimum value breakpoint data can have

[] | scalar

Specify the minimum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Min | BreakpointsForDimension2Min | ... | BreakpointsForDimension30Min

Type: character vector

Values: scalar

Default: '[]'

Breakpoints Maximum — Maximum value breakpoint data can have

[] | scalar

Specify the maximum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Max | BreakpointsForDimension2Max | ... | BreakpointsForDimension30Max

Type: character vector

Values: scalar

Default: '[]'

Fraction — Fraction data type

Inherit: Inherit via internal rule (default) | double | single | fixdt(1,16,0) | <data type expression>

Specify the fraction data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: FractionDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'double' | 'single' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Intermediate results — Intermediate results data type

Inherit: Same as output (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher (or lower) precision for internal computations than for table data or output data.

Programmatic Use

Block Parameter: IntermediateResultsDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as output'

Output — Output data type

Inherit: Same as input (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object

- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: 'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'Inherit: Same as first input' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression'

Default: 'Inherit: Same as first input'

Output Minimum — Minimum value the block can output

`[]` | scalar

Specify the minimum value that the block outputs. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use

Block Parameter: `OutMin`

Type: character vector

Values: scalar

Default: '`[]`'

Output Maximum — Maximum value the block can output

`[]` | scalar

Specify the maximum value that the block can output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use

Block Parameter: `OutMax`

Type: character vector

Values: scalar

Default: '`[]`'

Internal rule priority — Internal rule for intermediate calculations

Speed (default) | Precision

Specify the internal rule for intermediate calculations. Select Speed for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use**Block Parameter:** InternalRulePriority**Type:** character vector**Values:** 'Speed' | 'Precision'**Default:** 'Speed'**Require all inputs to have the same data type — Require all inputs to have the same data type**

on (default) | off

Select to require all inputs to have the same data type.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode — Rounding mode for fixed-point operations**

Simplest (default) | Ceiling | Convergent | Floor | Nearest | Round | Zero

Specify the rounding mode for fixed-point lookup table calculations that occur during simulation or execution of code generated from the model. For more information, see “Rounding” (Fixed-Point Designer).

This option does not affect rounding of values of block parameters. Simulink rounds such values to the nearest representable integer value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the edit field on the block dialog box.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Simplest'

Saturate on integer overflow – Method of overflow action

off (default) | on

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box (on).	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tip If you save your model as version R2009a or earlier, this check box setting has no effect and no saturation code appears. This behavior preserves backward compatibility.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

More About**Tunable Table Size in the Generated Code**

Suppose that you have a lookup table and want to make the size tunable in the generated code. When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to configure lookup table

data for calibration in the generated code, use the `SupportTunableSize` property of the objects to enable a tunable table size. When you do not use these classes, use the **Support tunable table size in code generation** parameter in an n-D Lookup Table block to enable a tunable table size.

Assume that:

- You define a `Simulink.Parameter` structure in the preload function of your model:

```
p = Simulink.Parameter;
p.Value.MaxIdx = [2 2];
p.Value.BP1 = [1 2 3];
p.Value.BP2 = [1 4 16];
p.Value.Table = [4 5 6; 16 19 20; 10 18 23];
p.DataType = 'Bus: slLookupTable';
p.CoderInfo.StorageClass = 'ExportedGlobal';

% Create bus object slBus1 from MATLAB structure
Simulink.Bus.createObject(p.Value);
slLookupTable = slBus1;
slLookupTable.Elements(1).DataType = 'uint32';
```

- These block parameters apply in the n-D Lookup Table block.

Parameter	Value
Number of table dimensions	2
Table data	p.Table
Breakpoints 1	p.BP1
Breakpoints 2	p.BP2
Support tunable table size in code generation	on
Maximum indices for each dimension	p.MaxIdx

The generated `model_types.h` header file contains a type definition that looks something like this.

```
typedef struct {
    uint32_T MaxIdx[2];
    real_T BP1[3];
    real_T BP2[3];
    real_T Table[9];
} slLookupTable;
```

The generated `model.c` file contains code that looks something like this.

```
/* Exported block parameters */
slLookupTable p = {
    { 2U, 2U },

    { 1.0, 2.0, 3.0 },

    { 1.0, 4.0, 16.0 },

    { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
};

/* More code */
```

```

/* Model output function */
static void ex_lut_nd_tunable_table_output(int_T tid)
{
  /* Lookup_n-D: '<Root>/n-D Lookup Table' incorporates:
   * Inport: '<Root>/In1'
   * Inport: '<Root>/In2'
   */
  Y = look2_binlcpw(U1, U2, p.BP1, p.BP2, p.Table, ...
p.MaxIdx, p.MaxIdx[0] + 1U);

  /* Outport: '<Root>/Out1' */
  ex_lut_nd_tunable_table_Y.Out1 = Y;

  /* tid is required for a uniform function interface.
   * Argument tid is not used in the function. */
  UNUSED_PARAMETER(tid);
}

```

The highlighted line of code specifies a tunable table size for the lookup table. You can change the size and values of the lookup table and breakpoint data without regenerating or recompiling the code.

Enumerated Values in Lookup Tables

Suppose that you have a lookup table with an enumerated class like this defined:

```

classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(-1),
        NEUTRAL(0)
    end
end

```

n-D Lookup block has these settings:

- **Number of dimensions** to 1.
- **Table data** value is [5 10 20 40 80 -5 0].
- **Breakpoints 1** value is enumeration('Gears').
- Interpolation method is Flat.
- For an unordered search, set **Index search method** to Linear search and clear the **Begin index search using previous index result** check box.

Simulation produces a vector [10 -5 80], which correspond to GEAR2, REVERSE, and SPORTS.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Restrictions

MAX 10 Device Settings

If you use Intel MAX 10 device, to map the lookup table to RAM, add this Tcl command when creating the project in the Quartus tool:

```
set_global_assignment -name INTERNAL_FLASH_UPDATE_MODE "SINGLE IMAGE WITH ERAM"
```

Required Block Settings

Block Setting	HDL Coder support
Number of table dimensions	Specify up to a maximum dimension of 2.
Breakpoints specification	Select either Explicit values or Even spacing.

Block Setting	HDL Coder support
Index search method	Select <code>Evenly spaced points</code> .
Extrapolation method	Select <code>Clip</code> . The code generator does not support extrapolation beyond even bounds.
Interpolation method	Select <code>Flat</code> or <code>Linear point-slope</code> .
Diagnostic for out-of-range input	Select <code>Error</code> . If you specify other options, HDL Coder generates a warning.
Use last table value for inputs at or above last breakpoint	Select this check box.
Require all inputs to have the same data type	Select this check box.
Fraction	Select <code>Inherit: Inherit via internal rule</code> .
Integer rounding mode	Select <code>Zero</code> , <code>Floor</code> , or <code>Simplest</code> .

Avoid Generation of Divide Operator

If HDL Coder encounters conditions under which a division operation is required to match the model simulation behavior, a warning is displayed. The conditions described cause this block to emit a divide operator. When you use this block for HDL code generation, avoid the following conditions:

- If the block is configured to use interpolation, a division operator is required. To avoid this requirement, set **Interpolation method** : to `Flat`.
- Uneven table spacing. HDL code generation requires the block to use the evenly spaced points algorithm. The block mapping from the input data type to the zero-based table index in general requires a division. When the breakpoint spacing is an exact power of 2, this divide is implemented as a shift instead of as a divide. To adjust the breakpoint spacing, adjust the number of breakpoints in the table, or the difference between the left and right bounds of the breakpoint range.

Table Data Typing and Sizing

- It is good practice to structure your table such that the spacing between breakpoints is a power of two. If the breakpoint spacing does not meet this condition, HDL Coder issues a warning. When the breakpoint spacing is a power of two, you can replace division operations in the prelookup step with right-shift operations.
- All ports on the block require scalar values.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Simulink PLC Coder has limited support for lookup table blocks. The coder does not support:

- Number of dimensions greater than 2
- Cubic spline interpolation method
- Begin index search using a previous index mode
- Cubic spline extrapolation method

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Lookup Table Dynamic

Approximate a one-dimensional function using dynamic table

Library: Simulink / Lookup Tables

Description

How This Block Differs from Other Lookup Table Blocks

The Lookup Table Dynamic block computes an approximation of a function $y = f(x)$ using `xdat` and `ydat` vectors. The lookup method can use interpolation, extrapolation, or the original values of the input.

Using the Lookup Table Dynamic block, you can change the table data without stopping the simulation. For example, you can incorporate new table data if the physical system you are simulating changes.

Inputs for Breakpoint and Table Data

The `xdat` vector is the breakpoint data, which must be *strictly monotonically increasing*. The value of the next element in the vector must be greater than the value of the preceding element after conversion to a fixed-point data type. Due to quantization, `xdat` can be strictly monotonic for a floating-point data type, but not after conversion to a fixed-point data type.

The `ydat` vector is the table data, which is an evaluation of the function at the breakpoint values.

Note The inputs to `xdat` and `ydat` cannot be scalar (one-element array) values. If you provide a scalar value to either of these inputs, you see an error upon simulation. Provide a 1-by-n vector to both the `xdat` and `ydat` inputs.

Lookup Table Definition

You define the lookup table by feeding `xdat` and `ydat` as 1-by-n vectors to the block. To reduce ROM usage in the generated code for this block, you can use different data types for `xdat` and `ydat`. However, these restrictions apply:

- The `xdat` breakpoint data and the `x` input vector must have the same sign, bias, and fractional slope. Also, the precision and range for `x` must be greater than or equal to the precision and range for `xdat`.
- The `ydat` table data and the `y` output vector must have the same sign, bias, and fractional slope.

Tip Breakpoints with even spacing can make Simulink Coder generated code division-free. For more information, see `fixpt_evenspace_cleanup` in the Simulink documentation and “Identify questionable fixed-point operations” (Embedded Coder) in the Simulink Coder documentation.

How the Block Generates Output

The block uses the input values to generate output using the method you select for **Lookup Method**:

Lookup Method	Block Action
Interpolation-Extrapolation	<p>Performs linear interpolation and extrapolation of the inputs.</p> <ul style="list-style-type: none"> If the input matches a breakpoint, the output is the corresponding element in the table data. If the input does not match a breakpoint, the block performs linear interpolation between two elements of the table to determine the output. If the input falls outside the range of breakpoint values, the block extrapolates using the first two or last two points. <p>Note If you select this lookup method, Simulink Coder software cannot generate code for this block.</p>
Interpolation-Use End Values (default)	Performs linear interpolation but does not extrapolate outside the end points of the breakpoint data. Instead, the block uses the end values.
Use Input Nearest	Finds the element in <code>xdat</code> nearest the current input. The corresponding element in <code>ydat</code> is the output.
Use Input Below	Finds the element in <code>xdat</code> nearest and below the current input. The corresponding element in <code>ydat</code> is the output. If there is no element in <code>xdat</code> below the current input, the block finds the nearest element.
Use Input Above	Finds the element in <code>xdat</code> nearest and above the current input. The corresponding element in <code>ydat</code> is the output. If there is no element in <code>xdat</code> above the current input, the block finds the nearest element.

Note The Use Input Nearest, Use Input Below, and Use Input Above methods perform the same action when the input `x` matches a breakpoint value.

Some continuous solvers subdivide the simulation time span into major and minor time steps. A minor time step is a subdivision of the major time step. The solver produces a result at each major time step and uses results at minor time steps to improve the accuracy of the result at the major time step. For continuous solvers, the output of the Lookup Table Dynamic block can appear like a stair step because the signal is fixed in minor time step to avoid incorrect results. For more information about the effect of solvers on block output, see “Compare Solvers” in the Simulink documentation.

Ports

Input

x — input vector

scalar | vector | 2-D array

The block accepts real-valued or complex-valued inputs.

Example: 2:12

Dependencies

The x input vector and the $xdat$ breakpoint data must have the same sign, bias, and fractional slope. Also, the precision and range for x must be greater than or equal to the precision and range for $xdat$.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `bus`

$xdat$ — breakpoint data

1-by- n vector of strictly monotonically increasing values

The $xdat$ vector is the breakpoint data, which must be strictly monotonically increasing. The value of the next element in the vector must be greater than the value of the preceding element after conversion to a fixed-point data type. Due to quantization, $xdat$ can be strictly monotonic for a floating-point data type, but not after conversion to a fixed-point data type.

Tip Breakpoints with even spacing can make Simulink Coder generated code division-free. For more information, see `fixpt_evenspace_cleanup` in the Simulink documentation and “Identify questionable fixed-point operations” (Embedded Coder) in the Simulink Coder documentation.

Example: 1:10

Dependencies

The $xdat$ breakpoint data and the x input vector must have the same sign, bias, and fractional slope. Also, the precision and range for x must be greater than or equal to the precision and range for $xdat$.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `bus`

$ydat$ — table data

1-by- n vector

The $ydat$ input is a 1-by- n vector of real-valued or complex-valued table data, which is an evaluation of the function at the breakpoint values.

Example: [0 3 12 27 48 75 108 147 192 243 300]

Dependencies

The $ydat$ table data and the y output vector must have the same sign, bias, and fractional slope.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `bus`

Output

y — Approximation of $y = f(x)$ using dynamic table data

1-by- n vector

The block computes an approximation of a function $y = f(x)$ using the $xdat$ and $ydat$ input vectors. The lookup method can use interpolation, extrapolation, or the original values of the input.

Dependencies

The ydat table data and the y output vector must have the same sign, bias, and fractional slope.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters**Main Tab****Lookup Method — Specify the lookup method**

Interpolation-Use End Values (default) | Interpolation-Extrapolation | Use Input Nearest | Use Input Below | Use Input Above

The block computes output by applying the **Lookup Method** you select to the input vectors of breakpoint data (xdat) and table data (ydat). For details, see “How the Block Generates Output” on page 1-890.

Programmatic Use

Block Parameter: LookUpMeth

Type: character vector

Values: 'Interpolation-Extrapolation' | 'Interpolation-Use End Values' | 'Use Input Nearest' | 'Use Input Below' | 'Use Input Above'

Default: 'Interpolation-Use End Values'

Signal Attributes Tab**Output data type — Output data type**

double (default) | 'Inherit: Inherit via back propagation' | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the data type of the output signal y.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

The ydat table data and the y output vector must have the same sign, bias, and fractional slope.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | <data type expression>

Default: 'double'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

The Simulink PLC Coder software does not support the Simulink Lookup Table Dynamic block. For your convenience, the plclib/Simulink/Lookup Tables library contains an implementation of a dynamic table lookup block using the Prelookup and Interpolation Using Prelookup blocks.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Magnitude-Angle to Complex

Convert magnitude and/or a phase angle signal to complex signal

Library: Simulink / Math Operations
HDL Coder / HDL Floating Point Operations

Description

Supported Operations

The Magnitude-Angle to Complex block converts magnitude and phase angle inputs to a complex output. The angle input must be in rad.

The block supports the following combinations of input dimensions when there are two block inputs:

- Two inputs of equal dimensions
- One scalar input and the other an n-dimensional array

If the block input is an array, the output is an array of complex signals. The elements of a magnitude input vector map to the magnitudes of the corresponding complex output elements. Similarly, the elements of an angle input vector map to the angles of the corresponding complex output elements. If one input is a scalar, it maps to the corresponding component (magnitude or angle) of all the complex output signals.

Effect of Out-of-Range Input on CORDIC Approximations

If you use the CORDIC approximation method [1], the block input for phase angle has the following restrictions:

- For signed fixed-point types, the input angle must fall within the range $[-2\pi, 2\pi)$ rad.
- For unsigned fixed-point types, the input angle must fall within the range $[0, 2\pi)$ rad.

The following table summarizes what happens for an out-of-range input:

Block Usage	Effect of Out-of-Range Input
Simulation	An error appears.
Generated code	Undefined behavior occurs.
Accelerator modes	

Ensure that you use an in-range input for the Magnitude-Angle to Complex block when you use the CORDIC approximation. Avoid relying on undefined behavior for generated code or accelerator modes.

Ports

Input

$|u|$ — Magnitude

scalar | vector | matrix

Magnitude, specified as a real-valued scalar, vector, or matrix.

Dependencies

- To enable this port, set **Input** to Magnitude and angle.

Limitations

- If one input has a floating-point data type, the other input must use the same data type. For example, both signals must be `double` or `single`.
- Fixed-point data types are supported only when you set the **Approximation method** to CORDIC. When one input has a fixed-point data type, the other input must also have a fixed-point data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

$\angle u$ — Radian phase angle

scalar | vector | matrix

Radian phase angle, specified as a real-valued scalar, vector, or matrix. To compute the CORDIC approximation, the input angle must be between:

- $[-2\pi, 2\pi)$ rad, for signed fixed-point types
- $[0, 2\pi)$ rad, for unsigned fixed-point types

For more information, see “Effect of Out-of-Range Input on CORDIC Approximations” on page 1-895.

Dependencies

- To enable this port, set **Input** to Magnitude and angle.

Limitations

- If one input has a floating-point data type, the other input must use the same data type. For example, both signals must be `double` or `single`.
- Fixed-point data types are supported only when you set the **Approximation method** to CORDIC. If one input has a fixed-point data type, the other input must also have a fixed-point data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Port_1 — Magnitude or radian phase angle

scalar | vector | matrix

Magnitude, or radian phase angle, specified as a real-valued scalar, vector, or matrix.

- When you set **Input** to Magnitude, you specify the magnitude at the input port, and the angle on the dialog box.

- When you set **Input** to **Angle**, you specify the angle at the input port, and the magnitude on the dialog box.

Dependencies

To enable this port, set **Input** to **Magnitude** or **Angle**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Port_1 — Complex signal

`scalar` | `vector` | `matrix`

Complex signal, formed from the magnitude and phase angle you specify.

If the block input is an array, the output is an array of complex signals. The elements of a magnitude input vector map to the magnitudes of the corresponding complex output elements. Similarly, the elements of an angle input vector map to the angles of the corresponding complex output elements. If one input is a scalar, it maps to the corresponding component (magnitude or angle) of all the complex output signals.

Data Types: `single` | `double` | `fixed point`

Parameters

Input — Type of input

`Magnitude (default)` | `Angle` | `Magnitude and angle`

Specify the kind of input: a magnitude input, an angle input, or both.

Programmatic Use

Block Parameter: `Input`

Type: `character vector`

Values: `'Magnitude'` | `'Angle'` | `'Magnitude and angle'`

Default: `'Magnitude and angle'`

Angle — Phase angle of output

`0` (default) | `real-valued scalar, vector, or matrix`

Constant phase angle of the output signal, in rad. To compute the CORDIC approximation, the input angle must be between:

- $[-2\pi, 2\pi)$ rad, for signed fixed-point types
- $[0, 2\pi)$ rad, for unsigned fixed-point types

For more information, see “Effect of Out-of-Range Input on CORDIC Approximations” on page 1-895.

Dependencies

To enable this parameter, set **Input** to **Magnitude**.

Programmatic Use

Block Parameter: `ConstantPart`

Type: `character vector`

Values: constant scalar

Default: '0'

Magnitude — Magnitude of output

0 (default) | real-valued scalar, vector, or matrix

Constant magnitude of the output signal, specified as a real-valued scalar, vector, or matrix.

Dependencies

To enable this parameter, set **Input** to Angle.

Programmatic Use

Block Parameter: ConstantPart

Type: character vector

Values: real-valued scalar, vector, or matrix

Default: '0'

Approximation method — CORDIC or none

None (default) | CORDIC

Specify the type of approximation for computing output.

Approximation Method	Data Types Supported	When to Use This Method
None (default)	Floating point	You want to use the default Taylor series algorithm.
CORDIC	Floating point and fixed point	You want a fast, approximate calculation.

When you use the CORDIC approximation, follow these guidelines for the input angle:

- For signed fixed-point types, the input angle must fall within the range $[-2\pi, 2\pi]$ rad.
- For unsigned fixed-point types, the input angle must fall within the range $[0, 2\pi]$ rad.

The block uses the following data type propagation rules:

Data Type of Magnitude Input	Approximation Method	Data Type of Complex Output
Floating point	None or CORDIC	Same as input
Signed, fixed point	CORDIC	$\text{fixdt}(1, WL + 2, FL)$ where WL and FL are the word length and fraction length of the magnitude
Unsigned, fixed point	CORDIC	$\text{fixdt}(1, WL + 3, FL)$ where WL and FL are the word length and fraction length of the magnitude

Programmatic Use

Block Parameter: ApproximationMethod

Type: character vector

Values: 'None' | 'CORDIC'

Default: 'None'

Number of iterations — Number of iterations for CORDIC algorithm

11 (default) | positive integer, less than or equal to word length of fixed-point input

Number of iterations to perform the CORDIC algorithm. The range of possible values depends on the data type of the input:

Data Type of Block Inputs	Value You Can Specify
Floating point	A positive integer
Fixed point	A positive integer that does not exceed the word length of the magnitude input or the word length of the phase angle input, whichever value is smaller

Dependencies

To enable this parameter, set **Approximation method** to CORDIC.

Programmatic Use

Block Parameter: NumberOfIterations

Type: character vector

Values: positive integer, less than or equal to word length of fixed-point input

Default: '11'

Scale output by reciprocal of gain factor — Scale real and imaginary parts of complex output

on (default) | off

Select this check box to scale the real and imaginary parts of the complex output by a factor of (1/ CORDIC gain). This value depends on the number of iterations you specify. As the number of iterations goes up, the value approaches 1.647.

This check box is selected by default, which leads to a more numerically accurate result for the complex output, $X + iY$. However, scaling the output adds two extra multiplication operations, one for X and one for Y .

Dependencies

To enable this parameter, set **Approximation method** to CORDIC.

Programmatic Use

Block Parameter: ScaleReciprocalGainFactor

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar or vector**Default:** '-1'**Block Characteristics**

Data Types	double single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About**CORDIC**

CORDIC is an acronym for COordinate Rotation DIGital Computer. The Givens rotation-based CORDIC algorithm is one of the most hardware-efficient algorithms available because it requires only iterative shift-add operations (see References). The CORDIC algorithm eliminates the need for explicit multipliers. Using CORDIC, you can calculate various functions, such as sine, cosine, arc sine, arc cosine, arc tangent, and vector magnitude. You can also use this algorithm for divide, square root, hyperbolic, and logarithmic functions.

Increasing the number of CORDIC iterations can produce more accurate results, but doing so also increases the expense of the computation and adds latency.

Manual Switch

Switch between two inputs

Library: Simulink / Signal Routing

Description

The Manual Switch block is a toggle switch that selects one of its two inputs to pass through to the output. To toggle between inputs, double-click the block. You control the signal flow by setting the switch before you start the simulation or by changing the switch while the simulation is executing. The Manual Switch block retains its current state when you save the model.

Note Double-clicking the Manual Switch block does not open the block dialog box. Instead, it toggles the input choice.

Ports

Input

Port_1 — First input signal

scalar | vector

First of two inputs to the Manual Switch block. The block propagates the selected input to the output. To select the input signal, toggle the switch by double-clicking the block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Port_2 — Second input signal

scalar | vector

Second of two inputs to the Manual Switch block. The block propagates the selected input to the output. To select the input signal, toggle the switch by double-clicking the block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal

scalar | vector

Output signal propagated from either the first or second input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

To view the block parameters, right-click the block and select **Block Parameters** (ManualSwitch).

Allow the two inputs to differ in size (Results in variable-size output signal) – Allow inputs of different sizes

off (default) | on

Select this check box to allow inputs with different sizes and propagate the selected input signal size to the output signal. If you clear the box, the block expands scalar inputs to have the same dimensions as nonscalar inputs. See “Scalar Expansion of Inputs and Parameters”.

Programmatic Use

Parameter: varsize

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Sample time – Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Manual Variant Sink | Manual Variant Source | Multipoint Switch | Switch

Introduced before R2006a

Manual Variant Sink

Switch between multiple variant choices at output

Library: Simulink / Signal Routing

Description

The Manual Variant Sink block is a toggle switch that activates one of its variant choices at the output to pass the input.

The block can have two or more output ports and has one input port. Each output port is associated with a variant control. To change the number of output ports, right-click the block and select **Mask Parameters**, then type a value in the **Number of choices** box.

To toggle between the variant choices at output, double-click the block. The block displays the active choice with a line connecting the input to the output. The block propagates the active variant choice at output and discards the blocks connected to inactive output ports during simulation.

Note Double-clicking the Manual Variant Sink block does not open the block dialog box instead it toggles the output choice.

Ports

Input

Port_1 – Input signal

scalar | vector

Input signal passed to the active output port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 – First variant output

scalar | vector

First variant output signal. The block passes the input signal to this output port when you connect the toggle switch to this port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Port_n – nth variant output

scalar | vector

nth variant output signal. The block passes the input signal to this output port when you connect the toggle switch to this port.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

To access the block parameter, right-click the block and select **Mask > Mask Parameters**.

Number of choices — Number of output choices

2 (default) | scalar

Specify the number of variant output ports.

Programmatic Use

Block Parameter: NumChoices

Type: character vector

Value: integer

Default: '2'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Manual Variant Source

Switch between multiple variant choices at input

Library: Simulink / Signal Routing

Description

The Manual Variant Source block is a toggle switch that activates one of its variant choices at the input to pass through to the output.

A Manual Variant Source block can have two or more input ports and has one output port. Each input port is associated with a variant control. To change the number of input ports, right-click the block and select **Mask Parameters**, then type a value in the **Number of choices** box.

To toggle between the variant choices at input, double-click the block. The block displays the active choice with a line connecting the input to the output. The block propagates the active variant choice at input directly to the output and discards the blocks connected to inactive input ports during simulation.

Note Double-clicking the Manual Variant Source block does not open the block dialog box instead it toggles the output choice.

Ports

Input

Port_1 — First variant input signal

scalar | vector

First variant input signal. The block passes this input signal to the output port when you connect the toggle switch to this port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Port_n — nth variant input signal

scalar | vector

nth variant input signal. The block passes this input signal to the output port when you connect the toggle switch to this port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal

scalar | vector

Output signal passed from the active variant input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

To access the block parameter, right-click the block and select **Mask > Mask Parameters**.

Number of choices — Number of input choices

2 (default) | scalar

Specify the number of variant input ports.

Programmatic Use

Block Parameter: NumChoices

Type: character vector

Value: integer

Default: '2'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

Math Function

Perform mathematical function

Library: Simulink / Math Operations
HDL Coder / Math Operations

Description

The Math Function block performs numerous common mathematical functions.

Tip To perform square root calculations, use the Sqrt block.

You can select one of these functions from the **Function** parameter list.

Function	Description	Mathematical Expression	MATLAB Equivalent
exp	Exponential	e^u	exp
log	Natural logarithm	$\ln u$	log
10^u	Power of base 10	10^u	10.^u (see power)
log10	Common (base 10) logarithm	$\log u$	log10
magnitude^2	Complex modulus	$ u ^2$	(abs(u)).^2 (see abs and power)
square	Power 2	u^2	u.^2 (see power)
pow	Power	$\text{sign}(u) * u ^v$ (default) or u^v	power
conj	Complex conjugate	\bar{u}	conj
reciprocal	Reciprocal	$1/u$	1./u (see rdivide)
hypot	Square root of sum squares	$(u^2+v^2)^{0.5}$	hypot
rem	Remainder after division	—	rem
mod	Modulus after division	—	mod
transpose	Transpose	u^T	u.' (see "Array vs. Matrix Operations" (MATLAB))

Function	Description	Mathematical Expression	MATLAB Equivalent
hermitian	Complex conjugate transpose	u^H	u' (see "Array vs. Matrix Operations" (MATLAB))

The block output is the result of the operation of the function on the input or inputs. The functions support these types of operations.

Function	Scalar Operations	Element-Wise Vector and Matrix Operations	Vector and Matrix Operations
exp	Yes	Yes	—
log	Yes	Yes	—
10 ^u	Yes	Yes	—
log10	Yes	Yes	—
magnitude ²	Yes	Yes	—
square	Yes	Yes	—
pow	Yes	Yes	—
conj	Yes	Yes	—
reciprocal	Yes	Yes	—
hypot	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
rem	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
mod	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
transpose	Yes	—	Yes
hermitian	Yes	—	Yes

The name of the function appears on the block. The appropriate number of input ports appears automatically.

Tip Use the Math Function block when you want vector or matrix output.

Data Type Support

This table shows the input data types that each function of the block can support.

Function	single	double	boolean	built-in integer	fixed point
exp	Yes	Yes	—	—	—
log	Yes	Yes	—	—	—
10 ^u	Yes	Yes	—	—	—
log ₁₀	Yes	Yes	—	—	—
magnitude ²	Yes	Yes	—	Yes	Yes
square	Yes	Yes	—	Yes	Yes
pow	Yes	Yes	—	—	—
conj	Yes	Yes	—	Yes	Yes
reciprocal	Yes	Yes	—	Yes	Yes
hypot	Yes	Yes	—	—	—
rem	Yes	Yes	—	Yes	—
mod	Yes	Yes	—	Yes	—
transpose	Yes	Yes	Yes	Yes	Yes
hermitian	Yes	Yes	—	Yes	Yes

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal specified as a scalar, vector, or matrix. All supported modes accept both real and complex inputs, except for `reciprocal`, which does not accept complex fixed-point inputs. See Description on page 1-911 for more information.

Dependencies

Data type support for this block depends on the **Function** you select and the size of the input(s). For more information, see “Data Type Support” on page 1-913.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_2 — Input signal

scalar | vector | matrix

Input signal specified as a scalar, vector, or matrix. All supported modes accept both real and complex inputs, except for `reciprocal`, which does not accept complex fixed-point inputs.

Dependencies

To enable this port, set **Function** to `hypot`, `rem`, or `mod`.

Data type support for this block depends on the **Function** you select, and the size of the input(s). For more information, see “Data Type Support” on page 1-913.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Result of the operation of the function on the input or inputs

scalar | vector | matrix

Output signal specified as a scalar, vector, or matrix. The dimensions of the block output depend on the **Function** you select and the size of the inputs. The block output is real or complex, depending on what you select for **Output signal type**. See Description on page 1-911 for more information.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Function — Math function

exp (default) | log | 10^u | log10 | magnitude² | square | pow | conj | reciprocal | hypot | rem | mod | transpose | hermitian

Specify the mathematical function. See Description on page 1-911 for more information about the options for this parameter.

Dependency

Setting **Function** to pow enables the **Signed power** parameter.

Programmatic Use

Block Parameter: Operator

Type: character vector

Values: 'exp' | 'log' | '10^u' | 'log10' | 'magnitude²' | 'square' | 'pow' | 'conj' | 'reciprocal' | 'hypot' | 'rem' | 'mod' | 'transpose' | 'hermitian'

Default: 'exp'

Signed power — Power signedness

on (default) | off

Take into account sign of the input signal when calculating power, specified as on or off.

- on — Calculate power of the absolute value of the input, multiplied by the sign of the input.
- off — Calculate power of the actual input value. If the first input is negative and the second input is a fractional exponent, return nan.

Dependency

Setting **Function** to pow enables this parameter.

Programmatic Use

Block Parameter: SignedPower

Type: character vector

Values: 'on' | 'off' |

Default: 'on'

Output signal type — Complexity of output signal

auto (default) | real | complex

Specify the output signal type of the Math Function block as auto, real, or complex.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
exp, log, 10u, log10, square, pow, reciprocal, conjugate, transpose, hermitian	real	real	real	complex
	complex	complex	error	complex
magnitude squared	real	real	real	complex
	complex	real	real	complex
hypot, rem, mod	real	real	real	complex
	complex	error	error	error

Programmatic Use

Block Parameter: OutputSignalType

Type: character vector

Values: 'auto' | 'real' | 'complex'

Default: 'auto'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output data type — Specify the output data type

Inherit: Same as first input (default) | Inherit: Inherit via internal rule |

Inherit: Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16

```
| int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) |
<data type expression>
```

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Same as first input'` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'Inherit: Same as first input'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

Saturate on integer overflow — Choose the behavior when integer overflow occurs

`on` (default) | `boolean`

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, `conj`, `reciprocal`, or `hermitian`.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Value:** 'off' | 'on'**Default:** 'on'**Block Characteristics**

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

You can generate HDL code for the Math architecture in native floating-point mode.

Architecture	Description
ComplexConjugate	Compute complex conjugate.
Hermitian	Compute hermitian.
Transpose	Compute array transpose. See Math Function in the Simulink documentation.

Reciprocal Architecture

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

Architecture	Parameters	Additional Cycles of Latency	Description
Reciprocal	None	0	Compute reciprocal as $1/N$, using the HDL divide (/) operator to implement the division.

Architecture	Parameters	Additional Cycles of Latency	Description
ReciprocalRsqrBasedNewton	Iterations	Signed input: Iterations + 5 Unsigned input: Iterations + 3	Use the iterative Newton method. Select this option to optimize area. The default value for Iterations is 3. The recommended value for Iterations is from 2 through 10. If Iterations is outside the recommended range, HDL Coder generates a message.
ReciprocalRsqrBasedNewtonSingleRate	Iterations	Signed input: (Iterations * 4) + 8 Unsigned input: (Iterations * 4) + 6	Use the single rate pipelined Newton method. Select this option to optimize speed, or if you want a single rate implementation. The default value for Iterations is 3. The recommended value for Iterations is from 2 through 10. If Iterations is outside the recommended range, the coder generates a message.

The Newton-Raphson iterative method:

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)} = x_i(1.5 - 0.5ax_i^2)$$

ReciprocalRsqrBasedNewton and ReciprocalRsqrBasedNewtonSingleRate implement the Newton-Raphson method with:

$$f(x) = \frac{1}{x^2} - 1$$

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).

General	
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
Native Floating Point	
CheckResetToZero	Use this property for the <code>mod</code> and <code>rem</code> functions of the Math Function block. If you have numbers <code>a</code> and <code>b</code> such that the quotient <code>a/b</code> is close to an integer, this setting treats <code>a</code> as an integral multiple of <code>b</code> , and <code>rem(a, b) = 0</code> . This result is numerically accurate and matches the simulation results. However, computing this result uses additional resources and increases the area footprint on the target FPGA device. For more information, see “CheckResetToZero” (HDL Coder).
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , <code>Zero</code> , or <code>Custom</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <code>Custom</code> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).
MaxIterations	Use this property for the <code>mod</code> and <code>rem</code> functions of the Math Function block. If you have numbers <code>a</code> and <code>b</code> that are significantly large integers, you can increase MaxIterations to match the simulation results. However, computing this result uses additional resources and increases the area footprint on the target FPGA device. For more information, see “MaxIterations” (HDL Coder).

Complex Data Support

The `conj`, `hermitian`, and `transpose` functions support complex data.

Restrictions

When you use a reciprocal implementation:

- Input must be scalar and must have integer or fixed-point (signed or unsigned) data type.
- The output must be scalar and have integer or fixed-point (signed or unsigned) data type.
- Only the `Zero` rounding mode is supported.
- The **Saturate on integer overflow** option on the block must be selected.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The Math Function block only supports fixed-point conversion in certain configurations. For more information, see the Block Support Table.

Topics

“hisl_0004: Usage of Math Function blocks (natural logarithm and base 10 logarithm)”

Introduced before R2006a

MATLAB Function

Include MATLAB code in models that generate embeddable C code

Library: Simulink / User-Defined Functions
HDL Coder / User-Defined Functions

Description

With a MATLAB Function block, you can write a MATLAB function for use in a Simulink model. The MATLAB function you create executes for simulation and generates code for a Simulink Coder target. If you are new to the Simulink and MATLAB products, see “Implementing MATLAB Functions Using Blocks” and “Create Custom Functionality Using MATLAB Function Block” for an overview.

Double-clicking the MATLAB Function block opens its editor, where you write the MATLAB function, as in this example:

```

1  function [mean,stdev] = stats(vals)
2  % #codegen
3
4  % calculates a statistical mean and a standard
5  % deviation for the values in vals.
6
7  - len = length(vals);
8  - mean = avg(vals,len);
9  - stdev = sqrt(sum((vals-avg(vals,len)).^2)/len);
10 - coder.extrinsic('plot');
11 - plot(vals,'-+');
12 |
13 function mean = avg(array,size)
14 - mean = sum(array)/size;

```

To learn more about this editor, see “MATLAB Function Block Editor”.

You specify input and output data to the MATLAB Function block in the function header as arguments and return values. The argument and return values of the preceding example function correspond to the inputs and outputs of the block in the model:

You can also define data, input triggers, and function call outputs using the Ports and Data Manager, which you access from the MATLAB Function Block Editor by selecting **Edit Data**. See “Ports and Data Manager”.

The MATLAB Function block generates efficient embeddable code based on an analysis that determines the size, class, and complexity of each variable. This analysis imposes the following restrictions:

- The first assignment to a variable defines its, size, class, and complexity.
See “Best Practices for Defining Variables for C/C++ Code Generation”.
- You cannot reassign variable properties after the initial assignment except when using variable-size data or reusing variables in the code for different purposes.

See “Reassignment of Variable Properties”.

In addition to language restrictions, the MATLAB Function block supports a subset of the functions available in MATLAB. A list of supported functions is given in “Functions and Objects Supported for C/C++ Code Generation”. These functions include functions in common categories, such as:

- Arithmetic operators like `plus`, `minus`, and `power`. For more information, see “Array vs. Matrix Operations” (MATLAB).
- Matrix operations like `size`, and `length`
- Advanced matrix operations like `lu`, `inv`, `svd`, and `chol`
- Trigonometric functions like `sin`, `cos`, `sinh`, and `cosh`

Note Although the code for this block attempts to produce exactly the same results as MATLAB, differences might occur due to rounding errors. These numerical differences, which might be a few `eps` initially, can magnify after repeated operations. Reliance on the behavior of `nan` is not recommended. Different C compilers can yield different results for the same computation.

Note In the MATLAB Function block, the `%#codegen` directive is included to emphasize that the block’s MATLAB algorithm is always intended for code generation. The `%#codegen` directive, or the absence of it, does not change the error checking behavior in the context of the MATLAB Function block. For more information see “Compilation Directive `%#codegen`”.

To support visualization of data, the MATLAB Function block supports calls to MATLAB functions for simulation only. See “Extrinsic Functions” to understand some of the limitations of this capability, and how it integrates with code analysis for this block. If these function calls do not directly affect any of the Simulink inputs or outputs, the calls do not appear in Simulink Coder generated code.

From MATLAB Function blocks, you can also call functions defined in a Simulink Function block. You can call Stateflow functions with **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** checked in the chart Properties dialog box.

In the Ports and Data Manager, you can declare a block input to be a Simulink parameter instead of a port. The MATLAB Function block also supports inheritance of types and size for inputs, outputs, and parameters. You can also specify these properties explicitly. See “Type Function Arguments”, “Size Function Arguments”, and “Add Parameter Arguments” for descriptions of variables that you use in MATLAB Function blocks.

Recursive calls are not allowed in MATLAB Function blocks.

By default, MATLAB Function blocks have direct feedthrough enabled. To disable it, in the Ports and Data Manager, clear the **Allow direct feedthrough** check box. Nondirect feedthrough enables semantics to ensure that outputs rely only on current state. Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops.

Ports

Input

u — Input argument u

scalar | vector | matrix

Input corresponding to the first input argument of the function inside the MATLAB Function block. If you rename the function argument in the editor, the block renames the port correspondingly.

Data types supported by MATLAB but not supported by Simulink may not be passed between the Simulink model and the function within the MATLAB Function block. These types may be used within the MATLAB Function block.

For more information on fixed-point support for this block, refer to “Fixed-Point Data Types with MATLAB Function Block” (Fixed-Point Designer) and “MATLAB Function Block with Data Type Override” (Fixed-Point Designer).

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

n — Input argument n

scalar | vector | matrix

nth input argument to the function in the MATLAB Function block. When you add the argument in the editor, the block adds the port correspondingly.

Data types supported by MATLAB but not supported by Simulink may not be passed between the Simulink model and the function within the MATLAB Function block. These types may be used within the MATLAB Function block.

For more information on fixed-point support for this block, refer to “Fixed-Point Data Types with MATLAB Function Block” (Fixed-Point Designer) and “MATLAB Function Block with Data Type Override” (Fixed-Point Designer).

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

y — Output argument

scalar | vector | matrix

First output argument of the function inside the MATLAB Function block. If you rename the function argument in the editor, the block renames the port correspondingly.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

n — Output argument n

scalar | vector | matrix

nth output argument from the function inside the MATLAB Function block. When you add the argument in the editor, the block adds the port correspondingly.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a integer ^a single ^a
Direct Feedthrough	no
Multidimensional Signals	limited ^a
Variable-Size Signals	limited ^a
Zero-Crossing Detection	no

a. Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. Actual data type or capability support depends on block implementation. For best practices of using the MATLAB Function block, see:

- “Design Guidelines for the MATLAB Function Block” (HDL Coder)
- “Generate Instantiable Code for Functions” (HDL Coder)
- “Optimize MATLAB Loops” (HDL Coder)
- “Pipeline MATLAB Expressions” (HDL Coder)

HDL Architecture

MATLAB Function (Default)	This is the default architecture for MATLAB Function blocks with fixed-point data types. When you use this architecture, you can use speed and area optimizations for blocks that surround the MATLAB Function block. The code inside the MATLAB Function block is not optimized.
MATLAB Datapath	<p>This is the default architecture for MATLAB Function blocks with floating-point data types. When you use this architecture, the code generator treats the MATLAB Function block like a regular Subsystem block. By enabling this architecture for fixed-point types, you can use speed and area optimizations for blocks inside the MATLAB Function block and across the MATLAB Function block with other Simulink blocks.</p> <p>This capability enables you to specify additional properties for the MATLAB Function block that you would specify for a Subsystem such as ClockRatePipelining and FlattenHierarchy.</p>

HDL Block Properties

AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “ClockRatePipelining” (HDL Coder).
ConstMultiplierOptimization	Canonical signed digit (CSD) or factored CSD optimization. The default is <code>none</code> . See also “ConstMultiplierOptimization” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is <code>0</code> . For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>off</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “InputPipeline” (HDL Coder).

InstantiateFunctions	Generate a VHDL entity or Verilog module for each function. The default is <code>off</code> . See also “InstantiateFunctions” (HDL Coder).
LoopOptimization	Unroll, stream, or do not optimize loops. The default is <code>none</code> . If you set Architecture to <code>MATLAB Datapath</code> , you can only unroll loops. If you want to use loop streaming with the <code>MATLAB Datapath</code> architecture, you can use the streaming optimization by specifying a StreamingFactor . See also “LoopOptimization” (HDL Coder).
MapPersistentVarsToRAM	Map persistent arrays to RAM. The default is <code>off</code> . See also “MapPersistentVarsToRAM” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “OutputPipeline” (HDL Coder).
ResetType	Suppress reset logic generation. The default is <code>default</code> , which generates reset logic. See also “ResetType” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is <code>0</code> . See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is <code>0</code> , which implements fully parallel data paths. To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “Streaming” (HDL Coder).
UseMatrixTypesInHDL	Generate 2-D matrices in HDL code. The default is <code>off</code> . To specify this property, set Architecture to <code>MATLAB Function</code> . See also “UseMatrixTypesInHDL” (HDL Coder).
VariablesToPipeline	<p>Warning <code>VariablesToPipeline</code> is not recommended. Use <code>coder.hdl.pipeline</code> instead.</p> <p>Insert a pipeline register at the output of the specified variable or variables. Specify the list of variables as a character vector, with spaces separating the variables. To specify this property, set Architecture to <code>MATLAB Function</code>.</p>

Complex Data Support

This block supports code generation for complex signals.

See also “Complex Data Type Support” (HDL Coder).

Tunable Parameter Support

HDL Coder supports both tunable and non-tunable parameters with the following data types:

- Scalar
- Vector
- Complex
- Structure
- Enumeration

For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder) and “Design Guidelines for the MATLAB Function Block” (HDL Coder)

Restrictions

- If the block contains a System object™, block inputs cannot have non-discrete (constant or Inf) sample time.
- HDL Coder does not support a MATLAB Function that contains the same variable as the input and output of the function. For example, this MATLAB code is not supported.

```
function y = myFun(y)
%#codegen

y = 3 * y;
```

For the MATLAB language subset supported for HDL code generation from a MATLAB Function block, see “Supported MATLAB Data Types, Operators, and Control Flow Statements” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

MATLAB System

Include System object in model

Library: Simulink / User-Defined Functions
HDL Coder / User-Defined Functions

Description

The MATLAB System block brings existing System objects (based on `matlab.System`) into Simulink. It also enables you to use System object APIs to develop new blocks for Simulink. For more information on this block, see “MATLAB System Block”.

For interpreted execution, the model simulates the block using the MATLAB execution engine.

For code generation, the model simulates the block using code generation (using the subset of MATLAB code supported for code generation). The MATLAB System block supports only a subset of the functions available in MATLAB. See “Functions and Objects Supported for C/C++ Code Generation” for a complete list of functions. These functions include those in common categories, such as:

- “Array vs. Matrix Operations” (MATLAB), like `plus`, `minus`, and `power`
- Matrix operations, like `size` and `length`
- Advanced matrix operations, like `lu`, `inv`, `svd`, and `chol`
- Trigonometric functions, like `sin`, `cos`, `sinh`, and `cosh`

System Objects

To use the MATLAB System block, you must first have a new System object or use an existing one. For more information, see “Integrate System Objects Using MATLAB System Block”.

Ports

Input

In — Signal input to a MATLAB System block

scalar | vector | matrix

The MATLAB System block accepts inputs of the types listed in the Block Characteristics table. It does not support virtual buses as input or output. It does not support nonvirtual buses that contain variable-size signals. For more information, see “Data Types Supported by Simulink”.

For information on fixed-point support for this block, see “Code Acceleration and Code Generation from MATLAB” (Fixed-Point Designer).

The MATLAB System block supports Simulink frames. For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Out — Signal output of a MATLAB System block

scalar | vector | matrix

Signal output of a MATLAB System block that the System object returns.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

System Object Name — Name of the System object

cell array (default)

Specify the full name of the user-defined System object class without the file extension. This entry is case sensitive. The class name must exist on the MATLAB path.

You can specify a System object name in one of these ways:

- Enter the name in the text box.
- Click the list arrow attached to the text box. If valid System objects exist in the current folder, the names appear in the list. Select a System object from this list.
- Browse to a folder that contains a valid System object. If the folder is not on your MATLAB path, the software prompts you to add it.

If you need to create a System object, you can create one from a template by clicking **New**.

After you save the System object, the name appears in the **System object name** text box.

Use the full name of the user-defined System object class name. The block does not accept a MATLAB variable that you have assigned to a System object class name.

Programmatic Use

Block Parameter: System

Type: character vector

Value: name of the System object

Default: ' '

New — Create a System object from a template

Basic (default) | Advanced | Simulink Extension

Select one of the options for a System object template.

Basic

Starts MATLAB Editor and displays a template for a simple System object using the fewest System object methods.

Advanced

Starts MATLAB Editor and displays a template for a more advanced System object using most of the System object methods.

Simulink Extension

Starts MATLAB Editor and displays a file that contains utilities for customizing the block for Simulink. This is the same file available in MATLAB when you select **New > System Object > Simulink Extension**.

After you save the System object, you can enter the name in the **System object name** text box.

Simulate using — Select the simulation mode

Code generation (default) | Interpreted Execution

Select the simulation mode.

Code generation

On the first model run, simulate and generate code for MATLAB System block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System Objects accept a maximum of 32 inputs.

Interpreted execution

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

Dependency — Dependency parameter for MATLAB System block

auto (default)

After you assign a valid System object class name to the block, the next time you open the block dialog box, the parameter is visible. This parameter appears for every MATLAB System block. You cannot remove it.

- If the block has no tabs, this parameter appears at the bottom of the dialog box.
- If the block has multiple tabs, this parameter appears at the bottom of the first tab of the dialog box.

Saturate on integer overflow — Specify whether overflows saturate

Off (default) | On

On

Overflows saturate to either the minimum or maximum value that the data type can represent. For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent. For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code. Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Dependency

This check box appears when you use the `showFiSettingsImpl` method in the System object.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Treat these inherited Simulink signal types as fi objects — Specify fi data types

Fixed-point (default) | Fixed-point & Integer

Select which inherited data types to treat fi data types,

Fixed-point

Treat fixed-point data types as fi data types.

Fixed-point & Integer

Treat fixed-point and integer data types as fi data types.

Dependency

This check box appears when you use the `showFiSettingsImpl` method in the System object.

MATLAB System fimath — Specify fixed-point settings to use

Same as MATLAB (default) | Specify Other

Select which fixed-point math settings to use.

Same as MATLAB

Use the current MATLAB fixed-point math settings.

Specify Other

Enable the edit box for specifying the desired fixed-point math settings. For information on setting fixed-point math, see `fimath`.

Dependency

This check box appears when you use the `showFiSettingsImpl` method in the System object.

Block Characteristics

Data Types	Boolean ^a bus ^{ba} double ^a enumerated ^a fixed point ^a integer ^a single ^a
Direct Feedthrough	no
Multidimensional Signals	limited ^a

Variable-Size Signals	limited ^{ca}
Zero-Crossing Detection	no

- Actual data type or capability support depends on block implementation.
- See Nonvirtual Buses and MATLAB System Block for more information.
- See Variable-Size Signals for more information.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

You can define a System object and use it in a MATLAB System block for HDL code generation.

Tunable Parameter Support

HDL Coder supports tunable parameters with the following data types:

- Numeric
- Fixed point
- Character
- Logical

When using tunable parameters with the MATLAB System block, the tunable parameter should be a Simulink.Parameter object with the StorageClass set to ExportedGlobal.

```
x = Simulink.Parameter
x.Value = 1
x.CoderInfo.StorageClass = 'ExportedGlobal'
```

For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

If you use a predefined System object, the HDL block properties available are the same as the properties available for the corresponding block.

By default, the following HDL block properties are available.

ConstMultiplierOptimization	Canonical signed digit (CSD) or factored CSD optimization. The default is none. See also “ConstMultiplierOptimization” (HDL Coder).
------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is off. See also “DistributedPipelining” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
LoopOptimization	Unroll, stream, or do not optimize loops. The default is none. See also “LoopOptimization” (HDL Coder).
MapPersistentVarsToRAM	Map persistent arrays to RAM. The default is off. See also “MapPersistentVarsToRAM” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
ResetType	Suppress reset logic generation. The default is default, which generates reset logic. See also “ResetType” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
VariablesToPipeline	<p>Warning VariablesToPipeline is not recommended. Use <code>coder.hdl.pipeline</code> instead.</p> <hr/> <p>Insert a pipeline register at the output of the specified MATLAB variable or variables. Specify the list of variables as a character vector, with spaces separating the variables.</p>

Restrictions

- The DUT subsystem must be single-rate.
- Inputs cannot have non-discrete (constant or Inf) sample time.
- The following predefined System objects are supported for code generation when you use them in the MATLAB System block:
 - `hdl.RAM`
 - `comm.HDLCRCDetector`
 - `comm.HDLCRCGenerator`
 - `comm.HDLRSDecoder`
 - `comm.HDLRSEncoder`
 - `dsp.DCBlocker`
 - `dsp.HDLComplexToMagnitudeAngle`
 - `dsp.HDLFFT`
 - `dsp.HDLIFFT`

- `dsp.HDLNCO`
- If you use a user-defined System object, it must support HDL code generation. For information about user-defined System objects and requirements for HDL code generation, see “HDL Code Generation for System Objects” (HDL Coder).

See also “Generate Code for User-Defined System Objects” (HDL Coder) and “HDL Code Generation for System Objects” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

Memory

Output input from previous time step

Library: Simulink / Discrete
HDL Coder / Discrete

Description

The Memory block holds and delays its input by one major integration time step. When placed in an iterator subsystem, it holds and delays its input by one iteration. This block accepts continuous and discrete signals. The block accepts one input and generates one output. Each signal can be a scalar, vector, matrix, or N-D array. If the input is non-scalar, the block holds and delays all elements of the input by the same time step.

You specify the block output for the first time step using the **Initial condition** parameter. Careful selection of this parameter can minimize unwanted output behavior. However, you cannot specify the sample time. This block's sample time depends on the type of solver used, or you can specify to inherit it. The **Inherit sample time** parameter determines whether sample time is inherited or based on the solver.

Tip Avoid using the Memory block when both these conditions are true:

- Your model uses the variable-step solver ode15s or ode113.
 - The input to the block changes during simulation.
-

When the Memory block inherits a discrete sample time, the block is analogous to the Unit Delay block. However, the Memory block does not support state logging. If logging the final state is necessary, use a Unit Delay block instead.

Comparison with Similar Blocks

The Memory, Unit Delay, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different.

This table shows recommended usage for each block.

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	<ul style="list-style-type: none"> • sldemo_enginewc (Compression subsystem)
Memory on page 1-937	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	<ul style="list-style-type: none"> • sldemo_bounce • sldemo_clutch (Friction Mode Logic/Lockup FSM subsystem)

Block	Purpose of the Block	Reference Examples
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	<ul style="list-style-type: none"> • <code>sldemo_radar_eml</code> • <code>aero_dap3dof</code>

Each block has the following capabilities.

Capability	Memory	Unit Delay	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time $t = 0$ must match the input value.
Specification of sample time	No, because the block can only inherit sample time from the driving block or the solver used for the entire model.	Yes	Yes
Support for frame-based signals	No	Yes	Yes
Support for state logging	No	Yes	No

Bus Support

The Memory block is a bus-capable block. The input can be a virtual or nonvirtual bus signal subject to the following restrictions:

- **Initial condition** must be zero, a nonzero scalar, or a finite numeric structure.
- If **Initial condition** is zero or a structure, and you specify a **State name**, the input cannot be a virtual bus.
- If **Initial condition** is a nonzero scalar, you cannot specify a **State name**.

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

All signals in a nonvirtual bus input to a Memory block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Modify Sample Times for Nonvirtual Buses” and Bus-Capable Blocks for more information.

You can use an array of buses as an input signal to a Memory block. You can specify the **Initial condition** parameter with:

- The value θ . In this case, all the individual signals in the array of buses use the initial value θ .
- An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
- A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. The input can be continuous or discrete, containing real, or complex values of any data type Simulink supports.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 – Input delayed by one major integration time step

scalar | vector | matrix | N-D array

Output is the input from the previous time step.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Main

Initial condition – Initial condition

0 (default) | scalar | vector | matrix | N-D array

Specify the output at the initial integration step. This value must be 0 when you do not use a built-in input data type.

Programmatic Use

Block Parameter: InitialCondition

Type: character vector

Values: scalar | vector

Default: '0'

Inherit sample time – Inherit sample time

off (default) | on

Select to inherit the sample time from the driving block:

- If the driving block has a discrete sample time, the block inherits the sample time.
- If the driving block has a continuous sample time, selecting this check box has no effect. The sample time depends on the type of solver used for simulating the model.

When this check box is cleared, the block sample time depends on the type of solver used for simulating the model:

- If the solver is a variable-step solver, the block sample time is continuous but fixed in minor time step: [0, 1].
- If the solver is a fixed-step solver, the [0, 1] sample time converts to the solver step size after sample-time propagation.

Programmatic Use**Block Parameter:** InheritSampleTime**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Direct feedthrough of input during linearization – Output the input during linearization and trim**

off (default) | on

Select to output the input during linearization and trim. This selection sets the block mode to direct feedthrough.

Selecting this check box can cause a change in the ordering of states in the model when using the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering, use the following commands.

First compile the model using the following command, where `model` is the name of the Simulink model.

```
[sizes, x0, x_str] = model([],[],[],'lincompile');
```

Next, terminate the compilation with this command.

```
model([],[],[],'term');
```

The output argument, `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When passing a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

Programmatic Use**Block Parameter:** LinearizeMemory**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Treat as a unit delay when linearizing with discrete sample time – Linearize to unit delay for discrete inputs**

off (default) | on

Select to linearize the Memory block to a unit delay when the Memory block is driven by a signal with a discrete sample time.

Programmatic Use**Block Parameter:** LinearizeAsDelay**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**State Attributes****State name – Unique name for block state**

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use

Block Parameter: StateName

Type: character vector

Values: unique name

Default: ''

State name must resolve to Simulink signal object — Require state name resolve to a signal object

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

Programmatic Use

Block Parameter: StateMustResolveToSignalObject

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Signal object class — Custom storage class package name

Simulink.Signal (default) | <StorageClass.PackageName>

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Programmatic Use

Block Parameter: StateSignalObject

Type: character vector

Values: 'Simulink.Signal' | '<StorageClass.PackageName>'

Default: 'Simulink.Signal'

Code generation storage class — State storage class for code generation

Auto (default) | Model default | ExportedGlobal | ImportedExtern | ImportedExternPointer | BitField (Custom) | Model default | ExportToFile (Custom) | ImportFromFile (Custom) | FileScope (Custom) | AutoScope (Custom) | Struct (Custom) | GetSet (Custom) | Reusable (Custom)

Select state storage class for code generation.

- Auto is the appropriate storage class for states that you do not need to interface to external code.
- *StorageClass* applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

Dependencies

To enable this parameter, specify a value for **State name**.

Programmatic Use

Block Parameter: StateStorageClass

Type: character vector

Values: 'Auto' | 'Model default' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...

Default: 'Auto'

TypeQualifier — Storage type qualifier

' ' (default) | const | volatile | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note TypeQualifier will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Minimum and Maximum values of the signal object

For more information, see “Data Objects”.

Dependencies

To enable this parameter, set **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `Model default`. This parameter is hidden unless you previously set its value.

Programmatic Use

Block Parameter: RTWStateStorageTypeQualifier

Type: character vector

Values: '' | 'const' | 'volatile' | ...

Default: ''

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
ResetType	Suppress reset logic generation. The default is default, which generates reset logic. See also “ResetType” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Merge

Combine multiple signals into single signal

Library: Simulink / Signal Routing

Description

The Merge block combines inputs into a single output. The output value at any time is equal to the most recently computed output of its driving blocks. Specify the number of inputs by setting the parameter **Number of inputs** parameter.

Use Merge blocks to interleave input signals that update at different times into a combined signal in which the interleaved values retain their separate identities and times. To combine signals that update at the same time into an array or matrix signal, use a Concatenate block.

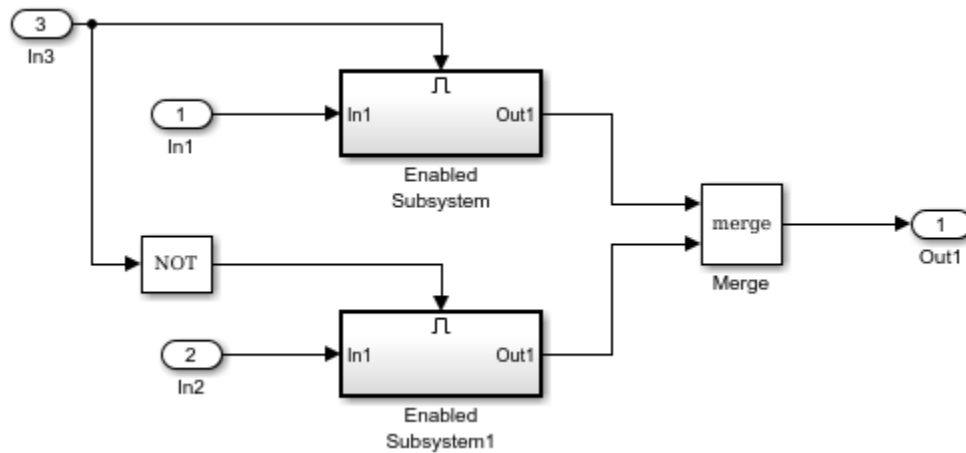

Guidelines for Using the Merge Block

When you use the Merge block, follow these guidelines:

- Always use conditionally executed subsystems to drive Merge blocks.
- Ensure that at most one of the driving conditionally executed subsystems executes at any time step.
- Ensure that all input signals have the same sample time.
- Do not branch a signal that inputs to a Merge block, if you use the default setting of `Classic` for the **Model Configuration Parameters > Diagnostics > Underspecified initialization detection** parameter.
- For all conditionally executed subsystem Output blocks that drive Merge blocks, set the **Output when disabled** parameter to `held`.
- If the output of a Model block is coming from a MATLAB Function block or a Stateflow chart, do not connect that output port to the input port of the Merge block.

For each input of a Merge block, the topmost nonatomic and nonvirtual source must be a conditionally executed subsystem that is not an Iterator Subsystem.

The next diagram shows valid Merge block usage, merging signals from two conditionally executed subsystems.

Bus Support

The Merge block is a bus-capable block. The inputs can be virtual or nonvirtual bus signals subject to these restrictions:

- The number of inputs must be greater than one.
- **Initial output** must be zero, a nonzero scalar, or a finite numeric structure.
- **Allow unequal port widths** must be disabled.
- All inputs to the merge must be buses and must be equivalent (same hierarchy with identical names and attributes for all elements).

All signals in a nonvirtual bus input to a Merge block must have the same sample time. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus.

Merging S-Function Outputs

The Merge block can merge a signal from an S-Function block only if the memory used to store the output from the S-Function is reusable. Simulink software displays an error message if you attempt to update or simulate a model that connects a nonreusable port of an S-Function block to a Merge block. See `ssSetOutputPortOptimOpts`.

Limitations

- All signals that connect to a Merge block, are functionally the same signal. Therefore, they are subject to the restriction that a given signal can have at most one associated signal object. See `Simulink.Signal` for more information.
- Run-time diagnostics do not run if the inputs to a merge block are from a single initiator. For example, a single initiator could be a Stateflow chart executing function-call subsystems that are connected to a Merge block.
- Do not set the outports of conditionally executed subsystems being merged to reset when disabled. This action can cause multiple subsystems to update the block at the same time. Specifically, the disabled subsystem updates the Merge block by resetting its output, while the enabled subsystem updates the block by computing its output.

To prevent this behavior, set the Outport block parameter **Output when disabled** to held for each conditionally executed subsystem being merged.

Note If you are using Simplified Initialization Mode, set the Outport block parameter **Output when disabled** to held.

- A Merge block does not accept input signals whose elements have been reordered or partially selected. In addition, do not connect input signals to the block that have been combined outside of a conditionally executed subsystem.

You can use an array of buses as an input signal to a Merge block with these limitations:

- **Allow unequal port widths** — Clear this parameter.
- **Initial condition** — You can specify this parameter using:
 - The value 0. In this case, each of the individual signals in the array of buses use the initial value 0.
 - An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
 - A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

Ports

Input

Port_1 — First input signal

scalar | vector

First input signal merged with the other input signals.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Port_n — nth input signal

scalar | vector

nth input signal merged with the other input signals.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal

scalar | vector

Output signal merged from the input signals.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Number of inputs — Number of input signals to merge

2 (default) | integer

Specify the number of input signals to merge. The block creates a port for each input signal.

Programmatic Use**Block Parameter:** Inputs**Type:** character vector**Values:** integer**Default:** '2'**Initial output — Initial output value**

[] (default) | scalar | vector

Specify the initial value of the output signal. If you do not specify an initial output value, then initial output depends on the initialization mode and the driving blocks.

In Simplified initialization mode, for an unspecified (empty matrix []) value of **Initial output**, the block uses the default initial value of the output data type. For information on the default initial value, see “Initialize Signal Values”. In Classic initialization mode, for an unspecified (empty matrix []) value of **Initial output**, the initial output of the block equals the most recently evaluated initial output of the driving blocks. Since the initialization ordering for these sources can vary, initialization can be inconsistent for the simulation and the code generation of a model.

Programmatic Use**Block Parameter:** InitialOutput**Type:** character vector**Values:** scalar | vector**Default:** '[]'**Allow unequal port widths — Allow inputs of unequal dimensions**

off (default) | on

Select this check box to allow the block to accept inputs having different numbers of elements. The block allows you to specify an offset for each input signal relative to the beginning of the output signal. The width of the output signal is

$$\max(w_1+o_1, w_2+o_2, \dots, w_n+o_n)$$

where w_1, \dots, w_n are the widths of the input signals and o_1, \dots, o_n are the offsets for the input signals.

If you clear this check box, the Merge block accepts only inputs of equal dimensions and outputs a signal of the same dimensions as the inputs.

Programmatic Use**Block Parameter:** AllowUnequalInputPortWidths**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Input port offsets — Offset for input signals**

[] (default) | vector

Enter a vector to specify the offset of each input signal relative to the beginning of the output signal.

Programmatic Use**Block Parameter:** InputPortOffsets**Type:** character vector**Values:** scalar | vector

Default: '[]'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

In the code generation workflow, when the Merge block receives a constant value and non-constant sample times, one of these conditions must hold. Otherwise Simulink displays an error.

- The source of the constant value is a grounded signal.
- The source of the constant value is a constant block with a non-tunable parameter.
 - There is only one constant block that feeds the Merge block.
 - All other input signals to the Merge block are from conditionally executed subsystems.
 - The Merge block and output blocks of all conditionally executed subsystems does not specify any initial outputs.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Entity Transport Delay

Introduce a delay in propagation of a SimEvents message

Library: Simulink / Continuous
SimEvents

Description

The Entity Transport Delay block delays an entity for a period of time, named *transport delay*. The first input is the entity that is transported from point A to point B on a constant-length moving surface whose speed changes over time. The value from the second input is the *instantaneous delay*. The speed of the surface is the reciprocal of instantaneous delay. The product of instantaneous delay and the speed is 1.

The block calculates the implemented transport delay by the distance-speed-time relationship, where the surface length (distance) is equal to the integral of the variable surface speed over the duration of the transport delay (time). For more information about this calculation, see Variable Transport Delay.

The Entity Transport Delay block connects SimEvents to Simulink using the input from a Simulink signal and computing the transport delay as a continuous process, and applying this delay to an entity in a discrete-event process. For an example that uses the Entity Transport Delay block, see “Modeling Cyber-Physical Systems” on page 14-656.

Ports

Input

Port_1 — Input entity

SimEvents entity

SimEvents entity or message. For more information on entities in SimEvents, see “Entities in a SimEvents Model” (SimEvents).

t_i — Instantaneous delay

scalar | vector | matrix

Instantaneous delay in the transport of the SimEvents entity. t_i is the reciprocal of the speed of the entity. For more information on the calculation of instantaneous delay, see “Variable Transport Delay” on page 1-1659.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | bus

Output

Port_1 — Delayed entity

SimEvents entity

SimEvents entity with the instantaneous delay t_i applied to it.

n – Number of delayed entities

real scalar

Secondary output signal of the block, which displays the number of entities processed in a time step.

Dependencies

To enable this port, enable the **Output number of entities in block, n** parameter

Data Types: double

Parameters**Capacity – Specify the capacity of the block**

inf (default) | scalar

Specify capacity to accept entities to be delayed.

Programmatic Use**Block Parameter:** Capacity**Type:** character vector**Values:** 'inf' | real scalar**Default:** 'inf'**Output number of entities in block, n – Outputs the number of delayed entities present in the block**

off (default) | on

Number of entities present in the block that are being delayed.

Programmatic Use**Block Parameter:** ShowNumberEntitiesInBlock**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	yes

“Establish Message Send and Receive Interfaces Between Software Components”

Introduced in R2019b

Receive, Message Receive

Extract data from received messages

Library: Simulink / Messages & Events
SimEvents

Description

The Send block extracts data from received messages and writes them to the output signal port. If there are no new messages when the block executes, the block uses the **Value source when queue is empty** value. Receive and Message Receive blocks are identical blocks.

- Select `Hold last value` to hold data read from the last message.
- Select `Use initial value` to write default data.

Ports

Input

Port_1 – Input message

scalar | vector | matrix

The input port for the message.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Output

Port_S – Show whether a message was received

scalar

Outputs 1 if the block receives a message successfully, and 0 otherwise.

Dependencies

To enable this port, select the check box labeled **Show receive status**.

Data Types: double

Port_1 – Output signal

scalar | vector | matrix

Output port for the signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Parameters

Use internal queue – Select to use an internal queue

on (default for SimEvents) | off (default for Simulink)

Select this check box if you use an internal queue to receive messages.

Programmatic Use**Block Parameter:** UseInternalQueue**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Overwrite the oldest element if queue is full — Specify queue overwriting policy**

on (default for Simulink) | off (default for SimEvents)

Select this check box to choose between two queue overwriting policies.

- If you select the check box, an incoming message overwrites the oldest if the queue is full.
- If you clear the check box, the block does not accept new messages if the queue is full.

Dependencies

This parameter is visible when you select the box labeled **Use internal queue**.

Programmatic Use**Block Parameter:** QueueOverwriting**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on' (for Simulink) and 'off' (for SimEvents)**Queue length — Specify the length of the message queue**

16 (default) | scalar

Specify message queue capacity. The queue length can be specified as a positive integer between 1 and $2^{26}-1$ (both included).

Dependencies

This parameter is visible when you select the box labeled **Use internal queue**.

Programmatic Use**Block Parameter:** QueueLength**Type:** character vector**Values:** '16' | scalar**Default:** '16'**Queue type — Specify message queue sorting policy**

FIFO (default) | LIFO | Priority

The block supports three message sorting policies:

- First-in-first-out (FIFO) — The oldest message in the storage departs first.
- Last-in-first-out (LIFO) — The newest message in the storage departs first.
- Priority — Messages or entities are sorted based on their priority.

The priority queue can be used only when the **Overwrite the oldest element if queue is full** check box is cleared.

Note Priority queue accepts only non-bus scalar and it does not support fixed point data type.

Dependencies

This parameter is visible when you select the box labeled **Use internal queue**.

Programmatic Use

Block Parameter: QueueType

Type: character vector

Values: 'FIFO' | 'LIFO' | 'Priority'

Default: 'FIFO'

Priority order — Specify message queue priority

Ascending (default) | Descending

Choose the direction of sorting messages based on priority.

- Ascending — Messages with smaller priority values appear in front of the queue.
- Descending — Messages with greater priority values appear in front of the queue.

Dependencies

This parameter is visible when you select the box labeled **Use internal queue** and **Queue type > Priority**.

Programmatic Use

Block Parameter: PriorityOrder

Type: character vector

Values: 'Ascending' | 'Descending'

Default: 'Ascending'

Show receive status — Show whether a message was received

off (default) | on

Select this check box to show whether a message was received. If this check box is selected the block outputs 1 if it receives a message successfully, and 0 otherwise.

Programmatic Use

Block Parameter: ShowQueueStatus

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Initial value — Set initial data value

[](unspecified) (default) | scalar

Enter an initial data value for the queue before the arrival of the first message. The default value [] (unspecified) is treated as 0 with data type double.

Programmatic Use

Block Parameter: InitialValue

Type: character vector

Values: '[]' | scalar

Default: '[]'

Value source when queue is empty — Value source for empty queue

Hold last value (default) | Use initial value

Specify the value to receive when received message queue is empty.

- **Hold last value (default)** — Holds data read from the last message.
Initially, if the block tries to receive a message and fails, it outputs the initial value.
- **Use initial value** — Writes default data.

Dependencies

This parameter is visible when you select the box labeled **Use internal queue**.

Programmatic Use

Block Parameter: ValueSourceWhenQueueIsEmpty

Type: character vector

Values: 'Hold last value' | 'Use initial value'

Default: 'Hold last value'

Sample time (-1 for inherited) — Specify the time interval between samples

-1 (default) | scalar

To inherit the sample time, set this parameter to -1. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: '-1' | scalar

Default: '-1'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Send

Topics

“Simulink Messages Overview”

Introduced in R2016a

Send, Message Send

Create and send message

Library: Simulink / Messages & Events
SimEvents

Description

The Send block reads the value of an input signal, and sends a message that carries this value. In message-based communication, a message is a discrete-item of interest that carry data of any type that Simulink supports. Send and Message Send blocks are identical blocks.

Ports

Input

Port_Enable — External enable signal

scalar

Input port to enable the block to send a message. For any input value that is greater than 0 send is enabled. For any value less than or equal to 0, the send is disabled.

Dependencies

To enable this port, select the box labeled **Show enable port**.

Data Types: double

Port_1 — Input signal

scalar | vector | matrix

This block accepts inputs of any type that Simulink supports, including enumerated types and converts the input signal to a message. For more information, see “Data Types Supported by Simulink”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Output

Port_1 — Output message

scalar | vector | matrix

The block outputs a message with constant priority 20.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Parameters

Show enable port — Display the enable port

off (default) | on

Select this check box to display enable port.

Programmatic Use

Block Parameter: ShowEnablePort

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

“Simulink Messages Overview”

Introduced in R2016a

MinMax

Output minimum or maximum input value

Library: Simulink / Math Operations
HDL Coder / Math Operations

Description

The MinMax block outputs either the minimum or the maximum element or elements of the inputs. You choose whether the block outputs the minimum or maximum values by setting the **Function** parameter.

The MinMax block ignores any input value that is NaN, except when every input value is NaN. When all input values are NaN, the output is NaN, either as a scalar or the value of each output vector element.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Provide an input signal from which the block outputs the maximum or minimum values.

- When the block has one input port, the input must be a scalar or a vector. The block outputs a scalar equal to the minimum or maximum element of the input vector.
- When the block has multiple input ports, all nonscalar inputs must have the same dimensions. The block expands any scalar inputs to have the same dimensions as the nonscalar inputs. The block outputs a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Dependencies

To support matrix input, you must set the **Number of input ports** parameter to an integer greater than one. All nonscalar inputs must have the same dimensions.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_N — N-th input signal

scalar | vector | matrix

Provide an input signal from which the block outputs the maximum or minimum values.

When the block has multiple input ports, all nonscalar inputs must have the same dimensions. The block expands any scalar inputs to have the same dimensions as the nonscalar inputs. The block outputs a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Dependencies

To provide more than one input signal, set the **Number of input ports** to an integer greater than 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Port_1 — Minimum or maximum values of inputs

`scalar` | `vector` | `matrix`

When the block has one input, the output is a scalar value, equal to the minimum or maximum of the input elements. When the block has multiple inputs, the output is a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Main

Function — Specify minimum or maximum

`min (default)` | `max`

Specify whether to apply the function `min` or `max` to the input.

Programmatic Use

Block Parameter: `Function`

Type: `character vector`

Values: `'min'` | `'max'`

Default: `'min'`

Number of input ports — Specify number of input ports

`1 (default)` | `positive integer`

Specify the number of inputs to the block.

Programmatic Use

Block Parameter: `Inputs`

Type: `character vector`

Values: `positive integer`

Default: `'1'`

Enable zero-crossing detection — Enable zero-crossing detection

`on (default)` | `Boolean`

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use

Block Parameter: `ZeroCross`

Type: `character vector, string`

Values: `'off'` | `'on'`

Default: 'on'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Signal Attributes

Require all inputs to have the same data type — Inputs must have the same data type

off (default) | on

Select this check box to require that all inputs have the same data type.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output maximum — Maximum output value for range checking**

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type — Specify the output data type**

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' |

'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools – Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (off).	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	yes

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

Architecture	Additional cycles of latency	Description
default Tree	0	Generates a tree structure of comparators.
Cascade	1, when block has a single vector input port.	This implementation is optimized for latency * area, with medium speed. See “Cascade Architecture Best Practices” (HDL Coder).

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
InstantiateStages	Generate a VHDL entity or Verilog module for each cascade stage. The default is off. See also “InstantiateStages” (HDL Coder).
SerialPartition	Specify partitions for Cascade-serial implementations as a vector of the lengths of each partition. The default setting uses the minimum number of stages. See also “SerialPartition” (HDL Coder).

Note To enable the **LatencyStrategy** setting for the MinMax block, you must specify Tree as the **HDL Architecture**.

Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to inherit, Max, Min, or Zero for the floating-point operator. The default is inherit. See also “LatencyStrategy” (HDL Coder).

MinMax Running Resettable

Introduced before R2006a

MinMax Running Resettable

Determine minimum or maximum of signal over time

Library: Simulink / Math Operations

Description

The MinMax Running Resettable block outputs the minimum or maximum of all past inputs u . You specify whether the block outputs the running minimum or maximum with the **Function** parameter.

The block can reset its state based on an external reset signal R . When the reset signal R is nonzero (`true`), the block resets the output to the value of the **Initial condition** parameter.

The input can be a scalar, vector, or matrix signal. The block outputs a signal having the same dimensions as the input. Each output element equals the running minimum or maximum of the corresponding input elements.

Ports

Input

u — Input signal

scalar | vector | matrix

Input signal as a scalar, vector, or matrix. Based on what you specify for the **Function** parameter, the block outputs the minimum or maximum value of all past inputs u .

If you specify a scalar value for the **Initial condition** parameter, the block expands the parameter to have the same dimensions as nonscalar input u .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `bus`

R — Reset signal

scalar | vector | matrix

The input port accepting the reset signal as a scalar, vector, or matrix. When the reset signal is nonscalar, it must have the same dimensions as input signal u . As long as the reset signal has a value of zero, the block outputs the running minimum or maximum value of input u . Whenever the reset signal has a nonzero value (`true`), the block resets the output to the value of the **Initial condition** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `bus`

Output

y — Running minimum or maximum value

scalar | vector | matrix

Output signal, specified as a scalar, vector, or matrix, where each output element equals the running minimum or maximum value of the corresponding input elements. Output signal **y** has the same data type and dimensions as input signal **u**.

When the block receives a nonzero (**true**) reset signal, the block resets the output to the value of the **Initial condition** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Function — Specify minimum or maximum

`min` (default) | `max`

Specify whether the block outputs the running minimum or maximum value of the corresponding input elements.

Programmatic Use

Block Parameter: `Function`

Type: character vector

Values: `'min'` | `'max'`

Default: `'min'`

Initial condition — Value to reset output to

`0.0` (default) | scalar or vector

Specify the initial condition value. When the reset input signal **R** is **true**, the block resets the output to the value you specify.

Programmatic Use

Block Parameter: `vinit`

Type: character vector

Values: scalar or vector

Default: `'0.0'`

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Model

Reference another model to create model hierarchy

Library: Simulink / Ports & Subsystems
HDL Coder / Ports & Subsystems

Description

The Model block includes a model as a block in another model. The included model is called a *referenced model*, and the model that contains the Model block is called the *parent model*.

The Model block displays input and output ports that correspond to the top-level input and output ports of the referenced model. Using these ports allow you to connect the referenced model to other blocks in the parent model.

By default, you can see the contents of a referenced model by double-clicking the Model block. However, if you have a Simulink Coder license, you can conceal the implementation details of a referenced model by protecting the model. See “Protect Models to Conceal Contents” (Simulink Coder). If you receive a protected model, see “Reference Protected Models from Third Parties”.

To specify the referenced model and set simulation parameters, open the Block Parameters dialog box and use the **Main** tab. To specify instance-specific values for model arguments, use the **Instance parameters** tab.

Ports

Input

Port_1 — Input port corresponding to root-level blocks of referenced model

real or complex values of any data type supported by Simulink

The Model block has an input port for each input port of the model it references. The input ports of referenced models are defined by Inport, In Bus Element, Trigger, and Enable blocks. The name of the Model block port matches the name of the corresponding port in the referenced model. The input signal for each Model block port must be valid for the corresponding port in the referenced model. See “Model Reference Interface and Boundary”.

Input signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. For details about data types, see “Data Types Supported by Simulink”.

Output

Port_1 — Output port corresponding to root-level blocks of referenced model

real or complex values of any data type supported by Simulink

The Model block has an output port for each output port of the model it references. The output ports of referenced models are defined by Outport and Out Bus Element blocks. The name of the Model block port matches the name of the corresponding port in the referenced model. The output signals of

the Model block are the signals connected to the Outport and Out Bus Element blocks in the referenced model. See “Model Reference Interface and Boundary”.

Output signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. For details about data types, see “Data Types Supported by Simulink”.

Parameters

Main

Model name — File name of referenced model

' ' (default) | character vector

File name of the referenced model, specified as a character vector. The file extension is optional.

The file name must be a valid MATLAB identifier for a model, as defined in “Model Names”.

To navigate to the model that you want to reference, click **Browse**.

To view the model that you specified, click **Open Model**.

Programmatic Use

Parameter: ModelFile

Type: character vector

Value: ' ' | '<file name>'

Default: ' '

Simulation mode — Simulation mode for model reference

Normal (default) | Accelerator | Software-in-the-loop (SIL) | Processor-in-the-loop (PIL)

Specify the simulation mode for the Model block. The simulation mode for the Model block can be different than the simulation mode of its referenced model and of other models in the model hierarchy.

- **Accelerator** — Create a MEX-file for the referenced model and then execute the referenced model by running the S-function.
- **Normal** — Execute the referenced model interpretively, as if the referenced model is an atomic subsystem implemented directly within the parent model.
- **Software-in-the-loop (SIL)** — This option requires an Embedded Coder license. Generate production code based on the **Code Interface** parameter setting. The code is compiled for, and executed on, the host platform.
- **Processor-in-the-loop (PIL)** — This option requires an Embedded Coder license. Generate production code based on the **Code Interface** parameter setting. This code is compiled for, and executed on, the target platform. A target connectivity API implementation supports the exchange of data between the host and target at each time step during the PIL simulation.

The corners of the Model block indicate the simulation mode of the Model block. For normal mode, the corners have empty triangles. For accelerator mode, the corner triangles are filled in. For SIL and PIL modes, the corners are filled in and the word (SIL) or (PIL) appears on the block icon.

Although you can specify any simulation mode for a model, when you reference that model, the Model block specifies the simulation mode of the referenced model instance. The simulation mode of a

parent model can override the simulation mode of a Model block. See “Overridden Simulation Modes”.

Programmatic Use

Parameter: SimulationMode

Type: character vector

Value: 'Normal' | 'Accelerator' | 'Software-in-the-loop' | 'Processor-in-the-loop'

Default: 'Normal'

Code interface — Generate code from top model or referenced model

Model reference (default) | Top model

Specify whether to generate the code from the top model or the referenced model for SIL and PIL simulation modes. To deploy the generated code as part of a larger application that uses the referenced model, specify Model reference. To deploy the generated code as a standalone application, specify Top model.

Model reference

The code is generated from the referenced model as part of a model hierarchy. Code generation uses the `slbuild('model', 'ModelReferenceCoderTarget')` command.

Top model

The code is generated from the top model with the standalone code interface. Code generation uses the `slbuild('model')` command.

Dependencies

To enable this parameter, set **Simulation mode** to either Software-in-the-loop (SIL) or Processor-in-the-loop (SIL).

Programmatic Use

Parameter: CodeInterface

Type: character vector

Value: 'Model reference' | 'Top model'

Default: 'Model reference'

Show model initialize port — Control display of initialize event port

off (default) | on

Control the display of the initialize event port on the Model block.

off

Remove the port.

on

Display the model initialize event port.

Programmatic Use

Block parameter: ShowModelInitializePort

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show model reset ports — Control display of reset event ports

off (default) | on

Control the display of the reset event ports on the Model block.

off

Remove the ports.

on

Display the model reset event ports.

Dependencies

To enable this parameter, add a Reset Function block to the referenced model. To specify the port name, use the **Event name** parameter of the Event Listener block in the Reset Function block.

Programmatic Use

Block parameter: ShowModelResetPorts

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show model terminate port — Control display of terminate event port

off (default) | on

Control the display of the terminate event port on the Model block.

off

Remove the port.

on

Display the model terminate event port.

Dependencies

To enable this parameter, select **Show model initialize port**.

Programmatic Use

Block parameter: ShowModelTerminatePort

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Schedule rates — Control display of periodic event ports

off (default) | on

Control the display of the periodic event ports on the Model block.

off

Hide the ports.

on

Display the ports for rate-based models. A rate-based model is a model with the **Sample time** for a connected Inport block specified.

If you want to manually specify the port rates, set the parameter `AutoFillPortDiscreteRates` to 'off', and then add the port rates to the parameter `PortDiscreteRates`.

Programmatic Use**Block parameter:** ScheduleRates**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Schedule rates with — Control display of periodic event ports**

Ports (default) | Schedule Editor

Control display of periodic event ports on Model block.

Ports

Display ports for rate-based models.

Schedule Editor

Create partitions for rate-based models.

Dependencies

To enable this parameter, select **Schedule rates**.

Programmatic Use**Block parameter:** ScheduleRatesWith**Type:** character vector**Value:** 'Ports' | 'ScheduleEditor'**Default:** 'Ports'**Instance Parameters****Instance parameters — Display instance parameters and specify values for referenced model**

number | workspace variable | mathematical expression | structure or structure field

Display instance parameters and specify instance-specific values. Instance parameters are block parameters that have been configured in the referenced model to use a different value for each instance of the model.

To specify instance-specific values, use the **Value** column in the table. To specify that a parameter value can be overridden by the parent model, select the **Argument** check box. For more information about configuring instance parameters in a referenced model and specifying instance-specific values at the Model block, see “Parameterize Instances of a Reusable Referenced Model”.

When changing instance-specific values, you can use a partial structure that has fields that correspond to only the instance parameters whose values you want to change. Instance parameters not included in the partial structure retain their values. In the structure, include the instance parameter names and values, specified as character vectors.

Programmatic Use**Block parameter:** ParameterArgumentValues**Type:** structure**Value:** structure**Default:** structure with no fields**Block parameter:** InstanceParameters**Type:** structure array**Value:** structure with fields: Name, Value, Path, and Argument.

Block Characteristics

Direct Feedthrough	no
Multidimensional Signals	limited ^a
Variable-Size Signals	limited ^a
Zero-Crossing Detection	no

a. Actual data type or capability support depends on block implementation.

Compatibility Considerations

Specifying variant models in Model blocks is no longer supported

Warns starting in R2019a

Starting in R2019a, specifying variant models in Model blocks is no longer supported. The Model Variants block, which was a Model block preconfigured to specify variant models, is also no longer supported. Loading a model that contains these blocks converts them to Variant Subsystem blocks that contain Model blocks that represent the variant choices.

Variant Subsystem blocks provide these advantages:

- You can mix Model blocks and Subsystem blocks as variant choices.
- You can specify variants that have different numbers of input and output ports.

The Variant Subsystem block parameter **Analyze all choices during update diagram and generate preprocessor conditionals** behaves differently from the Model block parameter **Generate preprocessor conditionals**. Instead of causing simulation and update diagram to compile the active variant only, the Variant Subsystem block parameter compiles all variants.

If you have scripts that use Model block parameters for variants, you must update them to use Variant Subsystem block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information about using the Model block for HDL code generation and best practices and limitations, see “Model Referencing for HDL Code Generation” (HDL Coder).

See also “Generate Black Box Interface for Referenced Model” (HDL Coder) and “Generate Parameterized Code for Referenced Models” (HDL Coder).

HDL Architecture

Architecture	Description
ModelReference (default)	When you want to generate code from a referenced model and any nested models, use the ModelReference implementation. For more information, see “How To Generate Code for a Referenced Model” (HDL Coder).
BlackBox	Use the BlackBox implementation to instantiate an HDL wrapper, or black box interface, for legacy or external HDL code. If you specify a black box interface, HDL Coder does not attempt to generate HDL code for the referenced model. For more information, see “Generate Black Box Interface for Referenced Model” (HDL Coder).

Black Box Interface Customization

For the BlackBox architecture, you can customize port names and set attributes of the external component interface. See “Customize Black Box or HDL Cosimulation Interface” (HDL Coder).

HDL Block Properties

BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>off</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . See also “DSPStyle” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

ReferenceModelPrefix	<p>Prefix of the referenced model to insert in the generated code. The code generator applies this prefix to submodel file names and HDL identifiers. The default prefix is <code>modelName_</code> where <code>modelName</code> is the name of the referenced model.</p> <hr/> <p>Note</p> <ul style="list-style-type: none"> • If you specify an empty prefix, the code generator does not add a prefix to submodel file names. This can cause HDL compilation errors due to naming collisions between the models. • If you use the referenced model as the DUT, the code generator ignores the prefix that you specify.
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also “Streaming” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

Model Info

Display model properties and text in model

Library: Simulink / Model-Wide Utilities
HDL Coder / Model-Wide Utilities

Description

The Model Info block displays model properties and text about a model on the mask of the block. Use the Model Info block dialog box to specify the content and format of the text that the block displays. You can select model properties to display on the block. In the text displayed on the block mask, Simulink replaces the property name with the current value of the property in the model.

Parameters

Specify Text and Properties to Display – Content and format of the text to display
no default

Use the **Enter text and tokens to display on Model Info block** edit box to specify the text and properties to display.

- In the edit box, enter any text you want to display on the block mask. Edit the default text Model Info.
- To display a model property on the block mask, select a property in the **Model properties** list and click the right arrow button.

The block adds a token of the form %<modelpropertyname> to the edit box. In the text the block mask displays, Simulink replaces the token with the value of the property.

- 1 For example, if you select **Description** in the **Model properties** list and click the right arrow button, then the token

```
%<Description>
```

appears in the right edit box.

- 2 You could add some explanatory text before the model property, e.g. "Model description:".
- 3 When you click **Apply** or **OK**, Simulink displays your new text and the current value of the model property on the block mask in the Model Editor.

See "Access Model Information Programmatically" for descriptions of the model properties.

If you are interested in source control information, for a flexible interface to source control tools, use a project. See "Source Control in Projects".

Block Characteristics

Data Types	
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Model Info block is ignored during code generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Best Practices

When using Model Info blocks in models targeted for HDL code generation, consider using only ASCII characters in the text that you enter to display on the Model Info block. If you have non-ASCII characters in the generated HDL code, RTL simulation and synthesis tools can fail to compile the code.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Multiport Switch

Select output signal based on control signal

Library: Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The Multiport Switch block determines which of several inputs to the block passes to the output. The block bases this decision on the value of the first input. The first input is the control input and the remaining inputs are the data inputs. The value of the control input determines which data input passes to the output.

The table summarizes how the block interprets the control input and determines the data input that is passed to the output.

Control Input	Truncation	Setting for Data Port Order	Block Behavior During Simulation	
			Indexing to Select Data Input	Out-of-Range Condition
Integer value	None	Zero-based contiguous	Zero-based indexing	The control input is less than 0 or greater than the number of data inputs minus one.
		One-based contiguous	One-based indexing	The control input is less than 1 or greater than the number of data inputs.
		Specify indices	Indices you specify	The control input does not correspond to any specified data port index.
Not an integer value	The block truncates the value to an integer by rounding to zero.	Zero-based contiguous	Zero-based indexing	The truncated control input is less than 0 or greater than the number of data inputs minus one.
		One-based contiguous	One-based indexing	The truncated control input is less than 1 or greater than the number of data inputs.
		Specify indices	Indices you specify	The truncated control input does not correspond to any specified data port index.

For information on how the block handles the out-of-range condition, see “How the Block Handles an Out-of-Range Control Input” on page 1-982.

Multiport Switch Configured as an Index Vector Block

An Index Vector is a special configuration of a Multiport Switch block in which you specify one data input and the control input is zero-based. The block output is the element of the input vector whose index matches the control input. For example, if the input vector is [18 15 17 10] and the control input is 3, the element that matches the index of 3 (zero-based) is 10, and that becomes the output value.

To configure a Multiport Switch block to work as an Index Vector block, set **Number of data ports** to 1 and **Data port order** to Zero-based contiguous.

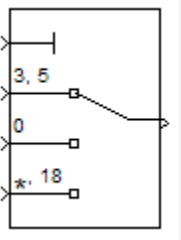

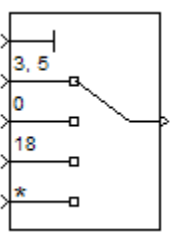

How the Block Handles an Out-of-Range Control Input

For an input with an integer value less than `intmax('int32')`, the input is out of range when the value does not match any data port indices. For a control input that is not an integer value, the input is out of range when the *truncated* value does not match any data port indices. In both cases, the block behavior depends on your settings for **Data port for default case** and **Diagnostic for default case**.

Note If the control input is larger than `intmax('int32')`, the block wraps the input value to an integer.

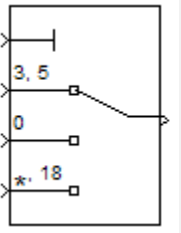

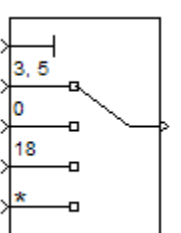

Behavior for Simulation

The following behavior applies only to simulation for your model.

Data Port for Default Case	Diagnostic for Default Case		
	None	Warning	Error
Last data port 	Use the last data port and do not report any warning or error.	Use the last data port and report a warning.	Report an error and stop simulation.
Additional data port 	Use the additional data port with a * label and do not report any warning or error.	Use the additional data port with a * label and report a warning.	Report an error and stop simulation.

Behavior for Code Generation

The following behavior applies to code generation for your model.

Data Port for Default Case	Diagnostic for Default Case		
	None	Warning	Error
Last data port 	Use the last data port.	Use the last data port.	Use the last data port.
Additional data port 	Use the additional data port with a * label.	Use the additional data port with a * label.	Use the additional data port with a * label.

Use Data Inputs That Have Different Dimensions

If two signals have a different number of dimensions or different dimension lengths, you can use the signals as data inputs to a Multiport Switch block. In the block dialog box, select the parameter **Allow different data input sizes**. In this case, the output of the block is a variable-size signal. If you do not select this parameter, the block generates an error.

For more information about the parameter, see “Allow different data input sizes (Results in variable-size output signal)” on page 1-0 . For more information about variable-size signals, see “Variable-Size Signal Basics”.

Rules That Determine the Block Behavior

You specify the number of data inputs with **Number of data ports**.

- If you set **Number of data ports** to 1, the block behaves as an *index selector* or *index vector* and not as a multiport switch. For more details, see “Multiport Switch Configured as an Index Vector Block” on page 1-982.
- If you set **Number of data ports** to an integer greater than 1, the block behaves as a multiport switch. The block output is the data input that corresponds to the value of the control input. If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If all the data inputs are scalar, the output is a scalar.

Guidelines on Setting Parameters for Enumerated Control Port

When the control port on the Multiport Switch block is of enumerated type, follow these guidelines:

Scenario	What to Do	Rationale
The enumerated type contains a value that represents invalid, out-of-range, or uninitialized values.	<ul style="list-style-type: none"> Set Data port order to Specify indices. Set Data port indices to use this value for the last data port. Set Data port for default case to Last data port. 	This block configuration handles invalid values that the enumerated type explicitly represents.
The enumerated type contains only valid enumerated values. However, a data input port can get invalid values of enumerated type.	<ul style="list-style-type: none"> Set Data port for default case to Additional data port. 	This block configuration handles invalid values that the enumerated type does not explicitly represent.
The enumerated type contains only valid enumerated values. Data input ports can never get invalid values of enumerated type.	<ul style="list-style-type: none"> Set Data port for default case to Last data port. Set Diagnostic for default case to None. 	This block configuration avoids unnecessary diagnostic action.
The block does not have a data input port for every value of the enumerated type.	<ul style="list-style-type: none"> Set Data port for default case to Additional data port. 	This block configuration handles enumerated values that do not have a data input port, along with invalid values.

Limitations

- If the data inputs to the Multiport Switch block are buses, the element names of both buses must be the same. Using the same element names ensures that the output bus has the same element names no matter which input bus the block selects. To ensure that your model meets this requirement, use a bus object to define the buses and set the **Element name mismatch** diagnostic to error. See “Connectivity Diagnostics Overview” for more information.

Ports

Input

Port_1 – Control signal

scalar

The control signal can be of any data type that Simulink supports, including fixed-point and enumerated types. When the control input is not an integer value, the block truncates the value to an integer by rounding to zero.

For information on control signals of enumerated type, see “Guidelines on Setting Parameters for Enumerated Control Port” on page 1-984.

For information on how the block handles the out-of-range condition, see “How the Block Handles an Out-of-Range Control Input” on page 1-982.

Limitations

- If the control signal is numeric, the control signal cannot be complex.
- If the control signal is an enumerated signal, the block uses the value of the underlying integer to select a data port.
- If the underlying integer does not correspond to a data port, an error occurs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

1 — First data input

`scalar` | `vector` | `matrix` | N-D array

First data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-983
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `string`

2 — Second data input

`scalar` | `vector` | `matrix` | N-D array

Second data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-983
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Dependencies

To enable this port, set **Number of data ports** to an integer greater than 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `string`

N – Nth data input

scalar | vector | matrix | N-D array

Nth data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-983
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Dependencies

To enable the Nth input port, set **Number of data ports** to an integer value greater than or equal to N.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | string

*** – Data port for out-of-range inputs**

scalar | vector | matrix | N-D array

Input data port for out-of-range control signal inputs, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports. If any data signal is of an enumerated type, all others must be of the same enumerated type. If any two signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-983.

Dependencies

To create an additional data port for out-of-range control signal inputs, set **Data port for default case** to **Additional data port**. When you set **Data port for default case** to **Last data port**, the block uses the last data port for output when the control signal value does not match any data port indices.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output**Port_1 – Selected data input, based on control signal value**

scalar | vector | matrix | N-D array

The block outputs one of the data inputs, selected according to the control signal value. The output has the same dimensions as the corresponding data input. When you select the **Allow different data input sizes** check box, the output of the block is a variable size signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | string

Parameters

Main

Data port order — Type of ordering for data input ports

One-based contiguous | Zero-based contiguous | Specify indices

Specify the type of ordering for your data input ports.

- **Zero-based contiguous** — Block uses zero-based indexing for ordering contiguous data ports. This is the default value of the Index Vector block.
- **One-based contiguous** — Block uses one-based indexing for ordering contiguous data ports. This is the default value of the Multiport Switch block.
- **Specify indices** — Block uses noncontiguous indexing for ordering data ports.

Tips

- When the control port is of enumerated type, select **Specify indices**.
- If you select **Zero-based contiguous** or **One-based contiguous**, verify that the control port is not of enumerated type. This configuration is deprecated and produces an error. You can run the Upgrade Advisor on your model to replace each Multiport Switch block of this configuration with a block that explicitly specifies data port indices. See “Model Upgrades”.
- Avoid situations where the block contains unused data ports for simulation or code generation. When the control port is of fixed-point or built-in data type, verify that all data port indices are representable with that type. Otherwise, the following block behavior occurs.

If the Block Has Unused Data Ports and Data Port Order Is:	The Block Produces:
Zero-based contiguous or One-based contiguous	A warning
Specify indices	An error

Dependencies

Selecting **Zero-based contiguous** or **One-based contiguous** enables the **Number of data ports** parameter.

Selecting **Specify indices** enables the **Data port indices** parameter.

Programmatic Use

Block Parameter: DataPortOrder

Type: character vector

Values: 'Zero-based contiguous' | 'One-based contiguous' | 'Specify indices'

Default: 'One-based contiguous' (Multiport Switch) 'Zero-based contiguous' (Index Vector)

Number of data ports — Number of data input ports

1 | 3 | integer between 1 and 65535

Specify the number of data input ports to the block. The total number of input ports is the number you specify, plus one for the control signal input port, and plus one more if you set **Data port for default case** to Additional data port.

Dependencies

To enable this parameter, set **Data port order** to Zero-based contiguous or One-based contiguous.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: integer between 1 and 65536

Default: '3' (Multiport Switch) '1' (Index Vector)

Data port indices — Array of indices for data ports

{1,2,3} (default) | array of indices

Specify an array of indices for your data ports. The block icon changes to match the data port indices you specify.

Tips

- To specify an array of indices that correspond to all values of an enumerated type, enter `enumeration('type_name')` for this parameter. Do not include braces.

For example, `enumeration('MyColors')` is a valid entry.

- To enter specific values of an enumerated type, use the `type_name.enumerated_name` format. Do not enter the underlying integer value.

For example, `{MyColors.Red, MyColors.Green, MyColors.Blue}` is a valid entry.

- To indicate that more than one value maps to a data port, use brackets.

For example, the following entries are both valid:

- `{MyColors.Red, MyColors.Green, [MyColors.Blue, MyColors.Yellow]}`
- `{[3,5],0,18}`
- If the control port is of fixed-point or built-in data type, the values for **Data port indices** must be representable with that type. Otherwise, an error appears at compile time to alert you to unused data ports.
- If the control port is of enumerated data type, the values for **Data port indices** must be enumerated values of that type.
- If **Data port indices** contains values of enumerated type, the control port must be of that data type.

Dependencies

To enable this parameter, set **Data port order** to Specify indices.

Programmatic Use

Block Parameter: DataPortIndices

Type: character vector

Values: array of indices

Default: '{1,2,3}'

Data port for default case — Port to use for out-of-range inputs

Last data port (default) | Additional data port

Specify whether to use the last data port for out-of-range inputs, or to use an additional port. An asterisk (*) next to the port name indicates the port the block uses when the control port value does not match any data port indices.

- **Last data port** — Block uses the last data port for output when the control port value does not match any data port indices.
- **Additional data port** — Block uses an additional data port for output when the control port value does not match any data port indices.

Tip

If you set this parameter to **Additional data port** and **Number of data ports** is 3, the number of input ports on the block is 5. The first input is the control port, the next three inputs are data ports, and the fifth input is the default port for out-of-range inputs.

Programmatic Use

Block Parameter: DataPortForDefault

Type: character vector

Values: 'Last data port' | 'Additional data port'

Default: 'Last data port'

Diagnostic for default case — Diagnostic action when control port value does not match data port indices

Error (default) | Warning | None

Specify the diagnostic action to take when the control port value does not match any data port indices.

- **None** — Produce no response.
- **Warning** — Display a warning and continue the simulation.
- **Error** — Terminate the simulation and display an error. In this case, the **Data port for default case** is used only for code generation and not simulation.

For more information, see “How the Block Handles an Out-of-Range Control Input” on page 1-982.

Programmatic Use

Block Parameter: DiagnosticForDefault

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'Error'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Signal Attributes

Require all data port inputs to have the same data type — Require all inputs to have the same data type

off (default) | on

Select this check box to require that all data input ports have the same data type. When you clear this check box, the block allows data port inputs to have different data types.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.

- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output data type — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2⁰,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule**—Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:
 - Specify the output data type explicitly.
 - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
 - To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Uses the data type of the driving block.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2⁰,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode — Specify the rounding mode for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Floor'**See Also**

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- off — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- on — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Allow different data input sizes (Results in variable-size output signal) — Allow input signals with different sizes**

off (default) | on

Select this check box to allow input signals with different sizes.

- On — Allows input signals with different sizes, and propagate the input signal size to the output signal. In this mode, the block produces a variable-size output signal.
- Off — Requires that all nonscalar data input signals be the same size.

Programmatic Use**Parameter:** AllowDiffInputSizes**Type:** character vector**Value:** 'on' | 'off'**Default:** 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

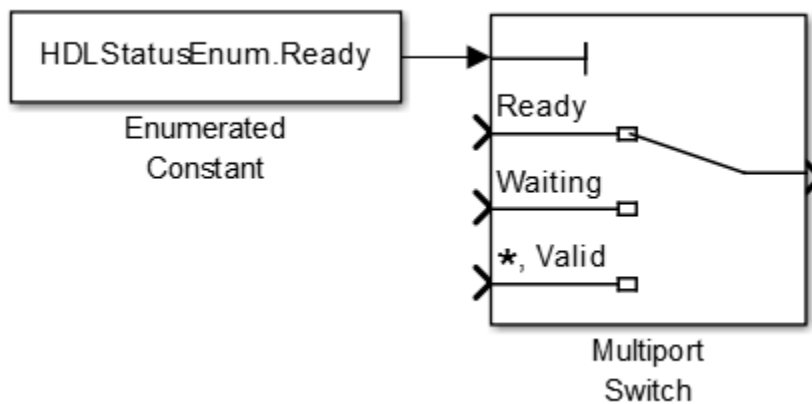

General	
CodingStyle	Specify whether to generate HDL code with case statements or if-else statements. By default, HDL Coder generates if-else statements. See also “CodingStyle” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Using an Enumerated Type as Port Index

You can set **Data port order** to **Specify indices**, and enter enumeration values for the **Data port indices**. For example, you can connect the Enumerated Constant block to the Multiport Switch control port and use the enumerated types as data port indices.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

“Variable-Size Signal Basics”

Introduced before R2006a

MultiStateImage

Display image reflecting input value

Library: Simulink / Dashboard

Description

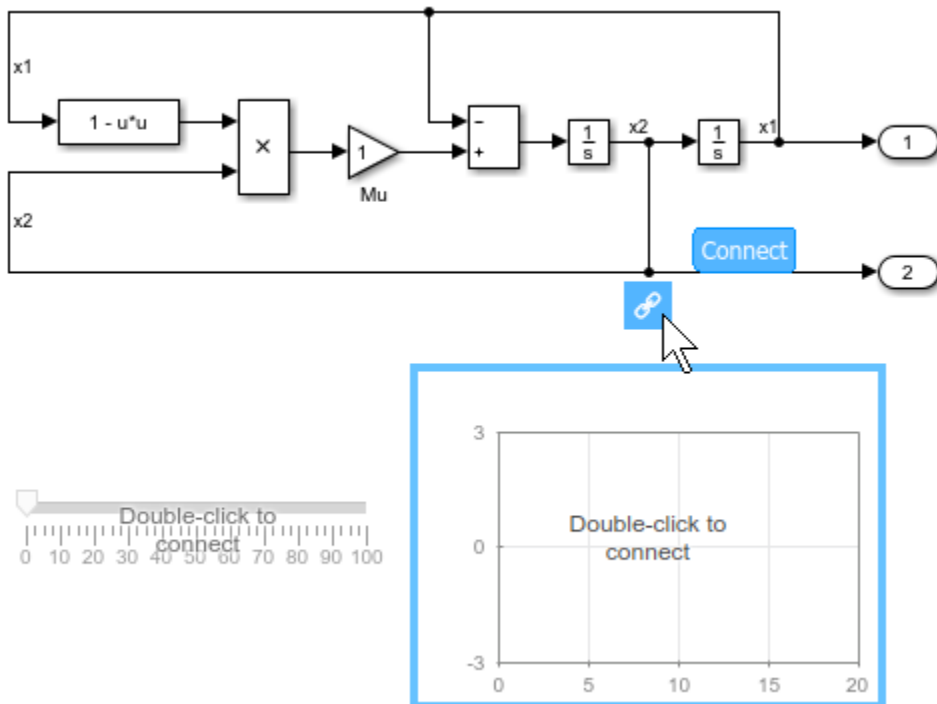

The MultiStateImage block displays an image to indicate the value of the input signal. You can use the MultiStateImage block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. You can specify pairs of input values and images to provide the information you want during simulation.

Connecting Dashboard Blocks

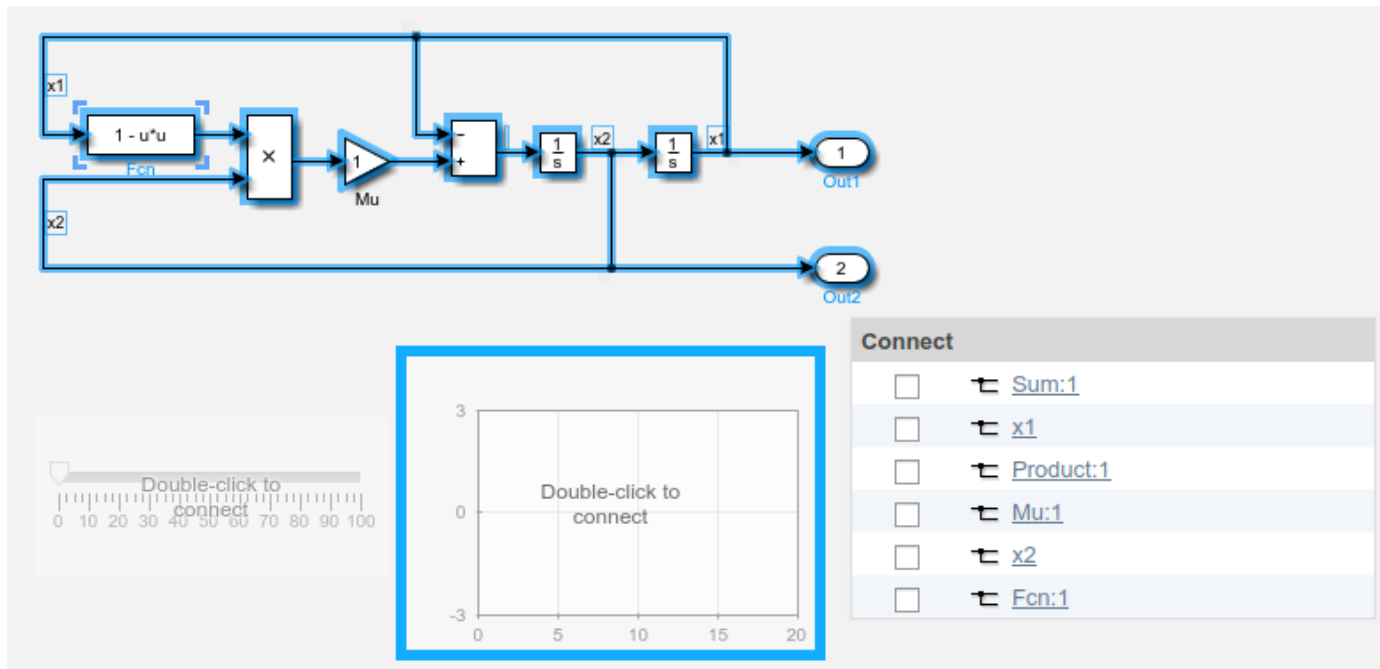

Dashboard blocks do not use ports to connect to signals. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks to signals in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above the block.

In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Scale Mode — Specify how to scale image

Fill with fixed aspect ratio (default) | Fixed | Fill

Specify how to scale the image.

Fill with fixed Aspect Ratio scales the image to the size of the block while retaining its original aspect ratio.

Fixed displays the image with its fixed true size.

Fill adjusts the image to fill the block.

Programmatic Use

Block Parameter: ScaleMode

Type: string or character vector

Values: 'Fill with fixed aspect ratio' | 'Fixed' | 'Fill'

Default: 'Fill with fixed aspect ratio'

States — Match values with images to display

scalar and image

States match an image to display with a value of the connected variable or parameter. Each state consists of a **State** and an image, displayed as a **Thumbnail** in the **States** table for the MultiStateImage block.

- **State** — Connected variable or parameter value that causes the MultiStateImage block to display the corresponding image.
- **Thumbnail** — Image to display when the connected variable or parameter value matches the corresponding **State**.

Click the **+** button to add another state.

Programmatic Use

To programmatically configure `State` and `Thumbnail` parameter values for the `MultiStateImage` block, use the `States` parameter. Specify the value for the `States` parameter as an array of structures with the fields:

- `State` — State value.
- `Size` — 1-by-2 vector containing the width and height for the image in that order, in pixels, specified as a `uint64`.
- `Image` — Character array of Base64 encoded image data.
- `Thumbnail` — Character array of Base64 encoded image data for the thumbnail image to display in the **States** table in the block dialog.

Include a structure in the array for each state you want to specify for the block. In the example, the `myBase64Image` and `myBase64Thumbnail` variables contain character vectors of the Base64 image data for the block image and thumbnail.

```
state1.State = 1;
state1.Size = [uint64(400) uint64(400)];
state1.Image = myBase64Image;
state1.Thumbnail = myBase64Thumbnail;
state2.State = 2;
state2.Size = [uint64(400) uint64(400)];
state2.Image = myBase64Image2;
state2.Thumbnail = myBase64Thumbnail2;
msiStates = [state1 state2];
```

Block Parameter: States

Type: structure array

The block displays the default image when the connected signal value does not correspond to any of the specified states. Specify the `DefaultImage` parameter as a structure containing the fields:

- `Size` — 1-by-2 vector containing the width and height for the image in that order, in pixels, specified as `uint64`.
- `Image` — Character array of Base64 encoded image data.
- `Thumbnail` — Character array of Base64 encoded image data for the thumbnail image to display in the **States** table in the block dialog.

Block Parameter: DefaultImage

Type: structure

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: `LabelPosition`

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Mux

Combine input signals of same data type and complexity into virtual vector

Library: Simulink / Commonly Used Blocks
 Simulink / Signal Routing
 HDL Coder / Commonly Used Blocks
 HDL Coder / Signal Routing

Description

The Mux block combines inputs with the same data type and complexity into a vector output. The output mux signal is flat, even if you create the mux signal from other mux signals. However, you can use multiple Mux blocks to create a mux signal in stages.

A mux signal simplifies the visual appearance of a model by combining two or more signal lines into one line. Mux signals do not affect simulation or code generation.

Tip If inputs have different data types or complexity, use a virtual bus to visually group the signals. For more information, see “Types of Composite Signals”.

Ports

Input

Port_1 – Input signal to include in mux signal

scalar | vector

Input signal to include in the mux signal, specified as a scalar or vector.

The input signals for a Mux block can be any combination of scalars and vectors, but they must have the same data type and complexity.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 – Output mux signal

vector

Output mux signal composed of the combined input signals, returned as a vector.

The elements of the output mux signal take their order from the port order of the input signals. For a description of the port order for various block orientations, see “Port Location After Rotating or Flipping”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

Number of inputs — Number of input signals

2 (default) | scalar | vector | cell array | comma-separated list of signal names

The number of input signals, specified as a scalar, vector, cell array, or comma-separated list of signal names. Some of these formats allow you to specify the signal names and sizes, as described by the following table.

Format	Block Behavior
Scalar	The number of inputs to the Mux block. When you use this format, the block accepts scalar or vector signals of any size. Simulink assigns each input the name <code>signalN</code> , where N is the input port number.
Vector	The length of the vector specifies the number of inputs. Each element specifies the size of the corresponding input. A positive value specifies that the corresponding port can accept only vectors of that size. For example, <code>[2 3]</code> specifies two input ports of sizes 2 and 3, respectively. If an input signal width does not match the expected width, an error message appears. A value of -1 specifies that the corresponding port can accept scalars or vectors of any size.
Cell array	The length of the cell array specifies the number of inputs. The value of each cell specifies the size of the corresponding input. A scalar value N specifies a vector of size N. A value of -1 means that the corresponding port can accept scalar or vector signals of any size.
Comma-separated list of signal names	A list of signal names separated by commas. Simulink assigns each name to the corresponding port and signal. For example, if you enter <code>position, velocity</code> , the Mux block has two inputs, named <code>position</code> and <code>velocity</code> .

Tip If you specify a scalar for the **Number of inputs** parameter and all of the input ports are connected, as you draw a new signal line close to input side of a Mux block, Simulink adds a port and updates the parameter.

Programmatic Use

Block Parameter: Inputs

Type: scalar, vector, cell array, comma-separated list of signal names

Values: integer, vector of port sizes, cell array, comma-separated list of signal names

Default: {'2'}

Display option — Block icon appearance

bar (default) | signal | none

Block icon appearance, specified as `bar`, `signal`, or `none`.

- `bar` — Displays no text
- `signal` — Displays the input signal names
- `none` — Displays the type of block (Mux)

Resize the block as necessary to fit the text on the block icon.

Programmatic Use

Block Parameter: `DisplayOption`

Type: character vector

Values: `'bar'` `'signals'` `'none'` `'bar'`

Default: `'bar'`

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Out Bus Element, Bus Element Out

Specify signal that connects to output port

Library: Simulink / Ports & Subsystems
 Simulink / Sinks
 HDL Coder / Ports & Subsystems
 HDL Coder / Sinks

 OutBus.signal1

Description

The Out Bus Element block, also known as the Bus Element Out block, combines the functionality of an Outport block and a Bus Creator block. This block is of the Outport block type and all Out Bus Element blocks that use the same port share a dialog box.

The output of an Out Bus Element is a virtual bus, regardless of the number and type of signals connected to it. You must connect an Out Bus Element block to each signal that you want the bus to contain.

Create Port and Related Blocks

When you insert an Out Bus Element block, the block label populates with default values. The label consists of two interactive text fields: the port name and the bus element. To change the name of the port associated with the block, edit the first text field in the label by clicking the text.

 OutBus.signal1

To output multiple signals in a bus, create one Out Bus Element block for each signal that you want to include in the bus. In the Block Parameters dialog box, you can select the **Add a new signal**  or **Add a new sub-bus**  buttons. Alternatively, hold **Ctrl** while you drag an existing Out Bus Element block to a new location. Upon releasing the mouse, click **Use Existing Port**.

If multiple blocks are associated with the same port and you change the name of the port, all blocks that share the port update to reflect the new port name.

To create a port, hold **Ctrl** while you drag an existing Out Bus Element block to a new location. Upon releasing the mouse, click **Create New Port**.

Modify Port Output

In the Block Parameters dialog box, you can:

- Change port and element names.
- Reorder bus elements by dragging and dropping a signal in the list of signals.
- Remove blocks associated with selected elements by clicking the **Remove blocks of selected signals** button .

Specify a Signal

To change the name of the bus element associated with the block, edit the second text field in the label by clicking the text.

All output signal names associated with the port must be unique. You cannot specify the same output signal name more than once for a port. Simulink does not support overlapping writes to the same port.

To create hierarchy in the output bus, use dots in the part of the label that describes the bus element. Each dot indicates a new level of bus hierarchy.

To reduce the size of the label, you can display only the signal name by selecting the block, pausing over the ellipsis, and selecting **Compact Notation** from the action bar. To show the signal hierarchy again, select **Expanded Notation** from the action bar.

Log Output Data

When you save output data to the workspace or a file, bus data defined by groups of root-level Out Bus Element blocks are logged along with root-level Outport block data.

Ports

Input

Port_1 — Output bus element

signal

Signal to be included in an output bus that is associated with an external subsystem or model port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Port name — Name of output port

OutBus (default) | port name

Specify a port name that is not already in use by another block or port. The name appears on the parent Subsystem or Model block. The name also appears next to the block. Multiple blocks can access the same port.

Programmatic Use

Block Parameter: PortName

Type: character vector

Values: 'OutBus' | '<port name>'

Default: 'OutBus'

Port number — Position of port on parent block

1 (default) | real integer

Specify the order in which the port that corresponds to the block appears on the parent Subsystem or Model block.

- If you add a block that creates another port, the port number is the next available number.
- Deleting all blocks associated with a port deletes the port. Other ports are renumbered so that they are sequential and do not skip any numbers.
- Specifying a port number that exceeds the number of ports creates a port for that number and for any skipped sequential numbers.

Programmatic Use

Block Parameter: Port

Type: character vector

Values: real integer

Default: '1'

Set color — Specify block background color

Black (default) | White | Red | Green | Blue | ... | ...

Specify the background color for bus element port blocks. This specification sets the color of blocks associated with selected bus elements, or of all blocks associated with the port if you do not select any bus elements.

You can specify Black, White, Red, Green, Blue, Cyan, Magenta, Yellow, Gray, Light Blue, Orange, Dark Green, and More Colors.

Programmatic Use

Block Parameter: BackgroundColor

Type: character vector

Values: 'black' | 'white' | 'red' | 'green' | 'blue' | 'cyan' | 'magenta' | 'yellow' | 'gray' | 'lightBlue' | 'orange' | 'darkGreen' | '[r,g,b]' where r, g, and b, are the red, green, blue values of the color in the range 0.0 to 1.0

Default: 'black'

Filter — Filter set of displayed signals

text

Specify a search term to use for filtering a long list of bus elements. Do not enclose the search term in quotation marks. The filter does a partial string search and supports regular expressions. To use a regular expression character as a literal, include an escape character (\). For example, to use a question mark, type `sig\?1`.

Signal Attributes

To specify signal attributes, click the pencil button or the specified attributes next to a signal name.

Data Type — Data type

Inherit: `auto (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | Bus: <object name> | <data type expression>`

Specify the data type. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. Do not specify a bus object as the expression.

Dimensions — Signal dimensions

`-1 (default) | integer | [integer, integer]`

Specify the dimensions of a signal.

<code>-1</code>	The signal can have any dimensions.
<code>N</code>	The signal must be a vector of size N.
<code>[R C]</code>	The signal must be a matrix having R rows and C columns.

Programmatic Use

Block Parameter: `PortDimensions`

Type: character vector

Values: `'-1' | integer | [integer, integer]`

Default: `'-1'`

Dims Mode — Allow variable-size signals

Inherit (default) | Fixed | Variable

Specify the type of signals allowed. To allow variable-size and fixed-size signals, select `Inherit`. To allow only variable-size signals, select `Variable`. To not allow variable-size signals, select `Fixed`.

Dependencies

When the signal is variable-sized, the **Dimensions** parameter specifies the maximum dimensions of the signal.

Command-Line Information

Parameter: `VarSizeSig`

Type: character vector

Value: `'Inherit' | 'No' | 'Yes'`

Default: `'Inherit'`

Unit — Physical unit of the signal

`inherit (default) | <Enter unit>`

Specify the physical unit of the signal. For a list of supported units, see [Allowed Unit Systems](#).

Programmatic Use**Block Parameter:** Unit**Type:** character vector**Values:** 'inherit' | '<Enter unit>'**Default:** 'inherit'**Sample time — Specify sample time**

-1 (default) | scalar

Specify the discrete interval between sample time hits or specify another appropriate sample time such as continuous or inherited.

By default, the signal inherits its sample time. To set a different sample time, enter a valid sample time based on the table in “Types of Sample Time”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar**Default:** '-1'**Complexity — Signal type**

auto (default) | real | complex

Specify the numeric type of the signal. To choose the numeric type of the signal, select auto. Otherwise, choose a real or complex signal type.

Programmatic Use**Block Parameter:** SignalType**Type:** character vector**Values:** 'auto' | 'real' | 'complex'**Default:** 'auto'**Minimum — Minimum value**

[] (default) | scalar

Lower value of the range that Simulink checks.

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'

Maximum — Maximum value

[] (default) | scalar

Upper value of the range that Simulink checks.

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** ' [] ' | scalar**Default:** ' [] '**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes

Outputport

Create output port for subsystem or external output

Library: Simulink / Commonly Used Blocks
Simulink / Ports & Subsystems
Simulink / Sinks
HDL Coder / Commonly Used Blocks
HDL Coder / Ports & Subsystems
HDL Coder / Sinks

Description

Outputport blocks link signals from a system to a destination outside of the system. They can connect signals flowing from a subsystem to other parts of the model. They can also supply external outputs at the top level of a model hierarchy.

Simulink software assigns Outputport block port numbers according to these rules:

- It automatically numbers the Outputport blocks within a root-level system or subsystem sequentially, starting with 1.
- If you add an Outputport block, it is assigned the next available number.
- If you delete an Outputport block, other port numbers are automatically renumbered to ensure that the Outputport blocks are in sequence and that no numbers are omitted.

Outputport Blocks in a Subsystem

Outputport blocks in a subsystem represent outputs from the subsystem. A signal arriving at an Outputport block in a subsystem flows out of the associated output port on that Subsystem block. The Outputport block associated with an output port is the block whose **Port number** parameter matches the relative position of the output port on the Subsystem block. For example, the Outputport block whose **Port number** parameter is 1 sends its signal to the block connected to the topmost output port on the Subsystem block.

If you renumber the **Port number** of an Outputport block, the block becomes connected to a different output port. The block continues to send the signal to the same block outside the subsystem.

Tip For models that include bus signals composed of many bus elements, consider using In Bus Element and Out Bus Element blocks. These blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

The In Bus Element block is of block type Inport and the Out Bus Element block is of block type Outputport.

Top-Level Output Block in a Model Hierarchy

Output blocks at the top level of a model hierarchy have two uses. They can supply external outputs to the base MATLAB workspace, and they provide a means for the `linmod` and `trim` analysis functions to obtain output from the system.

To supply external outputs to the workspace, use the **Configuration Parameters > Data Import/Export** pane (see Exporting Output Data to the MATLAB Workspace) or the `sim` command. For example, if a system has more than one Output block and the save format is array, the following command

```
[t,x,y] = sim(...);
```

writes `y` as a matrix, with each column containing data for a different Output block. The column order matches the order of the port numbers for the Output blocks.

If you specify more than one variable name after the second (state) argument, data from each Output block is written to a different variable. For example, if the system has two Output blocks, to save data from Output block 1 to `speed` and the data from Output block 2 to `dist`, specify this command:

```
[t,x,speed,dist] = sim(...);
```

Connecting Buses to Root-Level Outputs

A root-level Output block in a model can accept a virtual bus only if all elements of the bus have the same data type. The Output block automatically unifies the bus to a vector having the same number of elements as the bus, and provides that vector as output.

If you want a root-level Output of a model to accept a bus signal that contains mixed types, set Output block **Data type to Bus**: `<object name>`. If the bus signal is virtual, it is converted to nonvirtual, as described in “Virtual and Nonvirtual Bus Conversions”.

Associate Root-Level Output Block with Simulink.Signal Object

To associate a root-level Output block with a `Simulink.Signal` object, use the Model Data Editor. See “For Signals”.

Ports

Input

Port_1 – Output signal

scalar | vector

Input signal that flows through the output to an external subsystem or model.

An Output block can accept fixed-point and enumerated data types when the block is not a root-level output port. The complexity and data type of the block output are the same as its input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

Port number — Position of port on parent block

1 (default) | real integer

Specify the order in which the port that corresponds to the block appears on the parent Subsystem or Model block.

- If you add a block that creates another port, the port number is the next available number.
- Deleting all blocks associated with a port deletes the port. Other ports are renumbered so that they are sequential and do not skip any numbers.
- Specifying a port number that exceeds the number of ports creates a port for that number and for any skipped sequential numbers.

Programmatic Use

Block Parameter: Port

Type: character vector

Values: real integer

Default: '1'

Signal name — Signal name

' ' (default) | character vector

Specify the name of the corresponding signal data in the generated code. Use this parameter to specify a name for the signal data when you apply a storage class to a root-level Outport block.

Programmatic Use

Block Parameter: SignalName

Type: character vector

Values: character vector

Default: ' '

Icon display — Icon display

Port number (default) | Signal name | Port number and signal name

Specify the information displayed on the block icon.

Programmatic Use

Block Parameter: IconDisplay

Type: character vector

Values: 'Signal name' | 'Port number' | 'Port number and signal name'

Default: 'Port number'

Specify output when source is disconnected — Specify unconnected output value

off (default) | on

Specify a constant output value for when source is not connected.

Dependency

Available for unconnected Outport blocks inside a Variant Subsystem block.

Programmatic Use**Block Parameter:** OutputWhenUnconnected**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'**Constant value — Output value when the block is not connected**

0 (default) | scalar | vector

Specify a constant output value for when source is not connected.

Dependency

Available in a Variant Subsystem block for an unconnected Outport block with **Specify output when source is unconnected** selected.

Programmatic Use**Block Parameter:** OutputWhenUnconnectedValue**Type:** character vector**Values:** scalar | vector**Default:** '0'**Interpret vector parameters as 1-D — Treat vectors as 1-D**

on (default) | off

Select this check box to create a vector of length N at the output if the **Constant value** parameter evaluates to an N-element row or column vector.

Dependency

Available in a Variant Subsystem block on an unconnected Outport block when you select the **Specify output when source is unconnected** parameter.

Programmatic Use**Block Parameter:** VectorParamsAs1DForOutWhenUnconnected**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Ensure output is virtual — Ensure that output is virtual**

off (default) | on

Clear this check box to specify that Simulink uses a signal buffer on output port. This buffer ensures consistent initialization of the Outport block signal.

If you select this check box, Simulink tries to remove the signal buffer.

- If the signal buffer is not needed, Simulink removes the buffer.
- If the signal buffer is needed for data consistency and proper execution, Simulink displays an error indicating the buffer could not be removed.

Allow partial writes through Assignment blocks.

For examples with conditional writes and partial writes, see “Ensure Output is Virtual”.

Dependency

This parameter applies to these blocks:

- Conditional subsystem
- Assignment
- Merge
- Model with root Output block

Programmatic Use

Block Parameter: EnsureOutputIsVirtual

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Source of initial output value — Source of initial output value

Dialog (default) | Input signal

Select the source of the initial output value of the block. Select `Dialog` to specify that the initial output value is the value of the **Initial output** parameter. Select `Input signal` to specify that the initial output value is inherited from the input signal. See “Conditional Subsystem Initial Output Values”.

Tips

- If you are using classic initialization mode, selecting `Input signal` causes an error. To inherit the initial output value from the input signal, set this parameter to `Dialog` and specify `[]` (empty matrix) for the **Initial output** value. For more information, see “Conditional Subsystem Initial Output Values”.

Dependencies

Available for Output blocks inside a conditional subsystem.

Selecting `Dialog` exposes the following parameters:

- **Output when disabled**
- **Initial output**

Programmatic Use

Block Parameter: SourceOfInitialOutputValue

Type: character vector

Values: 'Dialog' | 'Input signal'

Default: 'Dialog'

Output when disabled — Output when disabled

held (default) | reset

Specify what happens to the block output when the subsystem is disabled. Select `held` to indicate that the output is held when the subsystem is disabled. Select `reset` to indicate that the output is reset to the value given by **Initial output** when the subsystem is disabled.

Dependencies

Available when you select `Dialog` as the value for the **Source of initial output** parameter for an Output block inside a conditional subsystem with valid enabling and disabling semantics. For

example, the parameter is available for an Output block inside an Enabled Subsystem block and not for an Output block inside a Triggered Subsystem block.

If an Output block is inside a Function-Call Subsystem block, this parameter is only meaningful if the Function-Call Subsystem block is connected to a state in a Stateflow chart. For more information, see “Bind a Function-Call Subsystem to a State” (Stateflow).

When connecting the output of a conditional subsystem to a Merge block, set this parameter to `held`. Setting it to `reset` returns an error.

Programmatic Use

Block Parameter: `OutputWhenDisabled`

Type: character vector

Values: `'held'` | `'reset'`

Default: `'held'`

Initial output — Initial output for conditionally executed subsystems

`[]` (default) | scalar | structure

For conditionally executed subsystems, specify the block output before the subsystem executes and while it is disabled. Specify `[]` to inherit the initial output value from the input signal. For more information, see “Conditional Subsystem Initial Output Values”.

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

Tips

If the conditional subsystem is driving a Merge block, you do not need to specify an Initial Condition (IC) for the Output block. For more information, see “Underspecified initialization detection”.

Dependencies

Available when **Source of initial output value** is set to `Dialog` for an Output block in a conditional subsystem.

Limitations

- This block does not allow an initial output of `inf` or `NaN`.
- When the input is a virtual bus, an **Initial output** value `[]` is treated as `double(0)`.
- When the input contains a nonvirtual bus, **Initial output** does not support nonzero scalar values.

Programmatic Use

Block Parameter: `InitialOutput`

Type: character vector

Values: `'[]'` | scalar | structure

Default: `'[]'`

Signal Attributes

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Minimum — Minimum output value

[] (default) | scalar

Lower value of the output range that Simulink checks.

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Maximum — Maximum output value**

[] (default) | scalar

Upper value of the output range that Simulink checks.

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use**Block Parameter:** OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Data type — Output data type

Inherit: auto (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | Bus: <object name> | <data type expression>

Specify the output data type of the external input. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Tips

You cannot enter the name of a `Simulink.Bus` object as a data type expression. To specify the **Data type** for the block using a Bus object, select the Bus: <object name> option and replace <object name> with the name of the Bus object.

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output as nonvirtual bus in parent model — Outport as nonvirtual bus in parent model

off (default) | on

Specify the outport bus to be nonvirtual in the parent model. Select this parameter if you want the bus emerging in the parent model to be nonvirtual. The bus that is input to the port can be virtual or nonvirtual, regardless of the setting of **Output as nonvirtual bus in parent model**.

Clear this parameter if you want the bus emerging in the parent model to be virtual.

Tips

- In a nonvirtual bus, all signals must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any operation that would result in a nonvirtual bus that violates this requirement generates an error. For details, see “Rate Transitions for Nonvirtual Buses”.

To use a multirate signal for a virtual bus, in the root-level Outport block, set the **Sample time** parameter to inherited (-1).

- For the top model in a model reference hierarchy, code generation creates a C structure to represent the bus signal output of this block.
- For referenced models, select this option to create a C structure. Otherwise, code generation creates an argument for each leaf element of the bus.

Dependency

Available when the **Data type** is set to Bus: <object name>.

Programmatic Use

Block Parameter: BusOutputAsStruct

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Unit (e.g., m, m/s², N*m) — Physical unit of the input signal to the block

inherit (default) | <Enter unit>

Specify the physical unit of the input signal to the block. To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

Programmatic Use

Block Parameter: Unit

Type: character vector

Values: 'inherit' | '<Enter unit>'

Default: 'inherit'

Port dimensions (-1 for inherited) — Port dimensions

-1 (default) | integer | [integer, integer]

Specify the dimensions that a signal must have to be connected to this Outport block.

-1	A signal of any dimensions can be connected to this port.
N	The signal connected to this port must be a vector of size N.
[R C]	The signal connected to this port must be a matrix having R rows and C columns.

Programmatic Use

Block Parameter: PortDimensions

Type: character vector

Values: '-1' | integer | [integer, integer]

Default: '-1'

Variable-size signal — Allow variable-size signals

Inherit (default) | No | Yes

Specify the type of signals allowed at the output of this port. To allow variable-size and fixed-size signals, select Inherit. To allow only variable-size signals, select Yes. To allow only fixed-size signals, select No.

Dependencies

When the signal at this port is a variable-size signal, the **Port dimensions** parameter specifies the maximum dimensions of the signal.

Command-Line Information

Parameter: VarSizeSig

Type: character vector

Value: 'Inherit' | 'No' | 'Yes'

Default: 'Inherit'

Sample time (-1 for inherited) — Specify sample time

-1 (default) | scalar

Specify the discrete interval between sample time hits or specify another appropriate sample time such as continuous or inherited.

By default, the block inherits its sample time based upon the context of the block within the model. To set a different sample time, enter a valid sample time based upon the table in “Types of Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar

Default: '-1'

Signal type — Output signal type

auto (default) | real | complex

Specify the numeric type of the signal output. To choose the numeric type of the signal that is connected to its input, select auto. Otherwise, choose a real or complex signal type.

Programmatic Use

Block Parameter: SignalType

Type: character vector

Values: 'auto' | 'real' | 'complex'

Default: 'auto'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string

Parameter Writer

Write to a model instance parameter

Library: Simulink / Signal Routing

Description

The Parameter Writer block changes block parameter values in a referenced model by writing to instance parameters belonging to a Model block referencing a model.

Use the Parameter Writer block with the Initialize Function and Reset Function blocks to respond to events. For example, an event could be reading the value from a hardware sensor, and then updating a model parameter based on the sensor value.

Ports

Input

In — Parameter value

scalar | vector

Parameter value written to a block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Parameter owner block — Show the parameter owner block

none (default)

Show the parameter owner block whose parameter value this block is writing. To change the parameter owner block, select a block from the **Parameter Owner Selector Tree**.

Programmatic Use

Block Parameter: ParameterOwnerBlock

Type: character vector

Value: '' | '<model path/block name>'

Default: ''

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no

Zero-Crossing Detection	no

Permute Dimensions

Rearrange dimensions of multidimensional array dimensions

Library: Simulink / Math Operations

Description

The Permute Dimensions block reorders the elements of the input signal by permuting its dimensions. You specify the permutation to be applied to the input signal using the **Order** parameter.

For example, to transpose a 3-by-5 input signal, specify the permutation vector [2 1] for the **Order** parameter. When you do, the block reorders the elements of the input signal and outputs a 3-by-5 matrix.

You can use an array of buses as an input signal to a Permute Dimensions block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

This port accepts scalar, vector, matrix, and N-dimensional signals of any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_2 — Permutation of input signal

scalar | vector | matrix | N-D array

The block outputs the permutation of the input signal, according to the value of the **Order** parameter. The output has the same data type as the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Order — Permutation vector

[2, 1] (default) | N-element vector, where N is the number of dimensions of the input signal

Specify the permutation order to apply to the dimensions of the input signal. The value of this parameter must be an N-element vector where N is the number of dimensions of the input signal. The elements of the permutation vector must be a rearrangement of the values from 1 to N.

For example, the permutation vector [2 1] applied to a 5-by-3 input signal results in a 3-by-5 output signal, in other words, the transpose of the input signal.

Programmatic Use

Block Parameter: Order

Type: character vector

Value: N-element vector

Default: '[2 1]'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

PID Controller

Continuous-time or discrete-time PID controller

Library: Simulink / Continuous

Description

The PID Controller block implements a PID controller (PID, PI, PD, P only, or I only). The block is identical to the Discrete PID Controller block with the **Time domain** parameter set to Continuous-time.

The block output is a weighted sum of the input signal, the integral of the input signal, and the derivative of the input signal. The weights are the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action.

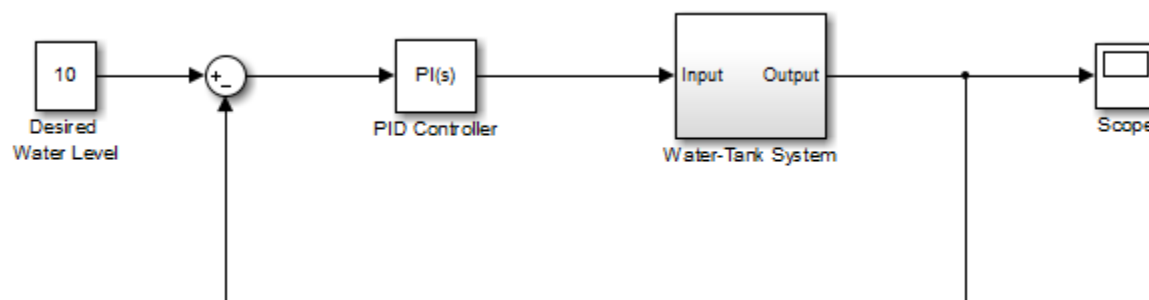

The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, PD, P only, or I only) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (continuous or discrete) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (See “Variant Subsystems” on page 14-387.) To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.

The input of the block is typically an error signal, which is the difference between a reference signal and the system output. For a two-input block that permits setpoint weighting, see PID Controller (2DOF).

PID Gain Tuning

The PID controller coefficients are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software. For more information about automatic tuning, see the **Select tuning method** parameter.

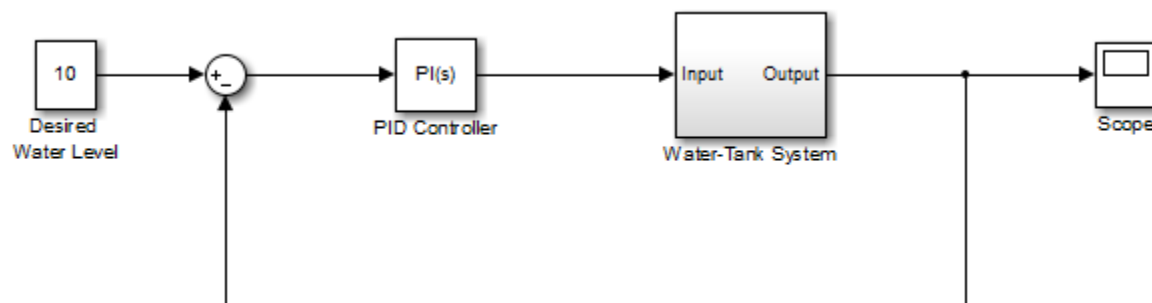

Ports

Input

Port_1(u) — Error signal input

scalar | vector

Difference between a reference signal and the output of the system under control, as shown.

When the error signal is a vector, the block acts separately on each signal, vectorizing the PID coefficients and producing a vector output signal of the same dimensions. You can specify the PID coefficients and some other parameters as vectors of the same dimensions as the input signal. Doing so is equivalent to specifying a separate PID controller for each entry in the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

P — Proportional gain

scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

I — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

D — Derivative gain

scalar | vector

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

N — Filter coefficient

scalar | vector

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Reset — External reset trigger

scalar

Trigger to reset the integrator and filter to their initial conditions. The value of the **External reset** parameter determines whether reset occurs on a rising signal, a falling signal, or a level signal. The port icon indicates the selected trigger type. For example, the following illustration shows a continuous-time PID block with **External reset** set to **rising**.

When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the **I₀** and **D₀** ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than **none**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point` | `Boolean`

I₀ — Integrator initial condition

scalar | vector

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to **external**, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

D₀ — Filter initial condition

scalar | vector

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to **external**, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

TR — Tracking signal

scalar | vector

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

T_{DTI} — Discrete-integrator time

scalar

Discrete-integrator time, provided as a scalar to the block. You can use your own value of discrete-time integrator sample time that defines the rate at which the block is going to be run either in Simulink or on external hardware. The value of the discrete-time integrator time should match the average sampling rate of the external interrupts, when the block is used inside a conditionally-executed subsystem.

In other words, you can specify T_s for any of the integrator methods below such that the value matches the average sampling rate of the external interrupts. In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

Backward Euler

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

Trapezoidal

$$\alpha(z) = \frac{T_s}{2} \frac{z + 1}{z - 1} \cdot$$

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page. For more information on conditionally executed subsystems, see “Conditionally Executed Subsystems Overview”.

Dependencies

To enable this port, set **Time Domain** to Discrete-time and select the **PID Controller is inside a conditionally executed subsystem** option.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Output

Port_1(y) – Controller output

scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as N independent PID controllers, where N is the number of signals in the input vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Controller – Controller type

PID (default) | PI | PD | P | I

Specify which of the proportional, integral, and derivative terms are in the controller.

PID

Proportional, integral, and derivative action.

PI

Proportional and integral action only.

PD

Proportional and derivative action only.

P

Proportional action only.

I

Integral action only.

Tip The controller transfer function for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector
Values: "PID", "PI", "PD", "P", "I"
Default: "PID"

Form — Controller structure

Parallel (default) | Ideal

Specify whether the controller structure is parallel or ideal.

Parallel

The controller output is the sum of the proportional, integral, and derivative actions, weighted independently by **P**, **I**, and **D**, respectively. For example, for a continuous-time parallel-form PID controller, the transfer function is:

$$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right).$$

For a discrete-time parallel-form controller, the transfer function is:

$$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1+N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Ideal

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time ideal-form PID controller, the transfer function is:

$$C_{id}(s) = P\left[1 + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right)\right].$$

For a discrete-time ideal-form controller, the transfer function is:

$$C_{id}(z) = P\left[1 + I\alpha(z) + D\frac{N}{1+N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $a(z)$ and $b(z)$, respectively.

Tip The controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "Parallel", "Ideal"

Default: "Parallel"

Time domain — Specify continuous-time or discrete-time controller

Continuous-time (default) | Discrete-time

When you select **Discrete-time**, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting **Discrete-time** also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select **Continuous-time**.

Note The PID Controller and Discrete PID Controller blocks are identical except for the default value of this parameter.

Programmatic Use**Block Parameter:** TimeDomain**Type:** string, character vector**Values:** "Continuous-time", "Discrete-time"**Default:** "Continuous-time"**PID Controller is inside a conditionally executed subsystem — Enable the discrete-integrator time port**

off (default) | on

For discrete-time PID controllers, enable the discrete-time integrator port to use your own value of discrete-time integrator sample time. To ensure proper integration, Use the T_{DTI} port to provide a scalar value of Δt for accurate discrete-time integration.

Dependencies

To enable this parameter, set **Time Domain** to **Discrete-time**.

Programmatic Use**Block Parameter:** UseExternalTs**Type:** string, character vector**Values:** "on", "off"**Default:** "off"**Sample time (-1 for inherited) — Discrete interval between samples**

-1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of -1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to **Continuous-time**.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to -1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Block Parameter: SampleTime

Type: scalar

Values: -1, positive scalar

Default: -1

Integrator method — Method for computing integral in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the integral term of the controller transfer function is $I\alpha(z)$, where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Note For the BackwardEuler or Trapezoidal methods, you cannot generate HDL code for the block if either:

- **Limit output** is selected and **Anti-Windup Method** is anything other than none.
 - **Enable tracking mode** is selected.
-

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and set **Controller** to a controller type with integral action.

Programmatic Use

Block Parameter: IntegratorMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Filter method – Method for computing derivative in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and enable **Use filtered derivative**.

Programmatic Use**Block Parameter:** FilterMethod**Type:** string, character vector**Values:** "Forward Euler", "Backward Euler", "Trapezoidal"**Default:** "Forward Euler"**Main****Source — Source for controller gains and filter coefficient**

internal (default) | external

Enabling external inputs for the parameters allows you to compute PID gains and filter coefficients externally to the block and provide them to the block as signal inputs.

internal

Specify the controller gains and filter coefficient using the block parameters **P**, **I**, **D**, and **N**.

external

Specify the PID gains and filter coefficient externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the input signal u is multiplied by the externally supplied integrator gain, I , before integration. This implementation yields:

$$y_i = \int uI dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain D to be differentiated.

Programmatic Use**Block Parameter:** ControllerParametersSource**Type:** string, character vector**Values:** "internal", "external"**Default:** "internal"

Proportional (P) — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- **Parallel** — Proportional action is independent of the integral and derivative actions. For instance, for a continuous-time parallel PID controller, the transfer function is:

$$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s + N}\right).$$

For a discrete-time parallel-form controller, the transfer function is:

$$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1 + N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- **Ideal** — The proportional gain multiples the integral and derivative terms. For instance, for a continuous-time ideal PID controller, the transfer function is:

$$C_{id}(s) = P\left[1 + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s + N}\right)\right].$$

For a discrete-time ideal-form controller, the transfer function is:

$$C_{id}(z) = P\left[1 + I\alpha(z) + D\frac{N}{1 + N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal** and set **Controller** to **PID**, **PD**, **PI**, or **P**.

Programmatic Use

Block Parameter: P

Type: scalar, vector

Default: 1

Integral (I) — Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: I

Type: scalar, vector

Default: 1

Derivative (D) – Derivative gain

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to PID or PD.

Programmatic Use

Block Parameter: D

Type: scalar, vector

Default: 0

Use filtered derivative – Apply filter to derivative term

on (default) | off

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller transfer function becomes:

$$D \frac{z - 1}{z T_s} \cdot$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time, and set **Controller** to a type that has derivative action.

Programmatic Use

Block Parameter: UseFilter

Type: string, character vector

Values: "on", "off"

Default: "on"

Filter coefficient (N) – Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is Continuous-time, the pole location is $s = -N$.
- When **Time domain** is Discrete-time, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
Forward Euler	$z_{pole} = 1 - NT_s$

Filter Method	Location of Filter Pole
Backward Euler	$z_{pole} = \frac{1}{1 + NT_s}$
Trapezoidal	$z_{pole} = \frac{1 - NT_s/2}{1 + NT_s/2}$

The block does not support $N = \text{Inf}$ (ideal unfiltered derivative). When the **Time domain** is Discrete-time, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal** and set **Controller** to **PID** or **PD**.

Programmatic Use

Block Parameter: N

Type: scalar, vector

Default: 100

Select tuning method — Tool for automatic tuning of controller coefficients

Transfer Function Based (PID Tuner App) (default) | Frequency Response Based

If you have Simulink Control Design software, you can automatically tune the PID coefficients. To do so, use this parameter to select a tuning tool, and click **Tune**.

Transfer Function Based (PID Tuner App)

Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. By default, **PID Tuner** works with a linearization of your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see “Introduction to Model-Based PID Tuning in Simulink” (Simulink Control Design).

Frequency Response Based

Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially useful for plants that are not linearizable or that linearize to zero. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

Enable zero-crossing detection — Detect zero crossings on reset and on entering or leaving a saturation state

on (default) | off

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: ZeroCross

Type: string, character vector

Values: "on", "off"

Default: "on"

Initialization

Source — Source for integrator and derivative initial conditions

`internal` (default) | `external`

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

`internal`

Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator** parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

`external`

Specify the initial conditions externally using block inputs. Additional input ports **I_o** and **D_o** appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at **D_o** instead of a filter initial condition.

Programmatic Use

Block Parameter: InitialConditionSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Integrator — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use**Block Parameter:** InitialConditionForIntegrator**Type:** scalar, vector**Default:** 0**Filter — Filter initial condition**

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use**Block Parameter:** InitialConditionForFilter**Type:** scalar, vector**Default:** 0**Differentiator — Initial condition for unfiltered derivative**

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, set **Time domain** to `Discrete-time`, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to `internal`.

Programmatic Use**Block Parameter:** DifferentiatorICPrevScaledInput**Type:** scalar, vector**Default:** 0**Initial condition setting — Location at which initial condition is applied**

State (most efficient) (default) | Output

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

State (most efficient)

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use

Block Parameter: InitialConditionSetting

Type: string, character vector

Values: "state", "output"

Default: "state"

External reset — Trigger for resetting integrator and filter values

none (default) | rising | falling | either | level

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and differentiator to initial conditions.) Selecting any option other than none enables the **Reset** port on the block for the external reset signal.

none

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

rising

Reset the outputs when the reset signal has a rising edge.

falling

Reset the outputs when the reset signal has a falling edge.

either

Reset the outputs when the reset signal either rises or falls.

level

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use

Block Parameter: ExternalReset

Type: string, character vector

Values: "none", "rising", "falling", "either", "level"

Default: "none"

Ignore reset when linearizing — Force linearization to ignore reset

off (default) | on

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use

Block Parameter: IgnoreLimit

Type: string, character vector

Values: "off", "on"

Default: "off"

Enable tracking mode — Activate signal tracking

off (default) | on

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain K_t , specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.

For more information, see “Bumpless Control Transfer” on page 13-102.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches, as in the following model.

The Inner Loop subsystem contains the blocks shown in the following diagram.

Because the PID controller tracks the output of the inner loop, its output never exceeds the saturated inner-loop output. For more details, see “Prevent Block Windup in Multiloop Control” on page 13-101.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: TrackingMode

Type: string, character vector

Values: "off", "on"

Default: "off"

Tracking coefficient (Kt) — Gain of signal-tracking feedback loop

1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain K_t . Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use

Block Parameter: Kt

Type: scalar

Default: 1

Output saturation

Limit Output — Limit block output to specified saturation values

off (default) | on

Activating this option limits the block output internally to the block, so that you do not need a separate Saturation on page 1-1255 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the saturation limits using the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use

Block Parameter: LimitOutput

Type: string, character vector

Values: "off", "on"

Default: "off"

Upper limit — Upper saturation limit for block output

Inf (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: UpperSaturationLimit

Type: scalar

Default: Inf

Lower limit — Lower saturation limit for block output

-Inf (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: LowerSaturationLimit

Type: scalar

Default: -Inf

Ignore saturation when linearizing — Force linearization to ignore output limits

off (default) | on

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: LinearizeAsGain

Type: string, character vector

Values: "off", "on"

Default: "off"

Anti-windup method — Integrator anti-windup method

none (default) | back-calculation | clamping

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the

sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the input signal never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the input signal changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

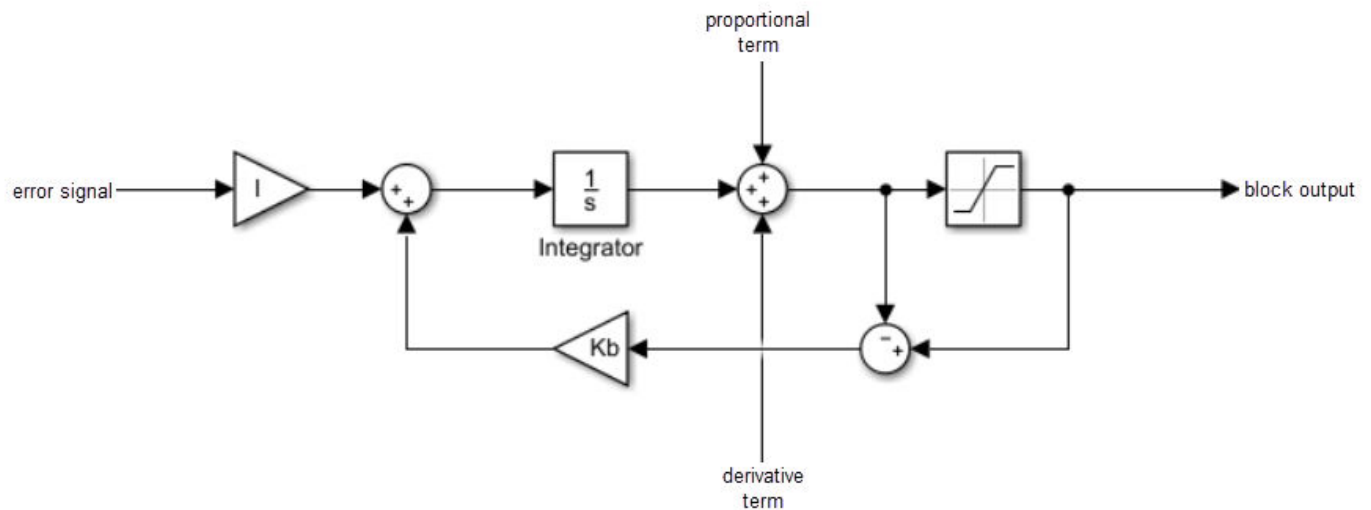

In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

none

Do not use an anti-windup mechanism.

back-calculation

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.

Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set $K_b = I$, or for controllers with derivative action, $K_b = \sqrt{I \cdot D}$. Back-calculation can be effective for plants with relatively large dead time [1].

clamping

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: AntiWindupMode

Type: string, character vector

Values: "none", "back-calculation", "clamping"

Default: "none"

Back-calculation coefficient (Kb) — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The **back-calculation** anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to **back-calculation**.

Programmatic Use

Block Parameter: Kb

Type: scalar

Default: 1

Data Types

The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click  to open the Data Type Assistant for the corresponding quantity. For more information, see “Specify Data Types Using Data Type Assistant”.

Main			Initialization			Output saturation			Data Types			State Attributes			
Fixed-point operational parameters															
Integer rounding mode:			Floor												
<input type="checkbox"/>			Saturate on integer overflow												
<input type="checkbox"/>			Lock data type settings against changes by the fixed-point tools									Open Fixed-Point Tool...			
Data Type				Minimum				Maximum							
P product output:				Inherit: Inherit via internal rule				>>				[]			
I product output:				Inherit: Inherit via internal rule				>>				[]			
D product output:				Inherit: Inherit via internal rule				>>				[]			
N product output:				Inherit: Inherit via internal rule				>>				[]			
b product output:				Inherit: Inherit via internal rule				>>				[]			
c product output:				Inherit: Inherit via internal rule				>>				[]			
Sum output:				Inherit: Inherit via internal rule				>>				[]			
▶ Additional data types															

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.
- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as SumI2. (See **Model Explorer**.)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.
For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**State Attributes**

The parameters in this tab are primarily of use in code generation.

State name (e.g., 'position') – Name for continuous-time filter and integrator states

' ' (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to Continuous-time.

Programmatic Use**Parameter:** IntegratorContinuousStateAttributes, FilterContinuousStateAttributes**Type:** character vector**Default:** ' '**State name – Names for discrete-time filter and integrator states**

empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Parameter: IntegratorStateIdentifier, FilterStateIdentifier

Type: string, character vector

Default: ""

State name must resolve to Simulink signal object — Require that state name resolve to a signal object

off (default) | on

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class** for the corresponding integrator or filter state.

Programmatic Use

Block Parameter: IntegratorStateMustResolveToSignalObject, FilterStateMustResolveToSignalObject

Type: string, character vector

Values: "off", "on"

Default: "off"

Code generation storage class — Storage class for code generation

Auto (default) | ExportedGlobal | ImportedExtern | ImportedExternPointer

Select state storage class for code generation. If you do not need to interface to external code, select Auto.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use

Block Parameter: IntegratorRTWStateStorageClass, FilterRTWStateStorageClass

Type: string, character vector

Values: "Auto", "ExportedGlobal", "ImportedExtern" | "ImportedExternPointer"

Default: "Auto"

Code generation storage type qualifier — Storage type qualifier

empty string (default) | character vector | "const" | "volatile" | ...

Specify a storage type qualifier such as const or volatile.

Note This parameter will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Dependencies

To enable this parameter, set **Code generation storage class** to any value other than Auto.

Programmatic Use

Block Parameter:

IntegratorRTWStateStorageTypeQualifier, FilterRTWStateStorageTypeQualifier

Type: string, character vector

Values: "", "const", "volatile"

Default: ""

Block Characteristics

Data Types	double fixed point integer single

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to **Continuous-time**):

- Consider using "Model Discretizer" to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, from your model, in the **Apps** tab, under **Control Systems**, click **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to **Discrete-time**):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on memcpy or memset functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Restrictions

- HDL code generation is supported for discrete-time PID controllers only (**Time domain** set to **Discrete-time**).
- If the **Integrator method** is set to **BackwardEuler** or **Trapezoidal**, you cannot generate HDL code for the block under either of the following conditions:

- **Limit output** is selected and the **Anti-Windup Method** is anything other than none.
- **Enable tracking mode** is selected.
- To generate HDL code:
 - Use a discrete-time PID controller. On the **Time domain** section, specify **Discrete-time**.
 - Leave the **Use filtered derivative** check box selected.
 - Specify the initial conditions of the filter and integrator internally. On the **Initialization** tab, specify **Source** as `internal`.

You can specify the filter coefficients internally and externally for HDL code generation. On the **Main** tab, for **Source**, you can use `internal` or `external`.

- Set **External reset** to none.
- When you use double inputs, do not set **Anti-windup Method** to clamping.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Fixed-point code generation is supported for discrete-time PID controllers only (**Time domain** set to `Discrete-time`).

Introduced in R2009b

PID Controller (2DOF)

Continuous-time or discrete-time two-degree-of-freedom PID controller

Library: Simulink / Continuous

Description

The PID Controller (2DOF) block implements a two-degree-of-freedom PID controller (PID, PI, or PD). The block is identical to the Discrete PID Controller (2DOF) block with the **Time domain** parameter set to Continuous-time.

The block generates an output signal based on the difference between a reference signal and a measured system output. The block computes a weighted difference signal for the proportional and derivative actions according to the setpoint weights (**b** and **c**) that you specify. The block output is the sum of the proportional, integral, and derivative actions on the respective difference signals, where each action is weighted according to the gain parameters **P**, **I**, and **D**. A first-order pole filters the derivative action.

The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, or PD) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (continuous or discrete) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (See “Variant Subsystems” on page 14-387.) To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.

For a single-input block that accepts an error signal (a difference between a setpoint and a system output), see PID Controller.

PID Gain Tuning

The PID controller coefficients and the setpoint weights are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software. For more information about automatic tuning, see the **Select tuning method** parameter.

Ports

Input

Ref — Reference signal

scalar | vector

Reference signal for plant to follow, as shown.

When the reference signal is a vector, the block acts separately on each signal, vectorizing the PID coefficients and producing a vector output signal of the same dimensions. You can specify the PID coefficients and some other parameters as vectors of the same dimensions as the input signal. Doing so is equivalent to specifying a separate PID controller for each entry in the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_1(y) — Measured system output

scalar | vector

Feedback signal for the controller, from the plant output.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

P — Proportional gain

scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

I — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to external, and set **Controller** to a controller type that has integral action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

D — Derivative gain

scalar | vector

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to external, and set **Controller** to a controller type that has derivative action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

N — Filter coefficient

scalar | vector

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

b — Proportional setpoint weight

scalar | vector

Proportional setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

c — Derivative setpoint weight

scalar | vector

Derivative setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Reset — External reset trigger

scalar

Trigger to reset the integrator and filter to their initial conditions. Use the **External reset** parameter to specify what kind of signal triggers a reset. The port icon indicates the trigger type specified in that parameter. For example, the following illustration shows a continuous-time PID Controller (2DOF) block with **External reset** set to `rising`.

When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the **I₀** and **D₀** ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than none.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | Boolean

I₀ — Integrator initial condition

scalar | vector

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to external, and set **Controller** to a controller type that has integral action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

D₀ — Filter initial condition

scalar | vector

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to external, and set **Controller** to a controller type that has derivative action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

TR — Tracking signal

scalar | vector

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

T_{DTI} – Discrete-integrator time

scalar

Discrete-integrator time, provided as a scalar to the block. You can use your own value of discrete-time integrator sample time that defines the rate at which the block is going to be run either in Simulink or on external hardware. The value of the discrete-time integrator time should match the average sampling rate of the external interrupts, when the block is used inside a conditionally-executed subsystem.

In other words, you can specify T_s for any of the integrator methods below such that the value matches the average sampling rate of the external interrupts. In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

$$\alpha(z) = \frac{T_s}{z - 1}.$$

Backward Euler

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

Trapezoidal

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page. For more information on conditionally executed subsystems, see “Conditionally Executed Subsystems Overview”.

Dependencies

To enable this port, set **Time Domain** to Discrete-time and select the **PID Controller is inside a conditionally executed subsystem** option.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Output

Port_1(u) – Controller output

scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the setpoint weights and by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as N independent PID controllers, where N is the number of signals in the input vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Controller — Controller type

PID (default) | PI | PD

Specify which of the proportional, integral, and derivative terms are in the controller.

PID

Proportional, integral, and derivative action.

PI

Proportional and integral action only.

PD

Proportional and derivative action only.

Tip The controller output for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "PID", "PI", "PD"

Default: "PID"

Form — Controller structure

Parallel (default) | Ideal

Specify whether the controller structure is parallel or ideal.

Parallel

The proportional, integral, and derivative gains **P**, **I**, and **D**, are applied independently. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output u is:

$$u = P(br - y) + I \frac{1}{s}(r - y) + D \frac{N}{1 + N \frac{1}{s}}(cr - y),$$

where r is the reference signal, y is the measured plant output signal, and b and c are the setpoint weights.

For a discrete-time 2-DOF controller in parallel form, the controller output is:

$$u = P(br - y) + I\alpha(z)(r - y) + D \frac{N}{1 + N\beta(z)}(cr - y),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Ideal

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P \left[(br - y) + I \frac{1}{s} (r - y) + D \frac{N}{1 + N \frac{1}{s}} (cr - y) \right]$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P \left[(br - y) + I\alpha(z)(r - y) + D \frac{N}{1 + N\beta(z)} (cr - y) \right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tip The controller output for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "Parallel", "Ideal"

Default: "Parallel"

Time domain — Specify continuous-time or discrete-time controller

Continuous-time (default) | Discrete-time

When you select **Discrete-time**, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting **Discrete-time** also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select **Continuous-time**.

Note The PID Controller (2DOF) and Discrete PID Controller (2DOF) blocks are identical except for the default value of this parameter.

Programmatic Use

Block Parameter: TimeDomain

Type: string, character vector

Values: "Continuous-time", "Discrete-time"

Default: "Continuous-time"

PID Controller is inside a conditionally executed subsystem — Enable the discrete-integrator time port

off (default) | on

For discrete-time PID controllers, enable the discrete-time integrator port to use your own value of discrete-time integrator sample time. To ensure proper integration, Use the T_{DTI} port to provide a scalar value of Δt for accurate discrete-time integration.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time.

Programmatic Use

Block Parameter: UseExternalTs

Type: string, character vector

Values: "on", "off"

Default: "off"

Sample time (-1 for inherited) – Discrete interval between samples

-1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of -1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to Continuous-time.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to -1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Block Parameter: SampleTime

Type: scalar

Values: -1, positive scalar

Default: -1

Integrator method – Method for computing integral in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the integral term of the controller transfer function is $Ia(z)$, where $a(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1}.$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and set **Controller** to a controller type with integral action.

Programmatic Use

Block Parameter: IntegratorMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Filter method — Method for computing derivative in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and enable **Use filtered derivative**.

Programmatic Use

Block Parameter: FilterMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Main

Source — Source for controller gains and filter coefficient

internal (default) | external

internal

Specify the controller gains, filter coefficient, and setpoint weights using the block parameters **P**, **I**, **D**, **N**, **b**, and **c** respectively.

external

Specify the PID gains, filter coefficient, and setpoint weights externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

Enabling external inputs for the parameters allows you to compute their values externally to the block and provide them to the block as signal inputs.

External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control.

In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. The derivative setpoint weight c is also differentiated. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the input signal u is multiplied by the externally supplied integrator gain, I , before integration. This implementation yields:

$$u_i = \int (r - y)I dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain D and the derivative setpoint weight c to be differentiated.

Programmatic Use

Block Parameter: ControllerParametersSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Proportional (P) — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- **Parallel** — Proportional action is independent of the integral and derivative actions. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output u is:

$$u = P(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y),$$

where r is the reference signal, y is the measured plant output signal, and b and c are the setpoint weights.

For a discrete-time 2-DOF controller in parallel form, the controller output is:

$$u = P(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- **Ideal** — The proportional gain multiplies the integral and derivative terms. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P \left[(br - y) + I \frac{1}{s} (r - y) + D \frac{N}{1 + N \frac{1}{s}} (cr - y) \right]$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P \left[(br - y) + I \alpha(z) (r - y) + D \frac{N}{1 + N \beta(z)} (cr - y) \right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, set the Controller parameters **Source** to `internal`.

Programmatic Use

Block Parameter: P

Type: scalar, vector

Default: 1

Integral (I) – Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: I

Type: scalar, vector

Default: 1

Derivative (D) – Derivative gain

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to `PID` or `PD`.

Programmatic Use

Block Parameter: D

Type: scalar, vector

Default: 0

Use filtered derivative – Apply filter to derivative term

on (default) | off

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller output becomes:

$$D \frac{z - 1}{z T_s} (cr - y) .$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time, and set **Controller** to a type that has a derivative term.

Programmatic Use

Block Parameter: UseFilter

Type: string, character vector

Values: "on", "off"

Default: "on"

Filter coefficient (N) – Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is Continuous-time, the pole location is $s = -N$.
- When **Time domain** is Discrete-time, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
Forward Euler	$z_{pole} = 1 - NT_s$
Backward Euler	$z_{pole} = \frac{1}{1 + NT_s}$
Trapezoidal	$z_{pole} = \frac{1 - NT_s/2}{1 + NT_s/2}$

The block does not support $N = \text{Inf}$ (ideal unfiltered derivative). When the **Time domain** is Discrete-time, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to `PID` or `PD`.

Programmatic Use

Block Parameter: `N`

Type: scalar, vector

Default: 100

Setpoint weight (b) — Proportional setpoint weight

1 (default) | scalar | vector

Setpoint weight on the proportional term of the controller. The proportional term of a 2-DOF controller output is $P(br-y)$, where r is the reference signal and y is the measured plant output. Setting b to 0 eliminates proportional action on the reference signal, which can reduce overshoot in the system response to step changes in the setpoint. Changing the relative values of b and c changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`.

Programmatic Use

Block Parameter: `b`

Type: scalar, vector

Default: 1

Setpoint weight (c) — Derivative setpoint weight

1 (default) | scalar | vector

Setpoint weight on the derivative term of the controller. The derivative term of a 2-DOF controller acts on $cr-y$, where r is the reference signal and y is the measured plant output. Thus, setting c to 0 eliminates derivative action on the reference signal, which can reduce transient response to step changes in the setpoint. Setting c to 0 can yield a controller that achieves both effective disturbance rejection and smooth setpoint tracking without excessive transient response. Changing the relative values of b and c changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to a type that has derivative action.

Programmatic Use

Block Parameter: `c`

Type: scalar, vector

Default: 1

Select tuning method — Tool for automatic tuning of controller coefficients

Transfer Function Based (PID Tuner App) (default) | Frequency Response Based

If you have Simulink Control Design software, you can automatically tune the PID coefficients when they are internal to the block. To do so, use this parameter to select a tuning tool, and click **Tune**.

Transfer Function Based (PID Tuner App)

Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. **PID Tuner** can tune all the coefficients **P**, **I**, **D**, and **N**, and the setpoint coefficients **b** and **c**. By default, **PID Tuner** works with a linearization of your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see “Design Two-Degree-of-Freedom PID Controllers” (Simulink Control Design).

Frequency Response Based

Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially useful for plants that are not linearizable or that linearize to zero. **Frequency Response Based PID Tuner** tunes the coefficients **P**, **I**, **D**, and **N**, but does not tune the setpoint coefficients **b** and **c**. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`.

Enable zero-crossing detection — Detect zero crossings on reset and on entering or leaving a saturation state

`on` (default) | `off`

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: `ZeroCross`

Type: string, character vector

Values: "on", "off"

Default: "on"

Initialization

Source — Source for integrator and derivative initial conditions

`internal` (default) | `external`

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

internal

Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator** parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

external

Specify the initial conditions externally using block inputs. Additional input ports **I_o** and **D_o** appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at **D_o** instead of a filter initial condition.

Programmatic Use

Block Parameter: InitialConditionSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Integrator — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: InitialConditionForIntegrator

Type: scalar, vector

Default: 0

Filter — Filter initial condition

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use**Block Parameter:** InitialConditionForFilter**Type:** scalar, vector**Default:** 0**Differentiator — Initial condition for unfiltered derivative**

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, set **Time domain** to Discrete-time, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to internal.

Programmatic Use**Block Parameter:** DifferentiatorICPrevScaledInput**Type:** scalar, vector**Default:** 0**Initial condition setting — Location at which initial condition is applied**

State (most efficient) (default) | Output

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

State (most efficient)

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use**Block Parameter:** InitialConditionSetting**Type:** string, character vector**Values:** "state", "output"**Default:** "state"**External reset — Trigger for resetting integrator and filter values**

none (default) | rising | falling | either | level

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and

differentiator to initial conditions.) Selecting any option other than **none** enables the **Reset** port on the block for the external reset signal.

none

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

rising

Reset the outputs when the reset signal has a rising edge.

falling

Reset the outputs when the reset signal has a falling edge.

either

Reset the outputs when the reset signal either rises or falls.

level

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use

Block Parameter: ExternalReset

Type: string, character vector

Values: "none", "rising", "falling", "either", "level"

Default: "none"

Ignore reset when linearizing — Force linearization to ignore reset

off (default) | on

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use

Block Parameter: IgnoreLimit

Type: string, character vector

Values: "off", "on"

Default: "off"

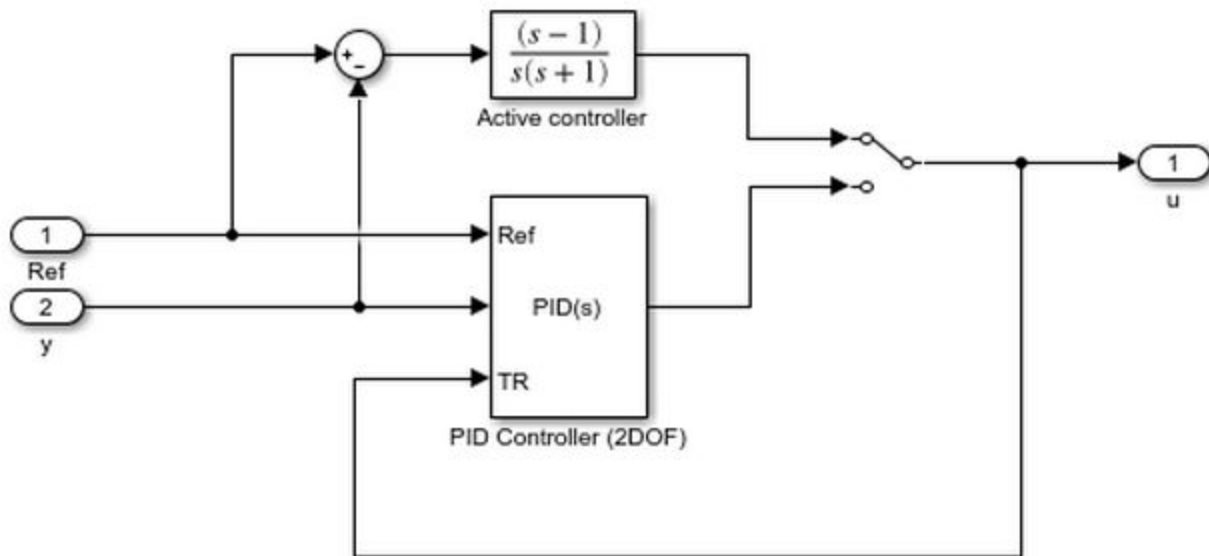

Enable tracking mode — Activate signal tracking

off (default) | on

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain K_t , specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.

For more information, see “Bumpless Control Transfer with a Two-Degree-of-Freedom PID Controller” on page 13-103.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches. For an example illustrating this approach with a 1DOF PID controller, see “Prevent Block Windup in Multiloop Control” on page 13-101.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: TrackingMode

Type: string, character vector

Values: "off", "on"

Default: "off"

Tracking coefficient (Kt) — Gain of signal-tracking feedback loop

1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain K_t . Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use**Block Parameter:** Kt**Type:** scalar**Default:** 1**Output saturation****Limit Output — Limit block output to specified saturation values**

off (default) | on

Activating this option limits the block output internally to the block, so that you do not need a separate Saturation on page 1-1255 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the saturation limits using the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use**Block Parameter:** LimitOutput**Type:** string, character vector**Values:** "off", "on"**Default:** "off"**Upper limit — Upper saturation limit for block output**

Inf (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use**Block Parameter:** UpperSaturationLimit**Type:** scalar**Default:** Inf**Lower limit — Lower saturation limit for block output**

-Inf (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use**Block Parameter:** LowerSaturationLimit**Type:** scalar**Default:** -Inf**Ignore saturation when linearizing — Force linearization to ignore output limits**

off (default) | on

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to

linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: LinearizeAsGain

Type: string, character vector

Values: "off", "on"

Default: "off"

Anti-windup method — Integrator anti-windup method

none (default) | back-calculation | clamping

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the signal entering the integrator never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the signal entering the integrator changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

none

Do not use an anti-windup mechanism.

back-calculation

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.

Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set $Kb = I$, or for controllers with derivative action, $Kb = \sqrt{I \cdot D}$. Back-calculation can be effective for plants with relatively large dead time [1].

clamping

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: AntiWindupMode

Type: string, character vector

Values: "none", "back-calculation", "clamping"

Default: "none"

Back-calculation coefficient (Kb) — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The **back-calculation** anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to back-calculation.

Programmatic Use

Block Parameter: Kb

Type: scalar

Default: 1

Data Types

The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click  to open the Data Type Assistant for the corresponding quantity. For more information, see “Specify Data Types Using Data Type Assistant”.

Main	Initialization	Output saturation	Data Types	State Attributes
Fixed-point operational parameters				
Integer rounding mode: Floor				
<input type="checkbox"/> Saturate on integer overflow				
<input type="checkbox"/> Lock data type settings against changes by the fixed-point tools Open Fixed-Point Tool...				
Data Type				
P product output:	Inherit: Inherit via internal rule	>>	[]	[]
I product output:	Inherit: Inherit via internal rule	>>	[]	[]
D product output:	Inherit: Inherit via internal rule	>>	[]	[]
N product output:	Inherit: Inherit via internal rule	>>	[]	[]
b product output:	Inherit: Inherit via internal rule	>>	[]	[]
c product output:	Inherit: Inherit via internal rule	>>	[]	[]
Sum output:	Inherit: Inherit via internal rule	>>	[]	[]
▶ Additional data types				

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.
- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as SumI2. (See **Model Explorer**.)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.
For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**State Attributes**

The parameters in this tab are primarily of use in code generation.

State name (e.g., 'position') – Name for continuous-time filter and integrator states

' ' (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to Continuous-time.

Programmatic Use**Parameter:** IntegratorContinuousStateAttributes, FilterContinuousStateAttributes**Type:** character vector**Default:** ' '**State name – Names for discrete-time filter and integrator states**

empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Parameter: IntegratorStateIdentifier, FilterStateIdentifier

Type: string, character vector

Default: ""

State name must resolve to Simulink signal object — Require that state name resolve to a signal object

off (default) | on

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class** for the corresponding integrator or filter state.

Programmatic Use

Block Parameter: IntegratorStateMustResolveToSignalObject, FilterStateMustResolveToSignalObject

Type: string, character vector

Values: "off", "on"

Default: "off"

Code generation storage class — Storage class for code generation

Auto (default) | ExportedGlobal | ImportedExtern | ImportedExternPointer

Select state storage class for code generation. If you do not need to interface to external code, select Auto.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder).

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use

Block Parameter: IntegratorRTWStateStorageClass, FilterRTWStateStorageClass

Type: string, character vector

Values: "Auto", "ExportedGlobal", "ImportedExtern" | "ImportedExternPointer"

Default: "Auto"

Code generation storage type qualifier — Storage type qualifier

empty string (default) | character vector | "const" | "volatile" | ...

Specify a storage type qualifier such as const or volatile.

Note This parameter will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Dependencies

To enable this parameter, set **Code generation storage class** to any value other than Auto.

Programmatic Use

Block Parameter:

IntegratorRTWStateStorageTypeQualifier, FilterRTWStateStorageTypeQualifier

Type: string, character vector

Values: "", "const", "volatile"

Default: ""

More About

Decomposition of 2-DOF PID Controllers

A 2-DOF PID controller can be interpreted as a PID controller with a prefilter, or a PID controller with a feedforward element.

Prefilter Decomposition

In parallel form, a two-degree-of-freedom PID controller can be equivalently modeled by the following block diagram, where C is a single degree-of-freedom PID controller and F is a prefilter on the reference signal.

Ref is the reference signal, y is the feedback from the measured system output, and u is the controller output. For a continuous-time 2-DOF PID controller in parallel form, the transfer functions for F and C are

$$F_{par}(s) = \frac{(bP + cDN)s^2 + (bPN + I)s + IN}{(P + DN)s^2 + (PN + I)s + IN},$$

$$C_{par}(s) = \frac{(P + DN)s^2 + (PN + I)s + IN}{s(s + N)},$$

where b and c are the setpoint weights.

For a 2-DOF PID controller in ideal form, the transfer functions are

$$F_{id}(s) = \frac{(b + cDN)s^2 + (bN + I)s + IN}{(1 + DN)s^2 + (N + I)s + IN},$$

$$C_{id}(s) = P \frac{(1 + DN)s^2 + (N + I)s + IN}{s(s + N)}.$$

A similar decomposition applies for a discrete-time 2-DOF controller.

Feedforward Decomposition

Alternatively, the parallel two-degree-of-freedom PID controller can be modeled by the following block diagram.

In this realization, Q acts as feed-forward conditioning on the reference signal. For a continuous-time 2-DOF PID controller in parallel form, the transfer function for Q is

$$Q_{par}(s) = \frac{((b-1)P + (c-1)DN)s + (b-1)PN}{s + N}.$$

For a 2-DOF PID controller in ideal form, the transfer function is

$$Q_{id}(s) = P \frac{((b-1) + (c-1)DN)s + (b-1)N}{s + N}.$$

The transfer functions for C are the same as in the filter decomposition.

A similar decomposition applies for a discrete-time 2-DOF controller.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to Continuous-time):

- Consider using "Model Discretizer" to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, in the **Apps** tab, under **Control Systems**, click **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to Discrete-time):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on memcpy or memset functions (string.h) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Fixed-point code generation is supported for discrete-time PID controllers only (**Time domain** set to **Discrete-time**).

Introduced in R2009b

Polynomial

Perform evaluation of polynomial coefficients on input values

Library: Simulink / Math Operations

Description

The Polynomial block evaluates $P(u)$ at each time step for the input u . You define a set of polynomial coefficients in the form that the MATLAB `polyval` command accepts.

Ports

Input

Port_1 — Input signal

real scalar or vector

Value at which to evaluate the polynomial $P(u)$.

Data Types: `single` | `double`

Output

Port_1 — Evaluated polynomial value

real scalar or vector

Value of the polynomial $P(u)$ evaluated at the input signal.

Data Types: `single` | `double`

Parameters

Polynomial coefficients — Coefficients of polynomial to be evaluated

[+2.081618890e-019, -1.441693666e-014, +4.719686976e-010, -8.536869453e-006, +1.621573104e-001, -8.087801117e+001] (default) | real array

Specify polynomial coefficients in MATLAB `polyval` form. The first coefficient corresponds to x^N and the remaining coefficients correspond to decreasing orders of x . The last coefficient represents the constant for the polynomial.

Programmatic Use

Block Parameter: `coefs`

Type: real array

Default: [+2.081618890e-019, -1.441693666e-014, +4.719686976e-010, -8.536869453e-006, +1.621573104e-001, -8.087801117e+001]

Prelookup

Compute index and fraction for Interpolation Using Prelookup block

Library: Simulink / Lookup Tables
HDL Coder / Lookup Tables

Description

The Prelookup block calculates the index and interval fraction that specify how its input value u relates to the breakpoint dataset. The Prelookup block works best with the Interpolation Using Prelookup block. Feed the resulting index and fraction values into an Interpolation Using Prelookup block to interpolate an n -dimensional table. These two blocks have distributed algorithms. When combined together, they perform the same operation as the integrated algorithm in the n-D Lookup Table block. However, the Prelookup and Interpolation Using Prelookup blocks offer greater flexibility and more efficient simulation and code generation than the n-D Lookup Table block. For more information, see “Efficiency of Performance”.

Supported Block Operations

To use the Prelookup block, you must specify a set of breakpoint values. You choose whether to specify the breakpoint values directly on the dialog box or by feeding the values to a **bp** input port by setting the **Source** parameter to **Dialog** or **Input port**. Typically, this breakpoint data set corresponds to one dimension of the table data in an Interpolation Using Prelookup block. The Prelookup block generates a pair of outputs for each input value u by calculating:

- The index of the breakpoint set element that is less than or equal to u and forms an interval containing u
- The interval fraction in the range $0 \leq f < 1$, representing the normalized position of u on the breakpoint interval between the index and the next index value for in-range input

For example, if the breakpoint data set is $[0 \ 5 \ 10 \ 20 \ 50 \ 100]$ and the input value u is 55, the index is 4 and the fractional value is 0.1. Labels for the index and interval fraction appear as **k** and **f** on the Prelookup block icon. The index value is zero based.

The interval fraction can be negative or greater than 1 for out-of-range input. See the **Extrapolation method** block parameter for more information.

Ports

Input

Port_1 — Input signal, u

scalar | vector | matrix

The Prelookup block accepts real-valued signals of any numeric data type that Simulink supports, except Boolean. The Prelookup block supports fixed-point data types for signals and breakpoint data.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | enumerated | bus

bp — Breakpoint data

1-D vector of real-valued signals

The Prelookup block accepts real-valued signals as breakpoint data of any numeric data type that Simulink supports, except Boolean.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point` | `enumerated`

Output**k — Index of the interval containing the input, u**

scalar | vector | matrix

The zero-based index, k , is a real-valued integer that specifies the interval containing the input, u .

Dependencies

To enable this port, set the **Output selection** to `Index` and `fraction` or `Index only`.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

f — Fraction representing the normalized position of the input, u, within the interval, k

scalar | vector | matrix

Fraction, f , represents the normalized position of the input, u , within the interval k .

Dependencies

To enable this port, set the **Output selection** to `Index` and `fraction`.

Data Types: `single` | `double` | `fixed point`

Port_2 — Bus containing index, k, and fraction, f

bus

Outputting the index, k , and fraction f , as a bus object can help simplify the model.

Dependencies

To enable this port, set the **Output selection** to `Index` and `fraction` as `bus`.

Data Types: `bus`

Parameters**Main****Breakpoints data****Specification — Choose how to enter breakpoint data**

`Explicit values (default)` | `Even spacing` | `Breakpoint object`

If you set this parameter to:

- `Explicit values`, the **Source** and **Value** parameters are visible on the dialog box.
- `Even spacing`, the **First point**, **Spacing**, and **Number of points** parameters are visible on the dialog box.

- Breakpoint object, the **Name** parameter is visible on the dialog box.

Programmatic Use

Block Parameter: BreakpointsSpecification

Type: character vector

Values: 'Explicit values' | 'Even spacing' | 'Breakpoint object'

Default: 'Explicit values'

Source — Specify source of breakpoint data

Dialog (default) | Input port

If you set **Source** to:

- Dialog, specify breakpoint data under **Value**.
- Input port, verify that an upstream signal supplies breakpoint data to the bp input port. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, your block inherits breakpoint attributes from the bp input port.

Dependencies

To enable this parameter, set **Specification** to Explicit values.

Programmatic Use

Block Parameter: BreakpointsDataSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Value — Breakpoint data values

[10:10:110] (default) | vector of strictly monotonically increasing values containing two or more elements

Explicitly specify the breakpoint data. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, you specify additional breakpoint attributes on the **Data Types** pane.

To open the Lookup Table Editor, click **Edit** (see “Edit Lookup Tables”).

Note When you set **Specification** to Explicit values and **Source** to Input port, verify that an upstream signal supplies breakpoint data to the bp input port. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, your block inherits breakpoint attributes (including data type) from the bp input port.

Dependencies

To enable this parameter, set **Specification** to Explicit values and **Source** to Dialog.

Programmatic Use

Block Parameter: BreakpointsData

Type: character vector

Values: vector of strictly monotonically increasing values containing two or more elements

Default: '[10:10:110]'

First point — First point in evenly spaced breakpoint data

10 (default) | real-valued scalar

Dependencies

To enable this parameter, set **Specification** to Even spacing.

Programmatic Use**Block Parameter:** BreakpointsFirstPoint**Type:** character vector**Values:** real-valued scalar**Default:** '10'**Spacing — Spacing between evenly spaced breakpoints**

10 (default) | real-valued, positive scalar

Dependencies

To enable this parameter, set **Specification** to Even spacing.

Programmatic Use**Block Parameter:** BreakpointsSpacing**Type:** character vector**Values:** real-valued, positive scalar**Default:** '10'**Number of points — Number of evenly spaced points**

11 (default) | real-valued, positive scalar

Dependencies

To enable this parameter, set **Specification** to Even spacing.

Programmatic Use**Block Parameter:** BreakpointsNumPoints**Type:** character vector**Values:** real-valued, positive scalar**Default:** '11'**Name — Name of a Simulink.Breakpoint object**

no default | Simulink.Breakpoint

Specify the name of a Simulink.Breakpoint object. A breakpoint object references Simulink

breakpoint objects. If a Simulink.Breakpoint object does not exist, click the action button  and select **Create**. The corresponding parameters of the new breakpoint object are automatically populated with the block information.

Dependencies

To enable this parameter, set **Specification** to Breakpoint object.

Programmatic Use**Block Parameter:** BreakpointObject**Type:** character vector**Values:** Simulink.Breakpoint object**Default:** ''

Algorithm

Output selection — Specify the signals the block outputs

Index and fraction (default) | Index and fraction as bus | Index only

If you want the block to output the index and interval fraction, you can specify whether the block outputs individual signals or a bus signal that includes both the index and fraction signals.

- `Index only` outputs just the index, without the fraction. Typical applications for this option include:
 - Feeding a Direct Lookup Table (n-D) block, with no interpolation on the interval
 - Feeding selection ports of a subtable selection for an Interpolation Using Prelookup block
 - Performing nonlinear quantizations
- `Index and fraction` outputs the index and fraction as individual signals.
- `Index and fraction as bus` outputs a bus signal that includes the index and fraction signals. Using a bus for these signals:
 - Simplifies the model by tying these two related signals together
 - Creates a testpoint `DpResult` structure for the AUTOSAR 4.0 library
 - For the AUTOSAR 4.0 library, avoids the creation of extra copies during code generation when the Prelookup and Interpolation Using Prelookup blocks are in separate models

Note Selecting `Index and fraction as bus` displays the **Output** parameter in the **Data Types** pane and sets the **Output** parameter to `Inherit: auto`. Change this default value to specify a user-defined bus object. For details about defining the bus object, see the **Output** parameter description.

Programmatic Use

Block Parameter: `OutputSelection`

Type: character vector

Values: `'Index and fraction'` | `'Index and fraction as bus'` | `'Index only'`

Default: `'Index and fraction'`

Index search method — Method for searching breakpoint data

Binary search (default) | Linear search | Evenly spaced points

Each search method has speed advantages in different situations:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting `Evenly spaced points` to calculate table indices. This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.
- For unevenly spaced breakpoint sets, follow these guidelines:
 - If input values for `u` do not vary significantly between time steps, selecting `Linear search` with **Begin index search using previous index result** produces the best performance.
 - If input values for `u` jump more than one or two table intervals per time step, selecting `Binary search` produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
 - The index search method is Evenly spaced points.
-

Programmatic Use

Block Parameter: IndexSearchMethod

Type: character vector

Values: 'Evenly spaced points' | 'Linear search' | 'Binary search'

Default: 'Binary search'

Begin index search using previous index result — Start search using the index found at the previous time step

off (default) | on

For input values of u that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Programmatic Use

Block Parameter: BeginIndexSearchUsingPreviousIndexResult

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Extrapolation method — Method for handling out-of-range input values

Clip (default) | Linear

Options include:

- Clip

Block Input	Block Outputs
Less than the first breakpoint	<ul style="list-style-type: none"> • Index of the first breakpoint (for example, 0) • Interval fraction of 0
Greater than the last breakpoint	<ul style="list-style-type: none"> • Index of the next-to-last breakpoint • Interval fraction of 1

Suppose the range is [1 2 3] and you select this option. If u is 0.5, the index is 0 and the interval fraction is 0. If u is 3.5, the index is 1 and the interval fraction is 1.

- Linear

Block Input	Block Outputs
Less than the first breakpoint	<ul style="list-style-type: none"> • Index of the first breakpoint (for example, 0) • Interval fraction that represents the linear distance from u to the first breakpoint

Block Input	Block Outputs
Greater than the last breakpoint	<ul style="list-style-type: none"> • Index of the next-to-last breakpoint • Interval fraction that represents the linear distance from the next-to-last breakpoint to u

Suppose the range is [1 2 3] and you select this option. If u is 0.5, the index is 0 and the interval fraction is -0.5. If u is 3.5, the index is 1 and the interval fraction is 1.5.

Note The Prelookup block supports linear extrapolation only when all of the following conditions are true:

- The input u , breakpoint data, and fraction output use floating-point data types.
- The index uses a built-in integer data type.

Programmatic Use

Block Parameter: ExtrapMethod

Type: character vector

Values: 'Clip' | 'Linear'

Default: 'Clip'

Use last breakpoint for input at or above upper limit – Method of handling inputs at or above upper limit

off (default) | on

Specify how to index input values of u that are greater than or equal to the last breakpoint. The index value is zero based. When input equals the last breakpoint, block outputs differ as follows.

Check Box	Block Outputs
Selected (on)	<ul style="list-style-type: none"> • Index of the last element in the breakpoint data set • Interval fraction of 0
Cleared (off)	<ul style="list-style-type: none"> • Index of the next-to-last breakpoint • Interval fraction of 1

Tip When you select **Use last breakpoint for input at or above upper limit** for a Prelookup block, you must also select **Valid index input may reach last index** for the Interpolation Using Prelookup block to which it connects. This action allows the blocks to use the same indexing convention when accessing the last elements of their breakpoint and table data sets.

Dependencies

This check box is visible only when:

- **Output only the index** is cleared
- **Extrapolation method** is Clip

However, when **Output only the index** is selected and **Extrapolation method** is `Clip`, the block behaves as if this check box is selected, even though it is invisible.

Programmatic Use

Block Parameter: `UseLastBreakpoint`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Diagnostic for out-of-range input – Block action when input is out of range

None (default) | Warning | Error

Options include:

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use

Block Parameter: `DiagnosticForOutOfRangeInput`

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'None'

Code generation

Remove protection against out-of-range input in generated code – Remove code that checks for out-of-range breakpoint inputs

Off (default) | On

Check Box	Result	When to Use
On	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code.	For code efficiency
Off	Generated code includes conditional statements to check for out-of-range breakpoint inputs.	For safety-critical applications

If your input is not out-of-range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to `Error`.

- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input is out-of-range, the behavior is undefined for generated code

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Programmatic Use

Block Parameter: RemoveProtectionInput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Data Types

Breakpoint — Breakpoint data type

Inherit: Same as input (default) | Inherit: Inherit from 'Breakpoint data' | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the breakpoint data type. You can set it to:

- A rule that inherits a data type, for example, **Inherit: Same as input**

- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip

- Specify a breakpoint data type different from the data type of input `u` for these cases:
 - Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal `u`
 - Sharing of prescaled breakpoint data between two Prelookup blocks with different data types for input `u`
 - Sharing of custom storage breakpoint data in the generated code for blocks with different data types for input `u`
- Enumerated data:
 - Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.
 - If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
 - For enumerated data, **Extrapolation method** must be `Clip`.
 - Because the fraction is 1 or 0, select **Output selection > Index only**.

If you are using the index only output selection setting with the Interpolation Using Prelookup block, consider using the **Number of sub-table selection dimensions** parameter.

These are limitations for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the enumeration function.
- When breakpoints data source is set to `Inport port`, the enumeration data type must have 0 as the default value. For example, for this enumeration class, the default value of `GEAR1` must be 0.

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(32),
        NEUTRAL(0)
```

```

    end
end

```

Dependencies

To enable this parameter, set the breakpoints data **Source** to Dialog.

Note When you set **Source** to Input port, the block inherits all breakpoint attributes (data type, minimum, and maximum) from the bp input port.

Programmatic Use

Block Parameter: BreakpointDataTypeStr

Type: character vector

Values: 'Inherit: Same as input' | 'Inherit: Inherit from 'Breakpoint data'' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as input'

Index — Index data type

uint32 (default) | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | <data type expression>

Specify a data type that can index all elements in the breakpoint data set. You can:

- Select a built-in integer data type from the list.
- Specify an integer data type using a fixed-point representation.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: IndexDataTypeStr

Type: character vector

Values:

'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | '<data type expression>'

Default: 'uint32'

Fraction — Fraction data type

Inherit: Inherit via internal rule (default) | double | single | fixdt(1,16,0) | <data type expression>

Specify the data type of the interval fraction. You can:

- Select a built-in data type from the list.
- Specify data type inheritance through an internal rule.
- Specify a fixed-point data type using the [Slope Bias] or binary-point-only scaling representation.
 - If you use the [Slope Bias] representation, the scaling must be trivial — that is, the slope is 1 and the bias is 0.

- If you use the binary-point-only representation, the fixed power-of-two exponent must be less than or equal to zero.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

This parameter displays only when you set **Output selection** on the **Main** tab to **Index** and **fraction**.

Programmatic Use

Block Parameter: FractionDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'double' | 'single' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Output — Output data type

Inherit: auto (default) | bus: <object name>

To output a virtual bus, use the **Inherit: auto** setting. The resulting virtual bus contains two elements, the index and the fraction signals.

To output and specify a nonvirtual bus, use the **Bus: <object name>** template. Replace <object name> with the name of a bus object that contains the index and fraction signals.

- The bus object must contain two elements. The first element corresponds to the index signal and the second to the fraction signal.
- The index and fraction bus element signals cannot be bus signals.
- The data type and the complexity of the bus elements must meet the same constraints that apply to the index and fraction signals if you set **Output selection** to **Index** and **fraction**.

To create the bus object with the index and fraction bus elements, use MATLAB code similar to this, customizing the bus object name and the names and data types of the bus elements.

```
% Bus object: kfBus
elems(1) = Simulink.BusElement;
elems(1).Name = 'Index';
elems(1).DataType = 'int8';

elems(2) = Simulink.BusElement;
elems(2).Name = 'Fraction';
elems(2).DataType = 'double';

kfBus = Simulink.Bus;
kfBus.Elements = elems;
clear elems;
```

Alternatively, you can use the Bus Editor to create or modify the bus object to use with the Prelookup block.

If you feed the bus output signal from this block to an Interpolation Using Prelookup block, select the **Require index and fraction as bus** check box in that block.

Note Use the Fixed-Point Tool data type override option to override bus objects with new bus objects that replace fixed-point data types with floating-point data types.

Overridden bus objects used with the Prelookup block can cause an error because the block does not accept floating-point data types for the first element in the bus.

If you encounter this issue, use the **Fix** button to redefine the original bus object and protect it from being overridden. For example, suppose you define the first element of the bus object to be an `int32`.

```
myBus.Elements(1).DataType
```

```
int32
```

Clicking the **Fix** button redefines the first bus element:

```
myBus.Elements(1).DataType = 'fixdt('int32','DataTypeOverride','Off')
```

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

This parameter displays only when you set **Output selection** on the **Main** tab to `Index` and `fraction` as `bus`.

Programmatic Use

Block Parameter: `OutputBusDataTypeStr`

Type: character vector

Values: `'Inherit: auto'` | `'Bus: <object name>'` | `'<data type expression>'`

Default: `'Inherit: auto'`

Breakpoint Minimum — Minimum value breakpoint data can have

`[]` (default) | scalar

Specify the minimum value that the breakpoint data can have. The default value is `[]` (unspecified).

Dependencies

To enable this parameter, set the breakpoints data **Source** to `Dialog` on the **Main** tab.

Programmatic Use

Block Parameter: `BreakpointMin`

Type: character vector

Value: scalar

Default: `'[]'`

Breakpoint Maximum — Maximum value breakpoint data can have

`[]` (default) | scalar

Specify the maximum value that the breakpoint data can have. The default value is `[]` (unspecified).

Dependencies

To enable this parameter, set the breakpoints data **Source** to `Dialog` on the **Main** tab.

Programmatic Use**Block Parameter:** BreakpointMax**Type:** character vector**Value:** scalar**Default:** '[]'**Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode — Rounding mode for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Floor'**Block Characteristics**

Data Types	double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

More About**Enumerated Values in Prelookup**

Simulate a Prelookup block with enumerated values.

Suppose that you have a Prelookup block with an enumerated class like this defined:

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(-1),
        NEUTRAL(0)
    end
end
```

Prelookup block has these settings:

- **Breakpoints data** value is enumeration('Gears').
- **Output selection** is Index only.
- For an unordered search, set **Index search method** to Linear search and clear the **Begin index search using previous index result** check box.
- **Extrapolation method** is Clip.

Interpolation using Prelookup block has these settings:

- **Number of dimensions** to 1.
- **Table data** value is [5 10 20 40 80 -5 0].
- **Interpolation method** is Flat.
- **Number of sub-table selection dimensions** is 1.

Simulation produces a vector [10 -5 80], which correspond to GEAR2, REVERSE, and SPORTS.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restrictions**Required Block Settings**

- **Breakpoint data:** For **Source**, select Dialog.
- **Specification:** You can select either Explicit values or Even spacing.
- **Index search method:** Select Evenly spaced points.
- **Extrapolation method:** Select Clip.
- **Diagnostic for out-of-range input:** Select Error.
- **Use last breakpoint for input at or above upper limit:** Select this check box.
- **Breakpoint:** For **Data Type**, select Inherit: Same as input.
- **Integer rounding mode:** Select Zero, Floor, or Simplest.

Table Data Typing and Sizing

- It is good practice to structure your table such that the spacing between breakpoints is a power of two. If the breakpoint spacing does not meet this condition, HDL Coder issues a warning. When the breakpoint spacing is a power of two, you can replace division operations in the prelookup step with right-shift operations.
- All ports on the block require scalar values.
- The coder permits floating-point data for breakpoints.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Simulink PLC Coder has limited support for lookup table blocks. The coder does not support:

- Number of dimensions greater than 2
- Cubic spline interpolation method
- Begin index search using a previous index mode
- Cubic spline extrapolation method

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Probe

Output signal attributes, including width, dimensionality, sample time, and complex signal flag

Library: Simulink / Signal Attributes
HDL Coder / Signal Attributes

Description

The Probe block outputs selected information about the signal on its input. The block can output the following attributes of the input signal: width, dimensionality, sample time, and a flag indicating whether the input is a complex-valued signal. The block has one input port. The number of output ports depends on the information that you select for probing, that is, signal dimensionality, sample time, and/or complex signal flag. Each probed value is output as a separate signal on a separate output port, with an independent data type control. During simulation, the block icon displays the probed data.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal to probe, specified as a scalar, vector, matrix, or N-D array. The block accepts real or complex-valued signals of any built-in data type.

You can use an array of buses as an input signal to a Probe block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 (W) — Signal width

scalar

Width, or number of elements, in the input signal, specified as a scalar. The width is also displayed on the block icon with the notation W :

Dependencies

To enable this port, select **Probe width**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_2 (Ts) — Sample time

vector

Sample time of the input signal, as a two-element vector that specifies the period and offset of the sample time, respectively. The sample time is also displayed on the block icon with the notation T_s :. See “Specify Sample Time” for more information.

Dependencies

To enable this port, select **Probe sample time**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_3 (C) — Signal complexity

scalar

Indication of input signal complexity:

- When the input signal is complex, the block outputs 1.
- When the input signal is real-valued, the block outputs 0.

The indication of signal complexity is also displayed on the block icon with the notation C :.

Dependencies

To enable this port, select **Detect complex signal**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_4 (D) — Signal dimensions

scalar | vector

Dimensions of the input signal, output as a scalar or vector. The signal dimensions are also displayed on the block icon with the notation D :.

Dependencies

To enable this port, select **Probe signal dimensions**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main

Probe width — Output width of the input signal

on (default) | off

Select to output the width, or number of elements, of the probed signal.

Programmatic Use

Block Parameter: ProbWidth

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Probe sample time — Output sample time of input signal

on (default) | off

Select to output the sample time of the probed signal. The output is a two-element vector that specifies the period and offset of the sample time, respectively. See “Specify Sample Time” for more information.

Programmatic Use**Block Parameter:** ProbeSampleTime**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Detect complex signal — Indicate the complexity of input signal**

on (default) | off

Select to output 1 if the probed signal is complex; otherwise, 0.

Programmatic Use**Block Parameter:** ProbeComplexSignal**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Probe signal dimensions — Output dimensions of input signal**

on (default) | off

Select to output the dimensions of the probed signal.

Programmatic Use**Block Parameter:** ProbeSignalDimensions**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Signal Attributes****Data type for width — Data type of signal width output**

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | Same as input

Select the output data type for the signal width.

Programmatic Use**Block Parameter:** ProbWidthDataType**Type:** character vector**Values:** 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'Same as input'**Default:** 'double'**Data type for sample time — Data type of sample time output**

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | Same as input

Select the output data type for the sample time information.

Programmatic Use**Block Parameter:** ProbeSampleTimeDataType**Type:** character vector**Values:** 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'Same as input'

Default: 'double'

Data type for signal complexity — Data type of complexity output

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | boolean | Same as input

Select the output data type for the complexity information.

Programmatic Use

Block Parameter: ProbeComplexityDataType

Type: character vector

Values: 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'Same as input'

Default: 'double'

Data type for signal dimensions — Data type for signal dimension output

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | Same as input

Select the output data type for the signal dimension output.

Programmatic Use

Block Parameter: ProbeDimensionsDataType

Type: character vector

Values: 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'Same as input'

Default: 'double'

Product

Multiply and divide scalars and nonscalars or multiply and invert matrices

Library: Simulink / Commonly Used Blocks
 Simulink / Math Operations
 HDL Coder / Commonly Used Blocks
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Product block outputs the result of multiplying two inputs: two scalars, a scalar and a nonscalar, or two nonscalars that have the same dimensions. The default parameter values that specify this behavior are:

- **Multiplication:** Element-wise (.*)
- **Number of inputs:** 2

This table shows the output of the Product block for example inputs using default block parameter values.

Inputs and Behavior	Example
Scalar X Scalar Output the product of the two inputs.	
Scalar X Nonscalar Output a nonscalar having the same dimensions as the input nonscalar. Each element of the output nonscalar is the product of the input scalar and the corresponding element of the input nonscalar.	
Nonscalar X Nonscalar Output a nonscalar having the same dimensions as the inputs. Each element of the output is the product of corresponding elements of the inputs.	

The Divide and Product of Elements blocks are variants of the Product block.

- For information on the Divide block, see Divide.
- For information on the Product of Elements block, see Product of Elements.

The Product block (or the Divide block or Product of Elements block, if appropriately configured) can:

- Numerically multiply and divide any number of scalar, vector, or matrix inputs
- Perform matrix multiplication and division on any number of matrix inputs

The Product block performs scalar or matrix multiplication, depending on the value of the **Multiplication** parameter. The block accepts one or more inputs, depending on the **Number of inputs** parameter. The **Number of inputs** parameter also specifies the operation to perform on each input.

The Product block can input any combination of scalars, vectors, and matrices for which the operation to perform has a mathematically defined result. The block performs the specified operations on the inputs, then outputs the result.

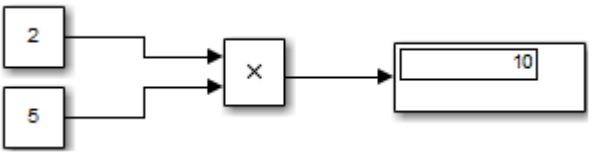

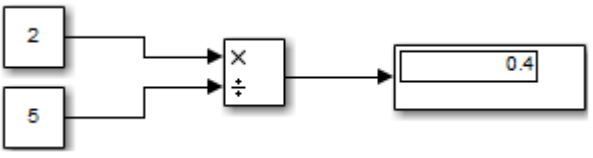

The Product block has two modes: *Element-wise mode*, which processes nonscalar inputs element by element, and *Matrix mode*, which processes nonscalar inputs as matrices.

Element-Wise Mode

When you set **Multiplication** to *Element-wise* (`.*`), the Product block is in *Element-wise mode*, in which it operates on the individual numeric elements of any nonscalar inputs. The MATLAB equivalent is the `.*` operator. In element-wise mode, the Product block can perform a variety of multiplication, division, and arithmetic inversion operations.

The value of the **Number of inputs** parameter controls both how many inputs exist and whether each is multiplied or divided to form the output. When the Product block is in element-wise mode and has only one input, it is functionally equivalent to a Product of Elements block. When the block has multiple inputs, any nonscalar inputs must have identical dimensions, and the block outputs a nonscalar with those dimensions. To calculate the output, the block first expands any scalar input to a nonscalar that has the same dimensions as the nonscalar inputs.

This table shows the output of the Product block for example inputs, using the indicated values for the **Number of inputs** parameter.

Parameter Values	Examples
Number of inputs: 2	
Number of inputs: */	

Parameter Values	Examples
Number of inputs: /**/	
Number of inputs:**	
Number of inputs: */*	

Matrix Mode

When the value of the **Multiplication** parameter is `Matrix(*)`, the Product block is in *Matrix mode*, in which it processes nonscalar inputs as matrices. The MATLAB equivalent is the `*` operator. In Matrix mode, the Product block can invert a single square matrix, or multiply and divide any number of matrices that have dimensions for which the result is mathematically defined.

The value of the **Number of inputs** parameter controls both how many inputs exist and whether each input matrix is multiplied or divided to form the output. The syntax of **Number of inputs** is the same as in element-wise mode. The difference between the modes is in the type of multiplication and division that occur.

Expected Differences Between Simulation and Code Generation

For element-wise operations on complex floating-point inputs, simulation and code generation results might differ in near-overflow cases. Although **complex numbers** is selected and **non-finite numbers** is not selected on the **Code Generation > Interface** pane of the Configuration Parameters dialog box, the code generator does not emit special case code for intermediate overflows. This method improves the efficiency of embedded operations for the general case that does not include extreme values. If the inputs could include extreme values, you must manage these cases explicitly.

The generated code might not produce the same pattern of NaN and inf values as simulation when these values are mathematically meaningless. For example, if the simulation output contains a NaN, output from the generated code also contains a NaN, but not necessarily in the same place.

Ports

Input

Port_1 — First input to multiply or divide

scalar | vector | matrix | N-D array

First input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Port_N — Nth input to multiply or divide

`scalar` | `vector` | `matrix` | N-D array

Nth input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

X — Input signal to multiply

`scalar` | `vector` | `matrix` | N-D array

Input signal to be multiplied with other inputs.

Dependencies

To enable one or more **X** ports, specify one or more * characters for the **Number of inputs** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

÷ — Input signal to divide or invert

`scalar` | `vector` | `matrix` | N-D array

Input signal for division or inversion operations.

Dependencies

To enable one or more ÷ ports, specify one or more / characters for the **Number of inputs** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Port_1 — Output computed by multiplying, dividing, or inverting inputs

`scalar` | `vector` | `matrix` | N-D array

Output computed by multiplying, dividing, or inverting inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Main

Number of inputs — Control number of inputs and type of operation

2 (default) | `scalar` | * or / for each input port

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

When you specify:

- **1 or * or /**

The block has one input port. In element-wise mode, the block processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is 1 or *, the block outputs the input value. If the value is /, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-Wise Mode” on page 1-1122 and “Matrix Mode” on page 1-1123 for more information.

- **Integer value > 1**

The block has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1122 and “Matrix Mode” on page 1-1123 for more information.

- **Unquoted string of two or more * and / characters**

The block has the number of inputs given by the length of the character vector. Each input that corresponds to a * character is multiplied into the output. Each input that corresponds to a / character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1122 and “Matrix Mode” on page 1-1123 for more information.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: '2' | '**' | '*/' | '*/*' | ...

Default: '2'

Multiplication — Element-wise (.) or Matrix (*) multiplication

Element-wise(.) (default) | Matrix(*)

Specify whether the block performs Element-wise(.) or Matrix(*) multiplication.

Programmatic Use

Block Parameter: Multiplication

Type: character vector

Values: 'Element-wise(.)' | 'Matrix(*)'

Default: 'Element-wise(.)'

Multiply over — All dimensions or specified dimension

All dimensions (default) | Specified dimension

Specify the dimension to multiply over as All dimensions, or Specified dimension. When you select Specified dimension, you can specify the **Dimension** as 1 or 2.

Dependencies

To enable this parameter, set **Number of inputs** to * and **Multiplication** to Element-wise (.).

Programmatic Use

Block Parameter: CollapseMode

Type: character vector

Values: 'All dimensions' | 'Specified dimension'

Default: 'All dimensions'

Dimension — Dimension to multiply over

1 (default) | 2 | ... | N

Specify the dimension to multiply over as an integer less than or equal to the number of dimensions of the input signal.

Dependencies

To enable this parameter, set:

- **Number of inputs** to *
- **Multiplication** to Element-wise (.*)
- **Multiply over** to Specified dimension

Programmatic Use

Block Parameter: CollapseDim

Type: character vector

Values: '1' | '2' | ...

Default: '1'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Signal Attributes

Require all inputs to have the same data type — Require that all inputs have the same data type

off (default) | on

Specify if input signals must all have the same data type. If you enable this parameter, then an error occurs during simulation if the input signal types are different.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** ' [] ' | scalar**Default:** ' [] '**Output maximum — Maximum output value for range checking**

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit: Keep MSB | Inherit: Match scaling | Inherit: Inherit via back propagation | Inherit: Same as first input | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Signal Data Types”.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified` (assume 32-bit Generic), in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.
- **Inherit: Keep MSB**— Simulink chooses a data type that maintains the full range of the operation, then reduces the precision of the output to a size appropriate for the embedded target hardware.

Tip For more efficient generated code, deselect the **Saturate on integer overflow** parameter.

This rule never produces overflows.

- **Inherit: Match scaling**— Simulink chooses a data type whose scaling matches the scaling of the input types. If the full range of the type does not fit on the embedded target hardware, the range is reduced yielding a type appropriate for the embedded target hardware. This rule can produce overflows. This rule does not support multiplication between complex signals

The **Inherit: Keep MSB** and **Inherit: Match scaling** rules do not support multiplication between complex signals or signals with non-zero bias. The rules support only multiplication and division ('**', '*/', '/*') between two inputs, matrix multiplication of two inputs, and collapsing product of two elements of a vector.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.

- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Use data type of the driving block.
- **Inherit: Same as first input** — Use data type of first input signal.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Keep MSB' | 'Inherit: Match scaling' | 'Inherit: Same as first input' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'uint64' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. You can select:

Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (off).	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors".</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

The default `Linear` implementation generates a chain of N operations (multipliers) for N inputs.

HDL Block Properties

If you use the block in matrix multiplication mode, you can specify the **DotProductStrategy**. This setting determines whether you want to implement the matrix multiplication by using a tree of adders and multipliers, or use the Multiply-Accumulate block implementation. The default is **Fully Parallel**. For more information, see “DotProductStrategy” (HDL Coder).

See also “Design Considerations for Matrices and Vectors” (HDL Coder).

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also “DSPStyle” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is inherit . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to inherit , Max , Min , Zero , or Custom for the floating-point operator. The default is inherit . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to Custom . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is inherit . See also “MantissaMultiplyStrategy” (HDL Coder).

Complex Data Support

The default (linear) implementation supports complex data.

Complex division is not supported. For block implementations of the Product block in divide mode or reciprocal mode, see “HDL Code Generation” on page 1-512 on the Divide block reference page.

Restrictions

HDL code generation does not support more than two inputs at the ports of the block when you use the block in matrix multiplication mode.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Product of Elements

Copy or invert one scalar input, or collapse one nonscalar input

Library: Simulink / Math Operations
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Product of Elements block inputs one scalar, vector, or matrix. You can use the block to:

- Copy a scalar input unchanged
- Invert a scalar input (divide 1 by it)
- Collapse a vector or matrix to a scalar by multiplying together all elements or taking successive inverses of the elements
- Collapse a matrix to a vector using one of these options:
 - Multiply together the elements of each row or column
 - Take successive inverses of the elements of each row or column

The Product of Elements block is functionally a Product block that has two preset parameter values:

- **Multiplication:** `Element-wise(.*)`
- **Number of inputs:** `*`

Setting nondefault values for either of those parameters can change a Product of Elements block to be functionally equivalent to a Product block or a Divide block.

Ports

Input

Port_1 — First input to multiply or divide

scalar | vector | matrix | N-D array

First input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Port_N — Nth input to multiply or divide

scalar | vector | matrix | N-D array

Nth input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

X — Input signal to multiply

scalar | vector | matrix | N-D array

Input signal to be multiplied with other inputs.

Dependencies

To enable one or more **X** ports, specify one or more * characters for the **Number of inputs** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

÷ — Input signal to divide or invert

scalar | vector | matrix | N-D array

Input signal for division or inversion operations.

Dependencies

To enable one or more **÷** ports, specify one or more / characters for the **Number of inputs** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output**Port_1 — Output computed by multiplying, dividing, or inverting inputs**

scalar | vector | matrix | N-D array

Output computed by multiplying, dividing, or inverting inputs.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters**Main****Number of inputs — Control number of inputs and type of operation**

* (default) | positive integer scalar | * or / for each input port

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

When you specify:

- **1 or * or /**

The block has one input port. In element-wise mode, the block processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is 1 or *, the block outputs the input value. If the value is /, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-Wise Mode” on page 1-1122 and “Matrix Mode” on page 1-1123 for more information.

- **Integer value > 1**

The block has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1122 and “Matrix Mode” on page 1-1123 for more information.

- **Unquoted string of two or more * and / characters**

The block has the number of inputs given by the length of the character vector. Each input that corresponds to a * character is multiplied into the output. Each input that corresponds to a / character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1122 and “Matrix Mode” on page 1-1123 for more information.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: '2' | '*' | '**' | '*/' | '*/*' | ...

Default: '*'

Multiplication — Element-wise (.) or Matrix (*) multiplication

Element-wise(.) (default) | Matrix(*)

Specify whether the block performs Element-wise(.) or Matrix(*) multiplication.

Programmatic Use

Block Parameter: Multiplication

Type: character vector

Values: 'Element-wise(.)' | 'Matrix(*)'

Default: 'Element-wise(.)'

Multiply over — All dimensions or specified dimension

All dimensions (default) | Specified dimension

Specify the dimension to multiply over as All dimensions, or Specified dimension.

When you select All dimensions and select configuration parameter **Use algorithms optimized for row-major array layout**, Simulink enables row-major algorithms for simulation. To generate row-major code, set configuration parameter **Array layout** (Simulink Coder) to Row-major in addition to selecting **Use algorithms optimized for row-major array layout**. The column-major and row-major algorithms differ only in the multiplication order. In some cases, due to different operation order on the same data set, you might experience minor numeric differences in the outputs of column-major and row-major algorithms.

When you select Specified dimension, you can specify the **Dimension** as 1 or 2.

Dependencies

To enable this parameter, set **Number of inputs** to * and **Multiplication** to Element-wise (.*).

Programmatic Use

Block Parameter: CollapseMode

Type: character vector

Values: 'All dimensions' | 'Specified dimension'

Default: 'All dimensions'

Dimension — Dimension to multiply over

1 (default) | 2 | ... | N

Specify the dimension to multiply over as an integer less than or equal to the number of dimensions of the input signal.

Dependencies

To enable this parameter, set:

- **Number of inputs** to *
- **Multiplication** to Element-wise (.*)
- **Multiply over** to Specified dimension

Programmatic Use**Block Parameter:** CollapseDim**Type:** character vector**Values:** '1' | '2' | ...**Default:** '1'**Sample time — Specify sample time as a value other than -1**

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar or vector**Default:** '-1'**Signal Attributes****Require all inputs to have the same data type — Require that all inputs have the same data type**

off (default) | on

Specify if input signals must all have the same data type. If you enable this parameter, then an error occurs during simulation if the input signal types are different.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Output minimum — Minimum output value for range checking**

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | Inherit: Same as first input | double | single | int8 | uint8 | int16 |

```
uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) |
fixdt(1,16,2^0,0) | <data type expression>
```

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Signal Data Types”.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If **Unspecified (assume 32-bit Generic)**, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Use data type of the driving block.
- **Inherit: Same as first input** — Use data type of first input signal.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as first input' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`

Default: `'Inherit: Inherit via internal rule'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

`off (default) | on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector
Values: 'off' | 'on'
Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. You can select:

Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

The Product of Elements block uses these algorithms to perform element-wise operations on inputs of floating-point, built-in integer, and fixed-point types.

Input	Element-Wise Operation	Algorithm
Real scalar, u	Multiplication	$y = u$
	Division	$y = 1/u$
Real vector or matrix with elements $u_1, u_2, u_3, \dots, u_N$	Multiplication	$y = u_1 * u_2 * u_3 * \dots * u_N$
	Division	$y = (((1/u_1)/u_2)/u_3) \dots /u_N$
Complex scalar, u	Multiplication	$y = u$
	Division	$y = 1/u$
Complex vector or matrix with elements $u_1, u_2, u_3, \dots, u_N$	Multiplication	$y = u_1 * u_2 * u_3 * \dots * u_N$
	Division	$y = (((1/u_1)/u_2)/u_3) \dots /u_N$

If the specified dimension for element-wise multiplication or division is a row or column of a matrix, the algorithm applies to that row or column. Consider this model.

The top Product of Elements block collapses the matrix input to a scalar by taking successive inverses of the four elements:

- $y = (((1/2+i)/3)/4-i)/5$

The bottom Product of Elements block collapses the matrix input to a vector by taking successive inverses along the second dimension:

- $y(1) = ((1/2+i)/3)$
- $y(2) = ((1/4-i)/5)$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

HDL Coder supports **Tree** and **Cascade** architectures for Product or Product of Elements blocks that have a single vector input with multiple elements.

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

Architecture	Additional cycles of latency	Description
Linear (default)	0	Generates a linear chain of adders to compute the sum of products.
Tree	0	Generates a tree structure of adders to compute the sum of products.
Cascade	1, when block has a single vector input port.	This implementation optimizes latency * area and is faster than the Tree implementation. It computes partial products and cascades multipliers. See “Cascade Architecture Best Practices” (HDL Coder).

Note The Product of Element block does not support HDL code generation with **double** data types in the **Native Floating Point** mode.

HDL Block Properties

If you use the block in matrix multiplication mode, you can specify the **DotProductStrategy**. This setting determines whether you want to implement the matrix multiplication by using a tree of adders and multipliers, or use the Multiply-Accumulate block implementation. The default is **Fully Parallel**. For more information, see “DotProductStrategy” (HDL Coder).

See also “Design Considerations for Matrices and Vectors” (HDL Coder).

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also “DSPStyle” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).

General	
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , <code>Zero</code> , or <code>Custom</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <code>Custom</code> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is <code>inherit</code> . See also “MantissaMultiplyStrategy” (HDL Coder).

Complex Data Support

The default (linear) implementation supports complex data.

Complex division is not supported. For block implementations of the Product block in divide mode or reciprocal mode, see “HDL Code Generation” on page 1-512 on the Divide block reference page.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Pulse Generator

Generate square wave pulses at regular intervals

Library: Simulink / Sources

Description

The Pulse Generator block generates square wave pulses at regular intervals. The block waveform parameters, **Amplitude**, **Pulse Width**, **Period**, and **Phase delay**, determine the shape of the output waveform. The following diagram shows how each parameter affects the waveform.

The Pulse Generator block can emit scalar, vector, or matrix signals of any real data type. To emit a scalar signal, use scalars to specify the waveform parameters. To emit a vector or matrix signal, use vectors or matrices, respectively, to specify the waveform parameters. Each element of the waveform parameters affects the corresponding element of the output signal. For example, the first element of a vector amplitude parameter determines the amplitude of the first element of a vector output pulse. All the waveform parameters must have the same dimensions after scalar expansion. The data type of the output is the same as the data type of the **Amplitude** parameter.

The block output can be generated in time-based or sample-based modes, determined by the **Pulse type** parameter.

Time-Based Mode

In time-based mode, Simulink computes the block output only at times when the output actually changes. This approach results in fewer computations for the block output over the simulation time period. Activate this mode by setting the **Pulse type** parameter to `Time based`.

The block does not support a time-based configuration that results in a constant output signal. Simulink returns an error if the parameters **Pulse Width** and **Period** satisfy either of these conditions:

$$Period * \frac{PulseWidth}{100} = 0$$

$$Period * \frac{PulseWidth}{100} = Period$$

Depending on the pulse waveform characteristics, the intervals between changes in the block output can vary. For this reason, a time-based Pulse Generator block has a variable sample time. The sample time color of such blocks is brown (see “View Sample Time Information” for more information).

Simulink cannot use a fixed-step solver to compute the output of a time-based pulse generator. If you specify a fixed-step solver for models that contain time-based pulse generators, Simulink computes a fixed sample time for the time-based pulse generators. Then the time-based pulse generators simulate as sample based.

If you use a fixed-step solver and the **Pulse type** is `Time based`, choose the step size such that the period, phase delay, and pulse width (in seconds) are integer multiples of the solver step size. For example, suppose that the period is 4 seconds, the pulse width is 75% (that is, 3 s), and the phase delay is 1 s. In this case, the computed sample time is 1 s. Therefore, choose a fixed-step size of 1 or a number that divides 1 exactly (for example, 0.25). To ensure this setting, select `auto` on the **Solver** pane of the Configuration Parameters dialog box.

Sample-Based Mode

In sample-based mode, the block computes its outputs at fixed intervals that you specify. Activate this mode by setting the **Pulse type** parameter to `Sample based`.

An important difference between the time-based and sample-based modes is that in time-based mode, the block output is based on simulation time, and in sample-based mode, the block output depends only on the simulation start, regardless of elapsed simulation time.

This block supports reset semantics in sample-based mode. For example, if a Pulse Generator block is in a resettable subsystem that hits a reset trigger, the block output resets to its initial condition.

Ports

Output

Port_1 — Output signal

scalar | vector | matrix

Generated square wave pulse signal specified by the parameters.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Pulse type — Computational technique

`Time based` (default) | `Sample based`

Computational technique to generate the type of square wave that this block generates, either time- or sample-based. Some parameters in the dialog box appear depending on whether you select time-based or sample-based.

Programmatic Use**Block Parameter:** PulseType**Type:** character vector**Values:** 'Time based' | 'Sample based'**Default:** 'Time based'**Time (t) — Source of time variable**

Use simulation time (default) | Use external signal

Specifies whether to use simulation time or an external signal as the source of values for the output pulse's time variable. If you specify an external source, the block displays an input port for connecting the source. The output pulse differs as follows:

- **Use simulation time:** The block generates an output pulse where the time variable equals the simulation time.
- **Use external signal:** The block generates an output pulse where the time variable equals the value from the input port, which can differ from the simulation time.

Programmatic Use**Block Parameter:** TimeSource**Type:** character vector**Values:** 'Use simulation time' | 'Use external signal'**Default:** 'Use simulation time'**Amplitude — Signal amplitude**

1 (default) | scalar

Specify the amplitude of the signal.

Programmatic Use**Block Parameter:** Amplitude**Type:** character vector**Value:** scalar**Default:** '1'**Period (secs) — Pulse period**

10 (default) | scalar

Pulse period specified in seconds if the pulse type is time-based. If the pulse type is sample-based, then the period is specified as the number of sample times.

Programmatic Use**Block Parameter:** Period**Type:** character vector**Value:** scalar**Default:** '10'**Pulse width — Duty cycle**

5 (default) | scalar in the range [0,100]

Duty cycle specified as the percentage of the pulse period that the signal is on if time-based or as number of sample times if sample-based.

Programmatic Use**Block Parameter:** PulseWidth

Type: character vector

Value: scalar

Default: '5'

Phase delay (secs) — Delay before pulse

0 (default) | scalar

Delay before the pulse is generated, specified in seconds, if the pulse type is time-based or as number of sample times if the pulse type is sample-based.

Programmatic Use

Block Parameter: PhaseDelay

Type: character vector

Value: scalar

Default: '0'

Sample time — Length of sample time

0 (default) | scalar | vector

Length of the sample time for this block in seconds. This parameter appears only if the block's pulse type is sample-based. See “Specify Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Value: scalar

Default: '0'

Interpret vector parameters as 1-D — Treat vectors as 1-D

on (default) | off

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.
- When you clear this check box, the block does not output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

Programmatic Use

Block Parameter: VectorParams1D

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	no

Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Cannot be used inside a triggered subsystem hierarchy.

These blocks do not reference absolute time when configured for sample-based operation. In time-based operation, they depend on absolute time.

Signal Generator | Waveform Generator

Introduced before R2006a

Push Button

Set value of parameter when button is pressed

Library: Simulink / Dashboard

Description

When you press the Push Button block during a simulation, the value of the connected block parameter changes to a specified value. Use the Push Button block with other Dashboard blocks to create an interactive dashboard to control your model.

Double-clicking the Push Button block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

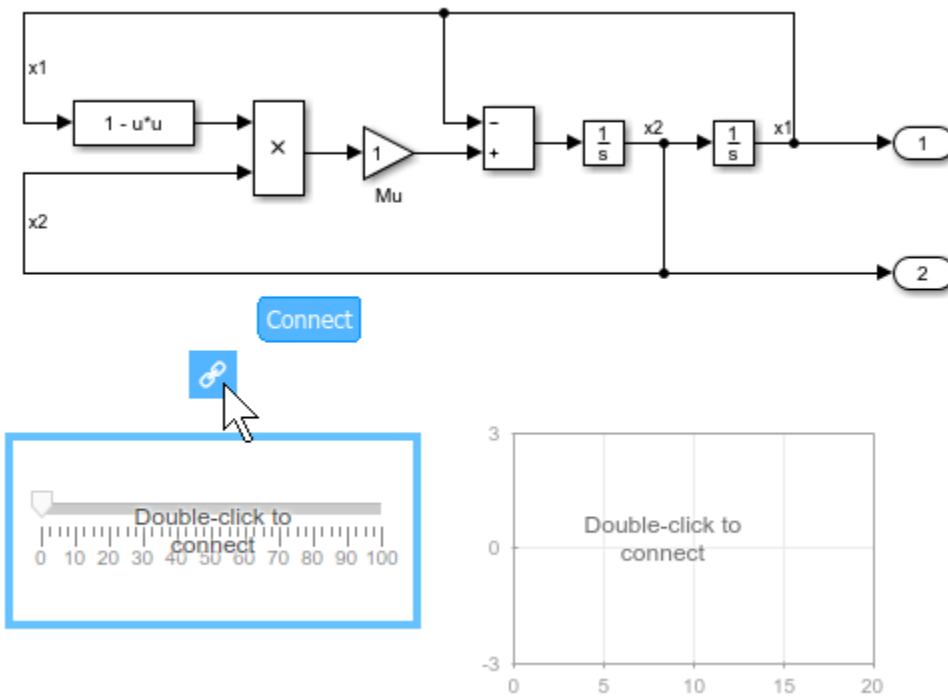

Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to make connections. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above it.

In connect mode, when you select one or more signals or blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block. To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a variable or parameter to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.
- When you specify a block parameter value by indexing a variable array, the parameter does not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect
variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.
- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: []

Button Text — Text displayed on button

Button (default) | character vector

The text displayed on the Push Button block in your model.

Programmatic Use

Block Parameter: ButtonText

Type: string or character array

Default: 'Button'

On Value — Value assigned to parameter when button is pressed

1 (default) | scalar

The value assigned to the connected block parameter when the button is pressed.

Programmatic Use

Block Parameter: OnValue

Type: string or character array

Default: '1'

Label — Block label position

Hide (default) | Bottom | Top

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Hide' | 'Bottom' | 'Top'

Default: 'Hide'

Block Characteristics

Data Types	double integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Quantizer

Discretize input at given interval

Library: Simulink / Discontinuities

Description

The Quantizer block discretizes the input signal using a quantization algorithm. The block uses a round-to-nearest method to map signal values to quantized values at the output that are defined by the **Quantization interval**. A smooth input signal can take on a stair-step shape after quantization.

This equation mathematically describes the round-to-nearest method:

$$y = q * \text{round}(u/q)$$

where y is the quantized output, u is the input, and q is the **Quantization interval**.

Ports

Input

Port_1 — Input signal to quantize

scalar | vector

Input signal to the quantization algorithm.

Data Types: single | double

Output

Port_1 — Quantized output signal

scalar | vector

Output signal composed of discrete values, quantized with a round-to-nearest approach:

$$y = q * \text{round}(u/q)$$

where y is the output, u is the input, and q is the **Quantization interval**.

Data Types: single | double

Parameters

Quantization interval — Interval that defines quantization levels for the output signal

0.5 (default) | scalar | vector

Specify the quantization interval used in the algorithm. Quantization levels for the Quantizer block output are integer multiples of the **Quantization interval**.

Programmatic Use

Block Parameter: QuantizationInterval

Type: character vector
Value: Any real or complex value
Default: '0.5'

Treat as gain when linearizing — Specify the gain value

On (default) | boolean

The linearization commands in Simulink software treat this block as a gain in state space. Select this check box to cause the commands to treat the gain as 1. Clear the box to have the commands treat the gain as 0.

Programmatic Use

Block Parameter: LinearizeAsGain

Type: character vector

Value: 'off' | 'on'

Default: 'on'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '-1'

Block Characteristics

Data Types	double single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Quarter Gauge

Display input value on quadrant scale

Library: Simulink / Dashboard

Description

The Quarter Gauge block displays the connected signal on a quadrant scale during simulation. You can use the Quarter Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Quarter Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Quarter Gauge block to fit your data. You can also customize the appearance of the Quarter Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connecting Dashboard Blocks

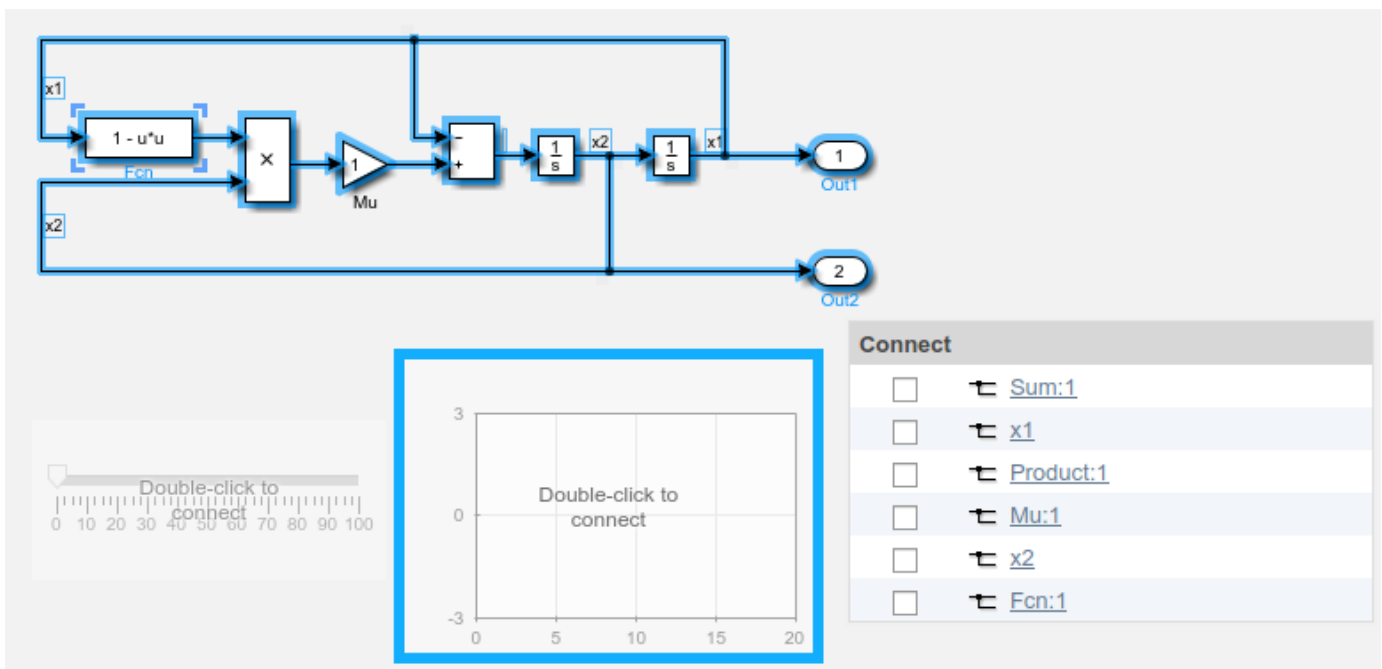

Dashboard blocks do not use ports to connect to signals. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above the block.

In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify `-1`.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Maximum — Maximum tick mark value**

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the **Maximum** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Tick Interval — Interval between major tick marks**

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to **auto**, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the **Tick Interval** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Scale Colors — Color indications on gauge scale**

colors for scale ranges

Color specifications for value ranges on the scale. Press the **+** button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the **Scale Colors** parameter, use an array of structures with the fields:

- **Min** — Minimum value for the color range on the scale
- **Max** — Maximum value for the color range on the scale
- **Color** — 1-by-3 vector of double values between 0 and 1 that specify the color for the range in the form [r g b]

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;
range1.Max = 10;
```

```
range1.Color = [0 0 1];
range2.Min = 10;
range2.Max = 15;
range2.Color = [0 1 0];
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors

Type: structure array

Default: 0x1 struct array

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Queue, Entity Queue

Enqueue messages and entities

Library: Simulink / Messages & Events
SimEvents

Description

This block stores entities or messages in a queue, based on the order of arrival or priority. Each element at the head of the queue departs when the downstream block is ready to accept it. The Queue block and the Entity Queue block are the same blocks with different default values for the **Overwrite the oldest element if queue is full** check box.

You can specify the capacity of the queue, and the policy when the queue is full. The block supports three different message or queue sorting policies, first-in-first out (FIFO), last-in-first out (LIFO), and priority. The priority queue can be used only when the **Overwrite the oldest element if queue is full** check box is cleared.

Ports

Input

Port_1 — Input entity or message

scalar | vector | matrix

Input entity or message that carries scalar, bus, or vector data to enter the queue.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Output

Port_1 — Output entity or message

scalar | vector | matrix

Output port that allows entities or messages at the head of the queue to depart when a downstream block is ready to accept them.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Port_d — Number of entities that have departed the block

scalar

Number of entities that have departed the block.

Dependencies

To enable this port, select **Overwrite the oldest element if queue is full** check box, and click the **Statistics** tab and select the box labeled **Number of entities departed, d**.

Data Types: double

Port_n – Number of entities that have not yet departed the block

scalar

Number of entities that have not yet departed the block.

Dependencies

To enable this port, select **Overwrite the oldest element if queue is full** check box, and click the **Statistics** tab and select the box labeled **Number of entities in block, n**.

Data Types: double

Port_w – Average wait time for entities in the block

scalar

Average wait time for entities in the block.

Dependencies

To enable this port, select **Overwrite the oldest element if queue is full** check box, and click the **Statistics** tab and select the box labeled **Average wait, w**.

Data Types: double

Port_l – Average length of the entity queue

scalar

Port_l outputs the average length of the entity queue.

Dependencies

To enable this port, select **Overwrite the oldest element if queue is full** check box, and click the **Statistics** tab and select the box labeled **Average queue length, l**.

Data Types: double

Port_ex – Number of entities extracted

scalar

Number of entities that are pulled out of this block.

Dependencies

To enable this port, select **Overwrite the oldest element if queue is full** check box, and click the **Statistics** tab and select the box labeled **Number of entities extracted, ex**.

Data Types: double

Parameters**Overwrite the oldest element if queue is full – Specify queue overwriting policy**

on (default for Simulink) | off (default for SimEvents)

Select this check box to choose between two queue overwriting policies.

- If you select the check box, an incoming message overwrites the oldest if the queue is full.

This mode represents a simple message buffer that you can use to generate asynchronous communication between Simulink components and production code.

- If you clear the check box, the block does not accept new messages if the queue is full.

In this mode, you can manipulate entity data using event actions and visualize statistics.

To customize actions when entities or messages enter, exit, or are blocked, enter MATLAB code in the **Entry action**, **Exit action**, or **Blocked action** field of the **Event actions** tab. For more information, see “Events and Event Actions” (SimEvents).

For an example, see “Manage Entities Using Event Actions” (SimEvents).

Programmatic Use

Block Parameter: QueueOverwriting

Type: character vector

Values: 'on' | 'off'

Default: 'on' (for Simulink) and 'off' (for SimEvents)

Capacity — Specify the capacity of the queue

25 (default) | scalar

Specify the capacity of the queue.

Programmatic Use

Block Parameter: Capacity

Type: character vector

Values: '25' | scalar

Default: '25'

Queue type — Choose the queue type

FIFO (default) | LIFO | Priority

Choose the queue type.

- FIFO — first-in-first-out
- LIFO — last-in-first-out
- Priority — store elements in order of priority, see “Serve High-Priority Customers by Sorting Entities Based on Priority” (SimEvents). Priority can be selected when you clear the **Overwrite the oldest element if queue is full** check box.

Note Priority queue does not support fixed point data type.

Programmatic Use

Block Parameter: QueueType

Type: character vector

Values: 'FIFO' | 'LIFO' | 'Priority'

Default: 'FIFO'

Multicast tag — Specify the tag when accepting entities broadcast via multicast sources

A (default) | character vector

Specify the tag when accepting entities broadcast via multicast sources. The Entity Multicast block requires SimEvents license.

Dependencies

This parameter is visible when you clear the **Overwrite the oldest element if queue is full** check box, and set **Entity arrival source** to Multicast.

Programmatic Use

Block Parameter: MulticastTag

Type: character vector

Values: 'A' | character vector

Default: 'A'

Priority source — Specify which attribute of the entity determines its priority

PriorityAttribute (default) | character vector

Specify which attribute of the entity determines its priority.

Dependencies

This parameter is visible when you clear the **Overwrite the oldest element if queue is full** check box, and set **Queue type** to Priority.

Programmatic Use

Block Parameter: PrioritySource

Type: character vector

Values: 'PriorityAttribute' | character vector

Default: 'PriorityAttribute'

Sorting direction — Choose the direction of sorting based on priority

Ascending (default) | Descending

Choose the direction of sorting based on priority.

- Ascending — Elements with smaller priority values appear in front of the queue.
- Descending — Elements with greater priority values appear in front of the queue.

Dependencies

This parameter is visible when you clear the **Overwrite the oldest element if queue is full** check box, and set **Queue type** to Priority.

Programmatic Use

Block Parameter: SortingDirection

Type: character vector

Values: 'Ascending' | 'Descending'

Default: 'Ascending'

Entity arrival source — Choose the source of arrival for the entities

Input port (default) | Multicast

Choose the source of arrival for the entities.

- Input port — Input port is source of messages or entities.
- Multicast — Entity Multicast block is source of entities. The Entity Multicast block requires SimEvents license.

Dependencies

This parameter is visible when you clear the **Overwrite the oldest element if queue is full** check box, and set **Queue type** to Priority.

Programmatic Use

Block Parameter: EntityArrivalSource

Type: character vector

Values: 'Input port' | 'Multicast'

Default: 'Input port'

Event action — Specify the behavior of the entity in certain events

Entry (default) | Exit | Blocked

Specify the behavior of the entity in certain events. Define the behavior in the **Event action** parameter. The **Entry** and the **Exit** actions are called just after the entity entry and just before entity exit. The **Blocked** action is called after an entity is blocked. For more information, see “Events and Event Actions” (SimEvents).

Note Event actions do not support fixed point data type.

Dependencies

Event actions are visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use

Block Parameter: EntryAction, ExitAction, BlockedAction

Type: character vector

Values: MATLAB code

Default: ''

Number of entities departed, d — Outputs the number of entities that have departed the block

off (default) | on

Number of entities that have departed the block.

Dependencies

Number of entities departed, d is visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use

Block Parameter: NumberEntitiesDeparted

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Number of entities in block, n — Outputs the number of entities present in the block, that are yet to depart

off (default) | on

Number of entities present in the block, but which are yet to depart.

Dependencies

Number of entities in block, n is visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use

Block Parameter: NumberEntitiesInBlock

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Average wait, w – Outputs the average wait time

off (default) | on

Sum of the wait times for entities departing the block divided by their total number. Wait time is the duration between the Entity Queue block entry and exit of an entity. For more information, see “Interpret SimEvents Models Using Statistical Analysis” (SimEvents).

Dependencies

Average wait, w is visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use

Block Parameter: AverageWait

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Average queue length, l – Outputs the average length of the entity queue

off (default) | on

Accumulated time-weighted average queue size. The block computes this value by:

- 1 Multiplying the size of the queue by its duration to calculate time-weighted queue size
- 2 Summing up all time-weighted queue sizes and averaging them over total time

For more information, see “Interpret SimEvents Models Using Statistical Analysis” (SimEvents).

Dependencies

Average queue length, l is visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use

Block Parameter: AverageQueueLength

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Number of entities extracted, ex – Number of entities extracted from this block

off (default) | on

Outputs the number of extracted entities which are pulled out from this block by the Entity Find block. The Entity Find block requires a SimEvents license. If the extracted entity is the first entity in the queue, the next entity is set as the pending entity to leave the block. If an entity attribute defines

the priority in a priority queue and it is modified by the Entity Find block, the queue is sorted again. When an entity is extracted, **Number of entities departed, d**, **Number of entities in block, n**, **Average wait, w**, and **Average queue length, l** statistics are updated accordingly. For more information about finding and extracting entities, see “Find and Extract Entities in SimEvents Models” (SimEvents).

Dependencies

Number of entities extracted, ex is visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use

Block Parameter: NumEntitiesExtracted

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Introduced in R2016a

Radio Button

Select parameter value

Library: Simulink / Dashboard

Description

The Radio Button block lets you change the value of the connected parameter during simulation. You can specify a list of values and labels and then select the value for the parameter from that list. Use the Radio Button block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Double-clicking the Radio Button block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

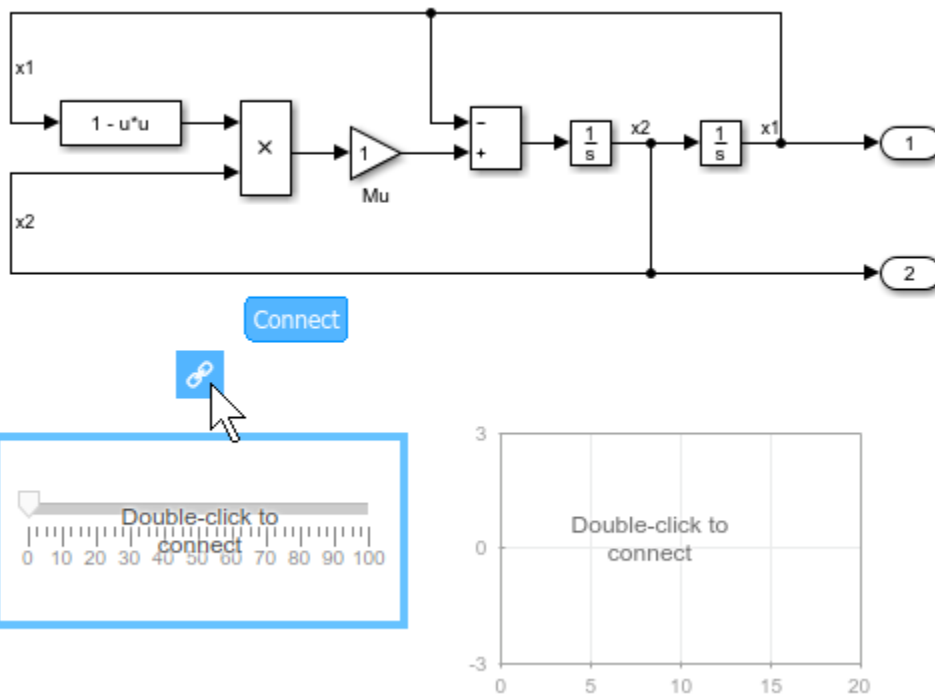

Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to make connections. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

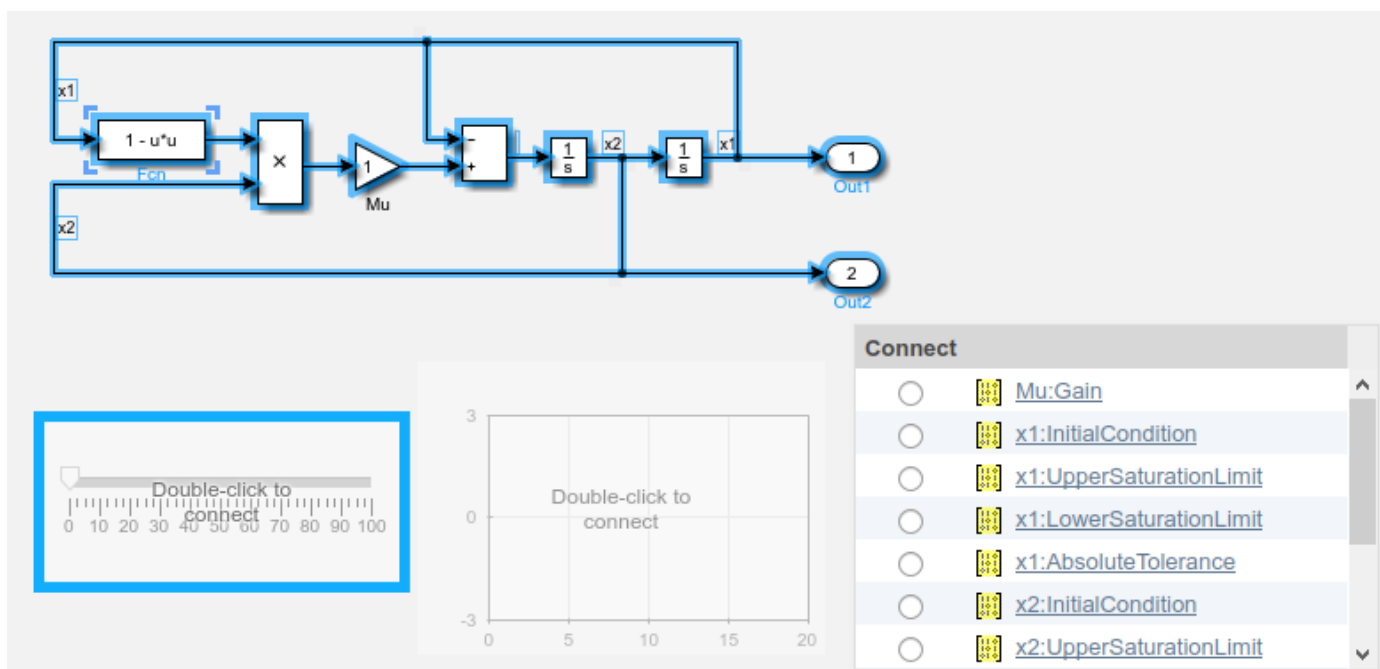

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, pause on an unconnected dashboard block and click the **Connect** button that appears above it.

In connect mode, when you select one or more signals or blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block. To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a variable or parameter to connect.

When you finish connecting the dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- Some signals are not available during accelerator mode simulations. To view these signals using a dashboard block, mark the signal for logging.
- When you specify a block parameter value by indexing a variable array, the parameter does not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect
variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.
- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

States — Set of states to select for connected parameter

scalar and character vector

Set of states from which to select a value for the connected parameter. Each **State** consists of a **State Value** and a **State Label**.

- **State Value** — Value assigned to the connected variable or parameter when you select the state with the corresponding **Label**.
- **State Label** — Label for each state. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the bottom, or you can enter a descriptive text label.

Click the **+** button to add additional **States**.

The default configuration for the block includes these **States**.

States

State Value	State Label
0	Label1
1	Label2
2	Label3

Programmatic Use

To programmatically configure the **States** for a block, use an array of structures containing the fields `Value` and `Label`. Include a structure in the array for each state you want to configure on the block.

```
state1.Value = 1;  
state1.Label = 'State 1';  
state2.Value = 2;  
state2.Label = 'State 2';  
radioStates = [state1 state2];
```

Block Parameter: States**Type:** structure**Default:** 3x1 structure array**Enumerated Data Type — Specify state values and labels using an enumerated data type**

off (default) | on

You can use an enumerated data type that pairs a numeric value with each enumeration to configure the state values and labels for the block. To specify the states for the block using an enumerated data type, first select the **Enumerated Data Type** option. Then, specify the name of the enumerated data type in the text box. The definition for the specified enumerated data type must be saved on the MATLAB path or in the base workspace.

Example: myEnumType

Programmatic Use

To programmatically specify the state labels and values for the block using an enumerated data type, specify 'on' for the UseEnumeratedDataType parameter and the name of the enumerated data type for the EnumeratedDataType parameter.

Block Parameter: UseEnumeratedDataType**Type:** string or character array**Values:** 'on' | 'off'**Default:** 'off'**Block Parameter:** EnumeratedDataType**Type:** string or character array**Default:** ''**Group Name — Radio Button group name**

RadioButtonGroup (default) | character vector

Name for the group of values displayed on the Radio Button block. Unlike the **Block Name** and **Label**, the **Group Name** always shows on the Radio Button block.

Example: Input Amplitude

Programmatic Use**Block Parameter:** ButtonGroupName**Type:** string or character array**Default:** 'Group'**Label — Block label position**

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Ramp

Generate constantly increasing or decreasing signal

Library: Simulink / Sources

Description

The Ramp block generates a signal that starts at a specified time and value and changes by a specified rate. The block's **Slope**, **Start time**, and **Initial output** parameters determine the characteristics of the output signal. All must have the same dimensions after scalar expansion.

Ports

Output

Port_1 — Output signal

scalar | vector | matrix

Generated output ramp signal characterized by the **Slope**, **Start time**, and **Initial output** parameters.

Data Types: double

Parameters

Slope — Slope of signal

1 (default) | scalar | vector | matrix

Specify the rate of change of the generated signal.

Programmatic Use

Block Parameter: slope

Type: character vector

Values: scalar

Default: '1'

Start time — Time output begins

0 (default) | scalar

Specify the time at which the block begins generating the signal.

Programmatic Use

Block Parameter: start

Type: character vector

Values: scalar

Default: '0'

Initial output — Initial value of output signal

0 (default) | scalar | vector | matrix

Specify the initial value of the output signal.

Programmatic Use**Block Parameter:** InitialOutput**Type:** character vector**Values:** scalar**Default:** '0'**Interpret vector parameters as 1-D — Treat vectors as 1-D**

on (default) | off

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.
- When you clear this check box, the block does not output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

Programmatic Use**Block Parameter:** VectorParams1D**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Block Characteristics**

Pulse Generator | Repeating Sequence

Introduced before R2006a

Random Number

Generate normally distributed random numbers

Library: Simulink / Sources

Description

The Random Number block generates normally distributed random numbers. To generate uniformly distributed random numbers, use the Uniform Random Number block. Both blocks use the Normal (Gaussian) random number generator ('v4': legacy MATLAB 4.0 generator of the `rng` function).

You can generate a repeatable sequence using any Random Number block with the same nonnegative seed and parameters. The seed resets to the specified value each time a simulation starts. By default, the block produces a sequence that has a mean of 0 and a variance of 1. To generate a vector of random numbers with the same mean and variance, specify the **Seed** parameter as a vector.

Avoid integrating a random signal, because solvers must integrate relatively smooth signals. Instead, use the Band-Limited White Noise block.
