Kernel naive Bayes	Kernel distribution You can specify the kernel type and support. Classification Learner automatically determines the kernel width using the underlying <code>fitcnb</code> function.	multivariate multinomial distribution

This example uses Fisher's iris data set, which contains measurements of flowers (petal length, petal width, sepal length, and sepal width) for specimens from three species. Train naive Bayes classifiers to predict the species based on the predictor measurements.

- 1 In the MATLAB Command Window, load the Fisher iris data set and create a table of measurement predictors (or features) using variables from the data set.

```
fishertable = readtable('fisheriris.csv');
```

- 2 Click the **Apps** tab, and then click the arrow at the right of the **Apps** section to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Classification Learner**.
- 3 On the **Classification Learner** tab, in the **File** section, select **New Session > From Workspace**.

- 4 In the New Session dialog box, select the table `fishertable` from the **Data Set Variable** list (if necessary).

As shown in the dialog box, the app selects the response and predictor variables based on their data type. Petal and sepal length and width are predictors, and species is the response that you want to classify. For this example, do not change the selections.

Data set

 No protection against overfitting.

[Read about validation](#)

Start Session Cancel

- 5 To accept the default validation scheme and continue, click **Start Session**. The default validation option is cross-validation, to protect against overfitting.

Classification Learner creates a scatter plot of the data.

- 6 Use the scatter plot to investigate which variables are useful for predicting the response. Select different options on the **X** and **Y** lists under **Predictors** to visualize the distribution of species and measurements. Observe which variables separate the species colors most clearly.

The *setosa* species (blue points) is easy to separate from the other two species with all four predictors. The *versicolor* and *virginica* species are much closer together in all predictor measurements and overlap, especially when you plot sepal length and width. *setosa* is easier to predict than the other two species.

- 7 Create a naive Bayes model. On the **Classification Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Naive Bayes Classifiers** group, click **Gaussian Naive Bayes**. Note that Classification Learner disables the **Advanced** button in the **Model Type** section, because this type of model has no advanced settings.

In the **Training** section, click **Train**.

Tip If you have Parallel Computing Toolbox the Opening Pool dialog box opens the first time you click **Train** (or when you click **Train** again after an extended period of time). The dialog box remains open while the app opens a parallel pool of workers. During this time, you cannot

interact with the software. After the pool opens, you can train multiple classifiers at once and continue working.

The app creates a Gaussian naive Bayes model, and plots the results.

The app displays the **Gaussian Naive Bayes** model in the History list. Check the model validation score in the **Accuracy** box. The score shows that the model performs well.

For the **Gaussian Naive Bayes** model, by default, the app models the distribution of numerical predictors using the Gaussian distribution, and models the distribution of categorical predictors using the multivariate multinomial distribution (MVMN).

Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

- 8 Examine the scatter plot. An X indicates misclassified points. The blue points (**setosa** species) are all correctly classified, but the other two species have misclassified points. Under **Plot**, switch between the **Data** and **Model predictions** options. Observe the color of the incorrect (X) points. Or, to view only the incorrect points, clear the **Correct** check box.
- 9 Train a kernel naive Bayes model for comparison. On the **Classification Learner** tab, in the **Model Type** section, click **Kernel Naive Bayes**. Note that Classification Learner enables the **Advanced** button, because this type of model has advanced settings.

The app displays a draft kernel naive Bayes model in the History list.

In the **Model Type** section, click **Advanced** to change settings in the Advanced Naive Bayes Options menu. Select **Triangle** from the **Kernel Type** list, and select **Positive** from the **Support** list.

Note The settings in the Advanced Naive Bayes Options menu are available for continuous data only. Pointing to **Kernel Type** displays the tooltip "Specify Kernel smoothing function for continuous variables," and pointing to **Support** displays the tooltip "Specify Kernel smoothing density support for continuous variables."

In the **Training** section, click **Train** to train the new model.

The History list now includes the new kernel naive Bayes model. Its model validation score is better than the score for the Gaussian naive Bayes model. The app highlights the **Accuracy** score of the best model by outlining it in a box.

- 10 In the History list, click each model to view and compare the results.

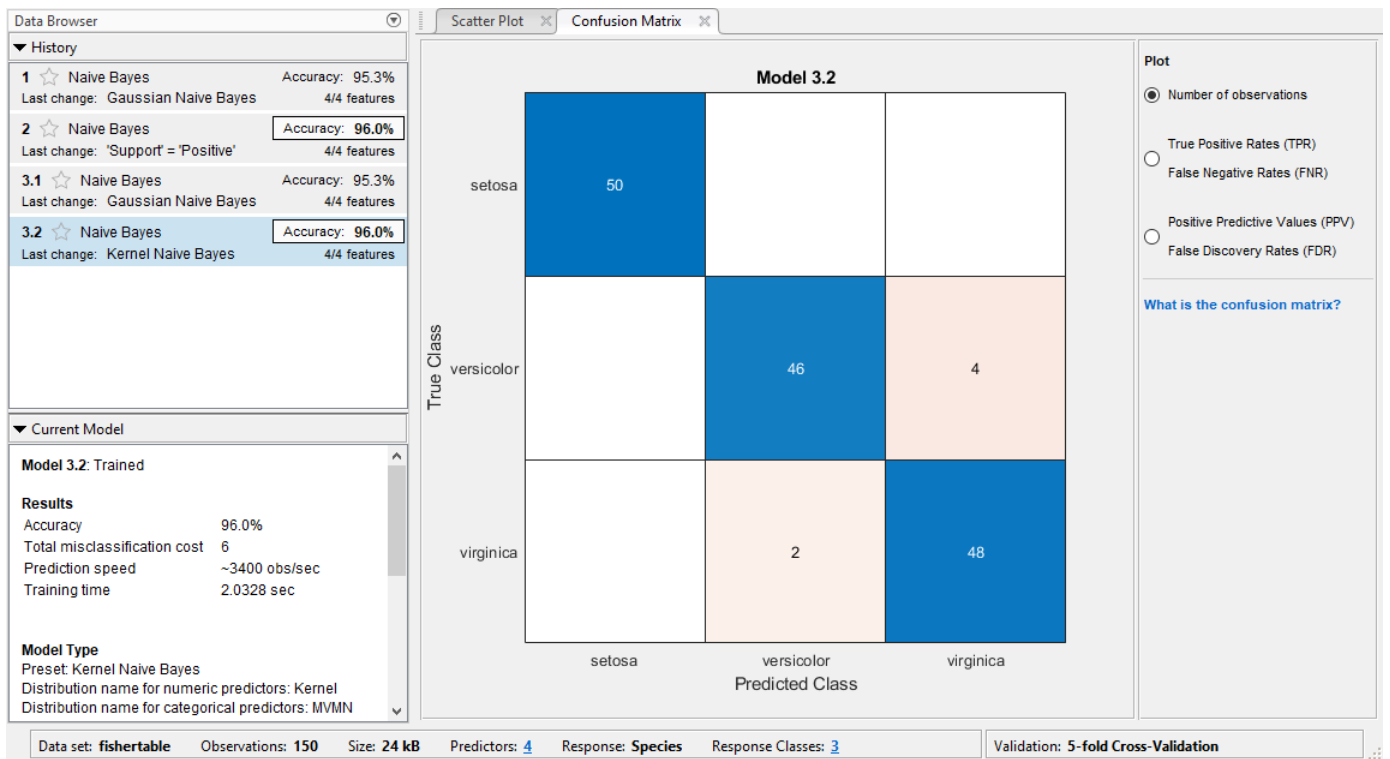

- 11 Train a Gaussian naive Bayes model and a kernel naive Bayes model simultaneously. On the **Classification Learner** tab, in the **Model Type** section, click **All Naive Bayes**. Classification Learner disables the **Advanced** button. In the **Training** section, click **Train**.

The app trains one of each naive Bayes model type and highlights the **Accuracy** score of the best model or models.

- 12 In the History list, click a model to view the results. Examine the scatter plot for the trained model and try plotting different predictors. Misclassified points appear as an X.
- 13 To inspect the accuracy of the predictions in each class, on the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix**. The app displays a matrix of true class and predicted class results.

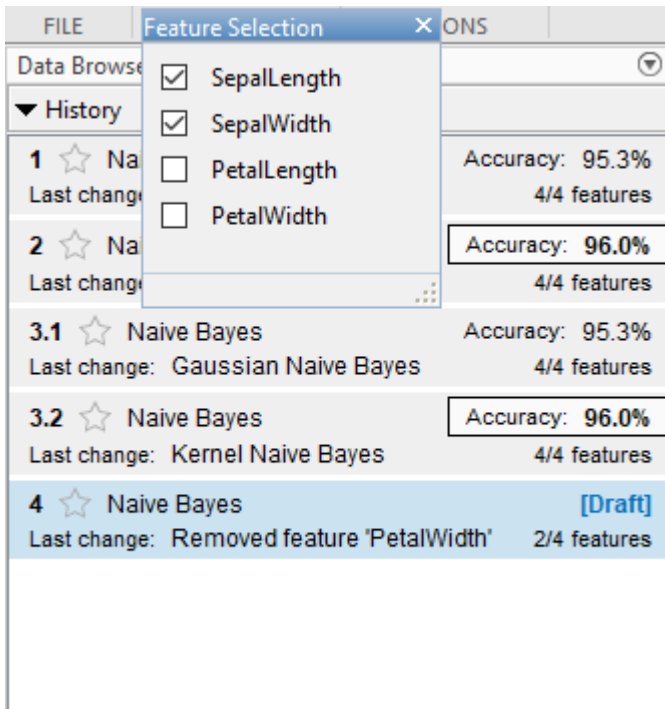

Note Validation introduces some randomness into the results. Your confusion matrix results can vary from the results shown in this example.

- 14 In the History list, click the other models and compare their results.
- 15 In the History list, click the model with the highest **Accuracy** score. To improve the model, try modifying its features. For example, see if you can improve the model by removing features with low predictive power.

On the **Classification Learner** tab, in the **Features** section, click **Feature Selection**.

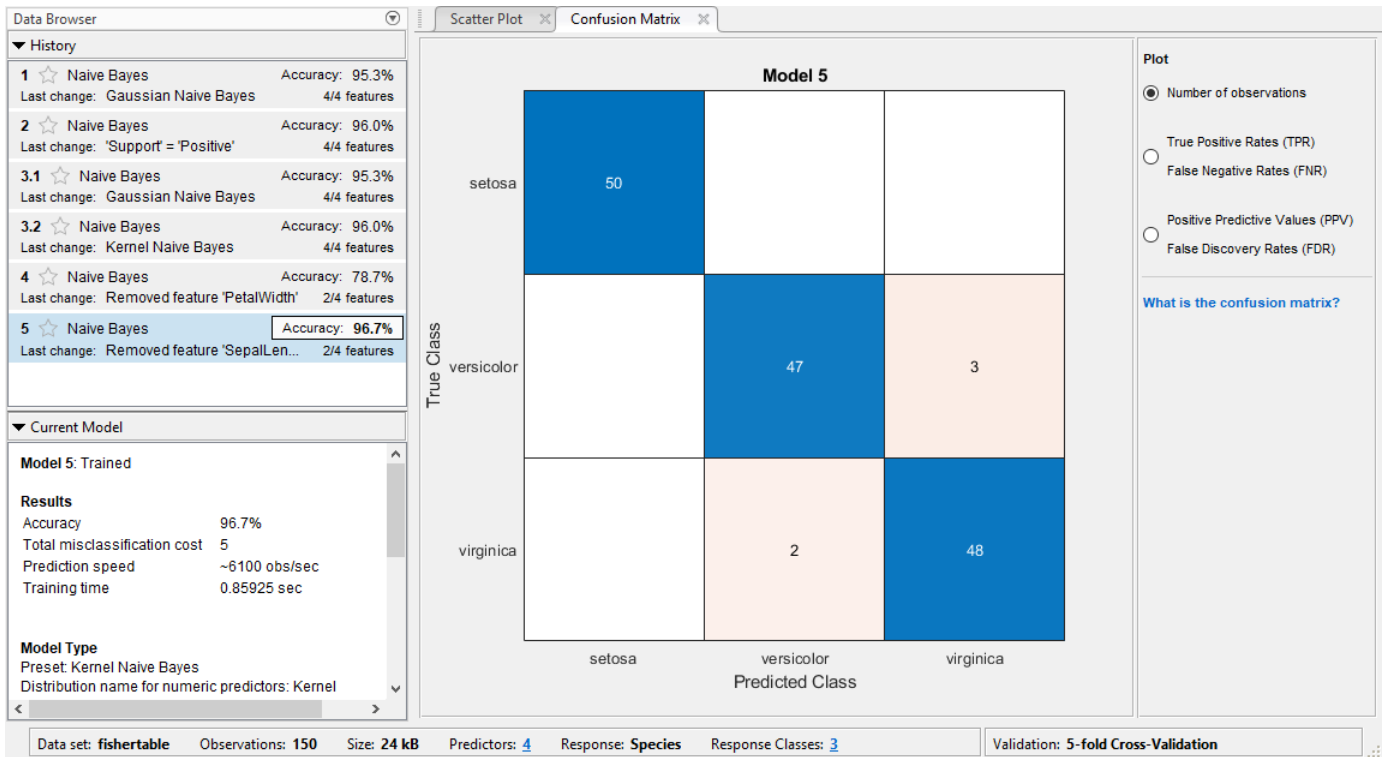

In the Feature Selection menu, clear the check boxes for **PetalLength** and **PetalWidth** to exclude them from the predictors. A new draft model (model 4) appears in the History list with the new settings (2/4 features), based on the kernel naive Bayes model (model 3.2 in the History list).

In the **Training** section, click **Train** to train a new kernel naive Bayes model using the new predictor options.

The History list now includes model 4. It is also a kernel naive Bayes model, trained using only 2 of 4 predictors.

- 16 To determine which predictors are included, click a model in the History list, then click **Feature Selection** in the **Features** section and note which check boxes are selected. The model with only sepal measurements (model 4) has a much lower **Accuracy** score than the models containing all predictors.
- 17 Train another kernel naive Bayes model including only the petal measurements. Change the selections in the Feature Selection menu and click **Train**.

The model trained using only petal measurements (model 5) performs comparably to the model containing all predictors. The models predict no better using all the measurements compared to only the petal measurements. If data collection is expensive or difficult, you might prefer a model that performs satisfactorily without some predictors.

- 18 To investigate features to include or exclude, use the parallel coordinates plot. On the **Classification Learner** tab, in the **Plots** section, click **Parallel Coordinates Plot**.
- 19 In the History list, click the model with the highest **Accuracy** score. To improve the model further, try changing naive Bayes settings (if available). On the **Classification Learner** tab, in the **Model Type** section, click **Advanced**. Recall that the **Advanced** button is enabled only for some models. Change a setting, then train the new model by clicking **Train**.
- 20 Export the trained model to the workspace. On the **Classification Learner** tab, in the **Export** section, select **Export Model > Export Model**. See “Export Classification Model to Predict New Data” on page 23-69.
- 21 Examine the code for training this classifier. In the **Export** section, click **Generate Function**.

Use the same workflow to evaluate and compare the other classifier types you can train in Classification Learner.

To try all the nonoptimizable classifier model presets available for your data set:

- 1 Click the arrow on the **Model Type** section to open the gallery of classifiers.
- 2 In the **Get Started** group, click **All**, then click **Train** in the **Training** section.

For information about other classifier types, see “Train Classification Models in Classification Learner App” on page 23-10.

Train and Compare Classifiers Using Misclassification Costs in Classification Learner App

This example shows how to create and compare classifiers that use specified misclassification costs in the Classification Learner app. Specify the misclassification costs before training, and use the accuracy and total misclassification cost results to compare the trained models.

- 1 In the MATLAB Command Window, read the sample file `CreditRating_Historical.dat` into a table. The predictor data consists of financial ratios and industry sector information for a list of corporate customers. The response variable consists of credit ratings assigned by a rating agency. Combine all the A ratings into one rating. Do the same for the B and C ratings, so that the response variable has three distinct ratings. Among the three ratings, A is considered the best and C the worst.

```
creditrating = readtable('CreditRating_Historical.dat');
Rating = categorical(creditrating.Rating);
Rating = mergecats(Rating, {'AAA', 'AA', 'A'}, 'A');
Rating = mergecats(Rating, {'BBB', 'BB', 'B'}, 'B');
Rating = mergecats(Rating, {'CCC', 'CC', 'C'}, 'C');
creditrating.Rating = Rating;
```

- 2 Assume these are the costs associated with misclassifying the credit ratings of customers.

		Customer Predicted Rating		
		A	B	C
Customer True Rating	A	\$0	\$100	\$200
	B	\$500	\$0	\$100
	C	\$1000	\$500	\$0

For example, the cost of misclassifying a C rating customer as an A rating customer is \$1000. The costs indicate that classifying a customer with bad credit as a customer with good credit is more costly than classifying a customer with good credit as a customer with bad credit.

Create a matrix variable that contains the misclassification costs. Create another variable that specifies the class names and their order in the matrix variable.

```
ClassificationCosts = [0 100 200; 500 0 100; 1000 500 0];
ClassNames = categorical({'A', 'B', 'C'});
```

Tip Alternatively, you can specify misclassification costs directly inside the Classification Learner app. See “Specify Misclassification Costs” on page 23-42 for more information.

- 3 Open Classification Learner. Click the **Apps** tab, and then click the arrow at the right of the **Apps** section to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Classification Learner**.

- 4 On the **Classification Learner** tab, in the **File** section, select **New Session > From Workspace**.

- In the New Session dialog box, select the table `creditrating` from the **Data Set Variable** list.

As shown in the dialog box, the app selects the response and predictor variables based on their data type. The default response variable is the `Rating` variable. The default validation option is cross-validation, to protect against overfitting. For this example, do not change the default settings.

Data set

Validation

Cross-Validation
Protects against overfitting by partitioning the data set into folds and estimating accuracy on each fold.

Cross-validation folds: 5 folds

Holdout Validation
Recommended for large data sets.

Percent held out: 25%

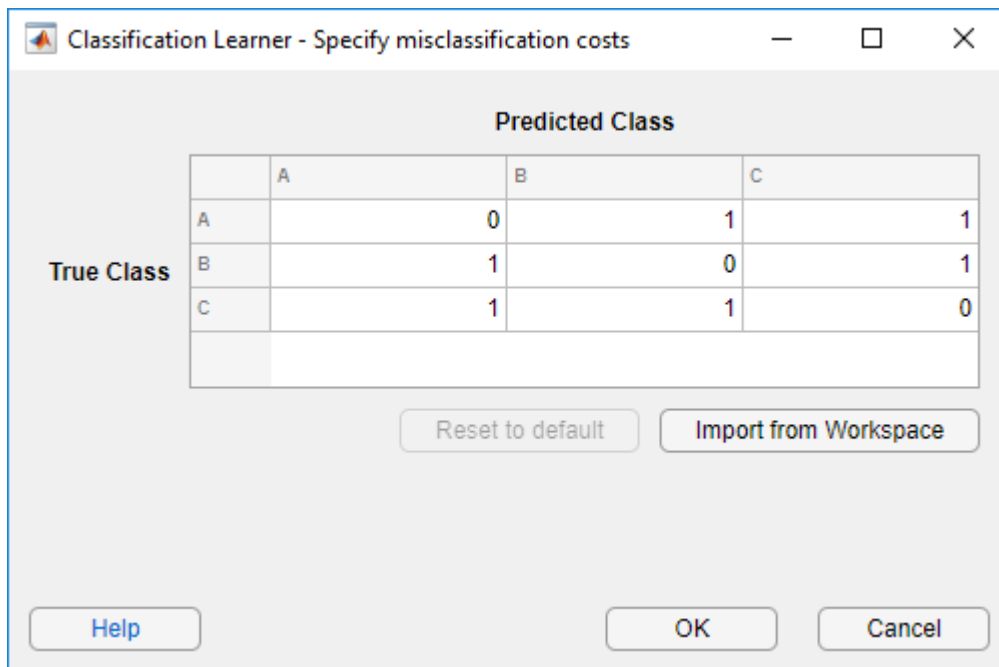

No Validation
No protection against overfitting.

[Read about validation](#)

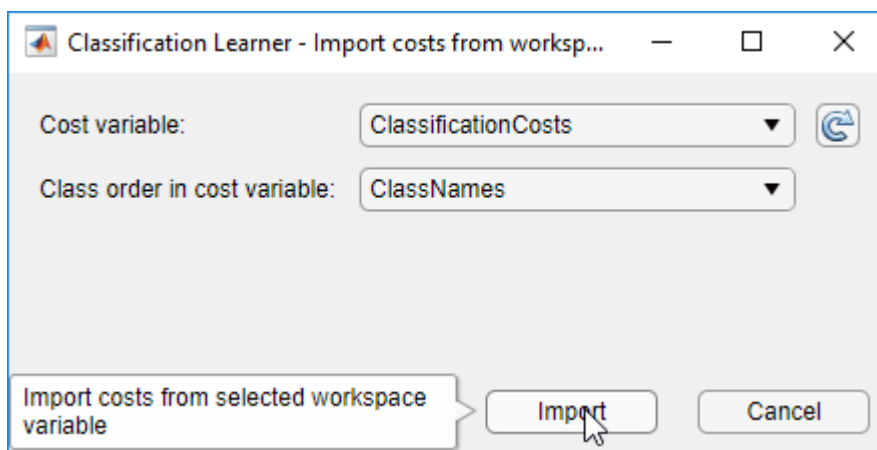

Start Session Cancel

- To accept the default settings, click **Start Session**.
- Specify the misclassification costs. On the **Classification Learner** tab, in the **Options** section, click **Misclassification Costs**. The app opens a dialog box showing the default misclassification costs.

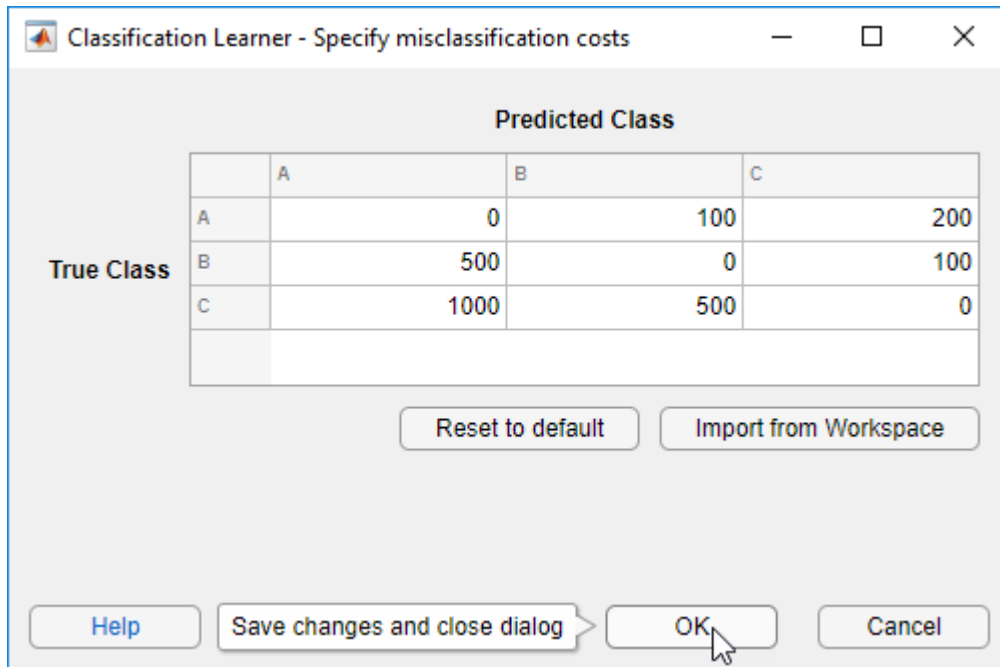

In the dialog box, click **Import from Workspace**.

In the import dialog box, select `ClassificationCosts` as the cost variable and `ClassNames` as the class order in the cost variable. Click **Import**.

The app updates the values in the misclassification costs dialog box. Click **OK** to save your changes.

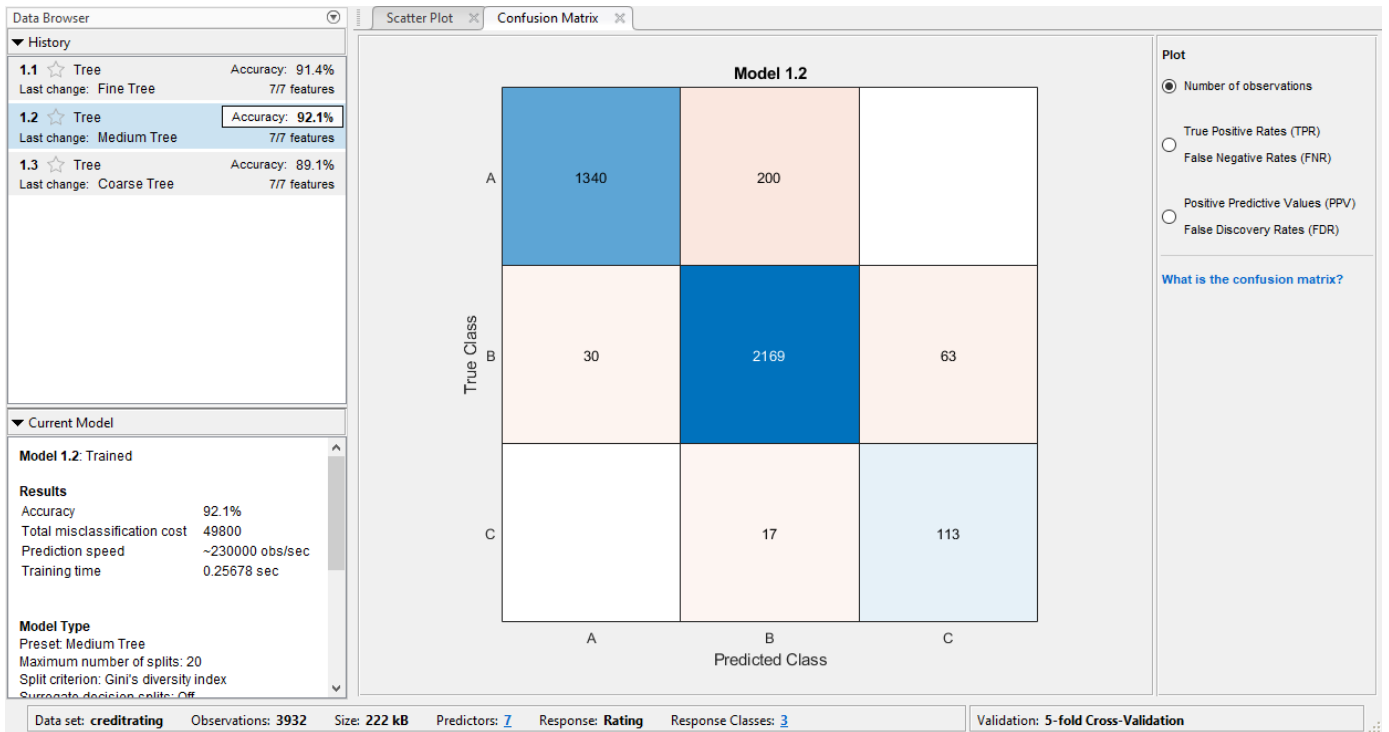

- 8 Train fine, medium, and coarse trees simultaneously. On the **Classification Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Decision Trees** group, click **All Trees**. In the **Training** section, click **Train**. The app trains one of each tree model type and displays the models in the **History** list.

Tip If you have Parallel Computing Toolbox, the Opening Pool dialog box opens the first time you click **Train** (or when you click **Train** again after an extended period of time). The dialog box remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, you can train multiple classifiers simultaneously and continue working.

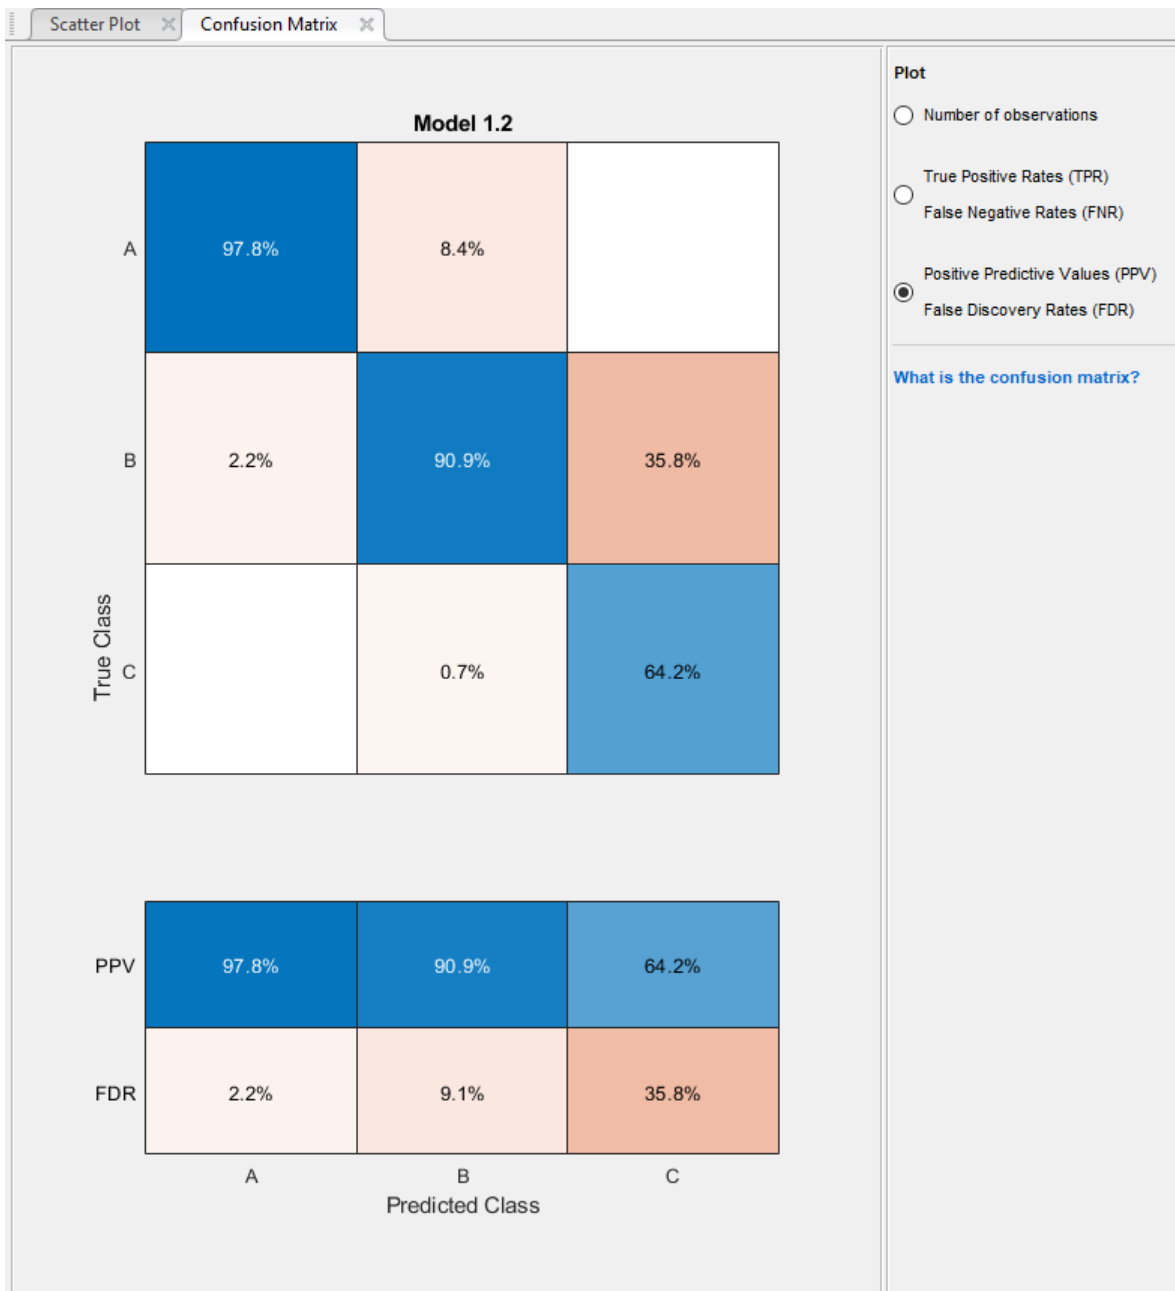

Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

- 9 In the **History** list, click a model to view the results, which are displayed in the **Current Model** pane. Each model has a validation **Accuracy** score that indicates the percentage of correctly predicted responses. In the **History** list, the app highlights the highest **Accuracy** score by outlining it in a box.
- 10 Inspect the accuracy of the predictions in each class. On the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix**. The app displays a matrix of true class and predicted class results for the selected model (in this case, for the medium tree).

- 11** You can also plot results per predicted class to investigate false discovery rates. Under **Plot**, select the **Positive Predictive Values (PPV) False Discovery Rates (FDR)** option.

In the confusion matrix for the medium tree, the entries below the diagonal have small percentage values. These values indicate that the model tries to avoid assigning a credit rating that is higher than the true rating for a customer.

- 12** Compare the total misclassification costs of the tree models. To inspect the total misclassification cost of a model, select the model in the **History** list, and then view the **Results** section of the **Current Model** pane. For example, the medium tree has these results.

▼ Current Model	
Model 1.2: Trained	
Results	
Accuracy	92.1%
Total misclassification cost	49800
Prediction speed	~230000 obs/sec
Training time	0.25678 sec
Model Type	
Preset: Medium Tree	
Maximum number of splits: 20	
Split criterion: Gini's diversity index	
Surrogate decision splits: Off	
Optimizer Options	
Hyperparameter options disabled	
Feature Selection	
All features used in the model, before PCA	
PCA	
PCA disabled	
Misclassification Costs	
Cost matrix: custom	

In general, choose a model that has high accuracy and low total misclassification cost. In this example, the medium tree has the highest validation accuracy value and the lowest total misclassification cost of the three models.

You can perform feature selection and transformation or tune your model just as you do in the workflow without misclassification costs. However, always check the total misclassification cost of your model when assessing its performance. For differences in the exported model and exported code when you use misclassification costs, see “Misclassification Costs in Exported Model and Generated Code” on page 23-46.

Train Classifier Using Hyperparameter Optimization in Classification Learner App

This example shows how to tune hyperparameters of a classification support vector machine (SVM) model by using hyperparameter optimization in the Classification Learner app. Compare the test set performance of the trained optimizable SVM to that of the best-performing preset SVM model.

- 1 In the MATLAB Command Window, load the `ionosphere` data set, and create a table containing the data. Separate the table into training and test sets.

```
load ionosphere
tbl = array2table(X);
tbl.Y = Y;

rng('default') % For reproducibility of the data split
partition = cvpartition(Y,'Holdout',0.15);
idxTrain = training(partition); % Indices for the training set
tblTrain = tbl(idxTrain,:);
tblTest = tbl(~idxTrain,:);
```

- 2 Open Classification Learner. Click the **Apps** tab, and then click the arrow at the right of the **Apps** section to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Classification Learner**.
- 3 On the **Classification Learner** tab, in the **File** section, select **New Session > From Workspace**.
- 4 In the New Session dialog box, select the `tblTrain` table from the **Data Set Variable** list.

As shown in the dialog box, the app selects the response and predictor variables. The default response variable is `Y`. The default validation option is 5-fold cross-validation, to protect against overfitting. For this example, do not change the default settings.

Data set

Data Set Variable: tblTrain (299x35 table)

Response: Y (cell, 2 unique)

Predictors:

	Name	Type	Range
<input checked="" type="checkbox"/>	X1	double	0 .. 1
<input checked="" type="checkbox"/>	X2	double	0 .. 0
<input checked="" type="checkbox"/>	X3	double	-1 .. 1
<input checked="" type="checkbox"/>	X4	double	-1 .. 1
<input checked="" type="checkbox"/>	X5	double	-1 .. 1
<input checked="" type="checkbox"/>	X6	double	-1 .. 1
<input checked="" type="checkbox"/>	X7	double	-1 .. 1
<input checked="" type="checkbox"/>	X8	double	-1 .. 1
<input checked="" type="checkbox"/>	X9	double	-1 .. 1
<input checked="" type="checkbox"/>	X10	double	-1 .. 1

Cross-Validation
Protects against overfitting by partitioning the data set into folds and estimating accuracy on each fold.
Cross-validation folds: 5 folds

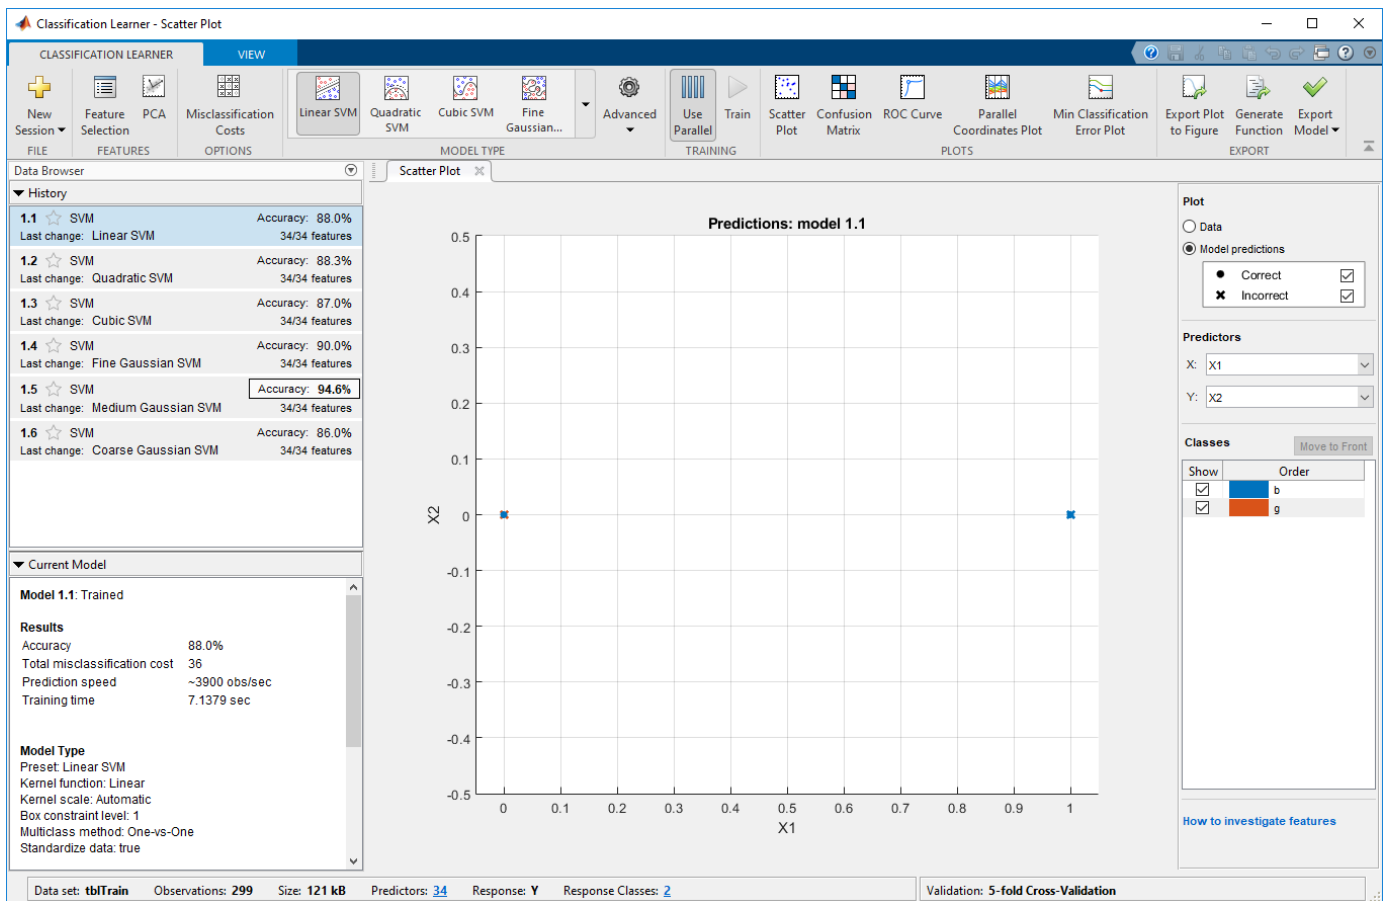

Holdout Validation
Recommended for large data sets.
Percent held out: 25%

No Validation
No protection against overfitting.

Buttons: [Read about validation](#), Start Session, Cancel

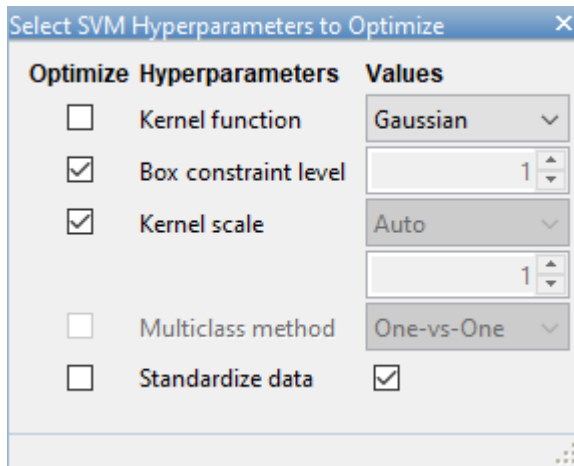

- 5 To accept the default options and continue, click **Start Session**.
- 6 Train all preset SVM models. On the **Classification Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Support Vector Machines** group, click **All SVMs**. In the **Training** section, click **Train**. The app trains one of each SVM model type and displays the models in the **History** list.

Tip If you have Parallel Computing Toolbox, the Opening Pool dialog box opens the first time you click **Train** (or when you click **Train** again after an extended period of time). The dialog box remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, you can train multiple models simultaneously and continue working.

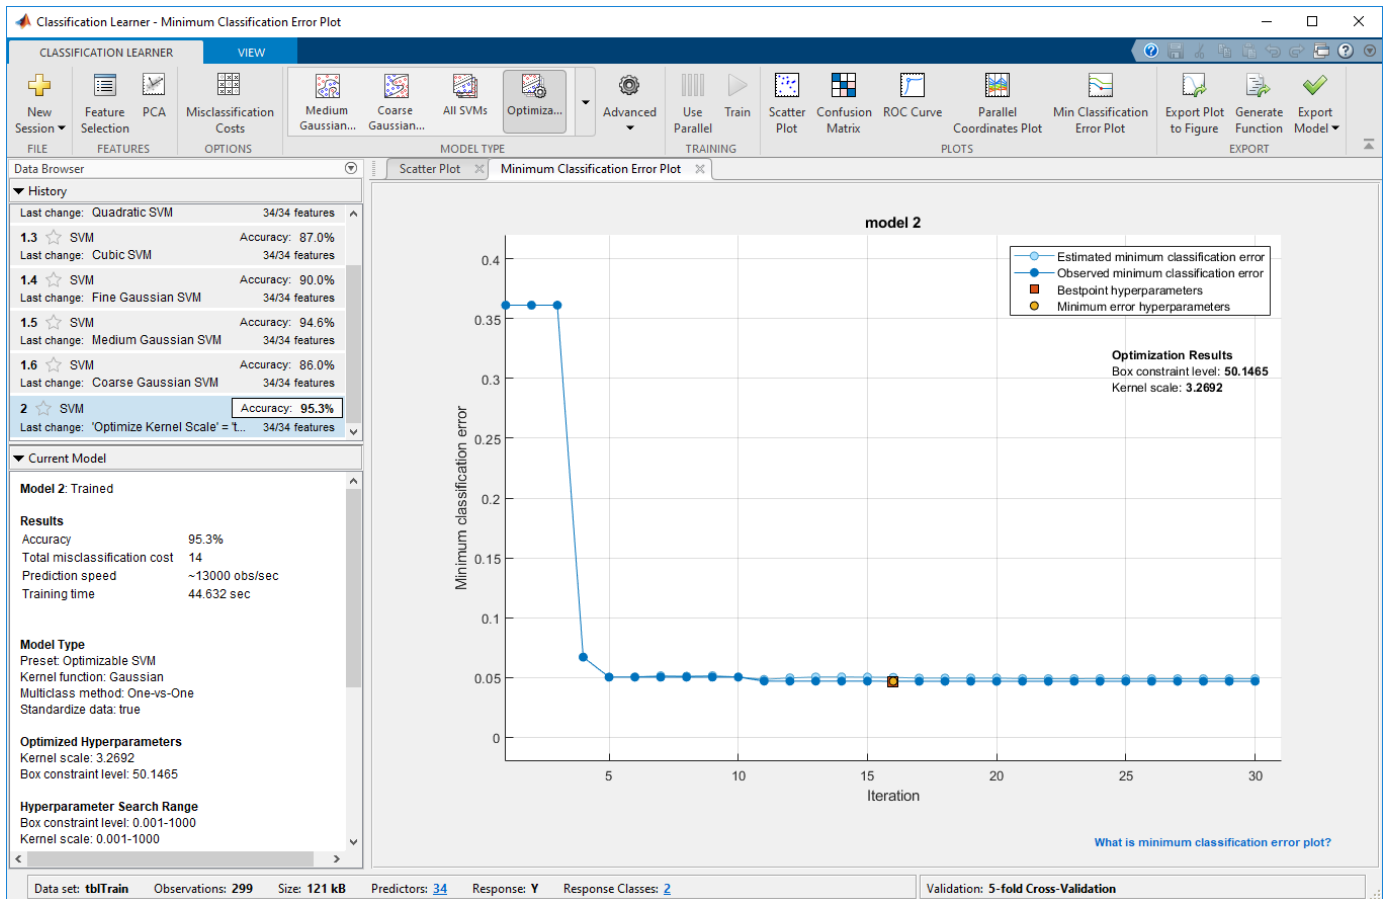

Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

- 7 Select an optimizable SVM model to train. On the **Classification Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Support Vector Machines** group, click **Optimizable SVM**. The app disables the **Use Parallel** button when you select an optimizable model.
- 8 Select the model hyperparameters to optimize. In the **Model Type** section, select **Advanced > Advanced**. The app opens a dialog box in which you can select **Optimize** check boxes for the hyperparameters that you want to optimize. By default, all the check boxes for the available hyperparameters are selected. For this example, clear the **Optimize** check boxes for **Kernel function** and **Standardize data**. By default, the app disables the **Optimize** check box for **Kernel scale** whenever the kernel function has a fixed value other than Gaussian. Select a Gaussian kernel function, and select the **Optimize** check box for **Kernel scale**.

- 9 In the **Training** section, click **Train**.
- 10 The app displays a **Minimum Classification Error Plot** as it runs the optimization process. At each iteration, the app tries a different combination of hyperparameter values and updates the plot with the minimum validation classification error observed up to that iteration, indicated in dark blue. When the app completes the optimization process, it selects the set of optimized hyperparameters, indicated by a red square. For more information, see “Minimum Classification Error Plot” on page 23-55.

The app lists the optimized hyperparameters in both the upper right of the plot and the **Optimized Hyperparameters** section of the **Current Model** pane.

Note In general, the optimization results are not reproducible.

- 11 Compare the trained preset SVM models to the trained optimizable model. In the **History** list, the app highlights the highest validation **Accuracy** by outlining it in a box. In this example, the trained optimizable SVM model outperforms the six preset models.

A trained optimizable model does not always have a higher accuracy than the trained preset models. If a trained optimizable model does not perform well, you can try to get better results by running the optimization for longer. In the **Model Type** section, select **Advanced > Optimizer Options**. In the dialog box, increase the **Iterations** value. For example, you can double-click the default value of 30 and enter a value of 60.

- 12 Because hyperparameter tuning often leads to overfitted models, check the test set performance of the SVM model with the optimized hyperparameters and compare it to the performance of the best preset SVM model. Begin by exporting the two models to the MATLAB workspace.
 - In the **History** list, select the **Medium Gaussian SVM** model. On the **Classification Learner** tab, in the **Export** section, select **Export Model > Export Model**. In the dialog box, name the model gaussianSVM.
 - In the **History** list, select the **Optimizable SVM** model. On the **Classification Learner** tab, in the **Export** section, select **Export Model > Export Model**. In the dialog box, name the model optimizableSVM.

- 13** Compute the accuracy of the two models on the `tblTest` data. In the MATLAB Command Window, use the `predictFcn` function in each exported model structure to predict the response values of the test set data. Then, use confusion matrices to visualize the results. Compute and compare the accuracy values for the models on the test set data.

```
testY = tblTest.Y;

labels = gaussianSVM.predictFcn(tblTest);
figure
cm = confusionchart(testY,labels);
title('Preset Model Results')

optLabels = optimizableSVM.predictFcn(tblTest);
figure
optcm = confusionchart(testY,optLabels);
title('Optimizable Model Results')

cmvalues = cm.NormalizedValues;
optcmvalues = optcm.NormalizedValues;
presetAccuracy = sum(diag(cmvalues))/sum(cmvalues,'all')*100
optAccuracy = sum(diag(optcmvalues))/sum(optcmvalues,'all')*100

presetAccuracy =

    92.3077

optAccuracy =

    88.4615
```

In this example, the trained optimizable SVM model does not perform as well as the trained preset model on the test set data.

Train Regression Models in Regression Learner App

In this section...

“Automated Regression Model Training” on page 24-2

“Manual Regression Model Training” on page 24-4

“Parallel Regression Model Training” on page 24-4

“Compare and Improve Regression Models” on page 24-5

You can use Regression Learner to train regression models including linear regression models, regression trees, Gaussian process regression models, support vector machines, and ensembles of regression trees. In addition to training models, you can explore your data, select features, specify validation schemes, and evaluate results. You can export a model to the workspace to use the model with new data or generate MATLAB code to learn about programmatic classification.

Training a model in Regression Learner consists of two parts:

- **Validated Model:** Training a model with a validation scheme. By default, the app protects against overfitting by applying cross-validation. Alternatively, you can choose holdout validation. The validated model is visible in the app.
- **Full Model:** Training a model on full data without validation. The app trains this model simultaneously with the validated model. However, the model trained on full data is not visible in the app. When you choose a regression model to export to the workspace, Regression Learner exports the full model.

The app displays the results of the validated model. Diagnostic measures, such as model accuracy, and plots, such as response plot or residuals plot reflect the validated model results. You can automatically train one or more regression models, compare validation results, and choose the best model that works for your regression problem. When you choose a model to export to the workspace, Regression Learner exports the full model. Because Regression Learner creates a model object of the full model during training, you experience no lag time when you export the model. You can use the exported model to make predictions on new data.

To get started by training a selection of model types, see “Automated Regression Model Training” on page 24-2. If you already know which regression model you want to train, see “Manual Regression Model Training” on page 24-4.

Automated Regression Model Training

You can use Regression Learner to automatically train a selection of different regression models on your data.

- Get started by automatically training multiple models simultaneously. You can quickly try a selection of models, and then explore promising models interactively.
- If you already know what model type you want, then you can train individual models instead. See “Manual Regression Model Training” on page 24-4.

- 1 On the **Apps** tab, in the **Machine Learning** group, click **Regression Learner**.
- 2 Click **New Session** and select data from the workspace or from file. Specify a response variable and variables to use as predictors. See “Select Data and Validation for Regression Problem” on page 24-8.

- 3 On the **Regression Learner** tab, in the **Model Type** section, click the arrow to expand the list of regression models. Select **All Quick-To-Train** . This option trains all the model presets that are fast to fit.

4

Click **Train**.

Note If you have Parallel Computing Toolbox, the app trains models in parallel. See “Parallel Regression Model Training” on page 24-4.

A selection of model types appears in the History list. When the models finish training, the best **RMSE** score is highlighted in a box.

▼ History		
1.1	☆ Linear Regression Last change: Linear	RMSE: 3.3815 7/7 features
1.2	☆ Tree Last change: Fine Tree	RMSE: 3.3849 7/7 features
1.3	☆ Tree Last change: Medium Tree	RMSE: 3.3102 7/7 features
1.4	☆ Tree Last change: Coarse Tree	RMSE: 3.8819 7/7 features

- 5 Click models in the History list to explore results in the plots.

For the next steps, see “Manual Regression Model Training” on page 24-4 or “Compare and Improve Regression Models” on page 24-5.

6

To try all the nonoptimizable model presets available, click **All** , and then click **Train**.

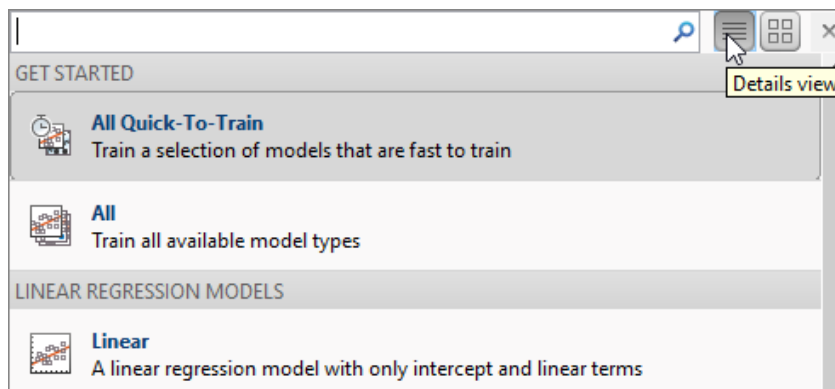

Manual Regression Model Training

To explore individual model types, you can train models one at a time or train a group of models of the same type.

- 1 Choose a model type. On the **Regression Learner** tab, in the **Model Type** section, click a model type. To see all available model options, click the arrow in the **Model Type** section to expand the list of regression models. The nonoptimizable model options in the gallery are preset starting points with different settings, suitable for a range of different regression problems.

To read descriptions of the models, switch to the details view or hover the mouse over a button to display its tooltip.

For more information on each option, see “Choose Regression Model Options” on page 24-12.

2

After selecting a model, click **Train**.

Repeat to explore different models.

Tip Select regression trees first. If your trained models do not predict the response accurately enough, then try other models with higher flexibility. To avoid overfitting, look for a less flexible model that provides sufficient accuracy.

- 3 If you want to try all nonoptimizable models of the same or different types, then select one of the **All** options in the gallery.

Alternatively, if you want to automatically tune hyperparameters of a specific model type, select the corresponding **Optimizable** model and perform hyperparameter optimization. For more information, see “Hyperparameter Optimization in Regression Learner App” on page 24-27.

For next steps, see “Compare and Improve Regression Models” on page 24-5.

Parallel Regression Model Training

You can train models in parallel using Regression Learner if you have Parallel Computing Toolbox. When you train models, the app automatically starts a parallel pool of workers, unless you turn off the default parallel preference **Automatically create a parallel pool**. If a pool is already open, the app

uses it for training. Parallel training allows you to train multiple models simultaneously and continue working.

- 1 The first time you click **Train**, you see a dialog box while the app opens a parallel pool of workers. After the pool opens, you can train multiple models at once.
- 2 When models are training in parallel, you see progress indicators on each training and queued model in the History list. If you want, you can cancel individual models. During training, you can examine results and plots from models, and initiate training of more models.

To control parallel training, toggle the **Use Parallel** button on the app toolstrip. (The **Use Parallel** button is only available if you have Parallel Computing Toolbox.)

If you have Parallel Computing Toolbox, then parallel training is available in Regression Learner, and you do not need to set the `UseParallel` option of the `statset` function. If you turn off the parallel preference to **Automatically create a parallel pool**, then the app does not start a pool for you without asking first.

Note You cannot perform hyperparameter optimization in parallel. The app disables the **Use Parallel** button when you select an optimizable model. If you then select a nonoptimizable model, the button is off by default.

Compare and Improve Regression Models

- 1 Click models in the History list to explore the results in the plots. Compare model performance by inspecting results in the plots. Examine the **RMSE** score reported in the History list for each model. See “Assess Model Performance in Regression Learner” on page 24-39.
- 2 Select the best model in the History list and then try including and excluding different features in

the model. Click **Feature Selection**.

Try the response plot to help you identify features to remove. See if you can improve the model by removing features with low predictive power. Specify predictors to include in the model, and train new models using the new options. Compare results among the models in the History list.

You also can try transforming features with PCA to reduce dimensionality.

See “Feature Selection and Feature Transformation Using Regression Learner App” on page 24-24.

- 3 Improve the model further by changing model parameter settings in the Advanced dialog box. Then, train using the new options. To learn how to control model flexibility, see “Choose Regression Model Options” on page 24-12. For information on how to tune model parameter settings automatically, see “Hyperparameter Optimization in Regression Learner App” on page 24-27.

If feature selection, PCA, or new parameter settings improve your model, try training **All** model types with the new settings. See if another model type does better with the new settings.

Tip To avoid overfitting, look for a less flexible model that provides sufficient accuracy. For example, look for simple models, such as regression trees that are fast and easy to interpret. If your models are not accurate enough, then try other models with higher flexibility, such as ensembles. To learn about the model flexibility, see “Choose Regression Model Options” on page 24-12.

This figure shows the app with a History list containing various regression model types.

Tip For a step-by-step example comparing different regression models, see “Train Regression Trees Using Regression Learner App” on page 24-54.

Next, you can generate code to train the model with different data or export trained models to the workspace to make predictions using new data. See “Export Regression Model to Predict New Data” on page 24-50.

Select Data and Validation for Regression Problem

In this section...

“Select Data from Workspace” on page 24-8

“Import Data from File” on page 24-9

“Example Data for Regression” on page 24-9

“Choose Validation Scheme” on page 24-10

Select Data from Workspace

Tip In Regression Learner, tables are the easiest way to work with your data, because they can contain numeric and label data. Use the Import Tool to bring your data into the MATLAB workspace as a table, or use the table functions to create a table from workspace variables. See “Tables” (MATLAB).

- 1 Load your data into the MATLAB workspace.

Predictor variables can be numeric, categorical, string, or logical vectors, cell arrays of character vectors, or character arrays. The response variable must be a floating-point vector (single or double precision).

Combine the predictor data into one variable, either a table or a matrix. You can additionally combine your predictor data and response variable, or you can keep them separate.

For example data sets, see “Example Data for Regression” on page 24-9.

- 2 On the **Apps** tab, click **Regression Learner** to open the app.
- 3 On the **Regression Learner** tab, in the **File** section, click **New Session > From Workspace**.
- 4 In the New Session dialog box, under **Data Set Variable**, select a table or matrix from the workspace variables.

If you select a matrix, choose whether to use rows or columns for observations by clicking the option buttons.

- 5 Under **Response**, observe the default response variable. The app tries to select a suitable response variable from the data set variable and treats all other variables as predictors.

If you want to use a different response variable, you can:

- Use the list to select another variable from the data set variable.
- Select a separate workspace variable by clicking the **From workspace** option button and then selecting a variable from the list.

- 6 Under **Predictors**, add or remove predictors using the check boxes. Add or remove all predictors by clicking **Add All** or **Remove All**. You can also add or remove multiple predictors by selecting them in the table, and then clicking **Add N** or **Remove N**, where **N** is the number of selected predictors. The **Add All** and **Remove All** buttons change to **Add N** and **Remove N** when you select multiple predictors.
- 7 Click **Start Session** to accept the default validation scheme and continue. The default validation option is 5-fold cross-validation, which protects against overfitting.

Tip If you have a large data set, you might want to switch to holdout validation. To learn more, see “Choose Validation Scheme” on page 24-10.

For next steps, see “Train Regression Models in Regression Learner App” on page 24-2.

Import Data from File

- 1 On the **Regression Learner** tab, in the **File** section, select **New Session > From File**.
- 2 Select a file type in the list, such as spreadsheets, text files, or comma-separated values (.csv) files, or select **All Files** to browse for other file types such as .dat.

Example Data for Regression

To get started using Regression Learner, try these example data sets.

Name	Size	Description
Cars	Number of predictors: 7 Number of observations: 406 Response: MPG (miles per gallon)	Data on different car models, 1970-1982. Predict the fuel economy (in miles per gallon), or one of the other characteristics. For a step-by-step example, see “Train Regression Trees Using Regression Learner App” on page 24-54.
	Create a table from variables in the <code>carbig.mat</code> file: <pre>load carbig cartable = table(Acceleration, Cylinders, Displacement,... Horsepower, Model_Year, Weight, Origin, MPG);</pre>	
Abalone	Number of predictors: 8 Number of observations: 4177 Response: Rings	Measurements of abalone (a group of sea snails). Predict the age of abalones, which is closely related to the number of rings in their shells.
	Download the data from the UCI Machine Learning Repository and save it in your current folder. Read the data into a table and specify the variable names. <pre>url = 'https://archive.ics.uci.edu/ml/machine-learning-databases/abalone/abalone. websave('abalone.csv',url); varnames = {'Sex'; 'Length'; 'Diameter'; 'Height'; 'Whole_weight';... 'Shucked_weight'; 'Viscera_weight'; 'Shell_weight'; 'Rings'}; abalonetable = readtable('abalone.csv'); abalonetable.Properties.VariableNames = varnames;</pre>	
Hospital	Number of predictors: 5 Number of observations: 100 Response: <code>BloodPressure_2</code>	Simulated hospital data. Predict the blood pressure of patients.
	Create a table from the <code>hospital</code> variable in the <code>hospital.mat</code> file: <pre>load hospital.mat hospitaltable = dataset2table(hospital(:,2:end-1));</pre>	

Choose Validation Scheme

Choose a validation method to examine the predictive accuracy of the fitted models. Validation estimates model performance on new data, and helps you choose the best model. Validation protects against overfitting. A model that is too flexible and suffers from overfitting has a worse validation accuracy. Choose a validation scheme before training any models so that you can compare all the models in your session using the same validation scheme.

Tip Try the default validation scheme and click **Start Session** to continue. The default option is 5-fold cross-validation, which protects against overfitting.

If you have a large data set and training the models takes too long using cross-validation, reimport your data and try the faster holdout validation instead.

- **Cross-Validation:** Select the number of folds (or divisions) to partition the data set using the slider control.

If you choose k folds, then the app:

- 1 Partitions the data into k disjoint sets or folds
- 2 For each fold:
 - a Trains a model using the out-of-fold observations
 - b Assesses model performance using in-fold data
- 3 Calculates the average test error over all folds

This method gives a good estimate of the predictive accuracy of the final model trained using the full data set. The method requires multiple fits, but makes efficient use of all the data, so it works well for small data sets.

- **Holdout Validation:** Select a percentage of the data to use as a validation set using the slider control. The app trains a model on the training set and assesses its performance with the validation set. The model used for validation is based on only a portion of the data, so holdout validation is appropriate only for large data sets. The final model is trained using the full data set.
- **No Validation:** No protection against overfitting. The app uses all the data for training and computes the error rate on the same data. Without any test data, you get an unrealistic estimate of the model's performance on new data. That is, the training sample accuracy is likely to be unrealistically high, and the predictive accuracy is likely to be lower.

To help you avoid overfitting to the training data, choose a validation scheme instead.

Note The validation scheme only affects the way that Regression Learner computes validation metrics. The final model is always trained using the full data set.

All the models you train after selecting data use the same validation scheme that you select in this dialog box. You can compare all the models in your session using the same validation scheme.

To change the validation selection and train new models, you can select data again, but you lose any trained models. The app warns you that importing data starts a new session. Save any trained models you want to keep to the workspace, and then import the data.

For next steps training models, see “Train Regression Models in Regression Learner App” on page 24-2.

Choose Regression Model Options

In this section...
“Choose Regression Model Type” on page 24-12
“Linear Regression Models” on page 24-14
“Regression Trees” on page 24-15
“Support Vector Machines” on page 24-17
“Gaussian Process Regression Models” on page 24-20
“Ensembles of Trees” on page 24-22

Choose Regression Model Type

You can use the Regression Learner app to automatically train a selection of different models on your data. Use automated training to quickly try a selection of model types, and then explore promising models interactively. To get started, try these options first

Get Started Regression Model Buttons	Description
All Quick-To-Train 	Try the All Quick-To-Train button first. The app trains all model types that are typically quick to train.
All 	Use the All button to train all available nonoptimizable model types. Trains every type regardless of any prior trained models. Can be time-consuming.

To learn more about automated model training, see “Automated Regression Model Training” on page 24-2.

If you want to explore models one at a time, or if you already know what model type you want, you can select individual models or train a group of the same type. To see all available regression model options, on the **Regression Learner** tab, click the arrow in the **Model Type** section to expand the list of regression models. The nonoptimizable model options in the gallery are preset starting points with different settings, suitable for a range of different regression problems. To use optimizable model options and tune model hyperparameters automatically, see “Hyperparameter Optimization in Regression Learner App” on page 24-27.

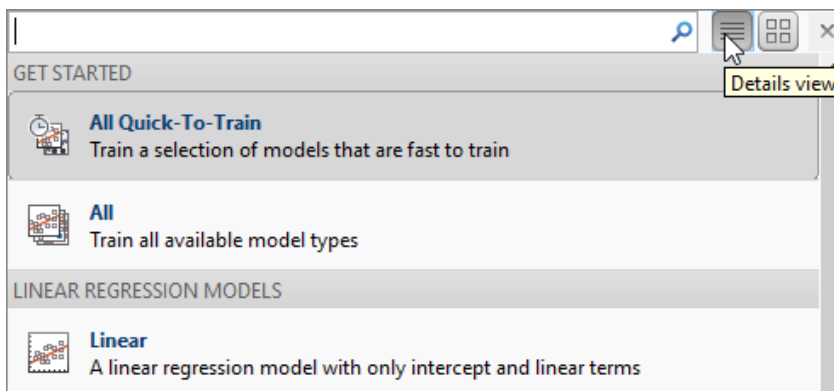

For help choosing the best model type for your problem, see the tables showing typical characteristics of different regression model types. Decide on the tradeoff you want in speed, flexibility, and interpretability. The best model type depends on your data.

Tip To avoid overfitting, look for a less flexible model that provides sufficient accuracy. For example, look for simple models such as regression trees that are fast and easy to interpret. If the models are not accurate enough predicting the response, choose other models with higher flexibility, such as ensembles. To control flexibility, see the details for each model type.

Characteristics of Regression Model Types

Regression Model Type	Interpretability
“Linear Regression Models” on page 24-14 	Easy
“Regression Trees” on page 24-15 	Easy
“Support Vector Machines” on page 24-17 	Easy for linear SVMs. Hard for other kernels.
“Gaussian Process Regression Models” on page 24-20 	Hard
“Ensembles of Trees” on page 24-22 	Hard

To read a description of each model in Regression Learner, switch to the details view in the list of all model presets.

Tip The nonoptimizable models in the **Model Type** gallery are preset starting points with different settings. After you choose a model type, such as regression trees, try training all the nonoptimizable presets to see which one produces the best model with your data.

For workflow instructions, see “Train Regression Models in Regression Learner App” on page 24-2.

Categorical Predictor Support

In Regression Learner, all model types support categorical predictors.

Tip If you have categorical predictors with many unique values, training linear models with interaction or quadratic terms and stepwise linear models can use a lot of memory. If the model fails to train, try removing these categorical predictors.

Linear Regression Models

Linear regression models have predictors that are linear in the model parameters, are easy to interpret, and are fast for making predictions. These characteristics make linear regression models popular models to try first. However, the highly constrained form of these models means that they often have low predictive accuracy. After fitting a linear regression model, try creating more flexible models, such as regression trees, and compare the results.

Tip In the **Model Type** gallery, click **All Linear**  to try each of the linear regression options and see which settings produce the best model with your data. Select the best model in the History list and try to improve that model by using feature selection and changing some advanced options.

Regression Model Type	Interpretability	Model Flexibility
Linear 	Easy	Very low
Interactions Linear 	Easy	Medium
Robust Linear 	Easy	Very low. Less sensitive to outliers, but can be slow to train.
Stepwise Linear 	Easy	Medium

Tip For a workflow example, see “Train Regression Trees Using Regression Learner App” on page 24-54.

Advanced Linear Regression Options

Regression Learner uses the `fitlm` function to train Linear, Interactions Linear, and Robust Linear models. The app uses the `stepwiselm` function to train Stepwise Linear models.

For Linear, Interactions Linear, and Robust Linear models you can set these options:

- **Terms**

Specify which terms to use in the linear model. You can choose from:

- **Linear.** A constant term and linear terms in the predictors
- **Interactions.** A constant term, linear terms, and interaction terms between the predictors
- **Pure Quadratic.** A constant term, linear terms, and terms that are purely quadratic in each of the predictors
- **Quadratic.** A constant term, linear terms, and quadratic terms (including interactions)
- **Robust option**

Specify whether to use a robust objective function and make your model less sensitive to outliers. With this option, the fitting method automatically assigns lower weights to data points that are more likely to be outliers.

Stepwise linear regression starts with an initial model and systematically adds and removes terms to the model based on the explanatory power of these incrementally larger and smaller models. For Stepwise Linear models, you can set these options:

- **Initial terms**

Specify the terms that are included in the initial model of the stepwise procedure. You can choose from **Constant**, **Linear**, **Interactions**, **Pure Quadratic**, and **Quadratic**.

- **Upper bound on terms**

Specify the highest order of the terms that the stepwise procedure can add to the model. You can choose from **Linear**, **Interactions**, **Pure Quadratic**, and **Quadratic**.

- **Maximum number of steps**

Specify the maximum number of different linear models that can be tried in the stepwise procedure. To speed up training, try reducing the maximum number of steps. Selecting a small maximum number of steps decreases your chances of finding a good model.

Tip If you have categorical predictors with many unique values, training linear models with interaction or quadratic terms and stepwise linear models can use a lot of memory. If the model fails to train, try removing these categorical predictors.

Regression Trees

Regression trees are easy to interpret, fast for fitting and prediction, and low on memory usage. Try to grow smaller trees with fewer larger leaves to prevent overfitting. Control the leaf size with the **Minimum leaf size** setting.

Tip In the **Model Type** gallery, click **All Trees**  to try each of the nonoptimizable regression tree options and see which settings produce the best model with your data. Select the best model in the History list, and try to improve that model by using feature selection and changing some advanced options.

Regression Model Type	Interpretability	Model Flexibility
Fine Tree 	Easy	High Many small leaves for a highly flexible response function (Minimum leaf size is 4.)
Medium Tree 	Easy	Medium Medium-sized leaves for a less flexible response function (Minimum leaf size is 12.)
Coarse Tree 	Easy	Low Few large leaves for a coarse response function (Minimum leaf size is 36.)

To predict a response of a regression tree, follow the tree from the root (beginning) node down to a leaf node. The leaf node contains the value of the response.

Statistics and Machine Learning Toolbox trees are binary. Each step in a prediction involves checking the value of one predictor variable. For example, here is a simple regression tree

This tree predicts the response based on two predictors, x_1 and x_2 . To make a prediction, start at the top node. At each node, check the values of the predictors to decide which branch to follow. When the branches reach a leaf node, the response is set to the value corresponding to that node.

You can visualize your regression tree model by exporting the model from the app, and then entering:

```
view(trainedModel.RegressionTree, 'Mode', 'graph')
```

Tip For a workflow example, see “Train Regression Trees Using Regression Learner App” on page 24-54.

Advanced Regression Tree Options

The Regression Learner app uses the `fitrtree` function to train regression trees. You can set these options:

- **Minimum leaf size**

Specify the minimum number of training samples used to calculate the response of each leaf node. When you grow a regression tree, consider its simplicity and predictive power. To change the minimum leaf size, click the buttons or enter a positive integer value in the **Minimum leaf size** box.

- A fine tree with many small leaves is usually highly accurate on the training data. However, the tree might not show comparable accuracy on an independent test set. A very leafy tree tends to overfit, and its validation accuracy is often far lower than its training (or resubstitution) accuracy.
- In contrast, a coarse tree with fewer large leaves does not attain high training accuracy. But a coarse tree can be more robust in that its training accuracy can be near that of a representative test set.

Tip Decrease the **Minimum leaf size** to create a more flexible model.

- **Surrogate decision splits** — For missing data only.

Specify surrogate use for decision splits. If you have data with missing values, use surrogate splits to improve the accuracy of predictions.

When you set **Surrogate decision splits** to `On`, the regression tree finds at most 10 surrogate splits at each branch node. To change the number of surrogate splits, click the buttons or enter a positive integer value in the **Maximum surrogates per node** box.

When you set **Surrogate decision splits** to `Find All`, the regression tree finds all surrogate splits at each branch node. The `Find All` setting can use considerable time and memory.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Regression Learner App” on page 24-27.

Support Vector Machines

You can train regression support vector machines (SVMs) in Regression Learner. Linear SVMs are easy to interpret, but can have low predictive accuracy. Nonlinear SVMs are more difficult to interpret, but can be more accurate.

Tip In the **Model Type** gallery, click **All SVMs**  to try each of the nonoptimizable SVM options and see which settings produce the best model with your data. Select the best model in the History list, and try to improve that model by using feature selection and changing some advanced options.

Regression Model Type	Interpretability	Model Flexibility
Linear SVM 	Easy	Low
Quadratic SVM 	Hard	Medium
Cubic SVM 	Hard	Medium
Fine Gaussian SVM 	Hard	High Allows rapid variations in the response function. Kernel scale is set to $\sqrt{P}/4$, where P is the number of predictors.
Medium Gaussian SVM 	Hard	Medium Gives a less flexible response function. Kernel scale is set to \sqrt{P} .
Coarse Gaussian SVM 	Hard	Low Gives a rigid response function. Kernel scale is set to $\sqrt{P} \cdot 4$.

Statistics and Machine Learning Toolbox implements linear epsilon-insensitive SVM regression. This SVM ignores prediction errors that are less than some fixed number ϵ . The support vectors are the data points that have errors larger than ϵ . The function the SVM uses to predict new values depends only on the support vectors. To learn more about SVM regression, see Understanding Support Vector Machine Regression on page 25-2.

Tip For a workflow example, see “Train Regression Trees Using Regression Learner App” on page 24-54.

Advanced SVM Options

Regression Learner uses the `fitrsvm` function to train SVM regression models.

You can set these options in the app:

- **Kernel function**

The kernel function determines the nonlinear transformation applied to the data before the SVM is trained. You can choose from:

- Gaussian or Radial Basis Function (RBF) kernel
- Linear kernel, easiest to interpret
- Quadratic kernel
- Cubic kernel

- **Box constraint mode**

The box constraint controls the penalty imposed on observations with large residuals. A larger box constraint gives a more flexible model. A smaller value gives a more rigid model, less sensitive to overfitting.

When **Box constraint mode** is set to Auto, the app uses a heuristic procedure to select the box constraint.

Try to fine-tune your model by specifying the box constraint manually. Set **Box constraint mode** to Manual and specify a value. Change the value by clicking the buttons or entering a positive scalar value in the **Manual box constraint** box. The app automatically preselects a reasonable value for you. Try to increase or decrease this value slightly and see if this improves your model.

Tip Increase the box constraint value to create a more flexible model.

- **Epsilon mode**

Prediction errors that are smaller than the epsilon (ϵ) value are ignored and treated as equal to zero. A smaller epsilon value gives a more flexible model.

When **Epsilon mode** is set to Auto, the app uses a heuristic procedure to select the kernel scale.

Try to fine-tune your model by specifying the epsilon value manually. Set **Epsilon mode** to Manual and specify a value. Change the value by clicking the buttons or entering a positive scalar value in the **Manual epsilon** box. The app automatically preselects a reasonable value for you. Try to increase or decrease this value slightly and see if this improves your model.

Tip Decrease the epsilon value to create a more flexible model.

- **Kernel scale mode**

The kernel scale controls the scale of the predictors on which the kernel varies significantly. A smaller kernel scale gives a more flexible model.

When **Kernel scale mode** is set to Auto, the app uses a heuristic procedure to select the kernel scale.

Try to fine-tune your model by specifying the kernel scale manually. Set **Kernel scale mode** to Manual and specify a value. Change the value by clicking the buttons or entering a positive scalar value in the **Manual kernel scale** box. The app automatically preselects a reasonable value for you. Try to increase or decrease this value slightly and see if this improves your model.

Tip Decrease the kernel scale value to create a more flexible model.

- **Standardize**

Standardizing the predictors transforms them so that they have mean 0 and standard deviation 1. Standardizing removes the dependence on arbitrary scales in the predictors and generally improves performance.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Regression Learner App” on page 24-27.

Gaussian Process Regression Models

You can train Gaussian process regression (GPR) models in Regression Learner. GPR models are often highly accurate, but can be difficult to interpret.

Tip In the **Model Type** gallery, click **All GPR Models**  to try each of the nonoptimizable GPR model options and see which settings produce the best model with your data. Select the best model in the History list, and try to improve that model by using feature selection and changing some advanced options.

Regression Model Type	Interpretability	Model Flexibility
Rational Quadratic 	Hard	Automatic
Squared Exponential 	Hard	Automatic
Matern 5/2 	Hard	Automatic
Exponential 	Hard	Automatic

In Gaussian process regression, the response is modeled using a probability distribution over a space of functions. The flexibility of the presets in the **Model Type** gallery is automatically chosen to give a small training error and, simultaneously, protection against overfitting. To learn more about Gaussian process regression, see Gaussian Process Regression Models on page 6-2.

Tip For a workflow example, see “Train Regression Trees Using Regression Learner App” on page 24-54.

Advanced Gaussian Process Regression Options

Regression Learner uses the `fitrgp` function to train GPR models.

You can set these options in the app:

- **Basis function**

The basis function specifies the form of the prior mean function of the Gaussian process regression model. You can choose from Zero, Constant, and Linear. Try to choose a different basis function and see if this improves your model.

- **Kernel function**

The kernel function determines the correlation in the response as a function of the distance between the predictor values. You can choose from Rational Quadratic, Squared Exponential, Matern 5/2, Matern 3/2, and Exponential.

To learn more about kernel functions, see Kernel (Covariance) Function Options on page 6-5.

- **Use isotropic kernel**

If you use an isotropic kernel, the correlation length scales are the same for all the predictors. With a nonisotropic kernel, each predictor variable has its own separate correlation length scale.

Using a nonisotropic kernel can improve the accuracy of your model, but can make the model slow to fit.

To learn more about nonisotropic kernels, see Kernel (Covariance) Function Options. on page 6-5

- **Kernel mode**

You can manually specify *initial* values of the kernel parameters **Kernel scale** and **Signal standard deviation**. The signal standard deviation is the prior standard deviation of the response values. By default the app locally optimizes the kernel parameters starting from the initial values. To use fixed kernel parameters, clear the **Optimize numeric parameters** check box in the advanced options.

When **Kernel scale mode** is set to Auto, the app uses a heuristic procedure to select the initial kernel parameters.

If you set **Kernel scale mode** to Manual, you can specify the initial values. Click the buttons or enter a positive scalar value in the **Kernel scale** box and the **Signal standard deviation** box.

If you clear the **Use isotropic kernel** check box, you cannot set initial kernel parameters manually.

- **Sigma mode**

You can specify manually the *initial* value of the observation noise standard deviation **Sigma**. By default the app optimizes the observation noise standard deviation, starting from the initial value. To use fixed kernel parameters, clear the **Optimize numeric parameters** check box in the advanced options.

When **Sigma mode** is set to Auto, the app uses a heuristic procedure to select the initial observation noise standard deviation.

If you set **Sigma mode** to Manual, you can specify the initial values. Click the buttons or enter a positive scalar value in the **Sigma** box.

- **Standardize**

Standardizing the predictors transforms them so that they have mean 0 and standard deviation 1. Standardizing removes the dependence on arbitrary scales in the predictors and generally improves performance.

- **Optimize numeric parameters**

With this option, the app automatically optimizes numeric parameters of the GPR model. The optimized parameters are the coefficients of the **Basis function**, the kernel parameters **Kernel scale** and **Signal standard deviation**, and the observation noise standard deviation **Sigma**.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Regression Learner App” on page 24-27.

Ensembles of Trees

You can train ensembles of regression trees in Regression Learner. Ensemble models combine results from many weak learners into one high-quality ensemble model.

Tip In the **Model Type** gallery, click **All Ensembles**  to try each of the nonoptimizable ensemble options and see which settings produce the best model with your data. Select the best model in the History list, and try to improve that model by using feature selection and changing some advanced options.

Regression Model Type	Interpretability	Ensemble Method	Model Flexibility
Boosted Trees 	Hard	Least-squares boosting (LSBoost) with regression tree learners.	Medium to high
Bagged Trees 	Hard	Bootstrap aggregating or bagging, with regression tree learners.	High

Tip For a workflow example, see “Train Regression Trees Using Regression Learner App” on page 24-54.

Advanced Ensemble Options

Regression Learner uses the `fitensemble` function to train ensemble models. You can set these options:

- **Minimum leaf size**

Specify the minimum number of training samples used to calculate the response of each leaf node. When you grow a regression tree, consider its simplicity and predictive power. To change the minimum leaf size, click the buttons or enter a positive integer value in the **Minimum leaf size** box.

- A fine tree with many small leaves is usually highly accurate on the training data. However, the tree might not show comparable accuracy on an independent test set. A very leafy tree tends to overfit, and its validation accuracy is often far lower than its training (or resubstitution) accuracy.
- In contrast, a coarse tree with fewer large leaves does not attain high training accuracy. But a coarse tree can be more robust in that its training accuracy can be near that of a representative test set.

Tip Decrease the **Minimum leaf size** to create a more flexible model.

- **Number of learners**

Try changing the number of learners to see if you can improve the model. Many learners can produce high accuracy, but can be time consuming to fit.

Tip Increase the **Number of learners** to create a more flexible model.

- **Learning rate**

For boosted trees, specify the learning rate for shrinkage. If you set the learning rate to less than 1, the ensemble requires more learning iterations but often achieves better accuracy. 0.1 is a popular initial choice.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Regression Learner App” on page 24-27.

Feature Selection and Feature Transformation Using Regression Learner App

In this section...

“Investigate Features in the Response Plot” on page 24-24

“Select Features to Include” on page 24-25

“Transform Features with PCA in Regression Learner” on page 24-26

Investigate Features in the Response Plot

In Regression Learner, use the response plot to try to identify predictors that are useful for predicting the response. To visualize the relation between different predictors and the response, under **X-axis**, select different variables in the **X** list.

Before you train a regression model, the response plot shows the training data. If you have trained a regression model, then the response plot also shows the model predictions.

Observe which variables are associated most clearly with the response. When you plot the carbig data set, the predictor Horsepower shows a clear negative association with the response.

Look for features that do not seem to have any association with the response and use **Feature**

Selection to remove those features from the set of used predictors.

You can export the response plots you create in the app to figures. See “Export Plots in Regression Learner App” on page 24-46.

Select Features to Include

In Regression Learner, you can specify different features (or predictors) to include in the model. See if you can improve models by removing features with low predictive power. If data collection is expensive or difficult, you might prefer a model that performs satisfactorily with fewer predictors.

1

On the **Regression Learner** tab, in the **Features** section, click **Feature Selection**.

2 In the Feature Selection window, clear the check boxes for the predictors you want to exclude.

Tip You can close the Feature Selection window, or move it. The choices you make in the window remain.

3 Click **Train** to train a new model using the new predictor options.

4 Observe the new model in the History list. The Current Model window displays how many predictors are excluded.

5 Check which predictors are included in a trained model. Click the model in the History list and look at the check boxes in the Feature Selection window.

6 Try to improve the model by including different features.

For an example using feature selection, see “Train Regression Trees Using Regression Learner App” on page 24-54.

Transform Features with PCA in Regression Learner

Use principal component analysis (PCA) to reduce the dimensionality of the predictor space. Reducing the dimensionality can create regression models in Regression Learner that help prevent overfitting. PCA linearly transforms predictors to remove redundant dimensions, and generates a new set of variables called principal components.

- 1 On the **Regression Learner** tab, in the **Features** section, select **PCA**.
- 2 In the Advanced PCA Options window, select the **Enable PCA** check box.

You can close the PCA window, or move it. The choices you make in the window remain.

- 3 Click **Train** again. The `pca` function transforms your selected features before training the model.

By default, PCA keeps only the components that explain 95% of the variance. In the PCA window, you can change the percentage of variance to explain in the **Explained variance** box. A higher value risks overfitting, while a lower value risks removing useful dimensions.

- 4 Manually limit the number of PCA components. In the **Component reduction criterion** list, select `Specify number of components`. Edit the number in the **Number of numeric components** box. The number of components cannot be larger than the number of numeric predictors. PCA is not applied to categorical predictors.

You can check PCA Options for trained models in the Current Model window. For example:

```
PCA is keeping enough components to explain 95% variance.  
After training, 2 components were kept.  
Explained variance per component (in order): 92.5%, 5.3%, 1.7%, 0.5%
```

Check the explained variance percentages to decide whether to change the number of components.

To learn more about how Regression Learner applies PCA to your data, generate code for your trained regression model. For more information on PCA, see the `pca` function.

Hyperparameter Optimization in Regression Learner App

In this section...

“Select Hyperparameters to Optimize” on page 24-27

“Optimization Options” on page 24-33

“Minimum MSE Plot” on page 24-34

“Optimization Results” on page 24-36

After you choose a particular type of model to train, for example a decision tree or a support vector machine (SVM), you can tune your model by selecting different advanced options. For example, you can change the minimum leaf size of a decision tree or the box constraint of an SVM. Some of these options are internal parameters of the model, or hyperparameters, that can strongly affect its performance. Instead of manually selecting these options, you can use hyperparameter optimization within the Regression Learner app to automate the selection of hyperparameter values. For a given model type, the app tries different combinations of hyperparameter values by using an optimization scheme that seeks to minimize the model mean squared error (MSE), and returns a model with the optimized hyperparameters. You can use the resulting model as you would any other trained model.

Note Because hyperparameter optimization can lead to an overfitted model, the recommended approach is to create a separate test set before importing your data into the Regression Learner app. After you train your optimizable model, you can export it from the app and see how it performs on your test set. For an example, see “Train Regression Model Using Hyperparameter Optimization in Regression Learner App” on page 24-63.

To perform hyperparameter optimization in Regression Learner, follow these steps:

- 1 Choose a model type and decide which hyperparameters to optimize. See “Select Hyperparameters to Optimize” on page 24-27.

Note Hyperparameter optimization is not supported for linear regression models.

- 2 (Optional) Specify how the optimization is performed. For more information, see “Optimization Options” on page 24-33.
- 3 Train your model. Use the “Minimum MSE Plot” on page 24-34 to track the optimization results.
- 4 Inspect your trained model. See “Optimization Results” on page 24-36.

Select Hyperparameters to Optimize

In the Regression Learner app, in the **Model Type** section of the **Regression Learner** tab, click the arrow to open the gallery. The gallery includes optimizable models that you can train using hyperparameter optimization.

After you select an optimizable model, you can choose which of its hyperparameters you want to optimize. In the **Model Type** section, select **Advanced > Advanced**. The app opens a dialog box in which you can select **Optimize** check boxes for the hyperparameters that you want to optimize. Under **Values**, specify the fixed values for the hyperparameters that you do not want to optimize or that are not optimizable.

This table describes the hyperparameters that you can optimize for each type of model and the search range of each hyperparameter. It also includes the additional hyperparameters for which you can specify fixed values.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes
Optimizable Tree 	<ul style="list-style-type: none"> • Minimum leaf size - The software searches among integers log-scaled in the range $[1, \max(2, \text{floor}(n/2))]$, where n is the number of observations. 	<ul style="list-style-type: none"> • Surrogate decision splits • Maximum surrogates per node 	For more information, see “Advanced Regression Tree Options” on page 24-17.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes
Optimizable SVM 	<ul style="list-style-type: none"> • Kernel function - The software searches among Gaussian, Linear, Quadratic, and Cubic. • Box constraint - The software searches among positive values log-scaled in the range $[0.001, 1000]$. • Kernel scale - The software searches among positive values log-scaled in the range $[0.001, 1000]$. • Epsilon - The software searches among positive values log-scaled in the range $[0.001, 100] * \text{iqr}(Y) / 1.349$, where Y is the response variable. • Standardize data - The software searches between true and false. 		<ul style="list-style-type: none"> • The Box constraint optimizable hyperparameter combines the Box constraint mode and Manual box constraint advanced options of the preset SVM models. • The Kernel scale optimizable hyperparameter combines the Kernel scale mode and Manual kernel scale advanced options of the preset SVM models. • You can optimize the Kernel scale optimizable hyperparameter only when the Kernel function value is Gaussian. Unless you specify a value for Kernel scale by clearing the Optimize check box, the app uses the Manual value of 1 by default when the Kernel function has a value other than Gaussian. • The Epsilon optimizable hyperparameter combines the Epsilon mode and Manual epsilon advanced options of the preset SVM models.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes
			For more information, see “Advanced SVM Options” on page 24-18.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes

Similarly, the LSBoost Ensemble method value specifies a Boosted Trees model. • The Number of predictors to sample optimizable hyperparameter is not available in the advanced options of the preset ensemble models. <p>For more information, see “Advanced Ensemble Options” on page 24-22.</p>

Optimization Options

By default, the Regression Learner app performs hyperparameter tuning by using Bayesian optimization. The goal of Bayesian optimization, and optimization in general, is to find a point that minimizes an objective function. In the context of hyperparameter tuning in the app, a point is a set of hyperparameter values, and the objective function is the loss function, or the mean squared error (MSE). For more information on the basics of Bayesian optimization, see “Bayesian Optimization Workflow” on page 10-25.

You can specify how the hyperparameter tuning is performed. For example, you can change the optimization method to grid search or limit the training time. On the **Regression Learner** tab, in the **Model Type** section, select **Advanced > Optimizer Options**. The app opens a dialog box in which you can select optimization options.

This table describes the available optimization options and their default values.

Option	Description
Optimizer	<p>The optimizer values are:</p> <ul style="list-style-type: none"> • Bayesopt (default) - Use Bayesian optimization. Internally, the app calls the <code>bayesopt</code> function. • Grid search - Use grid search with the number of values per dimension determined by the Number of grid divisions value. The app searches in a random order, using uniform sampling without replacement from the grid. • Random search - Search at random among points, where the number of points corresponds to the Iterations value.
Acquisition function	<p>When the app performs Bayesian optimization for hyperparameter tuning, it uses the acquisition function to determine the next set of hyperparameter values to try.</p> <p>The acquisition function values are:</p> <ul style="list-style-type: none"> • Expected improvement per second plus (default) • Expected improvement • Expected improvement plus • Expected improvement per second • Lower confidence bound • Probability of improvement <p>For details on how these acquisition functions work in the context of Bayesian optimization, see “Acquisition Function Types” on page 10-3.</p>

Option	Description
Iterations	<p>Each iteration corresponds to a combination of hyperparameter values that the app tries. When you use Bayesian optimization or random search, specify a positive integer that sets the number of iterations. The default value is 30.</p> <p>When you use grid search, the app ignores the Iterations value and evaluates the loss at every point in the entire grid. You can set a training time limit to stop the optimization process prematurely.</p>
Training time limit	To set a training time limit, select this option and set the Maximum training time in seconds option. By default, the app does not have a training time limit.
Maximum training time in seconds	Set the training time limit in seconds as a positive real number. The default value is 300. The run time can exceed the training time limit because this limit does not interrupt an iteration evaluation.
Number of grid divisions	When you use grid search, set a positive integer as the number of values the app tries for each numeric hyperparameter. The app ignores this value for categorical hyperparameters. The default value is 10.

Minimum MSE Plot

After specifying which model hyperparameters to optimize and setting any additional optimization options (optional), train your optimizable model. On the **Regression Learner** tab, in the **Training** section, click **Train**. The app creates a **Minimum MSE Plot** that it updates as the optimization runs.

Note When you train an optimizable model, the app disables the **Use Parallel** button. After the training is complete, the app makes the button available again when you select a nonoptimizable model. The button is off by default.

The minimum mean squared error (MSE) plot displays the following information:

- **Estimated minimum MSE** - Each light blue point corresponds to an estimate of the minimum MSE computed by the optimization process when considering all the sets of hyperparameter values tried so far, including the current iteration.

The estimate is based on an upper confidence interval of the current MSE objective model, as mentioned in the **Bestpoint hyperparameters** description.

If you use grid search or random search to perform hyperparameter optimization, the app does not display these light blue points.

- **Observed minimum MSE** - Each dark blue point corresponds to the observed minimum MSE computed so far by the optimization process. For example, at the third iteration, the blue point corresponds to the minimum of the MSE observed in the first, second, and third iterations.
- **Bestpoint hyperparameters** - The red square indicates the iteration that corresponds to the optimized hyperparameters. You can find the values of the optimized hyperparameters listed in the upper right of the plot under **Optimization Results**.

The optimized hyperparameters do not always provide the observed minimum MSE. When the app performs hyperparameter tuning by using Bayesian optimization (see “Optimization Options” on page 24-33 for a brief introduction), it chooses the set of hyperparameter values that minimizes an upper confidence interval of the MSE objective model, rather than the set that minimizes the MSE. For more information, see the 'Criterion', 'min-visited-upper-confidence-interval' name-value pair argument of `bestPoint`.

- **Minimum error hyperparameters** - The yellow point indicates the iteration that corresponds to the hyperparameters that yield the observed minimum MSE.

For more information, see the 'Criterion', 'min-observed' name-value pair argument of `bestPoint`.

If you use grid search to perform hyperparameter optimization, the **Bestpoint hyperparameters** and the **Minimum error hyperparameters** are the same.

Missing points in the plot correspond to NaN minimum MSE values.

Optimization Results

When the app finishes tuning model hyperparameters, it returns a model trained with the optimized hyperparameter values (**Bestpoint hyperparameters**). The model metrics, displayed plots, and exported model correspond to this trained model with fixed hyperparameter values.

To inspect the optimization results of a trained optimizable model, select the model in the **History** list and look at the **Current Model** pane.

▼ Current Model

Model 1: Trained

Results

RMSE	2.5377
R-Squared	0.89
MSE	6.4399
MAE	1.8162
Prediction speed	~25000 obs/sec
Training time	116.07 sec

Optimizer : Bayesian optimization
Acquisition function : Expected improvement per second plus
Iterations : 30
Training time limit : false

Feature Selection

All features used in the model, before PCA

PCA

PCA disabled

The **Current Model** pane includes these sections:

- **Results** - Shows the performance of the optimizable model. See “View Model Statistics in Current Model Window” on page 24-40
- **Model Type** - Displays the type of optimizable model and lists any fixed hyperparameter values
- **Optimized Hyperparameters** - Lists the values of the optimized hyperparameters
- **Hyperparameter Search Range** - Displays the search ranges for the optimized hyperparameters
- **Optimizer Options** - Shows the selected optimizer options

When you perform hyperparameter tuning using Bayesian optimization and you export a trained optimizable model to the workspace as a structure, the structure includes a

`BayesianOptimization` object in the `HyperParameterOptimizationResult` field. The object contains the results of the optimization performed in the app.

When you generate MATLAB code from a trained optimizable model, the generated code uses the fixed and optimized hyperparameter values of the model to train on new data. The generated code does not include the optimization process. For information on how to perform Bayesian optimization when you use a fit function, see “Bayesian Optimization Using a Fit Function” on page 10-26.

Assess Model Performance in Regression Learner

In this section...

- “Check Performance in History List” on page 24-39
- “View Model Statistics in Current Model Window” on page 24-40
- “Explore Data and Results in Response Plot” on page 24-40
- “Plot Predicted vs. Actual Response” on page 24-42
- “Evaluate Model Using Residuals Plot” on page 24-43

After training regression models in Regression Learner, you can compare models based on model statistics, visualize results in response plot, or by plotting actual versus predicted response, and evaluate models using the residual plot.

- If you use k -fold cross-validation, then the app computes the model statistics using the observations in the k validation folds and reports the average values. It makes predictions on the observations in the validation folds and the plots show these predictions. It also computes the residuals on the observations in the validation folds.

Note When you import data into the app, if you accept the defaults, the app automatically uses cross-validation. To learn more, see “Choose Validation Scheme” on page 23-18.

- If you use holdout validation, the app computes the accuracy scores using the observations in the validation fold and makes predictions on these observations. The app uses these predictions in the plots and also computes the residuals based on the predictions.
- If you choose not to use a validation scheme, the score is the resubstitution accuracy based on all the training data, and the predictions are resubstitution predictions.

Check Performance in History List

After training a model in Regression Learner, check the History list to see which model has the best overall score. The best score is highlighted in a box. This score is the root mean square error (RMSE) on the validation set. The score estimates the performance of the trained model on new data. Use the score to help you choose the best model.

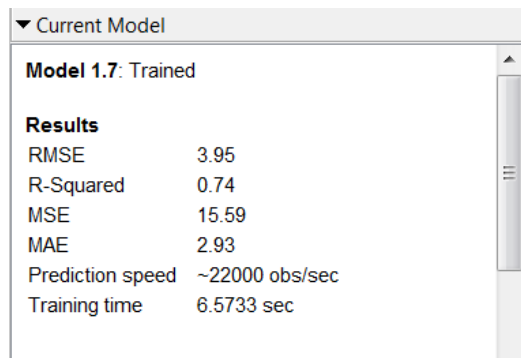

▼ History	
1.1 ☆ Linear Regression Last change: Linear	RMSE: 3.3815 777 features
1.2 ☆ Tree Last change: Fine Tree	RMSE: 3.3849 777 features
1.3 ☆ Tree Last change: Medium Tree	RMSE: 3.3102 777 features
1.4 ☆ Tree Last change: Coarse Tree	RMSE: 3.8819 777 features

- For cross-validation, the score is the RMSE on all observations, counting each observation when it was in a held-out fold.
- For holdout validation, the score is the RMSE on the held-out observations.
- For no validation, the score is the resubstitution RMSE on all the training data.

The best overall score might not be the best model for your goal. Sometimes a model with slightly lower overall score is the better model for your goal. You want to avoid overfitting, and you might want to exclude some predictors where data collection is expensive or difficult.

View Model Statistics in Current Model Window

You can view model statistics in the Current Model window and use these statistics to assess and compare models. The statistics are calculated on the validation set.

Model Statistics

Statistic	Description	Tip
RMSE	Root mean square error. The RMSE is always positive and its units match the units of your response.	Look for smaller values of the RMSE.
R-Squared	Coefficient of determination. R-squared is always smaller than 1 and usually larger than 0. It compares the trained model with the model where the response is constant and equals the mean of the training response. If your model is worse than this constant model, then R-Squared is negative.	Look for an R-Squared close to 1.
MSE	Mean squared error. The MSE is the square of the RMSE.	Look for smaller values of the MSE.
MAE	Mean absolute error. The MAE is always positive and similar to the RMSE, but less sensitive to outliers.	Look for smaller values of the MAE.

Explore Data and Results in Response Plot

In the response plot, view the regression model results. After you train a regression model, the response plot displays the predicted response versus record number. If you are using holdout or cross-validation, then these predictions are the predictions on the held-out observations. In other words, each prediction is obtained using a model that was trained without using the corresponding observation. To investigate your results, use the controls on the right. You can:

- Plot predicted and/or true responses. Use the check boxes under **Plot** to make your selection.
- Show prediction errors, drawn as vertical lines between the predicted and true responses, by selecting the **Errors** check box.
- Choose the variable to plot on the x-axis under **X-axis**. You can choose either the record number or one of your predictor variables.

- Plot the response as markers, or as a box plot under **Style**. You can only select **Box plot** when the variable on the x-axis has few unique values.

A box plot displays the typical values of the response and any possible outliers. The central mark indicates the median, and the bottom and top edges of the box are the 25th and 75th percentiles, respectively. Vertical lines, called whiskers, extend from the boxes to the most extreme data points that are not considered outliers. The outliers are plotted individually using the '+' symbol. For more information about box plots, see `boxplot`.

To export the response plots you create in the app to figures, see “Export Plots in Regression Learner App” on page 24-46.

Plot Predicted vs. Actual Response

Use the Predicted vs. Actual plot to check model performance. Use this plot to understand how well the regression model makes predictions for different response values. To view the Predicted vs. Actual plot after training a model, on the **Regression Learner** tab, in the **Plots** section, click

Predicted vs. Actual Plot 

When you open the plot, the predicted response of your model is plotted against the actual, true response. A perfect regression model has a predicted response equal to the true response, so all the points lie on a diagonal line. The vertical distance from the line to any point is the error of the prediction for that point. A good model has small errors, and so the predictions are scattered near the line.

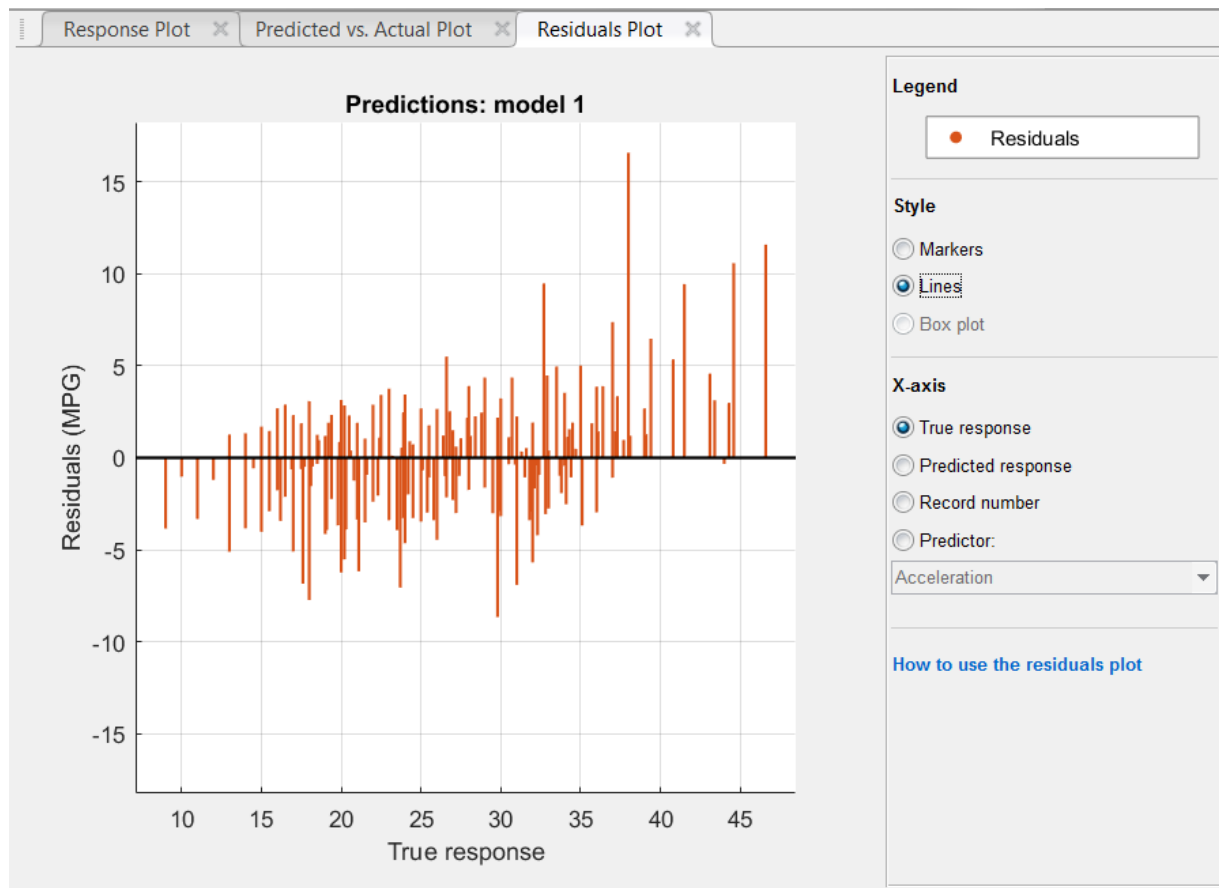

Usually a good model has points scattered roughly symmetrically around the diagonal line. If you can see any clear patterns in the plot, it is likely that you can improve your model. Try training a different model type or making your current model type more flexible using the **Advanced** options in the **Model Type** section. If you are unable to improve your model, it is possible that you need more data, or that you are missing an important predictor.

To export the Predicted vs. Actual plots you create in the app to figures, see “Export Plots in Regression Learner App” on page 24-46.

Evaluate Model Using Residuals Plot

Use the residuals plot to check model performance. To view the residuals plot after training a model,

on the **Regression Learner** tab, in the **Plots** section, click **Residuals Plot** . The residuals plot displays the difference between the predicted and true responses. Choose the variable to plot on the x-axis under **X-axis**. Choose either the true response, predicted response, record number, or one of your predictors.

Usually a good model has residuals scattered roughly symmetrically around 0. If you can see any clear patterns in the residuals, it is likely that you can improve your model. Look for these patterns:

- Residuals are not symmetrically distributed around 0.
- Residuals change significantly in size from left to right in the plot.
- Outliers occur, that is, residuals that are much larger than the rest of the residuals.
- Clear, nonlinear pattern appears in the residuals.

Try training a different model type, or making your current model type more flexible using the **Advanced** options in the **Model Type** section. If you are unable to improve your model, it is possible that you need more data, or that you are missing an important predictor.

To export the residuals plots you create in the app to figures, see “Export Plots in Regression Learner App” on page 24-46.

- “Train Regression Trees Using Regression Learner App” on page 24-54

Export Plots in Regression Learner App

After you create plots interactively in the Regression Learner app, you can export your app plots to MATLAB figures. You can then copy, save, or customize the new figures. Choose among the available plots: response plot on page 24-24, Predicted vs. Actual plot on page 24-42, residuals plot on page 24-43, and minimum MSE plot on page 24-34.

- Before exporting a plot, make sure the plot in the app displays the same data that you want in the new figure.
- On the **Regression Learner** tab, in the **Export** section, click **Export Plot to Figure**. The app creates a figure from the selected plot.
 - The new figure might not have the same interactivity options as the plot in the Regression Learner app.
 - Additionally, the figure might have a different axes toolbar than the one in the app plot. For plots in Regression Learner, an axes toolbar appears above the top right of the plot. The buttons available on the toolbar depend on the contents of the plot. The toolbar can include buttons to export the plot as an image, add data tips, pan or zoom the data, and restore the view.

- Copy, save, or customize the new figure, which is displayed in the figure window.
 - To copy the figure, select **Edit > Copy Figure**. For more information, see “Copy Figure to Clipboard from Edit Menu” (MATLAB).
 - To save the figure, select **File > Save As**. Alternatively, you can follow the workflow described in “Customize Figure Before Saving” (MATLAB).
 - To customize the figure, click the Edit Plot button  on the figure toolbar. Right-click the section of the plot that you want to edit. You can change the listed properties, which might include **Color**, **Font**, **Line Style**, and other properties. Or, you can use the **Property Inspector** to change the figure properties.

As an example, export a response plot in the app to a figure, customize the figure, and save the modified figure.

- 1 In the MATLAB Command Window, load the `carbig` data set.

```
load carbig
cartable = table(Acceleration,Cylinders,Displacement, ...
    Horsepower,Model_Year,Weight,Origin,MPG);
```
- 2 Click the **Apps** tab.
- 3 In the **Apps** section, click the arrow to open the gallery. Under **Machine Learning and Deep Learning**, click **Regression Learner**.

4

On the **Regression Learner** tab, in the **File** section, click .

- 5 In the New Session dialog box, select the table `cartable` from the **Workspace Variable** list.
- 6 Click **Start Session**. Regression Learner creates a response plot of the data by default.

- 7 Change the x-axis data in the response plot to Weight.

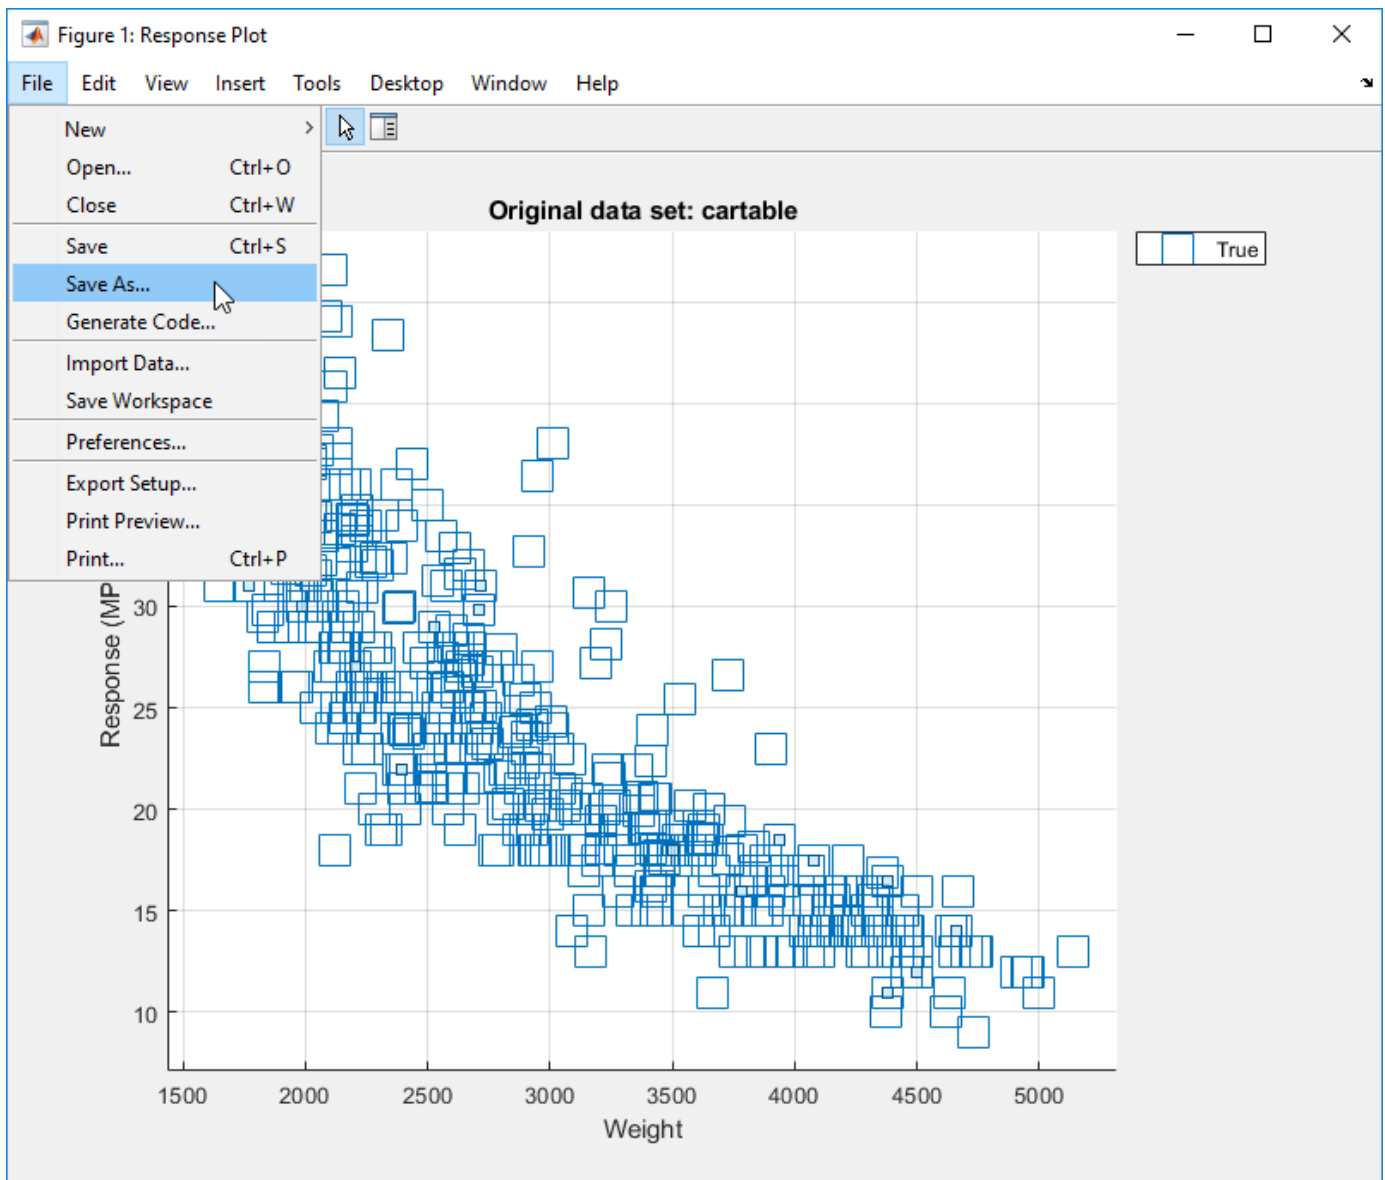

- 8 On the **Regression Learner** tab, in the **Export** section, click **Export Plot to Figure**.

- 9 In the new figure, click the Edit Plot button  on the figure toolbar. Right-click the points in the plot. In the context menu, select **Marker** > **square**.

10 To save the figure, select **File > Save As**. Specify the saved file location, name, and type.

Export Regression Model to Predict New Data

In this section...

“Export Model to Workspace” on page 24-50

“Make Predictions for New Data” on page 24-50

“Generate MATLAB Code to Train Model with New Data” on page 24-51

“Deploy Predictions Using MATLAB Compiler” on page 24-52

Export Model to Workspace

After you create regression models interactively in the Regression Learner app, you can export your best model to the workspace. Then you can use that trained model to make predictions using new data.

Note The final model Regression Learner exports is always trained using the full data set. The validation scheme that you use only affects the way that the app computes validation metrics. You can use the validation metrics and various plots that visualize results to pick the best model for your regression problem.

Here are the steps for exporting a model to the MATLABworkspace:

- 1 In the app, select the model you want to export in the History list.
- 2 On the **Regression Learner** tab, in the **Export** section, click one of the export options:
 - To include the data used for training the model, select **Export Model**.
You export the trained model to the workspace as a structure containing a regression model object.
 - To exclude the training data, select **Export Compact Model**. This option exports the model with unnecessary data removed where possible. For some models this is a compact object that does not include the training data, but you can still use it for making predictions on new data.
- 3 In the Export Model dialog box, check the name of your exported variable, and edit it if you want. Then, click **OK**. The default name for your exported model, `trainedModel`, increments every time you export to avoid overwriting your models (for example, `trainedModel1`).

The new variable (for example, `trainedModel`) appears in your workspace.

The app displays information about the exported model in the command window. Read the message to learn how to make predictions with new data.

Make Predictions for New Data

After you export a model to the workspace from Regression Learner, or run the code generated from the app, you get a `trainedModel` structure that you can use to make predictions using new data. The structure contains a model object and a function for prediction. The structure enables you to make predictions for models that include principal component analysis (PCA).

- 1 Use the exported model to make predictions for new data, T:

```
yfit = trainedModel.predictFcn(T)
```

where `trainedModel` is the name of your exported variable.

Supply the data `T` with the same format and data type as the training data used in the app (table or matrix).

- If you supply a table, then ensure that it contains the same predictor names as your training data. The `predictFcn` ignores additional variables in tables. Variable formats and types must match the original training data.
- If you supply a matrix, it must contain the same predictor columns or rows as your training data, in the same order and format. Do not include a response variable, any variables that you did not import in the app, or other unused variables.

The output `yfit` contains a prediction for each data point.

- 2 Examine the fields of the exported structure. For help making predictions, enter:

```
trainedModel.HowToPredict
```

You also can extract the model object from the exported structure for further analysis. If you use feature transformation such as PCA in the app, you must take into account this transformation by using the information in the PCA fields of the structure.

Generate MATLAB Code to Train Model with New Data

After you create regression models interactively in the Regression Learner app, you can generate MATLAB code for your best model. Then you can use the code to train the model with new data.

Generate MATLAB code to:

- Train on huge data sets. Explore models in the app trained on a subset of your data, and then generate code to train a selected model on a larger data set.
- Create scripts for training models without needing to learn syntax of the different functions.
- Examine the code to learn how to train models programmatically.
- Modify the code for further analysis, for example to set options that you cannot change in the app.
- Repeat your analysis on different data and automate training.

To generate code and use it to train a model with new data:

- 1 In the app, from the History list, select the model you want to generate code for.
- 2 On the **Regression Learner** tab, in the **Export** section, click **Generate Function**.

The app generates code from your session and displays the file in the MATLAB Editor. The file includes the predictors and response, the model training methods, and the validation methods. Save the file.

- 3 To retrain your model, call the function from the command line with your original data or new data as the input argument or arguments. New data must have the same shape as the original data.

Copy the first line of the generated code, excluding the word `function`, and edit the `trainingData` input argument to reflect the variable name of your training data or new data. Similarly, edit the `responseData` input argument (if applicable).

For example, to retrain a regression model trained with the `cartable` data set, enter:

```
[trainedModel, validationRMSE] = trainRegressionModel(cartable)
```

The generated code returns a `trainedModel` structure that contains the same fields as the structure you create when you export a model from Regression Learner to the workspace.

If you want to automate training the same model with new data, or learn how to programmatically train models, examine the generated code. The code shows you how to:

- Process the data into the right shape.
- Train a model and specify all the model options.
- Perform cross-validation.
- Compute statistics.
- Compute validation predictions and scores.

Note If you generate MATLAB code from a trained optimizable model, the generated code does not include the optimization process.

Deploy Predictions Using MATLAB Compiler

After you export a model to the workspace from Regression Learner, you can deploy it using MATLAB Compiler.

Suppose you export the trained model to MATLAB Workspace based on the instructions in “Export Model to Workspace” on page 24-50, with the name `trainedModel`. To deploy predictions, follow these steps.

- Save the `trainedModel` structure in a `.mat` file.

```
save mymodel trainedModel
```

- Write the code to be compiled. This code must load the trained model and use it to make a prediction. It must also have a pragma, so the compiler recognizes that Statistics and Machine Learning Toolbox code is needed in the compiled application. This pragma could be any function in the toolbox.

```
function ypred = mypredict(tbl)
    %#function fitrtree
    load('mymodel.mat');
    load('cartable.mat')
    ypred = trainedModel.predictFcn(cartable)
end
```

- Compile as a standalone application.

```
mcc -m mypredict.m
```

Train Regression Trees Using Regression Learner App

This example shows how to create and compare various regression trees using the Regression Learner app, and export trained models to the workspace to make predictions for new data.

You can train regression trees to predict responses to given input data. To predict the response of a regression tree, follow the tree from the root (beginning) node down to a leaf node. At each node, decide which branch to follow using the rule associated to that node. Continue until you arrive at a leaf node. The predicted response is the value associated to that leaf node.

Statistics and Machine Learning Toolbox trees are binary. Each step in a prediction involves checking the value of one predictor variable. For example, here is a simple regression tree:

This tree predicts the response based on two predictors, x_1 and x_2 . To predict, start at the top node. At each node, check the values of the predictors to decide which branch to follow. When the branches reach a leaf node, the response is set to the value corresponding to that node.

This example uses the `carbig` data set. This data set contains characteristics of different car models produced from 1970 through 1982, including:

- Acceleration
- Number of cylinders
- Engine displacement
- Engine power (Horsepower)
- Model year
- Country of origin
- Miles per gallon (MPG)

Train regression trees to predict the fuel economy in miles per gallon of a car model, given the other variables as inputs.

- 1 In MATLAB, load the `carbig` data set and create a table containing the different variables:

```
load carbig
cartable = table(Acceleration, Cylinders, Displacement,...
Horsepower, Model_Year, Weight, Origin, MPG);
```
- 2 On the **Apps** tab, in the **Machine Learning and Deep Learning** group, click **Regression Learner**.
- 3 On the **Regression Learner** tab, in the **File** section, select **New Session > From Workspace**.
- 4 Under **Data Set Variable** in the New Session dialog box, select `cartable` from the list of tables and matrices in your workspace.

Observe that the app has preselected response and predictor variables. MPG is chosen as the response, and all the other variables as predictors. For this example, do not change the selections.

Data set

Data Set Variable: cartable (406x8 table)

Response: From data set variable, From workspace

MPG (double, 9 .. 46.6)

	Name	Type	Range
<input checked="" type="checkbox"/>	Acceleration	double	8 .. 24.8
<input checked="" type="checkbox"/>	Cylinders	double	3 .. 8
<input checked="" type="checkbox"/>	Displacement	double	68 .. 455
<input checked="" type="checkbox"/>	Horsepower	double	46 .. 230
<input checked="" type="checkbox"/>	Model_Year	double	70 .. 82
<input checked="" type="checkbox"/>	Weight	double	1613 .. 5140
<input checked="" type="checkbox"/>	Origin	char	7 unique
<input type="checkbox"/>	MPG	double	9 .. 46.6

Validation

Cross-Validation
Protects against overfitting by partitioning the data set into folds and estimating accuracy on each fold.

Cross-validation folds: 5 folds

Holdout Validation
Recommended for large data sets.

Percent held out: 25%

No Validation
No protection against overfitting.

[Read about validation](#)

Start Session Cancel

- 5 To accept the default validation scheme and continue, click **Start Session**. The default validation option is cross-validation, to protect against overfitting.

Regression Learner creates a plot of the response with the record number on the x-axis.

- 6 Use the response plot to investigate which variables are useful for predicting the response. To visualize the relation between different predictors and the response, select different variables in the **X** list under **X-axis**.

Observe which variables are correlated most clearly with the response. **Displacement**, **Horsepower**, and **Weight** all have a clearly visible impact on the response and all show a negative association with the response.

- 7 Select the variable **Origin** under **X-axis**. A box plot is automatically displayed. A box plot shows the typical values of the response and any possible outliers. The box plot is useful when plotting markers results in many points overlapping. To show a box plot when the variable on the x-axis has few unique values, under **Style**, select **Box plot**.

- 8 Create a selection of regression trees. On the **Regression Learner** tab, in the **Model Type** section, click **All Trees** .

Then click **Train**.

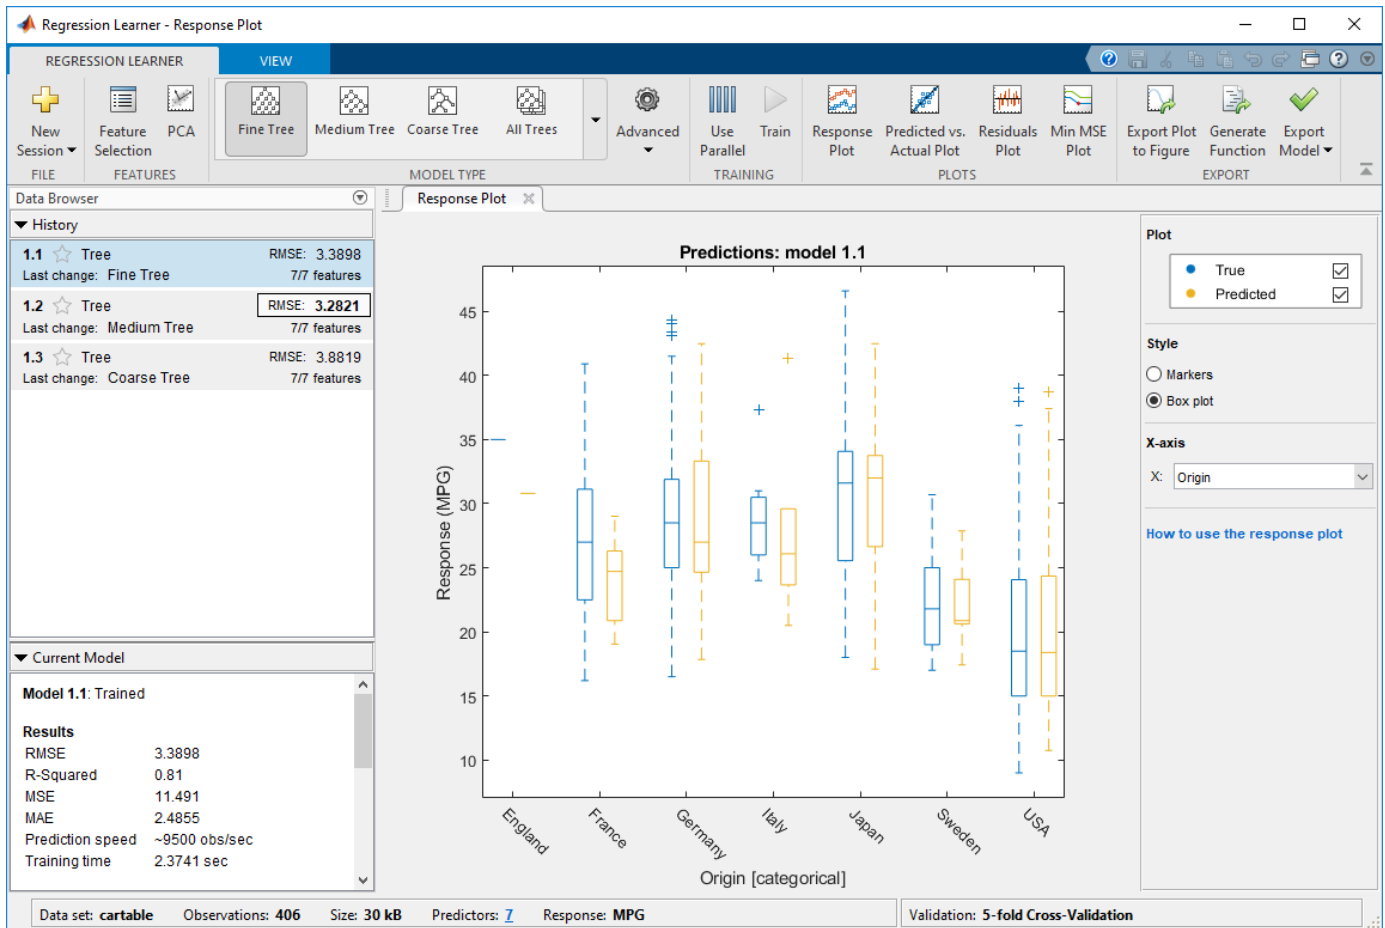

Tip If you have Parallel Computing Toolbox, then the first time you click **Train** you see a dialog box while the app opens a parallel pool of workers. After the pool opens, you can train multiple regression models simultaneously and continue working.

Regression Learner creates and trains three regression trees: a **Fine Tree**, a **Medium Tree**, and a **Coarse Tree**.

The three models appear in the History list. Check the validation **RMSE** (root mean square error) of the models. The best score is highlighted in a box.

The **Fine Tree** and the **Medium Tree** have similar RMSEs, while the **Coarse Tree** is less accurate.

Regression Learner plots both the true training response and the predicted response of the currently selected model.

Note If you are using validation, there is some randomness in the results and so your model validation score can differ from the results shown.

- 9 Choose a model in the History list to view the results of that model. Under **X-axis**, select Horsepower and examine the response plot. Both the true and predicted responses are now plotted. Show the prediction errors, drawn as vertical lines between the predicted and true responses, by selecting the **Errors** check box.
- 10 See more details on the currently selected model in the Current Model window. Check and compare additional model characteristics, such as R-squared (coefficient of determination), MAE (mean absolute error), and prediction speed. To learn more, see “View Model Statistics in Current Model Window” on page 24-40. In the Current Model window you also can find details on the currently selected model type, such as options used for training the model.
- 11 Plot the predicted response versus true response. On the **Regression Learner** tab, in the **Plots** section, click **Predicted vs. Actual Plot** . Use this plot to understand how well the regression model makes predictions for different response values.

A perfect regression model has predicted response equal to true response, so all the points lie on a diagonal line. The vertical distance from the line to any point is the error of the prediction for that point. A good model has small errors, so the predictions are scattered near the line. Usually a good model has points scattered roughly symmetrically around the diagonal line. If you can see any clear patterns in the plot, it is likely that you can improve your model.

- 12 Select the other models in the History list and compare the predicted versus actual plots.
- 13 In the **Model Type** gallery, select **All Trees** again. To try to improve the model, try including different features in the model. See if you can improve the model by removing features with low predictive power. On the **Regression Learner** tab, in the **Features** section, click **Feature**

In the Feature Selection window, clear the check boxes for **Acceleration** and **Cylinders** to exclude them from the predictors.

Click **Train** to train new regression trees using the new predictor settings.

- 14 Observe the new models in the History list. These models are the same regression trees as before, but trained using only five of seven predictors. The History list displays how many predictors are used. To check which predictors are used, click a model in the History list and observe the check boxes in the Feature Selection window.

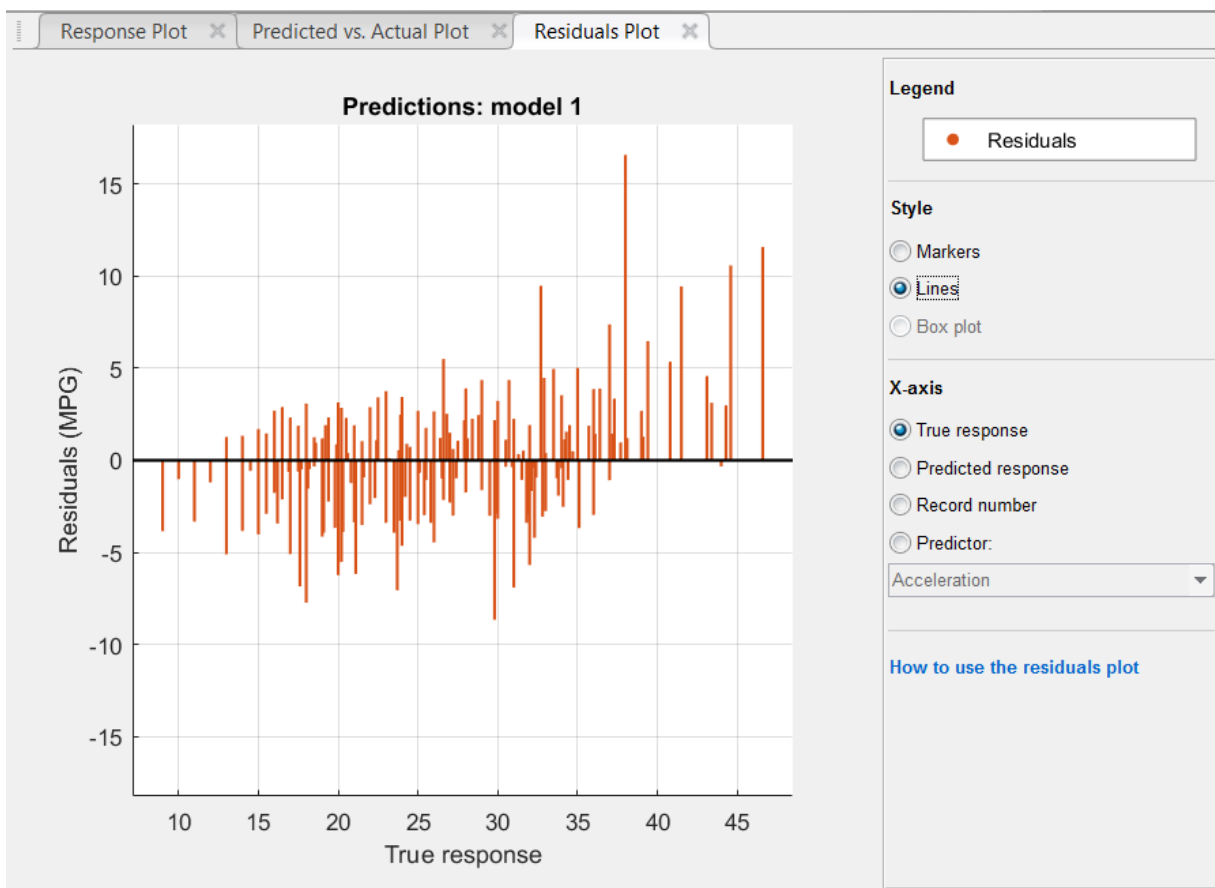

The models with the two features removed perform comparably to the models using all predictors. The models predict no better using all the predictors compared to using only a subset of the predictors. If data collection is expensive or difficult, you might prefer a model that performs satisfactorily without some predictors.

- 15 Train the three regression tree presets using only Horsepower as predictor. Change the selections in the Feature Selection window and click **Train**.

Using only the engine power as predictor results in models with lower accuracy. However, the models perform well given that they are using only a single predictor. With this simple one-dimensional predictor space, the coarse tree now performs as well as the medium and fine trees.

- 16 Select the best model in the History list and view the residuals plot. On the **Regression Learner** tab, in the **Plots** section, click **Residuals Plot** . The residuals plot displays the difference between the predicted and true responses. To display the residuals as a line graph, in the **Style** section, choose **Lines**.

Under **X-axis**, select the variable to plot on the x-axis. Choose either the true response, predicted response, record number, or one of your predictors.

Usually a good model has residuals scattered roughly symmetrically around 0. If you can see any clear patterns in the residuals, it is likely that you can improve your model.

- 17 To learn about model settings, choose the best model in the History list and view the advanced settings. The nonoptimizable model options in the **Model Type** gallery are preset starting points, and you can change additional settings. On the **Regression Learner** tab, in the **Model Type** section, click **Advanced**. Compare the different regression tree models in the History list, and observe the differences in the Advanced Regression Tree Options dialog box. The **Minimum leaf size** setting controls the size of the tree leaves, and through that the size and depth of the regression tree.

To try to improve the model further, change the **Minimum leaf size** setting to 8, and then train a new model by clicking **Train**.

View the settings for the selected trained model in the Current Model window or in the Advanced Regression Tree Options dialog box.

To learn more about regression tree settings, see “Regression Trees” on page 24-15.

- 18 Export the selected model to the workspace. On the **Regression Learner** tab, in the **Export** section, click **Export Model**. In the Export Model dialog box, click **OK** to accept the default variable name `trainedModel`.

To see information about the results, look in the command window.

- 19 Use the exported model to make predictions on new data. For example, to make predictions for the `cartable` data in your workspace, enter:

```
yfit = trainedModel.predictFcn(cartable)
```

The output `yfit` contains the predicted response for each data point.

- 20 If you want to automate training the same model with new data or learn how to programmatically train regression models, you can generate code from the app. To generate code for the best trained model, on the **Regression Learner** tab, in the **Export** section, click **Generate Function**.

The app generates code from your model and displays the file in the MATLAB Editor. To learn more, see “Generate MATLAB Code to Train Model with New Data” on page 24-51.

Tip Use the same workflow as in this example to evaluate and compare the other regression model types you can train in Regression Learner.

Train all the nonoptimizable regression model presets available:

- 1 On the far right of the **Model Type** section, click the arrow to expand the list of regression models.
- 2 Click **All** , and then click **Train**.

To learn about other regression model types, see “Train Regression Models in Regression Learner App” on page 24-2.

Train Regression Model Using Hyperparameter Optimization in Regression Learner App

This example shows how to tune hyperparameters of a regression ensemble by using hyperparameter optimization in the Regression Learner app. Compare the test set performance of the trained optimizable ensemble to that of the best-performing preset ensemble model.

- 1 In the MATLAB Command Window, load the `carbig` data set, and create a table containing most of the variables. Separate the table into training and test sets.

```
load carbig
cartable = table(Acceleration,Cylinders,Displacement, ...
    Horsepower,Model_Year,Weight,Origin,MPG);

rng('default') % For reproducibility of the data split
n = length(MPG);
partition = cvpartition(n,'HoldOut',0.15);
idxTrain = training(partition); % Indices for the training set
cartableTrain = cartable(idxTrain,:);
cartableTest = cartable(~idxTrain,:);
```

- 2 Open Regression Learner. Click the **Apps** tab, and then click the arrow at the right of the **Apps** section to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Regression Learner**.
- 3 On the **Regression Learner** tab, in the **File** section, select **New Session > From Workspace**.
- 4 In the New Session dialog box, select the `cartableTrain` table from the **Data Set Variable** list.

As shown in the dialog box, the app selects the response and predictor variables. The default response variable is `MPG`. The default validation option is 5-fold cross-validation, to protect against overfitting. For this example, do not change the default settings.

Data set

Data Set Variable: cartableTrain (346x8 table)

Response

From data set variable
 From workspace

MPG (double, 9 .. 46.6)

Predictors

	Name	Type	Range
<input checked="" type="checkbox"/>	Acceleration	double	8 .. 24.8
<input checked="" type="checkbox"/>	Cylinders	double	3 .. 8
<input checked="" type="checkbox"/>	Displacement	double	70 .. 455
<input checked="" type="checkbox"/>	Horsepower	double	46 .. 230
<input checked="" type="checkbox"/>	Model_Year	double	70 .. 82

Cross-validation folds: 5 folds

Holdout Validation
 Recommended for large data sets.

Percent held out: 25%

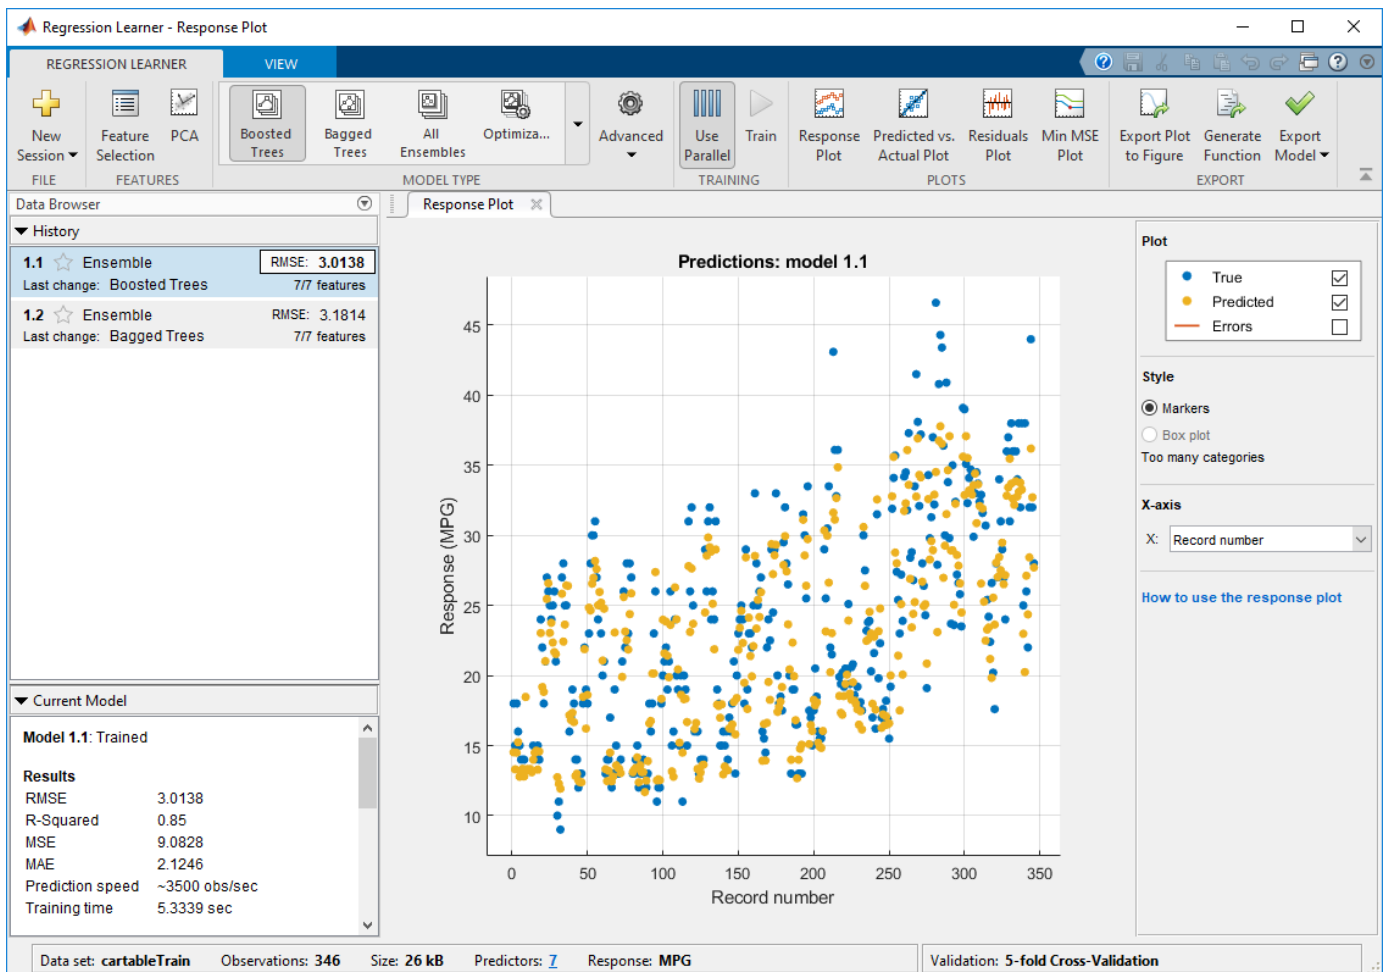

No Validation
 No protection against overfitting.

[Read about validation](#)

Start Session Cancel

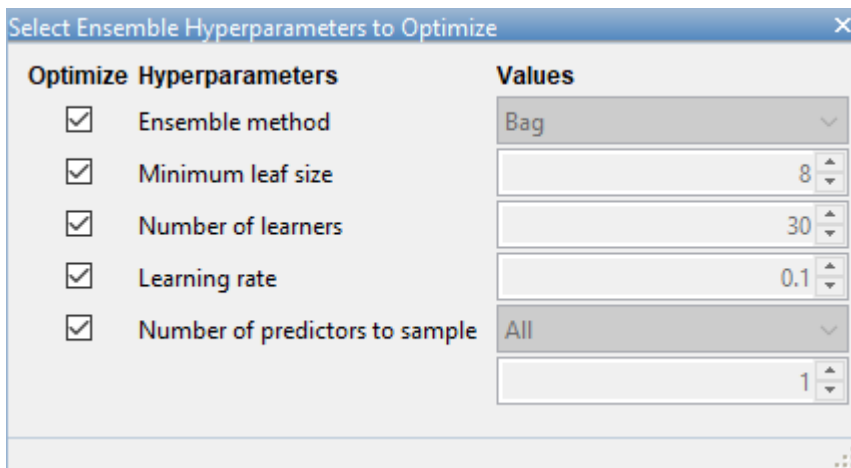

- To accept the default options and continue, click **Start Session**.
- Train all preset ensemble models. On the **Regression Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Ensembles of Trees** group, click **All Ensembles**. In the **Training** section, click **Train**. The app trains one of each ensemble model type and displays the models in the **History** list.

Tip If you have Parallel Computing Toolbox, the Opening Pool dialog box opens the first time you click **Train** (or when you click **Train** again after an extended period of time). The dialog box remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, you can train multiple models simultaneously and continue working.

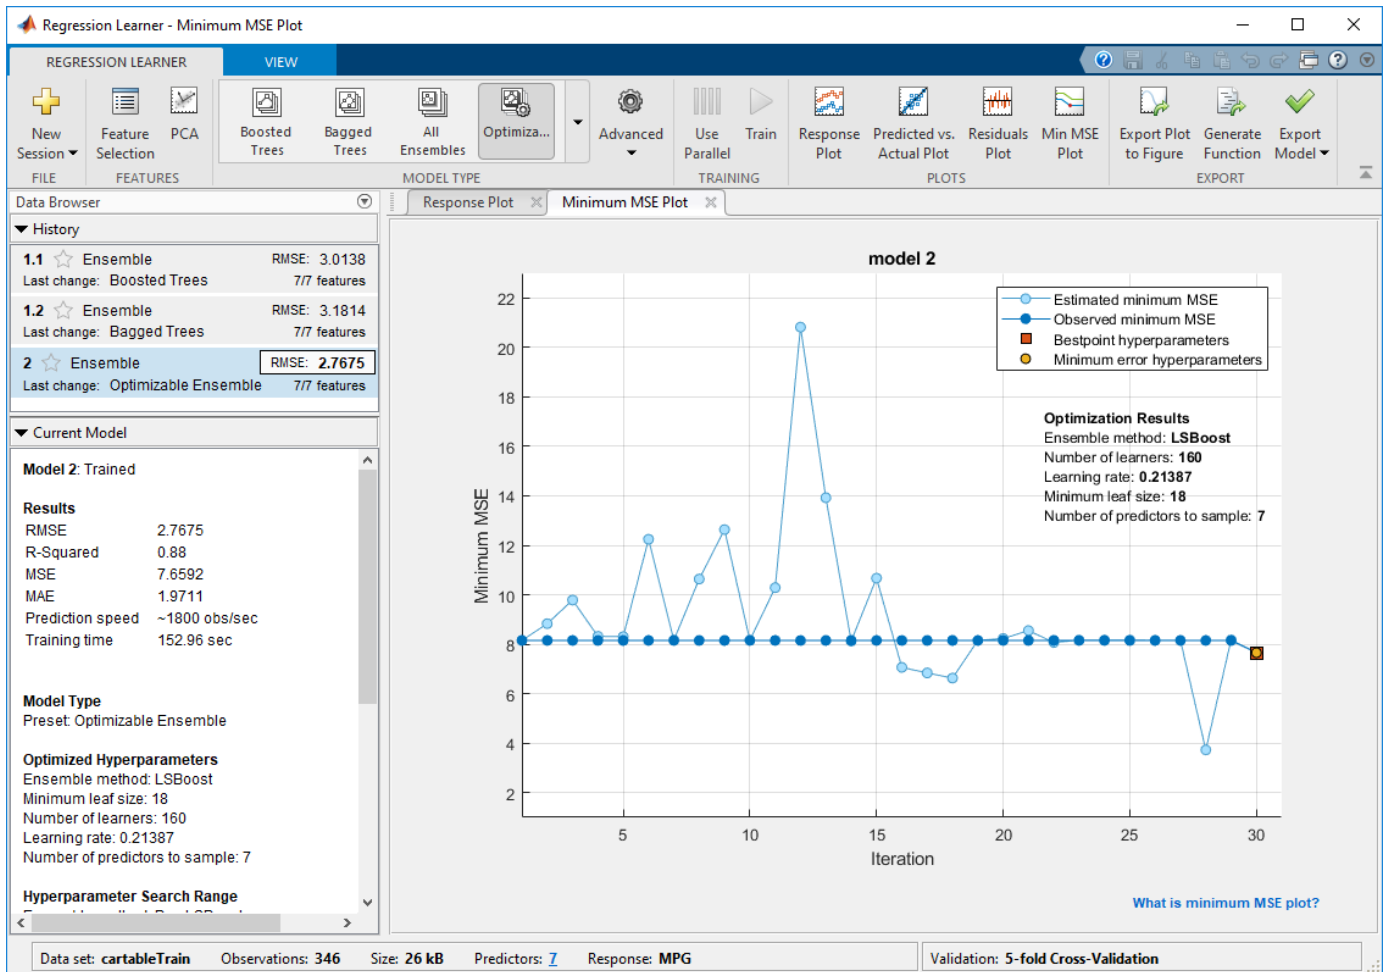

Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

- 7 Select an optimizable ensemble model to train. On the **Regression Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Ensembles of Trees** group, click **Optimizable Ensemble**. The app disables the **Use Parallel** button when you select an optimizable model.
- 8 Select the model hyperparameters to optimize. In the **Model Type** section, select **Advanced > Advanced**. The app opens a dialog box in which you can select **Optimize** check boxes for the hyperparameters that you want to optimize. By default, all the check boxes are selected. For this example, accept the default selections, and close the dialog box.

- 9 In the **Training** section, click **Train**.
- 10 The app displays a **Minimum MSE Plot** as it runs the optimization process. At each iteration, the app tries a different combination of hyperparameter values and updates the plot with the minimum validation mean squared error (MSE) observed up to that iteration, indicated in dark blue. When the app completes the optimization process, it selects the set of optimized hyperparameters, indicated by a red square. For more information, see “Minimum MSE Plot” on page 24-34.

The app lists the optimized hyperparameters in both the upper right of the plot and the **Optimized Hyperparameters** section of the **Current Model** pane.

Note In general, the optimization results are not reproducible.

- 11 Compare the trained preset ensemble models to the trained optimizable model. In the **History** list, the app highlights the lowest validation **RMSE** (root mean square error) by outlining it in a box. In this example, the trained optimizable ensemble outperforms the two preset models.

A trained optimizable model does not always have a lower RMSE than the trained preset models. If a trained optimizable model does not perform well, you can try to get better results by running the optimization for longer. In the **Model Type** section, select **Advanced > Optimizer Options**. In the dialog box, increase the **Iterations** value. For example, you can double-click the default value of 30 and enter a value of 60.

- 12 Because hyperparameter tuning often leads to overfitted models, check the test set performance of the ensemble model with the optimized hyperparameters and compare it to the performance of the best preset ensemble model. Begin by exporting the two models to the MATLAB workspace.
 - In the **History** list, select the **Boosted Trees** model. On the **Regression Learner** tab, in the **Export** section, select **Export Model > Export Model**. In the dialog box, name the model `treeEnsemble`.

- In the **History** list, select the **Optimizable Ensemble** model. On the **Regression Learner** tab, in the **Export** section, select **Export Model > Export Model**. In the dialog box, name the model `optimizableEnsemble`.
- 13** Compute the RMSE of the two models on the `cartableTest` data. In the MATLAB Command Window, use the `predictFcn` function in each exported model structure to predict the response values of the test set data. Then, compute the RMSE for each model on the test set data, omitting any NaN values. Compare the two RMSE values.

```
y = treeEnsemble.predictFcn(cartableTest);
presetRMSE = sqrt((1/length(y))*sum((cartableTest.MPG - y).^2,'omitnan'))

z = optimizableEnsemble.predictFcn(cartableTest);
optRMSE = sqrt((1/length(z))*sum((cartableTest.MPG - z).^2,'omitnan'))

presetRMSE =

    3.4591

optRMSE =

    3.1884
```

In this example, the trained optimizable ensemble still outperforms the trained preset model on the test set data.

“Solving the SVM Regression Optimization Problem” on page 25-5

Mathematical Formulation of SVM Regression

Overview

Support vector machine (SVM) analysis is a popular machine learning tool for classification and regression, first identified by Vladimir Vapnik and his colleagues in 1992[5]. SVM regression is considered a nonparametric technique because it relies on kernel functions.

Statistics and Machine Learning Toolbox implements linear epsilon-insensitive SVM (ε -SVM) regression, which is also known as $L1$ loss. In ε -SVM regression, the set of training data includes predictor variables and observed response values. The goal is to find a function $f(x)$ that deviates from y_n by a value no greater than ε for each training point x , and at the same time is as flat as possible.

Linear SVM Regression: Primal Formula

Suppose we have a set of training data where x_n is a multivariate set of N observations with observed response values y_n .

To find the linear function

$$f(x) = x'\beta + b,$$

and ensure that it is as flat as possible, find $f(x)$ with the minimal norm value ($\beta'\beta$). This is formulated as a convex optimization problem to minimize

$$J(\beta) = \frac{1}{2}\beta'\beta$$

subject to all residuals having a value less than ε ; or, in equation form:

$$\forall n: |y_n - (x_n'\beta + b)| \leq \varepsilon .$$

It is possible that no such function $f(x)$ exists to satisfy these constraints for all points. To deal with otherwise infeasible constraints, introduce slack variables ξ_n and ξ_n^* for each point. This approach is similar to the “soft margin” concept in SVM classification, because the slack variables allow regression errors to exist up to the value of ξ_n and ξ_n^* , yet still satisfy the required conditions.

Including slack variables leads to the objective function, also known as the primal formula[5]:

$$J(\beta) = \frac{1}{2}\beta'\beta + C \sum_{n=1}^N (\xi_n + \xi_n^*),$$

subject to:

$$\begin{aligned} \forall n: y_n - (x_n' \beta + b) &\leq \varepsilon + \xi_n \\ \forall n: (x_n' \beta + b) - y_n &\leq \varepsilon + \xi_n^* \\ \forall n: \xi_n^* &\geq 0 \\ \forall n: \xi_n &\geq 0 . \end{aligned}$$

The constant C is the box constraint, a positive numeric value that controls the penalty imposed on observations that lie outside the epsilon margin (ε) and helps to prevent overfitting (regularization). This value determines the trade-off between the flatness of $f(x)$ and the amount up to which deviations larger than ε are tolerated.

The linear ε -insensitive loss function ignores errors that are within ε distance of the observed value by treating them as equal to zero. The loss is measured based on the distance between observed value y and the ε boundary. This is formally described by

$$L_\varepsilon = \begin{cases} 0 & \text{if } |y - f(x)| \leq \varepsilon \\ |y - f(x)| - \varepsilon & \text{otherwise} \end{cases}$$

Linear SVM Regression: Dual Formula

The optimization problem previously described is computationally simpler to solve in its Lagrange dual formulation. The solution to the dual problem provides a lower bound to the solution of the primal (minimization) problem. The optimal values of the primal and dual problems need not be equal, and the difference is called the “duality gap.” But when the problem is convex and satisfies a constraint qualification condition, the value of the optimal solution to the primal problem is given by the solution of the dual problem.

To obtain the dual formula, construct a Lagrangian function from the primal function by introducing nonnegative multipliers α_n and α_n^* for each observation x_n . This leads to the dual formula, where we minimize

$$L(\alpha) = \frac{1}{2} \sum_{i=1}^N \sum_{j=1}^N (\alpha_i - \alpha_i^*) (\alpha_j - \alpha_j^*) x_i' x_j + \varepsilon \sum_{i=1}^N (\alpha_i + \alpha_i^*) + \sum_{i=1}^N y_i (\alpha_i^* - \alpha_i)$$

subject to the constraints

$$\begin{aligned} \sum_{n=1}^N (\alpha_n - \alpha_n^*) &= 0 \\ \forall n: 0 &\leq \alpha_n \leq C \\ \forall n: 0 &\leq \alpha_n^* \leq C . \end{aligned}$$

The β parameter can be completely described as a linear combination of the training observations using the equation

$$\beta = \sum_{n=1}^N (\alpha_n - \alpha_n^*) x_n .$$

The function used to predict new values depends only on the support vectors:

$$f(x) = \sum_{n=1}^N (\alpha_n - \alpha_n^*) (x_n' x) + b . \quad (25-1)$$

The Karush-Kuhn-Tucker (KKT) complementarity conditions are optimization constraints required to obtain optimal solutions. For linear SVM regression, these conditions are

$$\begin{aligned} \forall n: \alpha_n(\varepsilon + \xi_n - y_n + x_n' \beta + b) &= 0 \\ \forall n: \alpha_n^*(\varepsilon + \xi_n^* + y_n - x_n' \beta - b) &= 0 \\ \forall n: \xi_n(C - \alpha_n) &= 0 \\ \forall n: \xi_n^*(C - \alpha_n^*) &= 0 . \end{aligned}$$

These conditions indicate that all observations strictly inside the epsilon tube have Lagrange multipliers $\alpha_n = 0$ and $\alpha_n^* = 0$. If either α_n or α_n^* is not zero, then the corresponding observation is called a *support vector*.

The property Alpha of a trained SVM model stores the difference between two Lagrange multipliers of support vectors, $\alpha_n - \alpha_n^*$. The properties SupportVectors and Bias store x_n and b , respectively.

Nonlinear SVM Regression: Primal Formula

Some regression problems cannot adequately be described using a linear model. In such a case, the Lagrange dual formulation allows the previously-described technique to be extended to nonlinear functions.

Obtain a nonlinear SVM regression model by replacing the dot product $x_1'x_2$ with a nonlinear kernel function $G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle$, where $\varphi(x)$ is a transformation that maps x to a high-dimensional space. Statistics and Machine Learning Toolbox provides the following built-in semidefinite kernel functions.

Kernel Name	Kernel Function
Linear (dot product)	$G(x_j, x_k) = x_j'x_k$
Gaussian	$G(x_j, x_k) = \exp(-\ x_j - x_k\ ^2)$
Polynomial	$G(x_j, x_k) = (1 + x_j'x_k)^q$, where q is in the set $\{2, 3, \dots\}$.

The *Gram matrix* is an n -by- n matrix that contains elements $g_{i,j} = G(x_i, x_j)$. Each element $g_{i,j}$ is equal to the inner product of the predictors as transformed by φ . However, we do not need to know φ , because we can use the kernel function to generate Gram matrix directly. Using this method, nonlinear SVM finds the optimal function $f(x)$ in the transformed predictor space.

Nonlinear SVM Regression: Dual Formula

The dual formula for nonlinear SVM regression replaces the inner product of the predictors ($x_i'x_j$) with the corresponding element of the Gram matrix ($g_{i,j}$).

Nonlinear SVM regression finds the coefficients that minimize

$$L(\alpha) = \frac{1}{2} \sum_{i=1}^N \sum_{j=1}^N (\alpha_i - \alpha_i^*)(\alpha_j - \alpha_j^*)G(x_i, x_j) + \varepsilon \sum_{i=1}^N (\alpha_i + \alpha_i^*) - \sum_{i=1}^N y_i(\alpha_i - \alpha_i^*)$$

subject to

$$\begin{aligned} \sum_{n=1}^N (\alpha_n - \alpha_n^*) &= 0 \\ \forall n: 0 &\leq \alpha_n \leq C \\ \forall n: 0 &\leq \alpha_n^* \leq C . \end{aligned}$$

The function used to predict new values is equal to

$$f(x) = \sum_{n=1}^N (\alpha_n - \alpha_n^*)G(x_n, x) + b . \quad (25-2)$$

The KKT complementarity conditions are

$$\begin{aligned} \forall n: \alpha_n(\varepsilon + \xi_n - y_n + f(x_n)) &= 0 \\ \forall n: \alpha_n^*(\varepsilon + \xi_n^* + y_n - f(x_n)) &= 0 \\ \forall n: \xi_n(C - \alpha_n) &= 0 \\ \forall n: \xi_n^*(C - \alpha_n^*) &= 0 . \end{aligned}$$

Solving the SVM Regression Optimization Problem

Solver Algorithms

The minimization problem can be expressed in standard quadratic programming form and solved using common quadratic programming techniques. However, it can be computationally expensive to use quadratic programming algorithms, especially since the Gram matrix may be too large to be stored in memory. Using a decomposition method instead can speed up the computation and avoid running out of memory.

Decomposition methods (also called *chunking and working set methods*) separate all observations into two disjoint sets: the working set and the remaining set. A decomposition method modifies only the elements in the working set in each iteration. Therefore, only some columns of the Gram matrix are needed in each iteration, which reduces the amount of storage needed for each iteration.

Sequential minimal optimization (SMO) is the most popular approach for solving SVM problems[4]. SMO performs a series of two-point optimizations. In each iteration, a working set of two points are chosen based on a selection rule that uses second-order information. Then the Lagrange multipliers for this working set are solved analytically using the approach described in [2] and [1].

In SVM regression, the gradient vector ∇L for the active set is updated after each iteration. The decomposed equation for the gradient vector is

$$(\nabla L)_n = \begin{cases} \sum_{i=1}^N (\alpha_i - \alpha_i^*)G(x_i, x_n) + \varepsilon - y_n, & n \leq N \\ - \sum_{i=1}^N (\alpha_i - \alpha_i^*)G(x_i, x_n) + \varepsilon + y_n, & n > N \end{cases} .$$

Iterative single data algorithm (ISDA) updates one Lagrange multiplier with each iteration[3]. ISDA is often conducted without the bias term b by adding a small positive constant a to the kernel function. Dropping b drops the sum constraint

$$\sum_{n=1}^N (\alpha_n - \alpha_n^*) = 0$$

in the dual equation. This allows us to update one Lagrange multiplier in each iteration, which makes it easier than SMO to remove outliers. ISDA selects the worst KKT violator among all the α_n and α_n^* values as the working set to be updated.

Convergence Criteria

Each of these solver algorithms iteratively computes until the specified convergence criterion is met. There are several options for convergence criteria:

- *Feasibility gap* — The feasibility gap is expressed as

$$\Delta = \frac{J(\beta) + L(\alpha)}{J(\beta) + 1},$$

where $J(\beta)$ is the primal objective and $L(\alpha)$ is the dual objective. After each iteration, the software evaluates the feasibility gap. If the feasibility gap is less than the value specified by `GapTolerance`, then the algorithm met the convergence criterion and the software returns a solution.

- *Gradient difference* — After each iteration, the software evaluates the gradient vector, ∇L . If the difference in gradient vector values for the current iteration and the previous iteration is less than the value specified by `DeltaGradientTolerance`, then the algorithm met the convergence criterion and the software returns a solution.
- *Largest KKT violation* — After each iteration, the software evaluates the KKT violation for all the α_n and α_n^* values. If the largest violation is less than the value specified by `KKTolerance`, then the algorithm met the convergence criterion and the software returns a solution.

Markov Chains

Markov processes are examples of stochastic processes—processes that generate random sequences of outcomes or states according to certain probabilities. Markov processes are distinguished by being memoryless—their next state depends only on their current state, not on the history that led them there. Models of Markov processes are used in a wide variety of applications, from daily stock prices to the positions of genes in a chromosome.

A Markov model is given visual representation with a *state diagram*, such as the one below.

State Diagram for a Markov Model

The rectangles in the diagram represent the possible states of the process you are trying to model, and the arrows represent transitions between states. The label on each arrow represents the probability of that transition. At each step of the process, the model may generate an output, or emission, depending on which state it is in, and then make a transition to another state. An important characteristic of Markov models is that the next state depends only on the current state, and not on the history of transitions that lead to the current state.

For example, for a sequence of coin tosses the two states are heads and tails. The most recent coin toss determines the current state of the model and each subsequent toss determines the transition to the next state. If the coin is fair, the transition probabilities are all $1/2$. The emission might simply be the current state. In more complicated models, random processes at each state will generate emissions. You could, for example, roll a die to determine the emission at any step.

Markov chains are mathematical descriptions of Markov models with a discrete set of states. Markov chains are characterized by:

- A set of states $\{1, 2, \dots, M\}$
- An M -by- M transition matrix T whose i,j entry is the probability of a transition from state i to state j . The sum of the entries in each row of T must be 1, because this is the sum of the probabilities of making a transition from a given state to each of the other states.
- A set of possible outputs, or *emissions*, $\{s_1, s_2, \dots, s_N\}$. By default, the set of emissions is $\{1, 2, \dots, N\}$, where N is the number of possible emissions, but you can choose a different set of numbers or symbols.

- An M -by- N emission matrix E whose i,k entry gives the probability of emitting symbol s_k given that the model is in state i .

Markov chains begin in an initial state i_0 at step 0. The chain then transitions to state i_1 with probability T_{1i_1} , and emits an output s_{k_1} with probability $E_{i_1k_1}$. Consequently, the probability of observing the sequence of states $i_1i_2\dots i_r$ and the sequence of emissions $s_{k_1}s_{k_2}\dots s_{k_r}$ in the first r steps, is

$$T_{1i_1}E_{i_1k_1}T_{i_1i_2}E_{i_2k_2}\dots T_{i_{r-1}i_r}E_{i_rk_r}$$

Introduction to Hidden Markov Models (HMM)

A hidden Markov model (HMM) is one in which you observe a sequence of emissions, but do not know the sequence of states the model went through to generate the emissions. Analyses of hidden Markov models seek to recover the sequence of states from the observed data.

As an example, consider a Markov model with two states and six possible emissions. The model uses:

- A red die, having six sides, labeled 1 through 6.
- A green die, having twelve sides, five of which are labeled 2 through 6, while the remaining seven sides are labeled 1.
- A weighted red coin, for which the probability of heads is .9 and the probability of tails is .1.
- A weighted green coin, for which the probability of heads is .95 and the probability of tails is .05.

The model creates a sequence of numbers from the set $\{1, 2, 3, 4, 5, 6\}$ with the following rules:

- Begin by rolling the red die and writing down the number that comes up, which is the emission.
- Toss the red coin and do one of the following:
 - If the result is heads, roll the red die and write down the result.
 - If the result is tails, roll the green die and write down the result.
- At each subsequent step, you flip the coin that has the same color as the die you rolled in the previous step. If the coin comes up heads, roll the same die as in the previous step. If the coin comes up tails, switch to the other die.

The state diagram for this model has two states, red and green, as shown in the following figure.

You determine the emission from a state by rolling the die with the same color as the state. You determine the transition to the next state by flipping the coin with the same color as the state.

The transition matrix is:

$$T = \begin{bmatrix} 0.9 & 0.1 \\ 0.05 & 0.95 \end{bmatrix}$$

The emissions matrix is:

$$E = \begin{bmatrix} \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} \\ \frac{7}{12} & \frac{1}{12} & \frac{1}{12} & \frac{1}{12} & \frac{1}{12} & \frac{1}{12} \end{bmatrix}$$

The model is not hidden because you know the sequence of states from the colors of the coins and dice. Suppose, however, that someone else is generating the emissions without showing you the dice or the coins. All you see is the sequence of emissions. If you start seeing more 1s than other numbers, you might suspect that the model is in the green state, but you cannot be sure because you cannot see the color of the die being rolled.

Hidden Markov models raise the following questions:

- Given a sequence of emissions, what is the most likely state path?
- Given a sequence of emissions, how can you estimate transition and emission probabilities of the model?
- What is the *forward probability* that the model generates a given sequence?
- What is the *posterior probability* that the model is in a particular state at any point in the sequence?

Analyzing Hidden Markov Models

- “Estimating Posterior State Probabilities” on page 26-8
- “Changing the Initial State Distribution” on page 26-8

Statistics and Machine Learning Toolbox functions related to hidden Markov models are:

- `hmmgenerate` — Generates a sequence of states and emissions from a Markov model
- `hmmestimate` — Calculates maximum likelihood estimates of transition and emission probabilities from a sequence of emissions and a known sequence of states
- `hmmtrain` — Calculates maximum likelihood estimates of transition and emission probabilities from a sequence of emissions
- `hmmviterbi` — Calculates the most probable state path for a hidden Markov model
- `hmmdecode` — Calculates the posterior state probabilities of a sequence of emissions

This section shows how to use these functions to analyze hidden Markov models.

Generating a Test Sequence

The following commands create the transition and emission matrices for the model described in the “Introduction to Hidden Markov Models (HMM)” on page 26-4:

```
TRANS = [.9 .1; .05 .95];  
  
EMIS = [1/6, 1/6, 1/6, 1/6, 1/6, 1/6; ...  
7/12, 1/12, 1/12, 1/12, 1/12, 1/12];
```

To generate a random sequence of states and emissions from the model, use `hmmgenerate`:

```
[seq,states] = hmmgenerate(1000,TRANS,EMIS);
```

The output `seq` is the sequence of emissions and the output `states` is the sequence of states.

`hmmgenerate` begins in state 1 at step 0, makes the transition to state i_1 at step 1, and returns i_1 as the first entry in `states`. To change the initial state, see “Changing the Initial State Distribution” on page 26-8.

Estimating the State Sequence

Given the transition and emission matrices `TRANS` and `EMIS`, the function `hmmviterbi` uses the Viterbi algorithm to compute the most likely sequence of states the model would go through to generate a given sequence `seq` of emissions:

```
likelystates = hmmviterbi(seq, TRANS, EMIS);
```

`likelystates` is a sequence the same length as `seq`.

To test the accuracy of `hmmviterbi`, compute the percentage of the actual sequence `states` that agrees with the sequence `likelystates`.

```
sum(states==likelystates)/1000  
ans =  
    0.8200
```

In this case, the most likely sequence of states agrees with the random sequence 82% of the time.

Estimating Transition and Emission Matrices

- “Using `hmmestimate`” on page 26-6
- “Using `hmmtrain`” on page 26-7

The functions `hmmestimate` and `hmmtrain` estimate the transition and emission matrices `TRANS` and `EMIS` given a sequence `seq` of emissions.

Using `hmmestimate`

The function `hmmestimate` requires that you know the sequence of states `states` that the model went through to generate `seq`.

The following takes the emission and state sequences and returns estimates of the transition and emission matrices:

```
[TRANS_EST, EMIS_EST] = hmmestimate(seq, states)
```

```
TRANS_EST =
0.8989  0.1011
0.0585  0.9415
```

```
EMIS_EST =
0.1721  0.1721  0.1749  0.1612  0.1803  0.1393
0.5836  0.0741  0.0804  0.0789  0.0726  0.1104
```

You can compare the outputs with the original transition and emission matrices, TRANS and EMIS:

```
TRANS
TRANS =
0.9000  0.1000
0.0500  0.9500
```

```
EMIS
EMIS =
0.1667  0.1667  0.1667  0.1667  0.1667  0.1667
0.5833  0.0833  0.0833  0.0833  0.0833  0.0833
```

Using `hmmtrain`

If you do not know the sequence of states `states`, but you have initial guesses for TRANS and EMIS, you can still estimate TRANS and EMIS using `hmmtrain`.

Suppose you have the following initial guesses for TRANS and EMIS.

```
TRANS_GUESS = [.85 .15; .1 .9];
EMIS_GUESS = [.17 .16 .17 .16 .17 .17;.6 .08 .08 .08 .08 08];
```

You estimate TRANS and EMIS as follows:

```
[TRANS_EST2, EMIS_EST2] = hmmtrain(seq, TRANS_GUESS, EMIS_GUESS)
```

```
TRANS_EST2 =
0.2286  0.7714
0.0032  0.9968
```

```
EMIS_EST2 =
0.1436  0.2348  0.1837  0.1963  0.2350  0.0066
0.4355  0.1089  0.1144  0.1082  0.1109  0.1220
```

`hmmtrain` uses an iterative algorithm that alters the matrices TRANS_GUESS and EMIS_GUESS so that at each step the adjusted matrices are more likely to generate the observed sequence, `seq`. The algorithm halts when the matrices in two successive iterations are within a small tolerance of each other.

If the algorithm fails to reach this tolerance within a maximum number of iterations, whose default value is 100, the algorithm halts. In this case, `hmmtrain` returns the last values of TRANS_EST and EMIS_EST and issues a warning that the tolerance was not reached.

If the algorithm fails to reach the desired tolerance, increase the default value of the maximum number of iterations with the command:

```
hmmtrain(seq, TRANS_GUESS, EMIS_GUESS, 'maxiterations', maxiter)
```

where `maxiter` is the maximum number of steps the algorithm executes.

Change the default value of the tolerance with the command:

```
hmmtrain(seq, TRANS_GUESS, EMIS_GUESS, 'tolerance', tol)
```

where `tol` is the desired value of the tolerance. Increasing the value of `tol` makes the algorithm halt sooner, but the results are less accurate.

Two factors reduce the reliability of the output matrices of `hmmtrain`:

- The algorithm converges to a local maximum that does not represent the true transition and emission matrices. If you suspect this, use different initial guesses for the matrices `TRANS_EST` and `EMIS_EST`.
- The sequence `seq` may be too short to properly train the matrices. If you suspect this, use a longer sequence for `seq`.

Estimating Posterior State Probabilities

The posterior state probabilities of an emission sequence `seq` are the conditional probabilities that the model is in a particular state when it generates a symbol in `seq`, given that `seq` is emitted. You compute the posterior state probabilities with `hmmdecode`:

```
PSTATES = hmmdecode(seq, TRANS, EMIS)
```

The output `PSTATES` is an M -by- L matrix, where M is the number of states and L is the length of `seq`. `PSTATES(i, j)` is the conditional probability that the model is in state `i` when it generates the j th symbol of `seq`, given that `seq` is emitted.

`hmmdecode` begins with the model in state 1 at step 0, prior to the first emission. `PSTATES(i, 1)` is the probability that the model is in state `i` at the following step 1. To change the initial state, see “Changing the Initial State Distribution” on page 26-8.

To return the logarithm of the probability of the sequence `seq`, use the second output argument of `hmmdecode`:

```
[PSTATES, logpseq] = hmmdecode(seq, TRANS, EMIS)
```

The probability of a sequence tends to 0 as the length of the sequence increases, and the probability of a sufficiently long sequence becomes less than the smallest positive number your computer can represent. `hmmdecode` returns the logarithm of the probability to avoid this problem.

Changing the Initial State Distribution

By default, Statistics and Machine Learning Toolbox hidden Markov model functions begin in state 1. In other words, the distribution of initial states has all of its probability mass concentrated at state 1. To assign a different distribution of probabilities, $p = [p_1, p_2, \dots, p_M]$, to the M initial states, do the following:

- 1 Create an $M+1$ -by- $M+1$ augmented transition matrix, \hat{T} of the following form:

$$\hat{T} = \begin{bmatrix} 0 & p \\ 0 & T \end{bmatrix}$$

where T is the true transition matrix. The first column of \hat{T} contains $M+1$ zeros. p must sum to 1.

- 2 Create an $M+1$ -by- N augmented emission matrix, \hat{E} , that has the following form:

$$\hat{E} = \begin{bmatrix} 0 \\ E \end{bmatrix}$$

If the transition and emission matrices are TRANS and EMIS, respectively, you create the augmented matrices with the following commands:

```
TRANS_HAT = [0 p; zeros(size(TRANS,1),1) TRANS];
```

```
EMIS_HAT = [zeros(1,size(EMIS,2)); EMIS];
```

Design of Experiments

Passive data collection leads to a number of problems in statistical modeling. Observed changes in a response variable may be correlated with, but not caused by, observed changes in individual factors (process variables). Simultaneous changes in multiple factors may produce interactions that are difficult to separate into individual effects. Observations may be dependent, while a model of the data considers them to be independent.

Designed experiments address these problems. In a designed experiment, the data-producing process is actively manipulated to improve the quality of information and to eliminate redundant data. A common goal of all experimental designs is to collect data as parsimoniously as possible while providing sufficient information to accurately estimate model parameters.

For example, a simple model of a response y in an experiment with two controlled factors x_1 and x_2 might look like this:

$$y = \beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_3x_1x_2 + \varepsilon$$

Here ε includes both experimental error and the effects of any uncontrolled factors in the experiment. The terms β_1x_1 and β_2x_2 are main effects and the term $\beta_3x_1x_2$ is a two-way interaction effect. A designed experiment would systematically manipulate x_1 and x_2 while measuring y , with the objective of accurately estimating β_0 , β_1 , β_2 , and β_3 .

Full Factorial Designs

In this section...

“Multilevel Designs” on page 27-3

“Two-Level Designs” on page 27-3

Multilevel Designs

To systematically vary experimental factors, assign each factor a discrete set of levels. Full factorial designs measure response variables using every treatment (combination of the factor levels). A full factorial design for n factors with N_1, \dots, N_n levels requires $N_1 \times \dots \times N_n$ experimental runs—one for each treatment. While advantageous for separating individual effects, full factorial designs can make large demands on data collection.

As an example, suppose a machine shop has three machines and four operators. If the same operator always uses the same machine, it is impossible to determine if a machine or an operator is the cause of variation in production. By allowing every operator to use every machine, effects are separated. A full factorial list of treatments is generated by the Statistics and Machine Learning Toolbox function `fullfact`:

```
dFF = fullfact([3,4])
dFF =
     1     1
     2     1
     3     1
     1     2
     2     2
     3     2
     1     3
     2     3
     3     3
     1     4
     2     4
     3     4
```

Each of the $3 \times 4 = 12$ rows of `dFF` represent one machine/operator combination.

Two-Level Designs

Many experiments can be conducted with two-level factors, using two-level designs. For example, suppose the machine shop in the previous example always keeps the same operator on the same machine, but wants to measure production effects that depend on the composition of the day and night shifts. The Statistics and Machine Learning Toolbox function `ff2n` generates a full factorial list of treatments:

```
dFF2 = ff2n(4)
dFF2 =
     0     0     0     0
     0     0     0     1
     0     0     1     0
     0     0     1     1
     0     1     0     0
     0     1     0     1
```

0	1	1	0
0	1	1	1
1	0	0	0
1	0	0	1
1	0	1	0
1	0	1	1
1	1	0	0
1	1	0	1
1	1	1	0
1	1	1	1

Each of the $2^4 = 16$ rows of dFF2 represent one schedule of operators for the day (0) and night (1) shifts.

Fractional Factorial Designs

In this section...

“Introduction to Fractional Factorial Designs” on page 27-5

“Plackett-Burman Designs” on page 27-5

“General Fractional Designs” on page 27-5

Introduction to Fractional Factorial Designs

Two-level designs are sufficient for evaluating many production processes. Factor levels of ± 1 can indicate categorical factors, normalized factor extremes, or simply “up” and “down” from current factor settings. Experimenters evaluating process *changes* are interested primarily in the factor directions that lead to process improvement.

For experiments with many factors, two-level full factorial designs can lead to large amounts of data. For example, a two-level full factorial design with 10 factors requires $2^{10} = 1024$ runs. Often, however, individual factors or their interactions have no distinguishable effects on a response. This is especially true of higher order interactions. As a result, a well-designed experiment can use fewer runs for estimating model parameters.

Fractional factorial designs use a fraction of the runs required by full factorial designs. A subset of experimental treatments is selected based on an evaluation (or assumption) of which factors and interactions have the most significant effects. Once this selection is made, the experimental design must separate these effects. In particular, significant effects should not be confounded, that is, the measurement of one should not depend on the measurement of another.

Plackett-Burman Designs

Plackett-Burman designs are used when only main effects are considered significant. Two-level Plackett-Burman designs require a number of experimental runs that are a multiple of 4 rather than a power of 2. The MATLAB function `hadamard` generates these designs:

```
dPB = hadamard(8)
dPB =
    1    1    1    1    1    1    1    1
    1   -1    1   -1    1   -1    1   -1
    1    1   -1   -1    1    1   -1   -1
    1   -1   -1    1    1   -1   -1    1
    1    1    1    1   -1   -1   -1   -1
    1   -1    1   -1   -1    1   -1    1
    1    1   -1   -1   -1   -1    1    1
    1   -1   -1    1   -1    1    1   -1
```

Binary factor levels are indicated by ± 1 . The design is for eight runs (the rows of `dPB`) manipulating seven two-level factors (the last seven columns of `dPB`). The number of runs is a fraction $8/2^7 = 0.0625$ of the runs required by a full factorial design. Economy is achieved at the expense of confounding main effects with any two-way interactions.

General Fractional Designs

At the cost of a larger fractional design, you can specify which interactions you wish to consider significant. A design of resolution R is one in which no n -factor interaction is confounded with any

other effect containing less than $R - n$ factors. Thus, a resolution III design does not confound main effects with one another but may confound them with two-way interactions (as in “Plackett-Burman Designs” on page 27-5), while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

Specify general fractional factorial designs using a full factorial design for a selected subset of basic factors and generators for the remaining factors. Generators are products of the basic factors, giving the levels for the remaining factors. Use the Statistics and Machine Learning Toolbox function `fracfact` to generate these designs:

```
dff = fracfact('a b c d bcd acd')
dff =
    -1    -1    -1    -1    -1    -1
    -1    -1    -1     1     1     1
    -1    -1     1    -1     1     1
    -1    -1     1     1    -1    -1
    -1     1    -1    -1     1    -1
    -1     1    -1     1    -1     1
    -1     1     1    -1    -1     1
    -1     1     1     1     1    -1
     1    -1    -1    -1    -1     1
     1    -1    -1     1     1    -1
     1    -1     1    -1     1    -1
     1    -1     1     1    -1     1
     1     1    -1    -1     1     1
     1     1    -1     1    -1    -1
     1     1     1    -1    -1    -1
     1     1     1     1     1     1
```

This is a six-factor design in which four two-level basic factors (a, b, c, and d in the first four columns of `dff`) are measured in every combination of levels, while the two remaining factors (in the last three columns of `dff`) are measured only at levels defined by the generators `bcd` and `acd`, respectively. Levels in the generated columns are products of corresponding levels in the columns that make up the generator.

The challenge of creating a fractional factorial design is to choose basic factors and generators so that the design achieves a specified resolution in a specified number of runs. Use the Statistics and Machine Learning Toolbox function `fracfactgen` to find appropriate generators:

```
generators = fracfactgen('a b c d e f',4,4)
generators =
    'a'
    'b'
    'c'
    'd'
    'bcd'
    'acd'
```

These are generators for a six-factor design with factors a through f, using $2^4 = 16$ runs to achieve resolution IV. The `fracfactgen` function uses an efficient search algorithm to find generators that meet the requirements.

An optional output from `fracfact` displays the confounding pattern of the design:

```
[dff,confounding] = fracfact(generators);
confounding
confounding =
```

'Term'	'Generator'	'Confounding'
'X1'	'a'	'X1'
'X2'	'b'	'X2'
'X3'	'c'	'X3'
'X4'	'd'	'X4'
'X5'	'bcd'	'X5'
'X6'	'acd'	'X6'
'X1*X2'	'ab'	'X1*X2 + X5*X6'
'X1*X3'	'ac'	'X1*X3 + X4*X6'
'X1*X4'	'ad'	'X1*X4 + X3*X6'
'X1*X5'	'abcd'	'X1*X5 + X2*X6'
'X1*X6'	'cd'	'X1*X6 + X2*X5 + X3*X4'
'X2*X3'	'bc'	'X2*X3 + X4*X5'
'X2*X4'	'bd'	'X2*X4 + X3*X5'
'X2*X5'	'cd'	'X1*X6 + X2*X5 + X3*X4'
'X2*X6'	'abcd'	'X1*X5 + X2*X6'
'X3*X4'	'cd'	'X1*X6 + X2*X5 + X3*X4'
'X3*X5'	'bd'	'X2*X4 + X3*X5'
'X3*X6'	'ad'	'X1*X4 + X3*X6'
'X4*X5'	'bc'	'X2*X3 + X4*X5'
'X4*X6'	'ac'	'X1*X3 + X4*X6'
'X5*X6'	'ab'	'X1*X2 + X5*X6'

The confounding pattern shows that main effects are effectively separated by the design, but two-way interactions are confounded with various other two-way interactions.

Response Surface Designs

“Box-Behnken Designs” on page 27-10

Introduction to Response Surface Designs

Quadratic response surfaces are simple models that provide a maximum or minimum without making additional assumptions about the form of the response. Quadratic models can be calibrated using full factorial designs with three or more levels for each factor, but these designs generally require more runs than necessary to accurately estimate model parameters. This section discusses designs for calibrating quadratic models that are much more efficient, using three or five levels for each factor, but not using all combinations of levels.

Central Composite Designs

Central composite designs (CCDs), also known as Box-Wilson designs, are appropriate for calibrating full quadratic models. There are three types of CCDs—circumscribed, inscribed, and faced—pictured below:

Each design consists of a factorial design (the corners of a cube) together with center and star points that allow for estimation of second-order effects. For a full quadratic model with n factors, CCDs have enough design points to estimate the $(n+2)(n+1)/2$ coefficients in a full quadratic model with n factors.

The type of CCD used (the position of the factorial and star points) is determined by the number of factors and by the desired properties of the design. The following table summarizes some important properties. A design is rotatable if the prediction variance depends only on the distance of the design point from the center of the design.

Design	Rotatable	Factor Levels	Uses Points Outside ± 1	Accuracy of Estimates
Circumscribed (CCC)	Yes	5	Yes	Good over entire design space
Inscribed (CCI)	Yes	5	No	Good over central subset of design space
Faced (CCF)	No	3	No	Fair over entire design space; poor for pure quadratic coefficients

Generate CCDs with the Statistics and Machine Learning Toolbox function `ccdesign`:

```
dCC = ccdesign(3, 'type', 'circumscribed')
dCC =
-1.0000    -1.0000    -1.0000
-1.0000    -1.0000     1.0000
-1.0000     1.0000    -1.0000
-1.0000     1.0000     1.0000
 1.0000    -1.0000    -1.0000
 1.0000    -1.0000     1.0000
 1.0000     1.0000    -1.0000
 1.0000     1.0000     1.0000
-1.6818         0         0
 1.6818         0         0
         0    -1.6818         0
         0     1.6818         0
         0         0    -1.6818
         0         0     1.6818
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
```

The repeated center point runs allow for a more uniform estimate of the prediction variance over the entire design space.

Box-Behnken Designs

Like the designs described in “Central Composite Designs” on page 27-8, Box-Behnken designs are used to calibrate full quadratic models. Box-Behnken designs are rotatable and, for a small number of factors (four or less), require fewer runs than CCDs. By avoiding the corners of the design space, they allow experimenters to work around extreme factor combinations. Like an inscribed CCD, however, extremes are then poorly estimated.

The geometry of a Box-Behnken design is pictured in the following figure.

Design points are at the midpoints of edges of the design space and at the center, and do not contain an embedded factorial design.

Generate Box-Behnken designs with the Statistics and Machine Learning Toolbox function `bbdesign`:

```
dBB = bbdesign(3)
dBB =
    -1    -1     0
    -1     1     0
     1    -1     0
     1     1     0
    -1     0    -1
    -1     0     1
     1     0    -1
     1     0     1
     0    -1    -1
     0    -1     1
     0     1    -1
     0     1     1
     0     0     0
     0     0     0
     0     0     0
```

Again, the repeated center point runs allow for a more uniform estimate of the prediction variance over the entire design space.

D-Optimal Designs

Introduction to D-Optimal Designs

Traditional experimental designs (“Full Factorial Designs” on page 27-3, “Fractional Factorial Designs” on page 27-5, and “Response Surface Designs” on page 27-8) are appropriate for calibrating linear models in experimental settings where factors are relatively unconstrained in the region of interest. In some cases, however, models are necessarily nonlinear. In other cases, certain treatments (combinations of factor levels) may be expensive or infeasible to measure. D-optimal designs are model-specific designs that address these limitations of traditional designs.

A D-optimal design is generated by an iterative search algorithm and seeks to minimize the covariance of the parameter estimates for a specified model. This is equivalent to maximizing the determinant $D = |X^T X|$, where X is the design matrix of model terms (the columns) evaluated at specific treatments in the design space (the rows). Unlike traditional designs, D-optimal designs do not require orthogonal design matrices, and as a result, parameter estimates may be correlated. Parameter estimates may also be locally, but not globally, D-optimal.

There are several Statistics and Machine Learning Toolbox functions for generating D-optimal designs:

Function	Description
candexch	Uses a row-exchange algorithm to generate a D-optimal design with a specified number of runs for a specified model and a specified candidate set. This is the second component of the algorithm used by rowexch.
candgen	Generates a candidate set for a specified model. This is the first component of the algorithm used by rowexch.
cordexch	Uses a coordinate-exchange algorithm to generate a D-optimal design with a specified number of runs for a specified model.
daugment	Uses a coordinate-exchange algorithm to augment an existing D-optimal design with additional runs to estimate additional model terms.
dcovary	Uses a coordinate-exchange algorithm to generate a D-optimal design with fixed covariate factors.
rowexch	Uses a row-exchange algorithm to generate a D-optimal design with a specified number of runs for a specified model. The algorithm calls candgen and then candexch. (Call candexch separately to specify a candidate set.)

The following sections explain how to use these functions to generate D-optimal designs.

Note The Statistics and Machine Learning Toolbox function `rsmdemo` generates simulated data for experimental settings specified by either the user or by a D-optimal design generated by `cordexch`. It uses the `rstool` interface to visualize response surface models fit to the data, and it uses the `nlintool` interface to visualize a nonlinear model fit to the data.

Generate D-Optimal Designs

Two Statistics and Machine Learning Toolbox algorithms generate D-optimal designs:

- The `cordexch` function uses a coordinate-exchange algorithm
- The `rowexch` function uses a row-exchange algorithm

Both `cordexch` and `rowexch` use iterative search algorithms. They operate by incrementally changing an initial design matrix X to increase $D = |X^T X|$ at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally, D-optimal designs. Run each algorithm multiple times and select the best result for your final design. Both functions have a `'tries'` parameter that automates this repetition and comparison.

At each step, the row-exchange algorithm exchanges an entire row of X with a row from a design matrix C evaluated at a candidate set of feasible treatments. The `rowexch` function automatically generates a C appropriate for a specified model, operating in two steps by calling the `candgen` and `candexch` functions in sequence. Provide your own C by calling `candexch` directly. In either case, if C is large, its static presence in memory can affect computation.

The coordinate-exchange algorithm, by contrast, does not use a candidate set. (Or rather, the candidate set is the entire design space.) At each step, the coordinate-exchange algorithm exchanges a single element of X with a new element evaluated at a neighboring point in design space. The absence of a candidate set reduces demands on memory, but the smaller scale of the search means that the coordinate-exchange algorithm is more likely to become trapped in a local minimum than the row-exchange algorithm.

For example, suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_{12} x_1 x_2 + \beta_{13} x_1 x_3 + \beta_{23} x_2 x_3 + \varepsilon$$

Use `cordexch` to generate a D-optimal design with seven runs:

```

n factors = 3;
n runs = 7;
[dCE,X] = cordexch(n factors,n runs,'interaction','tries',10)
dCE =
    -1     1     1
    -1    -1    -1
     1     1     1
    -1     1    -1
     1    -1     1
     1    -1    -1
    -1    -1     1
X =
     1    -1     1     1    -1    -1     1
     1    -1    -1    -1     1     1     1
     1     1     1     1     1     1     1

```

```

1   -1   1   -1   -1   1   -1
1   1   -1   1   -1   1   -1
1   1   -1   -1   -1   -1   1
1   -1   -1   1   1   -1   -1

```

Columns of the design matrix X are the model terms evaluated at each row of the design dCE. The terms appear in order from left to right:

- 1 Constant term
- 2 Linear terms (1, 2, 3)
- 3 Interaction terms (12, 13, 23)

Use X in a linear regression model fit to response data measured at the design points in dCE.

Use `rowexch` in a similar fashion to generate an equivalent design:

```
[dRE,X] = rowexch(nfactors,nruns,'interaction','tries',10)
```

```

dRE =
-1   -1   1
 1   -1   1
 1   -1  -1
 1   1   1
-1   -1  -1
-1   1  -1
-1   1   1

X =
 1   -1  -1   1   1   -1  -1
 1   1  -1   1  -1   1  -1
 1   1  -1  -1  -1  -1   1
 1   1   1   1   1   1   1
 1  -1  -1  -1   1   1   1
 1  -1   1  -1  -1   1  -1
 1  -1   1   1  -1  -1   1

```

Augment D-Optimal Designs

In practice, you may want to add runs to a completed experiment to learn more about a process and estimate additional model coefficients. The `daugment` function uses a coordinate-exchange algorithm to augment an existing D-optimal design.

For example, the following eight-run design is adequate for estimating main effects in a four-factor model:

```

dCEmain = cordexch(4,8)
dCEmain =
 1   -1  -1   1
-1  -1   1   1
-1   1  -1   1
 1   1   1  -1
 1   1   1   1
-1   1  -1  -1
 1  -1  -1  -1
-1  -1   1  -1

```

To estimate the six interaction terms in the model, augment the design with eight additional runs:

```
dCEinteraction = daugment(dCEmain,8,'interaction')
dCEinteraction =
    1    -1    -1     1
   -1    -1     1     1
   -1     1    -1     1
    1     1     1    -1
    1     1     1     1
   -1     1    -1    -1
    1    -1    -1    -1
   -1    -1     1    -1
   -1     1     1     1
   -1    -1    -1    -1
    1    -1     1    -1
    1     1    -1     1
   -1     1     1    -1
    1     1    -1    -1
    1    -1     1     1
    1     1     1    -1
```

The augmented design is full factorial, with the original eight runs in the first eight rows.

The 'start' parameter of the candexch function provides the same functionality as daugment, but uses a row exchange algorithm rather than a coordinate-exchange algorithm.

Specify Fixed Covariate Factors

In many experimental settings, certain factors and their covariates are constrained to a fixed set of levels or combinations of levels. These cannot be varied when searching for an optimal design. The dcovary function allows you to specify fixed covariate factors in the coordinate exchange algorithm.

For example, suppose you want a design to estimate the parameters in a three-factor linear additive model, with eight runs that necessarily occur at different times. If the process experiences temporal linear drift, you may want to include the run time as a variable in the model. Produce the design as follows:

```
time = linspace(-1,1,8)';
[dCV,X] = dcovary(3,time,'linear')
dCV =
   -1.0000    1.0000    1.0000   -1.0000
    1.0000   -1.0000   -1.0000   -0.7143
   -1.0000   -1.0000   -1.0000   -0.4286
    1.0000   -1.0000    1.0000   -0.1429
    1.0000    1.0000   -1.0000    0.1429
   -1.0000    1.0000   -1.0000    0.4286
    1.0000    1.0000    1.0000    0.7143
   -1.0000   -1.0000    1.0000    1.0000
X =
    1.0000   -1.0000    1.0000    1.0000   -1.0000
    1.0000    1.0000   -1.0000   -1.0000   -0.7143
    1.0000   -1.0000   -1.0000   -1.0000   -0.4286
    1.0000    1.0000   -1.0000    1.0000   -0.1429
    1.0000    1.0000    1.0000   -1.0000    0.1429
    1.0000   -1.0000    1.0000   -1.0000    0.4286
    1.0000    1.0000    1.0000    1.0000    0.7143
    1.0000   -1.0000   -1.0000    1.0000    1.0000
```

The column vector `time` is a fixed factor, normalized to values between ± 1 . The number of rows in the fixed factor specifies the number of runs in the design. The resulting design `dCV` gives factor settings for the three controlled model factors at each time.

Specify Categorical Factors

Categorical factors take values in a discrete set of levels. Both `cordexch` and `rowexch` have a `'categorical'` parameter that allows you to specify the indices of categorical factors and a `'levels'` parameter that allows you to specify a number of levels for each factor.

For example, the following eight-run design is for a linear additive model with five factors in which the final factor is categorical with three levels:

```
dCEcat = cordexch(5,8,'linear','categorical',5,'levels',3)
dCEcat =
    -1    -1     1     1     2
    -1    -1    -1    -1     3
     1     1     1     1     3
     1     1    -1    -1     2
     1    -1    -1     1     3
    -1     1    -1     1     1
    -1     1     1    -1     3
     1    -1     1    -1     1
```

Specify Candidate Sets

The row-exchange algorithm exchanges rows of an initial design matrix X with rows from a design matrix C evaluated at a candidate set of feasible treatments. The `rowexch` function automatically generates a C appropriate for a specified model, operating in two steps by calling the `candgen` and `candexch` functions in sequence. Provide your own C by calling `candexch` directly.

For example, the following uses `rowexch` to generate a five-run design for a two-factor pure quadratic model using a candidate set that is produced internally:

```
dRE1 = rowexch(2,5,'purequadratic','tries',10)
dRE1 =
    -1     1
     0     0
     1    -1
     1     0
     1     1
```

The same thing can be done using `candgen` and `candexch` in sequence:

```
[dC,C] = candgen(2,'purequadratic') % Candidate set, C
dC =
    -1    -1
     0    -1
     1    -1
    -1     0
     0     0
     1     0
    -1     1
     0     1
     1     1
```

```

C =
    1  -1  -1   1   1
    1   0  -1   0   1
    1   1  -1   1   1
    1  -1   0   1   0
    1   0   0   0   0
    1   1   0   1   0
    1  -1   1   1   1
    1   0   1   0   1
    1   1   1   1   1
treatments = candexch(C,5,'tries',10) % D-opt subset
treatments =
     2
     1
     7
     3
     4
dRE2 = dC(treatments,:) % Display design
dRE2 =
     0    -1
    -1    -1
    -1     1
     1    -1
    -1     0

```

You can replace C in this example with a design matrix evaluated at your own candidate set. For example, suppose your experiment is constrained so that the two factors cannot have extreme settings simultaneously. The following produces a restricted candidate set:

```

constraint = sum(abs(dC),2) < 2; % Feasible treatments
my_dC = dC(constraint,:)
my_dC =
     0    -1
    -1     0
     0     0
     1     0
     0     1

```

Use the x2fx function to convert the candidate set to a design matrix:

```

my_C = x2fx(my_dC,'purequadratic')
my_C =
     1     0    -1     0     1
     1    -1     0     1     0
     1     0     0     0     0

     1     0     1     0     1

```

Find the required design in the same manner:

```

my_treatments = candexch(my_C,5,'tries',10) % D-opt subset
my_treatments =
     2
     4
     5
     1
     3
my_dRE = my_dC(my_treatments,:) % Display design

```

```
my_dRE =  
  -1  0  
   1  0  
   0  1  
   0 -1  
   0  0
```

Improve an Engine Cooling Fan Using Design for Six Sigma Techniques

This example shows how to improve the performance of an engine cooling fan through a Design for Six Sigma approach using Define, Measure, Analyze, Improve, and Control (DMAIC). The initial fan does not circulate enough air through the radiator to keep the engine cool during difficult conditions. First the example shows how to design an experiment to investigate the effect of three performance factors: fan distance from the radiator, blade-tip clearance, and blade pitch angle. It then shows how to estimate optimum values for each factor, resulting in a design that produces airflows beyond the goal of 875 ft³ per minute using test data. Finally it shows how to use simulations to verify that the new design produces airflow according to the specifications in more than 99.999% of the fans manufactured. This example uses MATLAB, Statistics and Machine Learning Toolbox, and Optimization Toolbox.

Define the Problem

This example addresses an engine cooling fan design that is unable to pull enough air through the radiator to keep the engine cool during difficult conditions, such as stop-and-go traffic or hot weather). Suppose you estimate that you need airflow of at least 875 ft³/min to keep the engine cool during difficult conditions. You need to evaluate the current design and develop an alternative design that can achieve the target airflow.

Assess Cooling Fan Performance

Load the sample data.

```
load(fullfile(matlabroot, 'help/toolbox/stats/examples', 'OriginalFan.mat'))
```

The data consists of 10,000 measurements (historical production data) of the existing cooling fan performance.

Plot the data to analyze the current fan's performance.

```
plot(originalfan)
xlabel('Observation')
ylabel('Max Airflow (ft^3/min)')
title('Historical Production Data')
```

The data is centered around 842 ft³/min and most values fall within the range of about 8 ft³/min. The plot does not tell much about the underlying distribution of data, however. Plot the histogram and fit a normal distribution to the data.

```
figure()
histfit(originalfan) % Plot histogram with normal distribution fit
format shortg
xlabel('Airflow (ft^3/min)')
ylabel('Frequency (counts)')
title('Airflow Histogram')
```

```
pd = fitdist(originalfan,'normal') % Fit normal distribution to data
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 841.652 [841.616, 841.689]
sigma = 1.8768 [1.85114, 1.90318]
```

`fitdist` fits a normal distribution to data and estimates the parameters from data. The estimate for the mean airflow speed is 841.652 ft³/min, and the 95% confidence interval for the mean airflow speed is (841.616, 841.689). This estimate makes it clear that the current fan is not close to the required 875 ft³/min. There is need to improve the fan design to achieve the target airflow.

Determine Factors That Affect Fan Performance

Evaluate the factors that affect cooling fan performance using design of experiments (DOE). The response is the cooling fan airflow rate (ft³/min). Suppose that the factors that you can modify and control are:

- Distance from radiator
- Pitch angle
- Blade tip clearance

In general, fluid systems have nonlinear behavior. Therefore, use a response surface design to estimate any nonlinear interactions among the factors. Generate the experimental runs for a Box-Behnken design on page 27-10 in coded (normalized) variables [-1, 0, +1].

```
CodedValue = bbdesign(3)
```

```
CodedValue =
```

```

-1    -1     0
-1     1     0
 1    -1     0
 1     1     0
-1     0    -1
-1     0     1
 1     0    -1
 1     0     1
 0    -1    -1
 0    -1     1
 0     1    -1
 0     1     1
 0     0     0
 0     0     0
 0     0     0

```

The first column is for the distance from radiator, the second column is for the pitch angle, and the third column is for the blade tip clearance. Suppose you want to test the effects of the variables at the following minimum and maximum values.

Distance from radiator: 1 to 1.5 inches

Pitch angle: 15 to 35 degrees

Blade tip clearance: 1 to 2 inches

Randomize the order of the runs, convert the coded design values to real-world units, and perform the experiment in the order specified.

```

runorder = randperm(15);    % Random permutation of the runs
bounds = [1 1.5;15 35;1 2]; % Min and max values for each factor

RealValue = zeros(size(CodedValue));
for i = 1:size(CodedValue,2) % Convert coded values to real-world units
    zmax = max(CodedValue(:,i));
    zmin = min(CodedValue(:,i));
    RealValue(:,i) = interp1([zmin zmax],bounds(i,:),CodedValue(:,i));
end

```

Suppose that at the end of the experiments, you collect the following response values in the variable `TestResult`.

```
TestResult = [837 864 829 856 880 879 872 874 834 833 860 859 874 876 875]';
```

Display the design values and the response.

```

disp({'Run Number','Distance','Pitch','Clearance','Airflow'})
disp(sortrows([runorder' RealValue TestResult]))

'Run Number'    'Distance'    'Pitch'    'Clearance'    'Airflow'
              1              1.5              35              1.5              856

```

2	1.25	25	1.5	876
3	1.5	25	1	872
4	1.25	25	1.5	875
5	1	35	1.5	864
6	1.25	25	1.5	874
7	1.25	15	2	833
8	1.5	15	1.5	829
9	1.25	15	1	834
10	1	15	1.5	837
11	1.5	25	2	874
12	1	25	1	880
13	1.25	35	1	860
14	1	25	2	879
15	1.25	35	2	859

Save the design values and the response in a table.

```
Expmt = table(runorder', CodedValue(:,1), CodedValue(:,2), CodedValue(:,3), ...
    TestResult, 'VariableNames', {'RunNumber', 'D', 'P', 'C', 'Airflow'});
```

D stands for Distance, P stands for Pitch, and C stands for Clearance. Based on the experimental test results, the airflow rate is sensitive to the changing factors values. Also, four experimental runs meet or exceed the target airflow rate of 875 ft³/min (runs 2, 4, 12, and 14). However, it is not clear which, if any, of these runs is the optimal one. In addition, it is not obvious how robust the design is to variation in the factors. Create a model based on the current experimental data and use the model to estimate the optimal factor settings.

Improve the Cooling Fan Performance

The Box-Behnken design enables you to test for nonlinear (quadratic) effects. The form of the quadratic model is:

$$AF = \beta_0 + \beta_1 * Distance + \beta_2 * Pitch + \beta_3 * Clearance + \beta_4 * Distance * Pitch + \beta_5 * Distance * Clearance + \beta_6 * Pitch * Clearance + \beta_7 * Distance^2 + \beta_8 * Pitch^2 + \beta_9 * Clearance^2,$$

where AF is the airflow rate and B_i is the coefficient for the term i . Estimate the coefficients of this model using the `fitlm` function from Statistics and Machine Learning Toolbox.

```
mdl = fitlm(Expmt, 'Airflow~D*P*C-D:P:C+D^2+P^2+C^2');
```

Display the magnitudes of the coefficients (for normalized values) in a bar chart.

```
figure()
h = bar(mdl.Coefficients.Estimate(2:10));
set(h, 'facecolor', [0.8 0.8 0.9])
legend('Coefficient')
set(gcf, 'units', 'normalized', 'position', [0.05 0.4 0.35 0.4])
set(gca, 'xticklabel', mdl.CoefficientNames(2:10))
ylabel('Airflow (ft^3/min)')
xlabel('Normalized Coefficient')
title('Quadratic Model Coefficients')
```

The bar chart shows that *Pitch* and *Pitch*² are dominant factors. You can look at the relationship between multiple input variables and one output variable by generating a response surface plot. Use `plotSlice` to generate response surface plots for the model `mdl` interactively.

```
plotSlice(mdl)
```

The plot shows the nonlinear relationship of airflow with pitch. Move the blue dashed lines around and see the effect the different factors have on airflow. Although you can use `plotSlice` to determine the optimum factor settings, you can also use Optimization Toolbox to automate the task.

Find the optimal factor settings using the constrained optimization function `fmincon`.

Write the objective function.

```
f = @(x) -x2fx(x, 'quadratic')*mdl.Coefficients.Estimate;
```

The objective function is a quadratic response surface fit to the data. Minimizing the negative airflow using `fmincon` is the same as maximizing the original objective function. The constraints are the upper and lower limits tested (in coded values). Set the initial starting point to be the center of the design of the experimental test matrix.

```
lb = [-1 -1 -1]; % Lower bound
ub = [1 1 1]; % Upper bound
x0 = [0 0 0]; % Starting point
[optfactors,fval] = fmincon(f,x0,[],[],[],[],lb,ub,[]); % Invoke the solver
```

Local minimum found that satisfies the constraints.

Optimization completed because the objective function is non-decreasing in feasible directions, to within the default value of the function tolerance, and constraints are satisfied to within the default value of the constraint tolerance.

Convert the results to a maximization problem and real-world units.

```
maxval = -fval;
maxloc = (optfactors + 1)';
bounds = [1 1.5;15 35;1 2];
maxloc=bounds(:,1)+maxloc .* ((bounds(:,2) - bounds(:,1))/2);
disp('Optimal Values:')
disp({'Distance', 'Pitch', 'Clearance', 'Airflow'})
disp([maxloc' maxval])
```

```
Optimal Values:
'Distance' 'Pitch' 'Clearance' 'Airflow'
```

1 27.275 1 882.26

The optimization result suggests placing the new fan one inch from the radiator, with a one-inch clearance between the tips of the fan blades and the shroud.

Because pitch angle has such a significant effect on airflow, perform additional analysis to verify that a 27.3 degree pitch angle is optimal.

```
load(fullfile(matlabroot, 'help/toolbox/stats/examples', 'AirflowData.mat'))
tbl = table(pitch, airflow);
mdl2 = fitlm(tbl, 'airflow~pitch^2');
mdl2.Rsquared.Ordinary

ans =

    0.99632
```

The results show that a quadratic model explains the effect of pitch on the airflow well.

Plot the pitch angle against airflow and impose the fitted model.

```
figure()
plot(pitch, airflow, '.r')
hold on
ylim([840 885])
line(pitch, mdl2.Fitted, 'color', 'b')
title('Fitted Model and Data')
xlabel('Pitch angle (degrees)')
ylabel('Airflow (ft^3/min)')
legend('Test data', 'Quadratic model', 'Location', 'se')
hold off
```

Find the pitch value that corresponds to the maximum airflow.

```
pitch(find(airflow==max(airflow)))
```

ans =

27

The additional analysis confirms that a 27.3 degree pitch angle is optimal.

The improved cooling fan design meets the airflow requirements. You also have a model that approximates the fan performance well based on the factors you can modify in the design. Ensure that the fan performance is robust to variability in manufacturing and installation by performing a sensitivity analysis.

Sensitivity Analysis

Suppose that, based on historical experience, the manufacturing uncertainty is as follows.

Factor	Real Values	Coded Values
Distance from radiator	1.00 +/- 0.05 inch	1.00 +/- 0.20 inch
Blade pitch angle	27.3 +/- 0.25 degrees	0.227 +/- 0.028 degrees
Blade tip clearance	1.00 +/- 0.125 inch	-1.00 +/- 0.25 inch

Verify that these variations in factors will enable to maintain a robust design around the target airflow. The philosophy of Six Sigma targets a defect rate of no more than 3.4 per 1,000,000 fans. That is, the fans must hit the 875 ft³/min target 99.999% of the time.

You can verify the design using Monte Carlo simulation. Generate 10,000 random numbers for three factors with the specified tolerance. First, set the state of the random number generators so results are consistent across different runs.

```
rng('default')
```

Perform the Monte Carlo simulation. Include a noise variable that is proportional to the noise in the fitted model, mdl (that is, the RMS error of the model). Because the model coefficients are in coded variables, you must generate dist, pitch, and clearance using the coded definition.

```
dist = random('normal',optfactors(1),0.20,[10000 1]);
pitch = random('normal',optfactors(2),0.028,[10000 1]);
clearance = random('normal',optfactors(3),0.25,[10000 1]);
noise = random('normal',0,mdl2.RMSE,[10000 1]);
```

Calculate airflow for 10,000 random factor combinations using the model.

```
simfactor = [dist pitch clearance];
X = x2fx(simfactor,'quadratic');
```

Add noise to the model (the variation in the data that the model did not account for).

```
simflow = X*mdl.Coefficients.Estimate+noise;
```

Evaluate the variation in the model's predicted airflow using a histogram. To estimate the mean and standard deviation, fit a normal distribution to data.

```
pd = fitdist(simflow,'normal');
histfit(simflow)
hold on
text(pd.mu+2,300,['Mean: ' num2str(round(pd.mu))])
text(pd.mu+2,280,['Standard deviation: ' num2str(round(pd.sigma))])
hold off
xlabel('Airflow (ft^3/min)')
ylabel('Frequency')
title('Monte Carlo Simulation Results')
```

The results look promising. The average airflow is 882 ft³/min and appears to be better than 875 ft³/min for most of the data.

Determine the probability that the airflow is at 875 ft³/min or below.

```
format long
pfail = cdf(pd,875)
pass = (1-pfail)*100

pfail =

    1.509289008603141e-07

pass =

    99.99984907109919
```

The design appears to achieve at least 875 ft³/min of airflow 99.999% of the time.

Use the simulation results to estimate the process capability.

```
S = capability(simflow,[875.0 890])
pass = (1-S.Pl)*100

S =

    mu: 8.822982645666709e+02
```

```
sigma: 1.424806876923940
P: 0.999999816749816
Pl: 1.509289008603141e-07
Pu: 3.232128339675335e-08
Cp: 1.754623760237126
Cpl: 1.707427788957002
Cpu: 1.801819731517250
Cpk: 1.707427788957002
```

```
pass =
```

```
99.9999849071099
```

The Cp value is 1.75. A process is considered high quality when Cp is greater than or equal to 1.6. The Cpk is similar to the Cp value, which indicates that the process is centered. Now implement this design. Monitor it to verify the design process and to ensure that the cooling fan delivers high-quality performance.

Control Manufacturing of the Improved Cooling Fan

You can monitor and evaluate the manufacturing and installation process of the new fan using control charts. Evaluate the first 30 days of production of the new cooling fan. Initially, five cooling fans per day were produced. First, load the sample data from the new process.

```
load(fullfile(matlabroot, 'help/toolbox/stats/examples', 'spcdata.mat'))
```

Plot the X-bar and S charts.

```
figure()
controlchart(spcflow, 'chart', {'xbar', 's'}) % Reshape the data into daily sets
xlabel('Day')
```

According to the results, the manufacturing process is in statistical control, as indicated by the absence of violations of control limits or nonrandom patterns in the data over time. You can also run a capability analysis on the data to evaluate the process.

```
[row,col] = size(spcflow);
S2 = capability(reshape(spcflow,row*col,1),[875.0 890])
pass = (1-S.Pl)*100
```

S2 =

```
mu: 8.821061141685465e+02
sigma: 1.423887508874697
P: 0.999999684316149
Pl: 3.008932155898586e-07
Pu: 1.479063578225176e-08
Cp: 1.755756676295137
Cpl: 1.663547652525458
Cpu: 1.847965700064817
Cpk: 1.663547652525458
```

pass =

```
99.9999699106784
```

The Cp value of 1.755 is very similar to the estimated value of 1.73. The Cpk value of 1.66 is smaller than the Cp value. However, only a Cpk value less than 1.33, which indicates that the process shifted

significantly toward one of the process limits, is a concern. The process is well within the limits and it achieves the target airflow (875 ft³/min) more than 99.999% of the time.

Statistical Process Control

- “Control Charts” on page 28-2
- “Capability Studies” on page 28-5

Control Charts

A control chart displays measurements of process samples over time. The measurements are plotted together with user-defined *specification limits* and process-defined *control limits*. The process can then be compared with its specifications—to see if it is *in control* or *out of control*.

The chart is just a monitoring tool. Control activity might occur if the chart indicates an undesirable, systematic change in the process. The control chart is used to discover the variation, so that the process can be adjusted to reduce it.

Control charts are created with the `controlchart` function. Any of the following chart types may be specified:

- Xbar or mean
- Standard deviation
- Range
- Exponentially weighted moving average
- Individual observation
- Moving range of individual observations
- Moving average of individual observations
- Proportion defective
- Number of defectives
- Defects per unit
- Count of defects

Control rules are specified with the `controlrules` function. The following example illustrates how to use Western Electric rules to mark out of control measurements on an Xbar chart.

First load the sample data.

```
load parts;
```

Construct the Xbar control chart using the Western Electric 2 rule (2 of 3 points at least 2 standard errors above the center line) to mark the out of control measurements.

```
st = controlchart(runout, 'rules', 'we2');
```

For a better understanding of the Western Electric 2 rule, calculate and plot the 2 standard errors line on the chart.

```
x = st.mean;
cl = st.mu;
se = st.sigma./sqrt(st.n);
hold on
plot(cl+2*se, 'm')
```

Identify the measurements that violate the control rule.

```
R = controlrules('we2',x,cl,se);
I = find(R)
```

```
I = 6x1
```

```
21
23
24
25
26
27
```

Capability Studies

Before going into production, many manufacturers run a *capability study* to determine if their process will run within specifications enough of the time. *Capability indices* produced by such a study are used to estimate expected percentages of defective parts.

Capability studies are conducted with the `capability` function. The following capability indices are produced:

- `mu` — Sample mean
- `sigma` — Sample standard deviation
- `P` — Estimated probability of being within the lower (L) and upper (U) specification limits
- `Pl` — Estimated probability of being below L
- `Pu` — Estimated probability of being above U
- `Cp` — $(U-L)/(6*\sigma)$
- `Cpl` — $(\mu-L)/(3.*\sigma)$
- `Cpu` — $(U-\mu)/(3.*\sigma)$
- `Cpk` — $\min(Cpl, Cpu)$

As an example, simulate a sample from a process with a mean of 3 and a standard deviation of 0.005:

```
rng default; % For reproducibility
data = normrnd(3,0.005,100,1);
```

Compute capability indices if the process has an upper specification limit of 3.01 and a lower specification limit of 2.99:

```
S = capability(data,[2.99 3.01])
```

```
S = struct with fields:
    mu: 3.0006
   sigma: 0.0058
      P: 0.9129
     Pl: 0.0339
     Pu: 0.0532
      Cp: 0.5735
     Cpl: 0.6088
     Cpu: 0.5382
     Cpk: 0.5382
```

Visualize the specification and process widths:

```
capaplot(data,[2.99 3.01]);
grid on
```

Tall Arrays

- “Logistic Regression with Tall Arrays” on page 29-2
- “Bayesian Optimization with Tall Arrays” on page 29-9

Logistic Regression with Tall Arrays

This example shows how to use logistic regression and other techniques to perform data analysis on tall arrays. Tall arrays represent data that is too large to fit into computer memory.

Define Execution Environment

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. To run the example using the local MATLAB session when you have Parallel Computing Toolbox, change the global execution environment by using the `mapreducer` function.

```
mapreducer(0)
```

Get Data into MATLAB

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. Treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Select a subset of the variables to work with, and include the name of the airline (`UniqueCarrier`) as a categorical variable. Create a tall table on top of the datastore.

```
ds = datastore('airlinesmall.csv');
ds.TreatAsMissing = 'NA';
ds.SelectedVariableNames = {'DayOfWeek','UniqueCarrier',...
    'ArrDelay','DepDelay','Distance'};
ds.SelectedFormats{2} = '%C';
tt = tall(ds);
tt.DayOfWeek = categorical(tt.DayOfWeek,1:7,...
    {'Sun','Mon','Tues','Wed','Thu','Fri','Sat'},'Ordinal',true)
```

```
tt =
```

```
Mx5 tall table
```

DayOfWeek	UniqueCarrier	ArrDelay	DepDelay	Distance
?	?	?	?	?
?	?	?	?	?
?	?	?	?	?
:	:	:	:	:
:	:	:	:	:

Late Flights

Determine the flights that are late by 20 minutes or more by defining a logical variable that is true for a late flight. Add this variable to the tall table of data, noting that it is not yet evaluated. A preview of this variable includes the first few rows.

```
tt.LateFlight = tt.ArrDelay>=20
```

```
tt =
```

```
Mx6 tall table
```

DayOfWeek	UniqueCarrier	ArrDelay	DepDelay	Distance	LateFlight
-----------	---------------	----------	----------	----------	------------

```

?      ?      ?      ?      ?      ?
?      ?      ?      ?      ?      ?
?      ?      ?      ?      ?      ?
:      :      :      :      :      :
:      :      :      :      :      :

```

Calculate the mean of `LateFlight` to determine the overall proportion of late flights. Use `gather` to trigger evaluation of the tall array and bring the result into memory.

```
m = mean(tt.LateFlight)
```

```
m =
```

```
tall double
```

```
?
```

```
m = gather(m)
```

```
Evaluating tall expression using the Local MATLAB Session:
```

```
- Pass 1 of 2: Completed in 1.9 sec
```

```
- Pass 2 of 2: Completed in 2.1 sec
```

```
Evaluation completed in 5.4 sec
```

```
m = 0.1580
```

Late Flights by Carrier

Examine whether certain types of flights tend to be late. First, check to see if certain carriers are more likely to have late flights.

```
tt.LateFlight = double(tt.LateFlight);
```

```
late_by_carrier = gather(grpstats(tt, 'UniqueCarrier', 'mean', 'DataVar', 'LateFlight'))
```

```
Evaluating tall expression using the Local MATLAB Session:
```

```
- Pass 1 of 1: Completed in 4.5 sec
```

```
Evaluation completed in 5.8 sec
```

```
late_by_carrier=29x4 table
```

    :

```

Carriers B6 and EV have higher proportions of late flights. Carriers AQ, ML (1), and HA have relatively few flights, but lower proportions of them are late.

Late Flights by Day of Week

Next, check to see if different days of the week tend to have later flights.

```
late_by_day = gather(grpstats(tt, 'DayOfWeek', 'mean', 'DataVar', 'LateFlight'))
```

Evaluating tall expression using the Local MATLAB Session:
 - Pass 1 of 1: Completed in 1.8 sec
 Evaluation completed in 2.2 sec

```
late_by_day=7x4 table
   GroupLabel   DayOfWeek   GroupCount   mean_LateFlight
   _____   _____   _____   _____
   {'Fri' }     Fri           15839         0.12899
   {'Mon' }     Mon           18077         0.14234
   {'Sat' }     Sat           16958         0.15603
   {'Sun' }     Sun           18019         0.15117
   {'Thu' }     Thu           18227         0.18418
   {'Tues' }    Tues           18163         0.15526
   {'Wed' }     Wed           18240         0.18399
```

Wednesdays and Thursdays have the highest proportion of late flights, while Fridays have the lowest proportion.

Late Flights by Distance

Check to see if longer or shorter flights tend to be late. First, look at the density of the flight distance for flights that are late, and compare that with flights that are on time.

```
ksdensity(tt.Distance(tt.LateFlight==1))
```

Evaluating tall expression using the Local MATLAB Session:
 - Pass 1 of 2: Completed in 2.2 sec
 - Pass 2 of 2: Completed in 1.8 sec
 Evaluation completed in 4.8 sec

```
hold on
ksdensity(tt.Distance(tt.LateFlight==0))
```

Evaluating tall expression using the Local MATLAB Session:
 - Pass 1 of 2: Completed in 1.4 sec
 - Pass 2 of 2: Completed in 3.1 sec
 Evaluation completed in 5 sec

```
hold off
legend('Late', 'On time')
```

Flight distance does not make a dramatic difference in whether a flight is early or late. However, the density appears to be slightly higher for on-time flights at distances of about 400 miles. The density is also higher for late flights at distances of about 2000 miles. Calculate some simple descriptive statistics for the late and on-time flights.

```
late_by_distance = gather(grpstats(tt, 'LateFlight', {'mean' 'std'}, 'DataVar', 'Distance'))
```

Evaluating tall expression using the Local MATLAB Session:

- Pass 1 of 1: Completed in 2.9 sec

Evaluation completed in 3.7 sec

```
late_by_distance=2x5 table
```

GroupLabel	LateFlight	GroupCount	mean_Distance	std_Distance
{'0'}	0	1.04e+05	693.14	544.75
{'1'}	1	19519	750.24	574.12

Late flights are about 60 miles longer on average, although this value makes up only a small portion of the standard deviation of the distance values.

Logistic Regression Model

Build a model for the probability of a late flight, using both continuous variables (such as `Distance`) and categorical variables (such as `DayOfWeek`) to predict the probabilities. This model can help to determine if the previous results observed for each predictor individually also hold true when you consider them together.

```
glm = fitglm(tt, 'LateFlight~Distance+DayOfWeek', 'Distribution', 'binomial')
```

```
Iteration [1]:      0% completed
Iteration [1]:     100% completed
Iteration [2]:      0% completed
Iteration [2]:     100% completed
Iteration [3]:      0% completed
Iteration [3]:     100% completed
Iteration [4]:      0% completed
Iteration [4]:     100% completed
Iteration [5]:      0% completed
Iteration [5]:     100% completed
```

```
glm =
Compact generalized linear regression model:
  logit(LateFlight) ~ 1 + DayOfWeek + Distance
  Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-1.855	0.023052	-80.469	0
DayOfWeek_Mon	-0.072603	0.029798	-2.4365	0.01483
DayOfWeek_Tues	0.026909	0.029239	0.92029	0.35742
DayOfWeek_Wed	0.2359	0.028276	8.343	7.2452e-17
DayOfWeek_Thu	0.23569	0.028282	8.3338	7.8286e-17
DayOfWeek_Fri	-0.19285	0.031583	-6.106	1.0213e-09
DayOfWeek_Sat	0.033542	0.029702	1.1293	0.25879
Distance	0.00018373	1.3507e-05	13.602	3.8741e-42

```
123319 observations, 123311 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 504, p-value = 8.74e-105
```

The model confirms that the previously observed conclusions hold true here as well:

- The Wednesday and Thursday coefficients are positive, indicating a higher probability of a late flight on those days. The Friday coefficient is negative, indicating a lower probability.
- The Distance coefficient is positive, indicating that longer flights have a higher probability of being late.

All of these coefficients have very small p-values. This is common with data sets that have many observations, since one can reliably estimate small effects with large amounts of data. In fact, the uncertainty in the model is larger than the uncertainty in the estimates for the parameters in the model.

Prediction with Model

Predict the probability of a late flight for each day of the week, and for distances ranging from 0 to 3000 miles. Create a table to hold the predictor values by indexing the first 100 rows in the original table `tt`.

```
x = gather(tt(1:100, {'Distance' 'DayOfWeek'}));
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 0.54 sec
Evaluation completed in 0.96 sec
```

```
x.Distance = linspace(0,3000)';
x.DayOfWeek(:) = 'Sun';
plot(x.Distance,predict(glm,x));

days = {'Sun' 'Mon' 'Tues' 'Wed' 'Thu' 'Fri' 'Sat'};
hold on
for j=2:length(days)
    x.DayOfWeek(:) = days{j};
    plot(x.Distance,predict(glm,x));
end
legend(days)
```

According to this model, a Wednesday or Thursday flight of 500 miles has the same probability of being late, about 18%, as a Friday flight of about 3000 miles.

Since these probabilities are all much less than 50%, the model is unlikely to predict that any given flight will be late using this information. Investigate the model more by focusing on the flights for which the model predicts a probability of 20% or more of being late, and compare that to the actual results.

```
C = gather(crosstab(tt.LateFlight,predict(glm,tt)>.20))
```

Evaluating tall expression using the Local MATLAB Session:

- Pass 1 of 1: Completed in 2.3 sec

Evaluation completed in 2.6 sec

C = 2×2

99613	4391
18394	1125

Among the flights predicted to have a 20% or higher probability of being late, about 20% were late $1125/(1125 + 4391)$. Among the remainder, less than 16% were late $18394/(18394 + 99613)$.

Bayesian Optimization with Tall Arrays

This example shows how to use Bayesian optimization to select optimal parameters for training a kernel classifier by using the 'OptimizeHyperparameters' name-value pair argument. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data and uses the tall table to run the optimization procedure.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Get Data into MATLAB®

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. For folders that contain a collection of files, you can specify the entire folder location, or use the wildcard character, `'*.csv'`, to include multiple files with the same file extension in the datastore. Select a subset of the variables to work with, and treat 'NA' values as missing data so that datastore replaces them with NaN values. Create a tall table that contains the data in the datastore.

```
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month','DayofMonth','DayOfWeek',...
                           'DepTime','ArrDelay','Distance','DepDelay'};
ds.TreatAsMissing = 'NA';
tt = tall(ds) % Tall table
```

tt =

M×7 tall table

Month	DayofMonth	DayOfWeek	DepTime	ArrDelay	Distance	DepDelay

1
0
0
:
:
```

Create a tall array for the predictor data.

```
X = tt{:,1:end-1} % Predictor data
```

```
X =
```

```
M×6 tall double matrix
```

```
10      21      3      642      8      308
10      26      1     1021      8      296
10      23      5     2055     21     480
10      23      5     1332     13     296
10      22      4      629      4     373
10      28      3     1446     59     308
10       8      4      928      3     447
10      10      6      859     11     954
:       :       :       :       :       :
:       :       :       :       :       :
```

Remove rows in X and Y that contain missing data.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:end-1);
Y = R(:,end);
```

Perform Bayesian Optimization Using `OptimizeHyperparameters`

Optimize hyperparameters automatically using the `'OptimizeHyperparameters'` name-value pair argument.

Standardize the predictor variables.

```
Z = zscore(X);
```

Find the optimal values for the `'KernelScale'` and `'Lambda'` name-value pair arguments that minimize five-fold cross-validation loss. For reproducibility, use the `'expected-improvement-plus'` acquisition function and set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```
rng('default')
tallrng('default')
Mdl = fitckernel(Z,Y,'Verbose',0,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-p
```

Properties, Methods

Perform Bayesian Optimization by Using `bayesopt`

Alternatively, you can use the `bayesopt` function to find the optimal values of hyperparameters.

Split the data set into training and test sets. Specify a 1/3 holdout sample for the test set.

```
rng('default') % For reproducibility
tallrng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',1/3);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Extract training and testing data and standardize the predictor data.

```
Ytrain = Y(trainingInds); % Training class labels
Xtrain = X(trainingInds,:);
[Ztrain,mu,stddev] = zscore(Xtrain); % Standardized training data

Ytest = Y(testInds); % Testing class labels
Xtest = X(testInds,:);
Ztest = (Xtest-mu)./stddev; % Standardized test data
```

Define the variables `sigma` and `lambda` to find the optimal values for the 'KernelScale' and 'Lambda' name-value pair arguments. Use `optimizableVariable` and specify a wide range for the variables because optimal values are unknown. Apply logarithmic transformation to the variables to search for the optimal values on a log scale.

```
N = gather(numel(Ytrain)); % Evaluate the length of the tall training array in memory
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 0.86 sec
Evaluation completed in 1 sec
```

```
sigma = optimizableVariable('sigma',[1e-3,1e3],'Transform','log');
lambda = optimizableVariable('lambda',[(1e-3)/N, (1e3)/N],'Transform','log');
```

Create the objective function for Bayesian optimization. The objective function takes in a table that contains the variables `sigma` and `lambda`, and then computes the classification loss value for the binary Gaussian kernel classification model trained using the `fitckernel` function. Set `'Verbose',0` within `fitckernel` to suppress the iterative display of diagnostic information.

```
minfn = @(z)gather(loss(fitckernel(Ztrain,Ytrain, ...
    'KernelScale',z.sigma,'Lambda',z.lambda,'Verbose',0), ...
    Ztest,Ytest));
```

Optimize the parameters [`sigma`, `lambda`] of the kernel classification model with respect to the classification loss by using `bayesopt`. By default, `bayesopt` displays iterative information about the optimization at the command line. For reproducibility, set the `AcquisitionFunctionName` option to `'expected-improvement-plus'`. The default acquisition function depends on run time and, therefore, can give varying results.

```
results = bayesopt(minfn,[sigma,lambda],'AcquisitionFunctionName','expected-improvement-plus')
```

        UserDataTrace: {30x1 cell}
ObjectiveEvaluationTimeTrace: [30x1 double]
        IterationTimeTrace: [30x1 double]
        ErrorTrace: [30x1 double]
        FeasibilityTrace: [30x1 logical]
    FeasibilityProbabilityTrace: [30x1 double]
        IndexOfMinimumTrace: [30x1 double]
        ObjectiveMinimumTrace: [30x1 double]
    EstimatedObjectiveMinimumTrace: [30x1 double]

```

Return the best feasible point in the Bayesian model results by using the `bestPoint` function. Use the default criterion `min-visited-upper-confidence-interval`, which determines the best feasible point as the visited point that minimizes an upper confidence interval on the objective function value.

```
zbest = bestPoint(results)
```

```
zbest=1x2 table
    sigma      lambda
    -----
    3.6538     3.4072e-07
```

The table `zbest` contains the optimal estimated values for the `'KernelScale'` and `'Lambda'` name-value pair arguments. You can specify these values when training a new optimized kernel classifier by using

```
Mdl = fitckernel(Ztrain,Ytrain,'KernelScale',zbest.sigma,'Lambda',zbest.lambda)
```

For tall arrays, the optimization procedure can take a long time. If the data set is too large to run the optimization procedure, you can try to optimize the parameters by using only partial data. Use the `datasample` function and specify `'Replace','false'` to sample data without replacement.

Quick Start Parallel Computing for Statistics and Machine Learning Toolbox

Note To use parallel computing as described in this chapter, you must have a Parallel Computing Toolbox license.

In this section...

“What Is Parallel Statistics Functionality?” on page 30-2

“How To Compute in Parallel” on page 30-4

What Is Parallel Statistics Functionality?

You can use any of the Statistics and Machine Learning Toolbox functions with Parallel Computing Toolbox constructs such as `parfor` and `spmd`. However, some functions, such as those with interactive displays, can lose functionality in parallel. In particular, displays and interactive usage are not effective on workers (see “Vocabulary for Parallel Computation” on page 30-8).

Additionally, the following functions are enhanced to use parallel computing internally. These functions use `parfor` internally to parallelize calculations.

- `bayesopt`
- `bootci`
- `bootstrp`
- `candexch`
- `compare` of `LinearMixedModel`
- `cordexch`
- `crossval`
- `daugment`
- `dcovary`
- `jackknife`
- `kmeans`
- `kmedoids`
- `lasso`
- `lassoglm`
- `nnmf`
- `oobPermutedPredictorImportance` of `ClassificationBaggedEnsemble`
- `oobPermutedPredictorImportance` of `RegressionBaggedEnsemble`
- `perfcurve`
- `plotPartialDependence`
- `plsregress`
- `rowexch`

- `sequentialfs`
- `testckfold`
- `TreeBagger`
- `growTrees` of `TreeBagger`

The following functions for fitting multiclass models for support vector machines and other classifiers are also enhanced to use parallel computing internally.

- `fitcecoc`
- Methods of the class `ClassificationECOC`:
 - `resubEdge`
 - `resubLoss`
 - `resubMargin`
 - `resubPredict`
 - `crossval`
- Methods of the class `CompactClassificationECOC`
 - `edge`
 - `loss`
 - `margin`
 - `predict`
- Methods of the class `ClassificationPartitionedECOC`
 - `kfoldEdge`
 - `kfoldLoss`
 - `kfoldMargin`
 - `kfoldPredict`
- Methods of the class `ClassificationPartitionedLinearECOC`
 - `kfoldEdge`
 - `kfoldLoss`
 - `kfoldMargin`
 - `kfoldPredict`

The following functions perform hyperparameter optimization in parallel.

- `fitcdiscr`
- `fitcecoc`
- `fitctree`
- `fitclinear`
- `fitcknn`
- `fitrgp`
- `fitrtree`
- `fitcensemble`

- `fitcnb`
- `fitcsvm`
- `fitrensemble`
- `fitrlinear`
- `fitrsvm`
- `fitrkernel`
- `fitckernel`

This chapter gives the simplest way to use these enhanced functions in parallel. For more advanced topics, including the issues of reproducibility and nested `parfor` loops, see the other sections in this chapter.

For information on parallel statistical computing at the command line, enter

```
help parallelstats
```

How To Compute in Parallel

To have a function compute in parallel:

1. “Set Up a Parallel Environment” on page 30-4
2. “Set the UseParallel Option to true” on page 30-4
3. “Call the Function Using the Options Structure” on page 30-4

Set Up a Parallel Environment

To run a statistical computation in parallel, first set up a parallel environment.

Note Setting up a parallel environment can take several seconds.

For a multicore machine, enter the following at the MATLAB command line:

```
parpool(n)
```

n is the number of workers you want to use.

Set the UseParallel Option to true

Create an options structure with the `statset` function. To run in parallel, set the `UseParallel` option to `true`:

```
paroptions = statset('UseParallel',true);
```

Call the Function Using the Options Structure

Call your function with syntax that uses the options structure. For example:

```
% Run crossval in parallel  
cvMse = crossval('mse',x,y,'predfun',regf,'Options',paroptions);
```

```
% Run bootstrp in parallel
```

```
sts = bootstrp(100,@(x)[mean(x) std(x)],y,'Options',paroptions);
```

```
% Run TreeBagger in parallel
```

```
b = TreeBagger(50,meas,spec,'OOBPred','on','Options',paroptions);
```

For more complete examples of parallel statistical functions, see “Use Parallel Processing for Regression TreeBagger Workflow” on page 30-6, “Implement Jackknife Using Parallel Computing” on page 30-17, “Implement Cross-Validation Using Parallel Computing” on page 30-18, and “Implement Bootstrap Using Parallel Computing” on page 30-20.

After you have finished computing in parallel, close the parallel environment:

```
delete mypool
```

Tip To save time, keep the pool open if you expect to compute in parallel again soon.

Use Parallel Processing for Regression TreeBagger Workflow

This example shows you how to:

- Use an ensemble of bagged regression trees to estimate feature importance.
- Improve computation speed by using parallel computing.

The sample data is a database of 1985 car imports with 205 observations, 25 predictors, and 1 response, which is insurance risk rating, or "symboling." The first 15 variables are numeric and the last 10 are categorical. The symboling index takes integer values from -3 to 3.

Load the sample data and separate it into predictor and response arrays.

```
load imports-85;
Y = X(:,1);
X = X(:,2:end);
```

Set up the parallel environment to use two cores.

```
mypool = parpool(2)
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 2).
```

```
mypool =
```

```
LocalProcessesPool with properties:
```

```
    Connected: true
    NumWorkers: 2
    Cluster: local
    AttachedFiles: {}
    AutoAddClientPath: true
    IdleTimeout: 30 minutes (30 minutes remaining)
    SpmdEnabled: true
```

Set the options to use parallel processing.

```
paroptions = statset('UseParallel',true);
```

Estimate feature importance using leaf size 1 and 5000 trees in parallel. Time the function for comparison purposes.

```
tic
b = TreeBagger(5000,X,Y,'Method','r','OOBVarImp','on', ...
    'cat',16:25,'MinLeafSize',1,'Options',paroptions);
toc
```

```
Elapsed time is 30.297706 seconds.
```

Perform the same computation in serial for timing comparison.

```
tic
b = TreeBagger(5000,X,Y,'Method','r','OOBVarImp','on', ...
    'cat',16:25,'MinLeafSize',1);
toc
```

```
Elapsed time is 32.935544 seconds.
```

The results show that computing in parallel takes a fraction of the time it takes to compute serially. Note that the elapsed time can vary depending on your operating system.

Concepts of Parallel Computing in Statistics and Machine Learning Toolbox

In this section...
“Subtleties in Parallel Computing” on page 30-8
“Vocabulary for Parallel Computation” on page 30-8

Subtleties in Parallel Computing

There are two main subtleties in parallel computations:

- Nested parallel evaluations (see “No Nested `parfor` Loops” on page 30-11). Only the outermost `parfor` loop runs in parallel, the others run serially.
- Reproducible results when using random numbers (see “Reproducibility in Parallel Statistical Computations” on page 30-13). How can you get exactly the same results when repeatedly running a parallel computation that uses random numbers?

Vocabulary for Parallel Computation

- `worker` — An independent MATLAB session that runs code distributed by the client.
- `client` — The MATLAB session with which you interact, and that distributes jobs to workers.
- `parfor` — A Parallel Computing Toolbox function that distributes independent code segments to workers (see “Working with `parfor`” on page 30-11).
- `random stream` — A pseudorandom number generator, and the sequence of values it generates. MATLAB implements random streams with the `RandStream` class.
- `reproducible computation` — A computation that can be exactly replicated, even in the presence of random numbers (see “Reproducibility in Parallel Statistical Computations” on page 30-13).

When to Run Statistical Functions in Parallel

In this section...
“Why Run in Parallel?” on page 30-9
“Factors Affecting Speed” on page 30-9
“Factors Affecting Results” on page 30-9

Why Run in Parallel?

The main reason to run statistical computations in parallel is to gain speed, meaning to reduce the execution time of your program or functions. “Factors Affecting Speed” on page 30-9 discusses the main items affecting the speed of programs or functions. “Factors Affecting Results” on page 30-9 discusses details that can cause a parallel run to give different results than a serial run.

Note Some Statistics and Machine Learning Toolbox functions have built-in parallel computing capabilities. See Quick Start Parallel Computing for Statistics and Machine Learning Toolbox on page 30-2. You can also use any Statistics and Machine Learning Toolbox functions with Parallel Computing Toolbox functions such as `parfor` loops. To decide when to call functions in parallel, consider the factors affecting speed and results.

Factors Affecting Speed

Some factors that can affect the speed of execution of parallel processing are:

- Parallel environment setup. It takes time to run `parpool` to begin computing in parallel. If your computation is fast, the setup time can exceed any time saved by computing in parallel.
- Parallel overhead. There is overhead in communication and coordination when running in parallel. If function evaluations are fast, this overhead could be an appreciable part of the total computation time. Thus, solving a problem in parallel can be slower than solving the problem serially. For an example, see Improving Optimization Performance with Parallel Computing in MATLAB Digest, March 2009.
- No nested `parfor` loops. This is described in “Working with `parfor`” on page 30-11. `parfor` does not work in parallel when called from within another `parfor` loop. If you have programmed your custom functions to take advantage of parallel processing, the limitation of no nested `parfor` loops can cause a parallel function to run slower than expected.
- When executing serially, `parfor` loops run slightly slower than `for` loops.
- Passing parameters. Parameters are automatically passed to worker sessions during the execution of parallel computations. If there are many parameters, or they take a large amount of memory, passing parameters can slow the execution of your computation.
- Contention for resources: network and computing. If the pool of workers has low bandwidth or high latency, parallel computation can be slow.

Factors Affecting Results

Some factors can affect results when using parallel processing. You might need to adjust your code to run in parallel, for example, you need independent loops and the workers must be able to access the variables. Some important factors are:

- Persistent or global variables. If any functions use persistent or global variables, these variables can take different values on different worker processors. The body of a `parfor` loop cannot contain global or persistent variable declarations.
- Accessing external files. The order of computations is not guaranteed during parallel processing, so external files can be accessed in unpredictable order, leading to unpredictable results. Furthermore, if multiple processors try to read an external file simultaneously, the file can become locked, leading to a read error, and halting function execution.
- Noncomputational functions, such as `input`, `plot`, and `keyboard`, can behave badly when used in your custom functions. Do not use these functions in a `parfor` loop, because they can cause a worker to become nonresponsive, since it is waiting for input.
- `parfor` does not allow `break` or `return` statements.
- The random numbers you use can affect the results of your computations. See “Reproducibility in Parallel Statistical Computations” on page 30-13.

For advice on converting for loops to use `parfor`, see “Parallel for-Loops (`parfor`)” (Parallel Computing Toolbox).

Working with parfor

In this section...

“How Statistical Functions Use parfor” on page 30-11

“Characteristics of parfor” on page 30-11

How Statistical Functions Use parfor

parfor is a Parallel Computing Toolbox function similar to a for loop. Parallel statistical functions call parfor internally. parfor distributes computations to worker processors.

Characteristics of parfor

You might need to adjust your code to run in parallel, for example, you need independent loops and the workers must be able to access the variables. For advice on using `parfor`, see “Parallel for-Loops (`parfor`)” (Parallel Computing Toolbox).

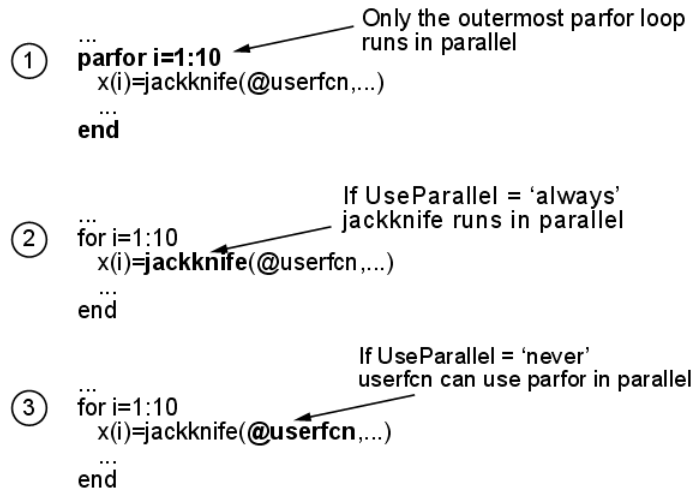

No Nested parfor Loops

`parfor` does not work in parallel when called from within another `parfor` loop, or from an `spmd` block. Parallelization occurs only at the outermost level.

Suppose, for example, you want to apply `jackknife` to your function `userfcn`, which calls `parfor`, and you want to call `jackknife` in a loop. The following figure shows three cases:

- 1 The outermost loop is `parfor`. Only that loop runs in parallel.
- 2 The outermost `parfor` loop is in `jackknife`. Only `jackknife` runs in parallel.
- 3 The outermost `parfor` loop is in `userfcn`. `userfcn` uses `parfor` in parallel.

Bold indicates the function that runs in parallel

When parfor Runs in Parallel

For help converting nested loops to use `parfor`, see “Convert for-Loops Into `parfor`-Loops” (Parallel Computing Toolbox).

See also Quick Start Parallel Computing for Statistics and Machine Learning Toolbox on page 30-2.

Reproducibility in Parallel Statistical Computations

In this section...

“Issues and Considerations in Reproducing Parallel Computations” on page 30-13

“Running Reproducible Parallel Computations” on page 30-13

“Parallel Statistical Computation Using Random Numbers” on page 30-14

Issues and Considerations in Reproducing Parallel Computations

A reproducible computation is one that gives the same results every time it runs. Reproducibility is important for:

- **Debugging** — To correct an anomalous result, you need to reproduce the result.
- **Confidence** — When you can reproduce results, you can investigate and understand them.
- **Modifying existing code** — When you change existing code, you want to ensure that you do not break anything.

Generally, you do not need to ensure reproducibility for your computation. Often, when you want reproducibility, the simplest technique is to run in serial instead of in parallel. In serial computation you can simply call the `rng` function as follows:

```
s = rng % Obtain the current state of the random stream
% run the statistical function
rng(s) % Reset the stream to the previous state
% run the statistical function again, obtain identical results
```

This section addresses the case when your function uses random numbers, and you want reproducible results in parallel. This section also addresses the case when you want the same results in parallel as in serial.

Running Reproducible Parallel Computations

To run a Statistics and Machine Learning Toolbox function reproducibly:

- 1 Set the `UseSubstreams` option to `true`.
- 2 Set the `Streams` option to a type that supports substreams: `'mlfg6331_64'` or `'mrg32k3a'`. For information on these streams, see “Choosing a Random Number Generator” (MATLAB).
- 3 To compute in parallel, set the `UseParallel` option to `true`.
- 4 Call the function with the options structure.
- 5 To reproduce the computation, reset the stream, then call the function again.

To understand why this technique gives reproducibility, see “How Substreams Enable Reproducible Parallel Computations” on page 30-14.

For example, to use the `'mlfg6331_64'` stream for reproducible computation:

- 1 Create an appropriate options structure:

```
s = RandStream('mlfg6331_64');
options = statset('UseParallel',true, ...
    'Streams',s,'UseSubstreams',true);
```

- 2 Run your parallel computation. For instructions, see Quick Start Parallel Computing for Statistics and Machine Learning Toolbox on page 30-2.
- 3 Reset the random stream:

```
reset(s);
```

- 4 Rerun your parallel computation. You obtain identical results.

For an example of a parallel computation run this reproducible way, see “Reproducible Parallel Bootstrap” on page 30-21.

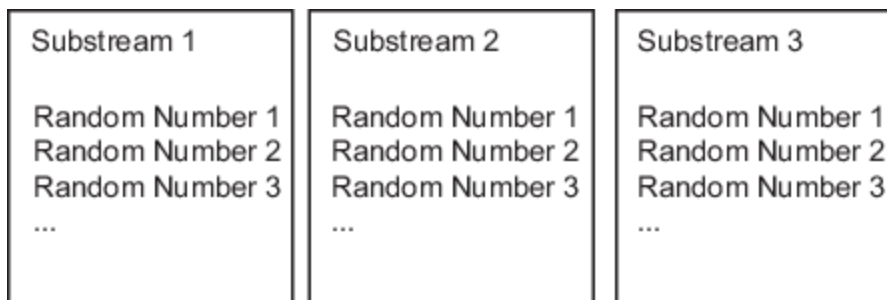

Parallel Statistical Computation Using Random Numbers

What Are Substreams?

A substream is a portion of a random stream that `RandStream` can access quickly. There is a number M such that for any positive integer k , `RandStream` can go to the kM th pseudorandom number in the stream. From that point, `RandStream` can generate the subsequent entries in the stream. Currently, `RandStream` has $M = 2^{72}$, about $5e21$, or more.

The entries in different substreams have good statistical properties, similar to the properties of entries in a single stream: independence, and lack of k -way correlation at various lags. The substreams are so long that you can view the substreams as being independent streams, as in the following picture.

Two `RandStream` stream types support substreams: `'mlfg6331_64'` and `'mrg32k3a'`.

How Substreams Enable Reproducible Parallel Computations

When MATLAB performs computations in parallel with `parfor`, each worker receives loop iterations in an unpredictable order. Therefore, you cannot predict which worker gets which iteration, so cannot determine the random numbers associated with each iteration.

Substreams allow MATLAB to tie each iteration to a particular sequence of random numbers. `parfor` gives each iteration an index. The iteration uses the index as the substream number. Since the random numbers are associated with the iterations, not with the workers, the entire computation is reproducible.

To obtain reproducible results, simply reset the stream, and all the substreams generate identical random numbers when called again. This method succeeds when all the workers use the same stream, and the stream supports substreams. This concludes the discussion of how the procedure in “Running Reproducible Parallel Computations” on page 30-13 gives reproducible parallel results.

Random Numbers on the Client or Workers

A few functions generate random numbers on the client before distributing them to parallel workers. The workers do not use random numbers, so operate purely deterministically. For these functions, you can run a parallel computation reproducibly using any random stream type.

The functions that operate this way include:

- `crossval`
- `plsregress`
- `sequentialfs`

To obtain identical results, reset the random stream on the client, or the random stream you pass to the client. For example:

```
s = rng % Obtain the current state of the random stream
% run the statistical function
rng(s) % Reset the stream to the previous state
% run the statistical function again, obtain identical results
```

While this method enables you to run reproducibly in parallel, the results can differ from a serial computation. The reason for the difference is `parfor` loops run in reverse order from `for` loops. Therefore, a serial computation can generate random numbers in a different order than a parallel computation. For unequivocal reproducibility, use the technique in “Running Reproducible Parallel Computations” on page 30-13.

Distributing Streams Explicitly

For testing or comparison using particular random number algorithms, you must set the random number generators. How do you set these generators in parallel, or initialize streams on each worker in a particular way? Or you might want to run a computation using a different sequence of random numbers than any other you have run. How can you ensure the sequence you use is statistically independent?

Parallel Statistics and Machine Learning Toolbox functions allow you to set random streams on each worker explicitly. For information on *creating* multiple streams, enter `help RandStream/create` at the command line. To create four independent streams using the 'mrg32k3a' generator:

```
s = RandStream.create('mrg32k3a', 'NumStreams', 4, ...
    'CellOutput', true);
```

Pass these streams to a statistical function using the `Streams` option. For example:

```
parpool(4) % if you have at least 4 cores
s = RandStream.create('mrg32k3a', 'NumStreams', 4, ...
    'CellOutput', true); % create 4 independent streams
paroptions = statset('UseParallel', true, ...
    'Streams', s); % set the 4 different streams
x = [randn(700,1); 4 + 2*randn(300,1)];
latt = -4:0.01:12;
```

```
myfun = @(X) ksdensity(X,latt);  
pdfestimate = myfun(x);  
B = bootstrp(200,myfun,x,'Options',paroptions);
```

This method of distributing streams gives each worker a different stream for the computation. However, it does not allow for a reproducible computation, because the workers perform the 200 bootstraps in an unpredictable order. If you want to perform a reproducible computation, use substreams as described in “Running Reproducible Parallel Computations” on page 30-13.

If you set the `UseSubstreams` option to `true`, then set the `Streams` option to a single random stream of the type that supports substreams (`'mlfg6331_64'` or `'mrg32k3a'`). This setting gives reproducible computations.

Implement Jackknife Using Parallel Computing

This example is from the `jackknife` function reference page, but runs in parallel.

Generate a sample data of size 10000 from a normal distribution with mean 0 and standard deviation 5.

```
sigma = 5;
rng('default')
y = normrnd(0,sigma,10000,1);
```

Run `jackknife` in parallel to estimate the variance. To do this, use `statset` to create the options structure and set the `UseParallel` field to true.

```
opts = statset('UseParallel',true);
m = jackknife(@var,y,1,'Options',opts);
```

Compare the known bias formula with the jackknife bias estimate.

```
n = length(y);
bias = -sigma^2/n % Known bias formula
jbias = (n-1)*(mean(m)-var(y,1)) % jackknife bias estimate
```

Starting parallel pool (parpool) using the 'local' profile ...

Connected to the parallel pool (number of workers: 6).

```
bias =
    -0.0025
```

```
jbias =
    -0.0025
```

Compare how long it takes to compute in serial and in parallel.

```
tic;m = jackknife(@var,y,1);toc % Serial computation
```

Elapsed time is 1.638026 seconds.

```
tic;m = jackknife(@var,y,1,'Options',opts);toc % Parallel computation
```

Elapsed time is 0.507961 seconds.

`jackknife` does not use random numbers, so gives the same results every time, whether run in parallel or serial.

Implement Cross-Validation Using Parallel Computing

In this section...

“Simple Parallel Cross Validation” on page 30-18

“Reproducible Parallel Cross Validation” on page 30-18

Simple Parallel Cross Validation

In this example, use `crossval` to compute a cross-validation estimate of mean-squared error for a regression model. Run the computations in parallel.

```
mypool = parpool()
Starting parpool using the 'local' profile ... connected to 2 workers.
```

```
mypool =
```

```
Pool with properties:
```

```
AttachedFiles: {0x1 cell}
NumWorkers: 2
IdleTimeout: 30
Cluster: [1x1 parallel.cluster.Local]
RequestQueue: [1x1 parallel.RequestQueue]
SpmEnabled: 1
```

```
opts = statset('UseParallel',true);

load('fisheriris');
y = meas(:,1);
X = [ones(size(y,1),1),meas(:,2:4)];
regf=@(XTRAIN,ytrain,XTEST)(XTEST*regress(ytrain,XTRAIN));

cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)

cvMse =

    0.1028
```

This simple example is not a good candidate for parallel computation:

```
% How long to compute in serial?
tic;cvMse = crossval('mse',X,y,'Predfun',regf);toc
Elapsed time is 0.073438 seconds.

% How long to compute in parallel?
tic;cvMse = crossval('mse',X,y,'Predfun',regf,...
'Options',opts);toc
Elapsed time is 0.289585 seconds.
```

Reproducible Parallel Cross Validation

To run `crossval` in parallel in a reproducible fashion, set the options and reset the random stream appropriately (see “Running Reproducible Parallel Computations” on page 30-13).

```
mypool = parpool()

Starting parpool using the 'local' profile ... connected to 2 workers.

mypool =

  Pool with properties:

    AttachedFiles: {0x1 cell}
    NumWorkers: 2
    IdleTimeout: 30
    Cluster: [1x1 parallel.cluster.Local]
    RequestQueue: [1x1 parallel.RequestQueue]
    SpmEnabled: 1

s = RandStream('mlfg6331_64');
opts = statset('UseParallel',true,...
    'Streams',s,'UseSubstreams',true);

load('fisheriris');
y = meas(:,1);
X = [ones(size(y,1),1),meas(:,2:4)];
regf=@(XTRAIN,ytrain,XTEST)(XTEST*regress(ytrain,XTRAIN));

cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)

cvMse =

    0.1020

Reset the stream:

reset(s)
cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)

cvMse =

    0.1020
```

Implement Bootstrap Using Parallel Computing

In this section...

“Bootstrap in Serial and Parallel” on page 30-20

“Reproducible Parallel Bootstrap” on page 30-21

Bootstrap in Serial and Parallel

Here is an example timing a bootstrap in parallel versus in serial. The example generates data from a mixture of two Gaussians, constructs a nonparametric estimate of the resulting data, and uses a bootstrap to get a sense of the sampling variability.

- 1 Generate the data:

```
% Generate a random sample of size 1000,
% from a mixture of two Gaussian distributions
x = [randn(700,1); 4 + 2*randn(300,1)];
```

- 2 Construct a nonparametric estimate of the density from the data:

```
latt = -4:0.01:12;
myfun = @(X) ksdensity(X,latt);
pdfestimate = myfun(x);
```

- 3 Bootstrap the estimate to get a sense of its sampling variability. Run the bootstrap in serial for timing comparison.

```
tic;B = bootstrp(200,myfun,x);toc
```

Elapsed time is 10.878654 seconds.

- 4 Run the bootstrap in parallel for timing comparison:

```
mypool = parpool()
Starting parpool using the 'local' profile ... connected to 2 workers.
```

```
mypool =
```

```
Pool with properties:
```

```
AttachedFiles: {0x1 cell}
  NumWorkers: 2
  IdleTimeout: 30
    Cluster: [1x1 parallel.cluster.Local]
  RequestQueue: [1x1 parallel.RequestQueue]
  SpmdEnabled: 1
```

```
opt = statset('UseParallel',true);
tic;B = bootstrp(200,myfun,x,'Options',opt);toc
```

Elapsed time is 6.304077 seconds.

Computing in parallel is nearly twice as fast as computing in serial for this example.

Overlay the `ksdensity` density estimate with the 200 bootstrapped estimates obtained in the parallel bootstrap. You can get a sense of how to assess the accuracy of the density estimate from this plot.

```

hold on
for i=1:size(B,1),
    plot(latt,B(i,:), 'c: ')
end
plot(latt,pdfestimate);
xlabel('x');ylabel('Density estimate')

```

Reproducible Parallel Bootstrap

To run the example in parallel in a reproducible fashion, set the options appropriately (see “Running Reproducible Parallel Computations” on page 30-13). First set up the problem and parallel environment as in “Bootstrap in Serial and Parallel” on page 30-20. Then set the options to use substreams along with a stream that supports substreams.

```

s = RandStream('mlfg6331_64'); % has substreams
opts = statset('UseParallel',true,...
    'Streams',s,'UseSubstreams',true);
B2 = bootstrp(200,myfun,x,'Options',opts);

```

To rerun the bootstrap and get the same result:

```

reset(s) % set the stream to initial state
B3 = bootstrp(200,myfun,x,'Options',opts);
isequal(B2,B3) % check if same results

```

ans =
1

Introduction to Code Generation

In this section...

“Code Generation Workflows” on page 31-2

“Code Generation Applications” on page 31-4

MATLAB Coder generates readable and portable C and C++ code from Statistics and Machine Learning Toolbox functions that support code generation. You can integrate the generated code into your projects as source code, static libraries, or dynamic libraries. You can also use the generated code within the MATLAB environment to accelerate computationally intensive portions of your MATLAB code.

Generating C/C++ code requires MATLAB Coder and has the following limitations:

- You cannot call any function at the top level when generating code by using `codegen`. Instead, call the function within an *entry-point* function, and then generate code from the entry-point function. The entry-point function, also known as the *top-level* or *primary* function, is a function you define for code generation. All functions within the entry-point function must support code generation.
- The MATLAB Coder limitations also apply to Statistics and Machine Learning Toolbox for code generation. For details, see “MATLAB Language Features Supported for C/C++ Code Generation” (MATLAB Coder).
- Code generation in Statistics and Machine Learning Toolbox does not support sparse matrices and categorical arrays. Code generation supports numeric tables for most prediction functions.
- For the code generation usage notes and limitations for each function, see the Code Generation section on the function reference page.

For a list of Statistics and Machine Learning Toolbox functions that support code generation, see Function List (C/C++ Code Generation).

Code Generation Workflows

You can generate C/C++ code for the Statistics and Machine Learning Toolbox functions in several ways.

- General code generation workflow for functions that are not the object functions of machine learning models

Define an *entry-point* function that calls the function that supports code generation, generate C/C++ code for the entry-point function by using `codegen`, and then verify the generated code. The entry-point function, also known as the *top-level* or *primary* function, is a function you define for code generation. Because you cannot call any function at the top level using `codegen`, you must define an entry-point function. All functions within the entry-point function must support code generation.

For details, see “General Code Generation Workflow” on page 31-5.

- Code generation workflow for the object function (`predict`, `random`, `knnsearch`, or `rangesearch`) of a machine learning model

Save a trained model by using `saveLearnerForCoder`, and define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the object function. Then generate code for the entry-point function by using `codegen`, and verify the generated code. The input arguments of the entry-point function cannot be classification or regression model objects. Therefore, you need to work around this limitation by using `saveLearnerForCoder` and `loadLearnerForCoder`.

For details, see these examples

- “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-9
- “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-16
- “Code Generation for Nearest Neighbor Searcher” on page 31-13
- “Code Generation and Classification Learner App” on page 31-25
- “Specify Variable-Size Arguments for Code Generation” on page 31-38

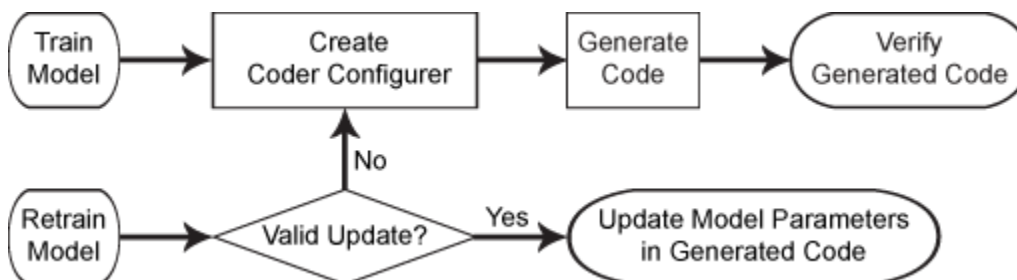

You can also generate fixed-point C/C++ code for the prediction of a support vector machine (SVM) model, a decision tree model, and an ensemble of decision trees for classification and regression. This type of code generation requires Fixed-Point Designer™.

Fixed-point code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using the data type function generated by `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. You can also optimize the fixed-point data types before generating code.

For details, see “Fixed-Point Code Generation for Prediction of SVM” on page 31-75.

- Code generation workflow for the `predict` and `update` functions of a tree model, an SVM model, a linear model, or a multiclass error-correcting output codes (ECOC) classification model using SVM or linear binary learners

Create a coder configurer by using `learnerCoderConfigurer`, generate code by using `generateCode`, and then verify the generated code. You can configure code generation options and specify the coder attributes of the model parameters using object properties. After you retrain

the model with new data or settings, you can update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code.

For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 31-68.

Code Generation Applications

Code generation for the Statistics and Machine Learning Toolbox functions also works with other toolboxes such as Simulink®, System object™, and Stateflow®, as described in these examples:

- “Predict Class Labels Using MATLAB Function Block” on page 31-34
- “System Objects for Classification and Code Generation” on page 31-47
- “Predict Class Labels Using Stateflow” on page 31-55

For more applications of code generation, see these examples:

- “Code Generation for Image Classification”
- “Human Activity Recognition Simulink Model for Smartphone Deployment” on page 31-59

General Code Generation Workflow

The general code generation workflow for the Statistics and Machine Learning Toolbox functions that are not the object functions of machine learning models is the same as the workflow described in MATLAB Coder. For details, see “Get Started with MATLAB Coder” (MATLAB Coder). To learn how to generate code for the object functions of machine learning models, see “Introduction to Code Generation” on page 31-2.

This example briefly explains the general code generation workflow as summarized in this flow chart:

Define Entry-Point Function

An *entry-point* function, also known as the *top-level* or *primary* function, is a function you define for code generation. Because you cannot call any function at the top level using `codegen`, you must define an entry-point function that calls code-generation-enabled functions, and generate C/C++ code for the entry-point function by using `codegen`. All functions within the entry-point function must support code generation.

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would cause errors during code generation. See “Check Code with the Code Analyzer” (MATLAB Coder).

For example, to generate code that estimates the interquartile range of a data set using `iqr`, define this function.

```

function r = iqrCodeGen(x) %#codegen
%IQRCODEGEN Estimate interquartile range
% iqrCodeGen returns the interquartile range of the data x,
% a single- or double-precision vector.
r = iqr(x);
end
  
```

You can allow for optional input arguments by specifying `varargin` as an input argument. For details, see “Code Generation for Variable Length Argument Lists” (MATLAB Coder) and “Specify Variable-Size Arguments for Code Generation” on page 31-38.

Generate Code

Set Up Compiler

To generate C/C++ code, you must have access to a compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. To view and change the default C compiler, enter:

```
mex -setup
```

For more details, see “Change Default Compiler” (MATLAB).

Generate Code Using `codegen`

After setting up your compiler, generate code for the entry-point function by using `codegen` or the MATLAB Coder app. To learn how to generate code using the MATLAB Coder app, see “Generate MEX Functions by Using the MATLAB Coder App” (MATLAB Coder).

To generate code at the command line, use `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Specify the data types and sizes of all inputs of the entry-point function when you call `codegen` by using the `-args` option.

- To specify the data type and exact input array size, pass a MATLAB expression that represents the set of values with a certain data type and array size. For example, to specify that the generated code from `iqrCodeGen.m` must accept a double-precision numeric column vector with 100 elements, enter:

```
testX = randn(100,1);
codegen iqrCodeGen -args {testX} -report
```

The `-report` flag generates a code generation report. See “Code Generation Reports” (MATLAB Coder).

- To specify that at least one of the dimensions can have any length, use the `-args` option with `coder.typeof` as follows.

```
-args {coder.typeof(example_value, size_vector, variable_dims)}
```

The values of `example_value`, `size_vector`, and `variable_dims` specify the properties of the input array that the generated code can accept.

- An input array has the same data type as the example values in `example_value`.
- `size_vector` is the array size of an input array if the corresponding `variable_dims` value is `false`.
- `size_vector` is the upper bound of the array size if the corresponding `variable_dims` value is `true`.
- `variable_dims` specifies whether each dimension of the array has a variable size or a fixed size. A value of `true` (logical 1) means that the corresponding dimension has a variable size; a value of `false` (logical 0) means that the corresponding dimension has a fixed size.

Specifying a variable-size input is convenient when you have data with an unknown number of observations at compile time. For example, to specify that the generated code from `iqrCodeGen.m` can accept a double-precision numeric column vector of any length, enter:

```
testX = coder.typeof(0,[Inf,1],[1,0]);
codegen iqrCodeGen -args {testX} -report
```

`0` for the `example_value` value implies that the data type is `double` because `double` is the default numeric data type of MATLAB. `[Inf,1]` for the `size_vector` value and `[1,0]` for the `variable_dims` value imply that the size of the first dimension is variable and unbounded, and the size of the second dimension is fixed to be 1.

- To specify a character array, such as supported name-value pair arguments, specify the character array as a constant using `coder.Constant`. For example, suppose that 'Name' is a valid name-value pair argument for `iqrCodeGen.m`, and the corresponding value `value` is numeric. Then enter:

```
codegen iqrCodeGen -args {testX,coder.Constant('Name'),value} -report
```

For more details, see “Generate C Code at the Command Line” (MATLAB Coder) and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

Build Type

MATLAB Coder can generate code for these types:

- MEX (MATLAB Executable) function
- Standalone C/C++ code
- Standalone C/C++ code compiled to a static library
- Standalone C/C++ code compiled to a dynamically linked library
- Standalone C/C++ code compiled to an executable

You can specify the build type using the `-config` option of `codegen`. For more details on setting code generation options, see “Configure Build Settings” (MATLAB Coder).

By default, `codegen` generates a MEX function. A MEX function is a C/C++ program that is executable from MATLAB. You can use a MEX function to accelerate MATLAB algorithms and to test the generated code for functionality and run-time issues. For details, see “MATLAB Algorithm Acceleration” (MATLAB Coder) and “Why Test MEX Functions in MATLAB?” (MATLAB Coder).

Code Generation Report

You can use the `-report` flag to produce a code generation report. This report helps you debug code generation issues and view the generated C/C++ code. For details, see “Code Generation Reports” (MATLAB Coder).

Verify Generated Code

Test a MEX function to verify that the generated code provides the same functionality as the original MATLAB code. To perform this test, run the MEX function using the same inputs that you used to run the original MATLAB code, and then compare the results. Running the MEX function in MATLAB before generating standalone code also enables you to detect and fix run-time errors that are much harder to diagnose in the generated standalone code. For more details, see “Why Test MEX Functions in MATLAB?” (MATLAB Coder).

Pass some data to verify whether `iqr`, `iqrCodeGen`, and `iqrCodeGen_mex` return the same interquartile range.

```
testX = randn(100,1);
r = iqr(testX);
r_entrypoint = iqrCodeGen(testX);
r_mex = iqrCodeGen_mex(testX);
```

Compare the outputs by using `isequal`.

```
isequal(r,r_entrypoint,r_mex)
```

`isequal` returns logical 1 (true) if all the inputs are equal.

You can also verify the MEX function using a test file and `coder.runTest`. For details, see “Testing Code Generated from MATLAB Code” (MATLAB Coder).

Code Generation for Prediction of Machine Learning Model at Command Line

This example shows how to generate code for the prediction of classification and regression model objects at the command line. You can also generate code using the MATLAB® Coder™ app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-16 for details.

Certain classification and regression model objects have a `predict` or `random` function that supports code generation. Prediction using these object functions requires a trained classification or regression model object, but the `-args` option of `codegen` does not accept these objects. Work around this limitation by using `saveLearnerForCoder` and `loadLearnerForCoder` as described in this example.

This flow chart shows the code generation workflow for the object functions of classification and regression model objects.

After you train a model, save the trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the object function. Then generate code for the entry-point function by using `codegen`, and verify the generated code.

Train Classification Model

Train a classification model object equipped with a code-generation-enabled `predict` function. In this case, train a support vector machine (SVM) classification model.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
Y = species(inds);
Mdl = fitcsvm(X,Y);
```

This step can include data preprocessing, feature selection, and optimizing the model using cross-validation, for example.

Save Model Using `saveLearnerForCoder`

Save the classification model to the file `SVMMoDel.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'SVMMoDel');
```

`saveLearnerForCoder` saves the classification model to the MATLAB binary file `SVMMoDel.mat` as a structure array in the current folder.

Define Entry-Point Function

An *entry-point* function, also known as the *top-level* or *primary* function, is a function you define for code generation. Because you cannot call any function at the top level using `codegen`, you must define an entry-point function that calls code-generation-enabled functions, and generate C/C++ code

for the entry-point function by using `codegen`. All functions within the entry-point function must support code generation.

Define an entry-point function that returns predicted labels for input predictor data. Within the function, load the trained classification model by using `loadLearnerForCoder`, and then pass the loaded model to `predict`. In this case, define the `predictLabelsSVM` function, which predicts labels using the SVM model `Mdl`.

```
type predictLabelsSVM.m % Display contents of predictLabelsSVM.m file

function label = predictLabelsSVM(x) %#codegen
%PREDICTLABELSSVM Label new observations using trained SVM model Mdl
% predictLabelsSVM predicts the vector of labels label using
% the saved SVM model Mdl and the predictor data x.
Mdl = loadLearnerForCoder('SVMModel');
label = predict(Mdl,x);
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation. See “Check Code with the Code Analyzer” (MATLAB Coder).

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Set Up Compiler

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate Code Using `codegen`

Generate code for the entry-point function using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Specify the data types and sizes of all inputs of the entry-point function when you call `codegen` by using the `-args` option.

In this case, pass `X` as a value of the `-args` option to specify that the generated code must accept an input that has the same data type and array size as the training data `X`.

```
codegen predictLabelsSVM -args {X}
```

If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-38 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder)

Build Type

MATLAB Coder can generate code for the following build types:

- MEX (MATLAB Executable) function

- Standalone C/C++ code
- Standalone C/C++ code compiled to a static library
- Standalone C/C++ code compiled to a dynamically linked library
- Standalone C/C++ code compiled to an executable

You can specify the build type using the `-config` option of `codegen`. For more details on setting code generation options, see the `-config` option of `codegen` and “Configure Build Settings” (MATLAB Coder).

By default, `codegen` generates a MEX function. A MEX function is a C/C++ program that is executable from MATLAB. You can use a MEX function to accelerate MATLAB algorithms and to test the generated code for functionality and run-time issues. For details, see “MATLAB Algorithm Acceleration” (MATLAB Coder) and “Why Test MEX Functions in MATLAB?” (MATLAB Coder).

Code Generation Report

You can use the `-report` flag to produce a code generation report. This report helps you debug code generation issues and view the generated C/C++ code. For details, see “Code Generation Reports” (MATLAB Coder).

Verify Generated Code

Test a MEX function to verify that the generated code provides the same functionality as the original MATLAB code. To perform this test, run the MEX function using the same inputs that you used to run the original MATLAB code, and then compare the results. Running the MEX function in MATLAB before generating standalone code also enables you to detect and fix run-time errors that are much harder to diagnose in the generated standalone code. For more details, see “Why Test MEX Functions in MATLAB?” (MATLAB Coder).

Pass some predictor data to verify whether `predict`, `predictLabelsSVM`, and the MEX function return the same labels.

```
labels1 = predict(Mdl,X);
labels2 = predictLabelsSVM(X);
labels3 = predictLabelsSVM_mex(X);
```

Compare the predicted labels by using `isequal`.

```
verifyMEX = isequal(labels1,labels2,labels3)
```

```
verifyMEX = logical
           1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The comparison confirms that the `predict` function, `predictLabelsSVM` function, and MEX function return the same labels.

Code Generation for Nearest Neighbor Searcher

The object functions `knnsearch` and `rangesearch` of the nearest neighbor searcher objects, `ExhaustiveSearcher` and `KDTreeSearcher`, support code generation. This example shows how to generate code for finding the nearest neighbor using an exhaustive searcher object at the command line. The example shows two different ways to generate code, depending on the way you use the object: load the object by using `loadLearnerForCoder` in an entry-point function, and pass a compile-time constant object to the generated code.

Train Exhaustive Nearest Neighbor Searcher

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng('default');           % For reproducibility
n = size(meas,1);         % Sample size
qIdx = randsample(n,5);   % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Prepare an exhaustive nearest neighbor searcher using the training data. Specify the 'Distance' and 'P' name-value pair arguments to use the Minkowski distance with an exponent of 1 for finding the nearest neighbor.

```
Mdl = ExhaustiveSearcher(X,'Distance','minkowski','P',1);
```

Find the index of the training data (X) that is the nearest neighbor of each point in the query data (Y).

```
Idx = knnsearch(Mdl,Y);
```

Generate Code Using `saveLearnerForCoder` and `loadLearnerForCoder`

Generate code that loads an exhaustive searcher, takes query data as an input argument, and then finds the nearest neighbor.

Save the exhaustive searcher to a file using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'searcherModel')
```

`saveLearnerForCoder` saves the model to the MATLAB binary file `searcherModel.mat` as a structure array in the current folder.

Define the entry-point function `myknnsearch1` that takes query data as an input argument. Within the function, load the searcher object by using `loadLearnerForCoder`, and then pass the loaded model to `knnsearch`.

```
type myknnsearch1.m % Display contents of myknnsearch1.m file
```

```
function idx = myknnsearch1(Y) %#codegen
Mdl = loadLearnerForCoder('searcherModel');
idx = knnsearch(Mdl,Y);
end
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function files, `myknnsearch1.m`, `myknnsearch2.m`, and `myknnsearch3.m`.

Generate code for `myknnsearch1` by using `codegen`. Specify the data type and dimension of the input argument by using `coder.typeof` so that the generated code accepts a variable-size array.

```
codegen myknnsearch1 -args {coder.typeof(Y,[Inf,4],[1,0])}
```

For a more detailed code generation example that uses `saveLearnerForCoder` and `loadLearnerForCoder`, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-9. For more details about specifying variable-size arguments, see “Specify Variable-Size Arguments for Code Generation” on page 31-38.

Pass the query data (`Y`) to verify that `myknnsearch1` and the MEX file return the same indices.

```
myIdx1 = myknnsearch1(Y);
myIdx1_mex = myknnsearch1_mex(Y);
```

Compare `myIdx1` and `myIdx1_mex` by using `isequal`.

```
verifyMEX1 = isequal(Idx,myIdx1,myIdx1_mex)

verifyMEX1 = logical
            1
```

`isequal` returns logical 1 (true) if all the inputs are equal. This comparison confirms that `myknnsearch1` and the MEX file return the same results.

Generate Code with Constant Folded Model Object

Nearest neighbor searcher objects can be an input argument of a function you define for code generation. The `-args` option of `codegen` accept a compile-time constant searcher object.

Define the entry-point function `myknnsearch2` that takes both an exhaustive searcher model and query data as input arguments instead of loading the model in the function.

```
type myknnsearch2.m % Display contents of myknnsearch2.m file
```

```
function idx = myknnsearch2(Mdl,Y) %#codegen
idx = knnsearch(Mdl,Y);
end
```

To generate code that takes the model object as well as the query data, designate the model object as a compile-time constant by using `coder.Constant` and include the constant folded model object in the `-args` value of `codegen`.

```
codegen myknnsearch2 -args {coder.Constant(Mdl),coder.typeof(Y,[Inf,4],[1,0])}
```

The code generation workflow with a constant folded model object follows general code generation workflow. For details, see “General Code Generation Workflow” on page 31-5.

Verify that `myknnsearch2` and the MEX file return the same results.

```
myIdx2 = myknnsearch2(Mdl,Y);
myIdx2_mex = myknnsearch2_mex(Mdl,Y);
verifyMEX2 = isequal(Idx,myIdx2,myIdx2_mex)
```

```
verifyMEX2 = logical
    1
```

Generate Code with Name-Value Pair Arguments

Define the entry-point function `myknnsearch3` that takes a model object, query data, and name-value pair arguments. You can allow for optional name-value arguments by specifying `varargin` as an input argument. For details, see “Code Generation for Variable Length Argument Lists” (MATLAB Coder).

```
type myknnsearch3.m % Display contents of myknnsearch3.m file
```

```
function idx = myknnsearch3(Mdl,Y,varargin) %#codegen
idx = knnsearch(Mdl,Y,varargin{:});
end
```

To generate code that allows a user-defined exponent for the Minkowski distance, include `{coder.Constant('P'),0}` in the `-args` value of `codegen`. Use `coder.Constant` because the name of a name-value pair argument must be a compile-time constant.

```
codegen myknnsearch3 -args {coder.Constant(Mdl),coder.typeof(Y,[Inf,4],[1,0]),coder.Constant('P')}
```

Verify that `myknnsearch3` and the MEX file return the same results.

```
newIdx = knnsearch(Mdl,Y,'P',2);
myIdx3 = myknnsearch3(Mdl,Y,'P',2);
myIdx3_mex = myknnsearch3_mex(Mdl,Y,'P',2);
verifyMEX3 = isequal(newIdx,myIdx3,myIdx3_mex)

verifyMEX3 = logical
    1
```

Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App

This example shows how to generate C/C++ code for the prediction of classification and regression model objects by using the MATLAB® Coder™ app. You can also generate code at the command line using `codegen`. See “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-9 for details.

Certain classification and regression model objects have a `predict` or `random` function that supports code generation. Prediction using these object functions requires a trained classification or regression model object, but an entry-point function for code generation cannot have these objects as input variables. Work around this limitation by using `saveLearnerForCoder` and `loadLearnerForCoder` as described in this example.

This flow chart shows the code generation workflow for the object functions of classification and regression model objects.

In this example, you train a classification ensemble model using k -nearest-neighbor weak learners and save the trained model by using `saveLearnerForCoder`. Then, define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the object function. Write a script to test the entry-point function. Finally, generate code by using the MATLAB Coder app and verify the generated code.

Train Classification Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Train a classification ensemble model with k -nearest-neighbor weak learners by using the random subspace method. For details of classifications that use a random subspace ensemble, see “Random Subspace Classification” on page 18-103.

```
rng('default') % For reproducibility
learner = templateKNN('NumNeighbors',2);
Mdl = fitcensemble(X,Y,'Method','Subspace','NPredToSample',5, ...
    'Learners',learner,'NumLearningCycles',13);
```

Save Model Using `saveLearnerForCoder`

Save the trained ensemble model to a file named `knnEnsemble.mat` in your current folder.

```
saveLearnerForCoder(Mdl,'knnEnsemble')
```

`saveLearnerForCoder` makes the full classification model `Mdl` compact, and then saves it to the MATLAB binary file `knnEnsemble.mat` as a structure array in the current folder.

Define Entry-Point Function

An *entry-point* function, also known as the *top-level* or *primary* function, is a function you define for code generation. You must define an entry-point function that calls code-generation-enabled functions

and generate C/C++ code from the entry-point function. All functions within the entry-point function must support code generation.

In a new file in your current folder, define an entry-point function named `myknnEnsemblePredict` that does the following:

- Accept input data (`X`), the file name of the saved model (`fileName`), and valid name-value pair arguments of the `predict` function (`varargin`).
- Load a trained ensemble model by using `loadLearnerForCoder`.
- Predict labels and corresponding scores from the loaded model.

You can allow for optional name-value arguments by specifying `varargin` as an input argument. For details, see “Code Generation for Variable Length Argument Lists” (MATLAB Coder).

```
type myknnEnsemblePredict.m % Display the contents of myknnEnsemblePredict.m file.

function [label,score] = myknnEnsemblePredict(X,fileName,varargin) %#codegen
CompactMdl = loadLearnerForCoder(fileName);
[label,score] = predict(CompactMdl,X,varargin{:});
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation. See “Check Code with the Code Analyzer” (MATLAB Coder).

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file (`myknnEnsemblePredict.m`) and the test file (`test_myknnEnsemblePredict.m`, described later on).

Set Up Compiler

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Create Test File

Write a test script that calls the `myknnEnsemblePredict` function. In the test script, specify the input arguments and name-value pair arguments that you use in the generated code. You use this test script to define input types automatically when generating code using the MATLAB Coder app.

In this example, create the `test_myknnEnsemblePredict.m` file in your current folder, as shown.

```
type test_myknnEnsemblePredict.m % Display the contents of test_myknnEnsemblePredict.m file.

%% Load Sample data
load ionosphere

%% Test myknnEnsemblePredict
[label,score] = myknnEnsemblePredict(X,'knnEnsemble','Learners',1:13);
```

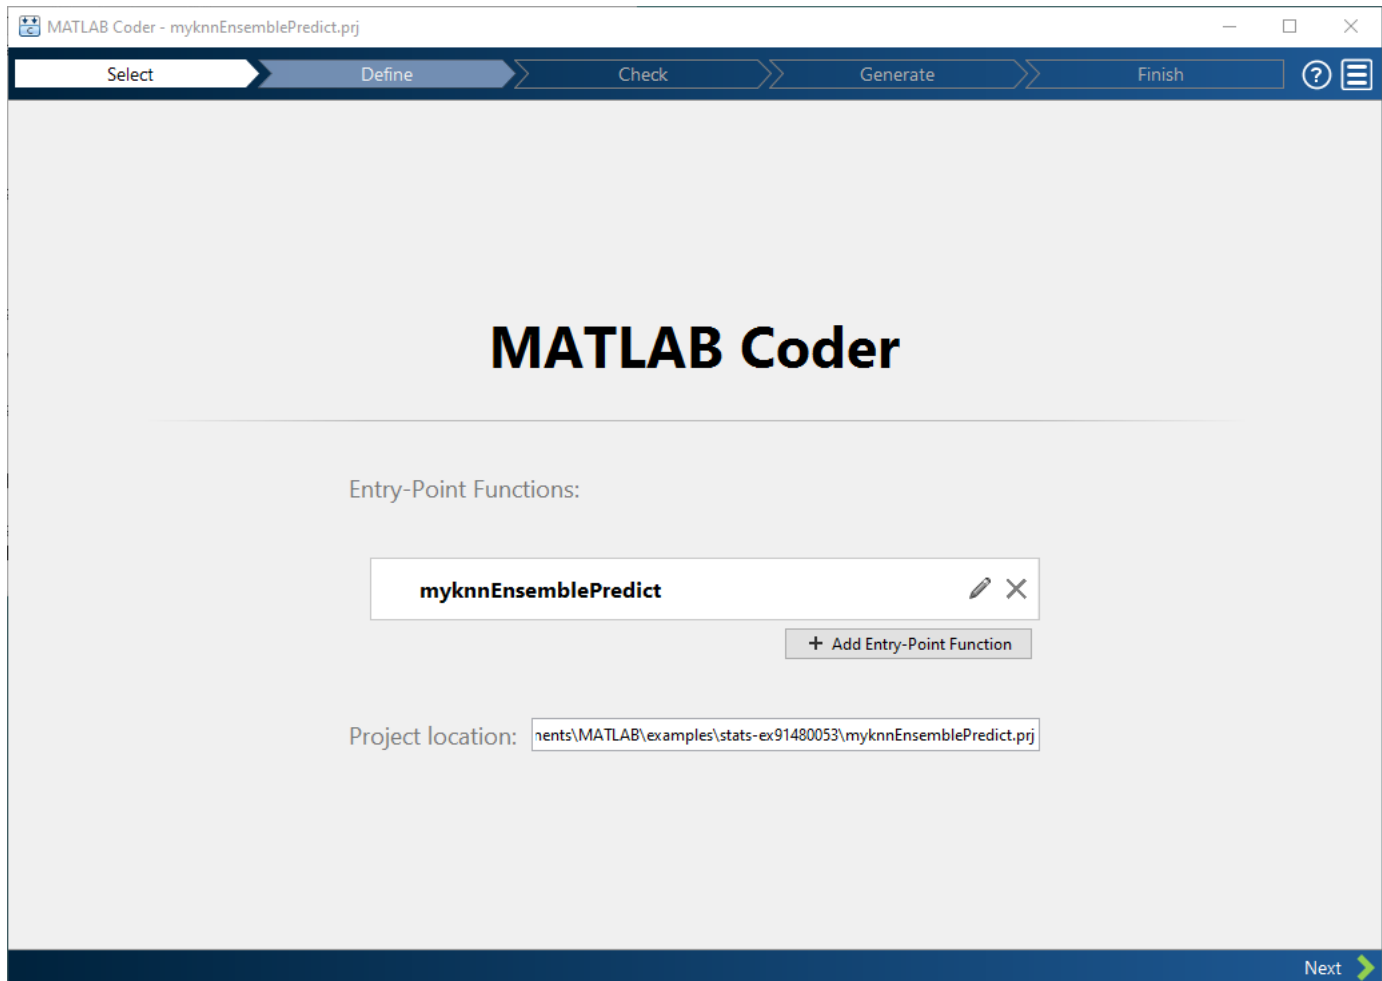

For details, see “Automatically Define Input Types by Using the App” (MATLAB Coder).

Generate Code Using MATLAB Coder App

The MATLAB Coder app generates C or C++ code from MATLAB® code. The workflow-based user interface steps you through the code generation process. The following steps describe a brief workflow of the MATLAB Code App. For more details, see MATLAB Coder and “Generate C Code by Using the MATLAB Coder App” (MATLAB Coder).

1. Open the MATLAB Code App and Select the Entry-Point Function File.

On the **Apps** tab, in the **Apps** section, click the **Show more** arrow to open the apps gallery. Under **Code Generation**, click **MATLAB Coder**. The app opens the **Select Source Files** page. Enter or select the name of the entry-point function, `myknnEnsemblePredict`.

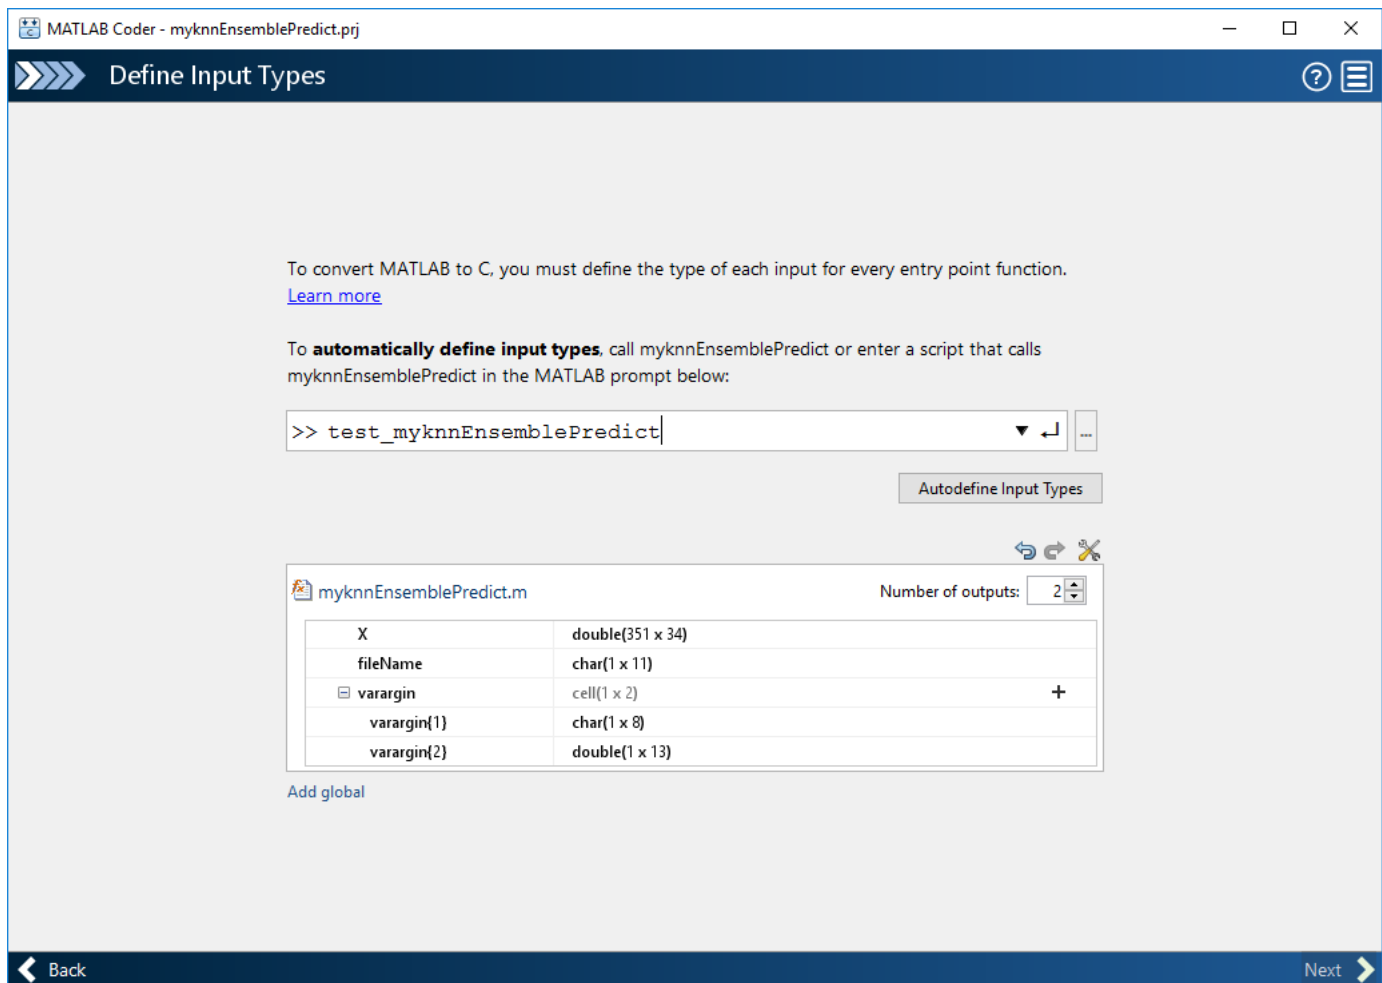

Click **Next** to go to the **Define Input Types** page.

2. Define Input Types

Because C uses static typing, MATLAB Coder must determine the properties of all variables in the MATLAB files at compile time. Therefore, you need to specify the properties of the entry-point function inputs.

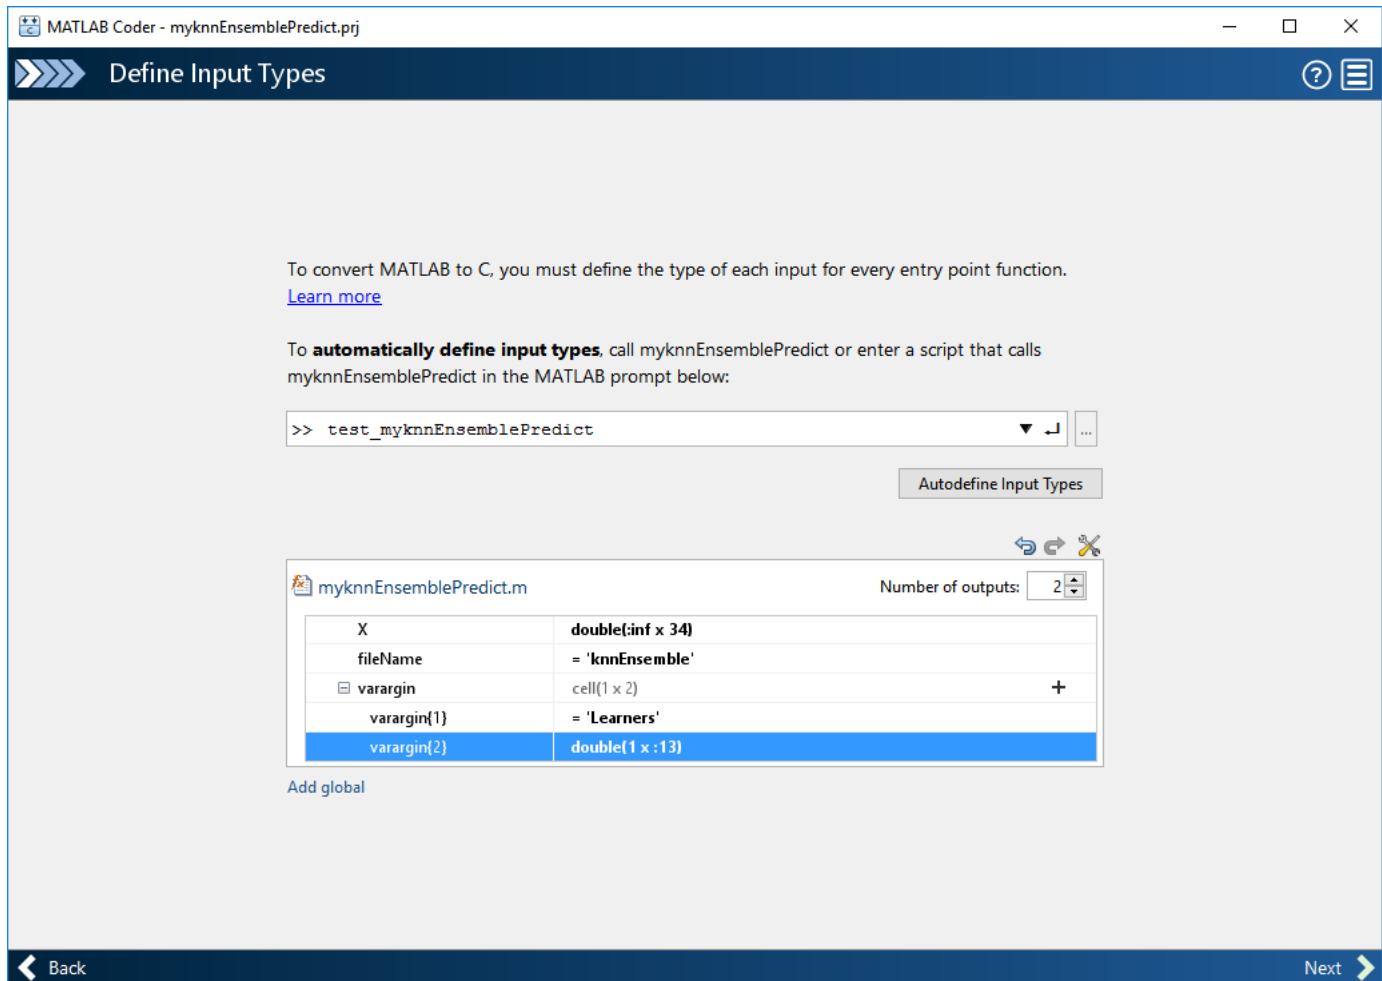

Enter or select the test script `test_myknnEnsemblePredict` and click **Autodefine Input Types**.

The MATLAB Coder app recognizes input types of the `myknnEnsemblePredict` function based on the test script.

Modify the input types:

- `X` — The app infers that input `X` is `double(351x34)`. The number of predictors must be fixed to be the same as the number of predictors in the trained model. However, you can have a different number of observations for prediction. If the number of observations is unknown, change `double(351x34)` to `double(: :351x34)` or `double(: :infx34)`. The setting `double(: :351x34)` allows the number of observations up to 351, and the setting `double(: :infx34)` allows an unbounded number of observations. In this example, specify `double(: :infx34)` by clicking 351 and selecting `:inf`.
- `fileName` — Click **char**, select **Define Constant**, and type the file name with single quotes, `'knnEnsemble'`.
- `varargin{1}` — Names in name-value pair arguments must be compile-time constants. Click **char**, select **Define Constant**, and type `'Learners'`.
- `varargin{2}` — To allow user-defined indices up to 13 weak learners in the generated code, change `double(1x13)` to `double(1x:13)`.

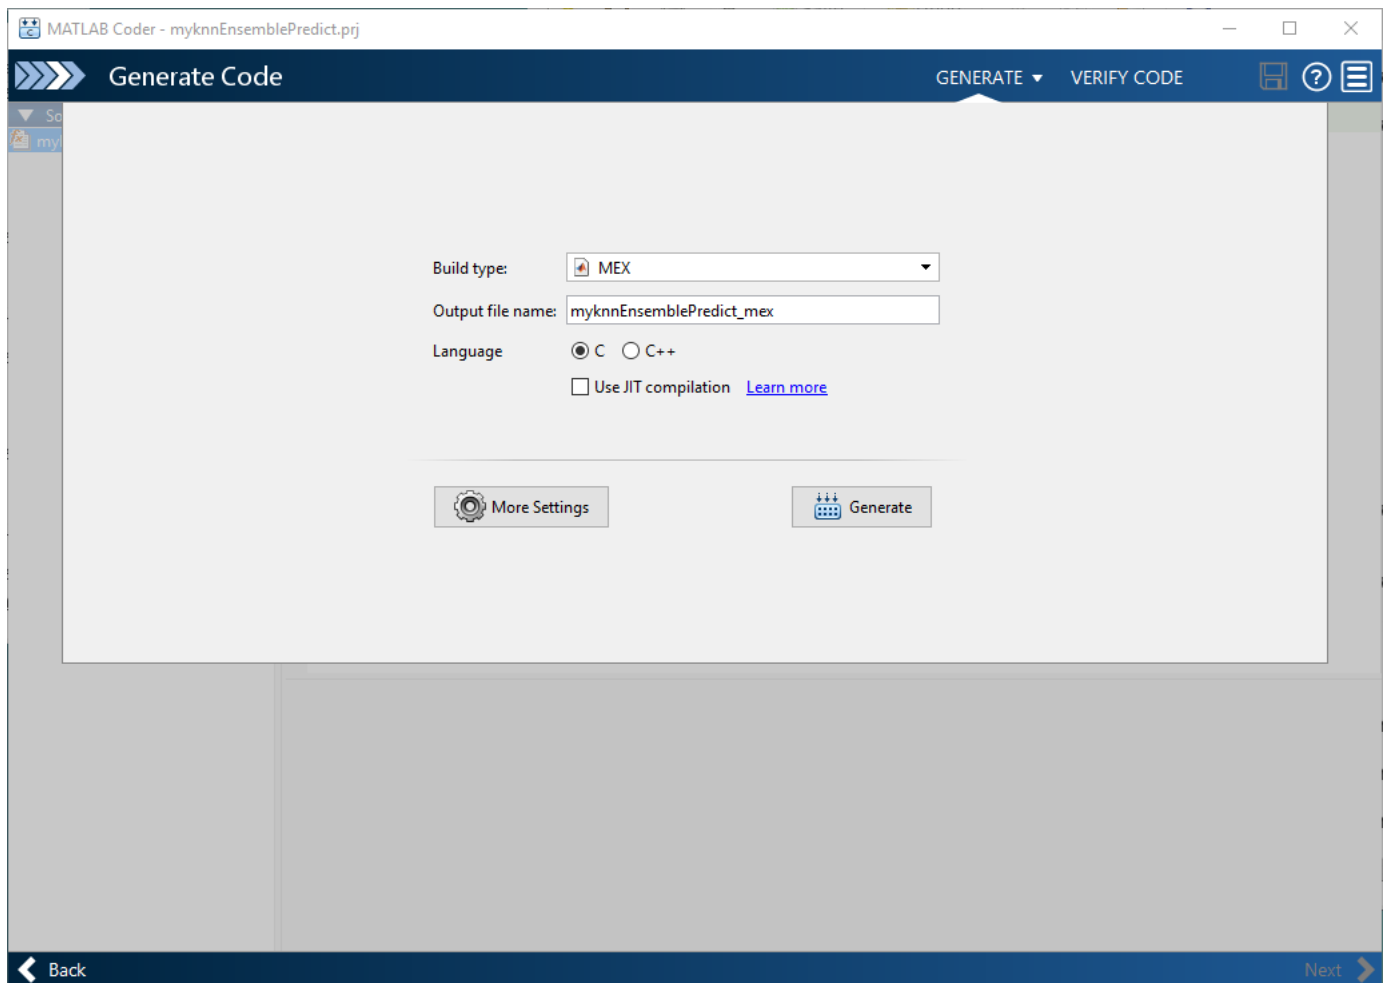

Click **Next** to go to the **Check for Run-Time Issues** page. This optional step generates a MEX file, runs the MEX function, and reports issues. Click **Next** to go to the **Generate Code** page.

3. Generate C Code

Set **Build type** to MEX and click **Generate**. The app generates a MEX function, myknnEnsemblePredict_mex. A MEX function is a C/C++ program that is executable from MATLAB. You can use a MEX function to accelerate MATLAB algorithms and to test the generated code for functionality and run-time issues. For details, see “MATLAB Algorithm Acceleration” (MATLAB Coder) and “Why Test MEX Functions in MATLAB?” (MATLAB Coder).

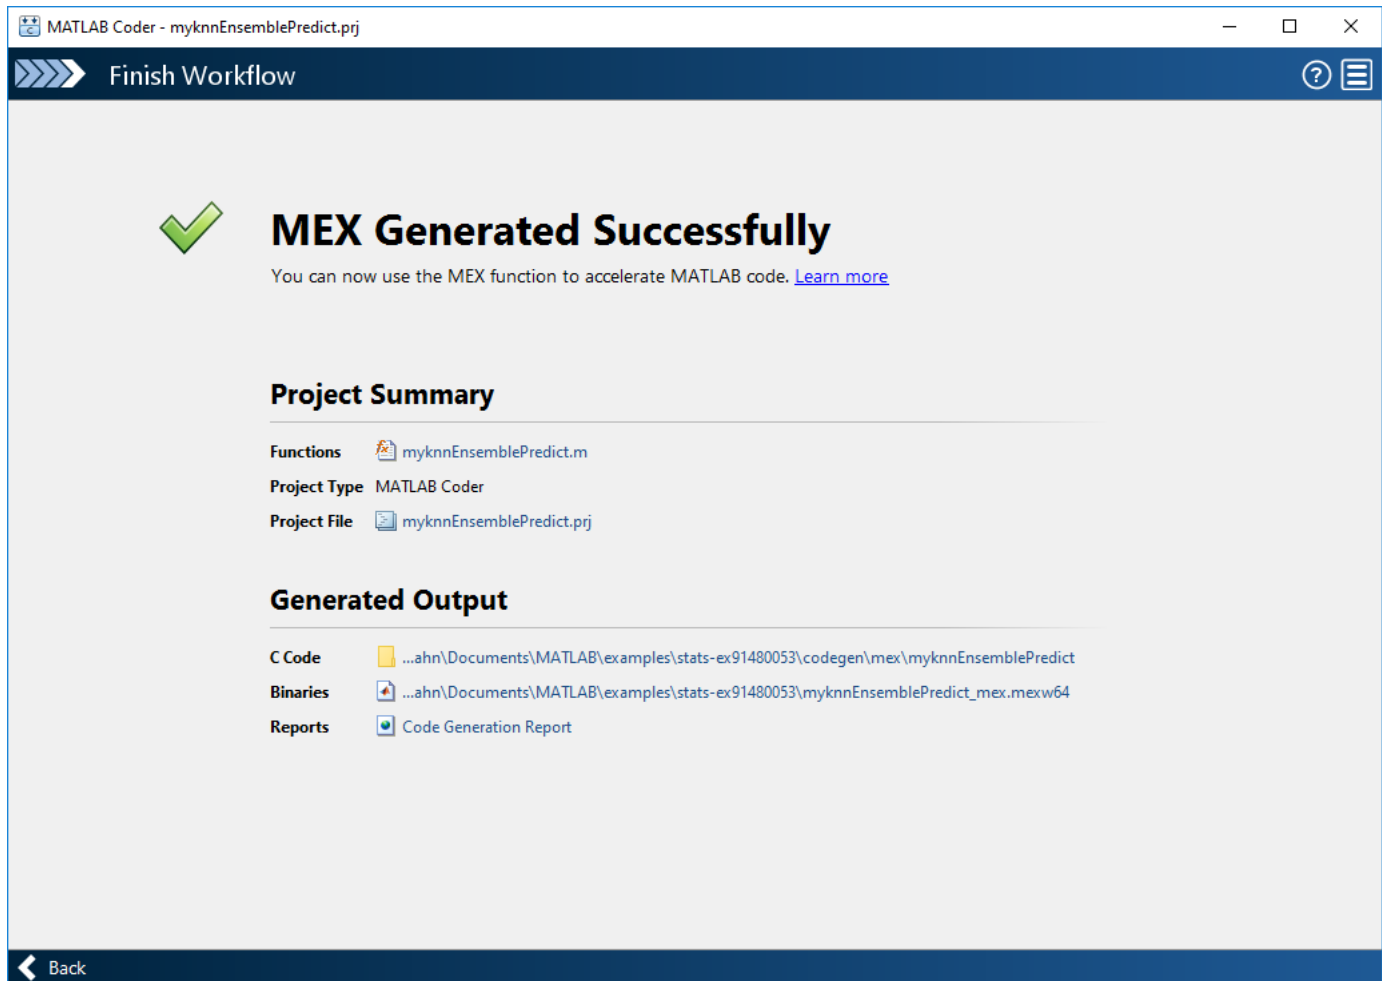

Depending on the specified build type, MATLAB Coder generates a MEX function or standalone C/C++ code compiled to a static library, dynamic linked library, or executable. For details on setting a build type, see “Configure Build Settings” (MATLAB Coder).

Click **Next** to go to the **Finish Workflow** page.

4. Review the Finish Workflow Page

The **Finish Workflow** page indicates that code generation succeeded. This page also provides a project summary and links to generated output.

Generate Code Using Script

You can convert a MATLAB Coder project to the equivalent script of MATLAB commands after you define input types. Then you run the script to generate code. For details, see “Convert MATLAB Coder Project to MATLAB Script” (MATLAB Coder).

On the MATLAB Coder app toolbar, click the **Open action menu** button: 

Select **Convert to script**, and then click **Save**. The app creates the file `myknnEnsemblePredict_script.m`, which reproduces the project in a configuration object and runs the `codegen` function.

Display the contents of the file `myknnEnsemblePredict_script.m`.

```
type myknnEnsemblePredict_script.m
```

```
% MYKNNENSEMBLEPREDICT_SCRIPT    Generate MEX-function myknnEnsemblePredict_mex
%   from myknnEnsemblePredict.
%
% Script generated from project 'myknnEnsemblePredict.prj' on 17-Nov-2017.
%
```

```
% See also CODER, CODER.CONFIG, CODER.TYPEOF, CODEGEN.

%% Create configuration object of class 'coder.MexCodeConfig'.
cfg = coder.config('mex');
cfg.GenerateReport = true;
cfg.ReportPotentialDifferences = false;

%% Define argument types for entry-point 'myknnEnsemblePredict'.
ARGS = cell(1,1);
ARGS{1} = cell(4,1);
ARGS{1}{1} = coder.typeof(0,[Inf 34],[1 0]);
ARGS{1}{2} = coder.Constant('knnEnsemble');
ARGS{1}{3} = coder.Constant('Learners');
ARGS{1}{4} = coder.typeof(0,[1 13],[0 1]);

%% Invoke MATLAB Coder.
codegen -config cfg myknnEnsemblePredict -args ARGS{1} -nargout 2
```

Run the script.

```
myknnEnsemblePredict_script
```

Code generation successful: To view the report, open('codegen\mex\myknnEnsemblePredict\html\report.html')

Verify Generated Code

Test a MEX function to verify that the generated code provides the same functionality as the original MATLAB code. To perform this test, run the MEX function using the same inputs that you used to run the original MATLAB code, and then compare the results. Running the MEX function in MATLAB before generating standalone code also enables you to detect and fix run-time errors that are much harder to diagnose in the generated standalone code. For more details, see “Why Test MEX Functions in MATLAB?” (MATLAB Coder).

Pass some predictor data to verify that `myknnEnsemblePredict` and the MEX function return the same results.

```
[label1,score1] = predict(Mdl,X,'Learners',1:10);
[label2,score2] = myknnEnsemblePredict(X,'knnEnsemble','Learners',1:10);
[label3,score3] = myknnEnsemblePredict_mex(X,'knnEnsemble','Learners',1:10);
```

Compare `label1`, `label2`, and `label3` by using `isequal`.

```
isequal(label1,label2,label3)
```

```
ans = logical
     1
```

`isequal` returns logical 1 (true), which means all the inputs are equal.

The `score3` output from the MEX function might include round-off differences compared with the output from the `predict` function. In this case, compare `score1` and `score3`, allowing a small tolerance.

```
find(abs(score1-score3) > 1e-12)
```

```
ans =
```

```
0x1 empty double column vector
```

`find` returns an empty vector if the element-wise absolute difference between `score1` and `score3` is not larger than the specified tolerance `1e-12`. The comparisons confirm that `myknnEnsemblePredict` and the MEX function return the same results.

- Function List (C/C++ Code Generation)

Code Generation and Classification Learner App

Classification Learner is well suited for choosing and training classification models interactively, but it does not generate C/C++ code that labels data based on a trained model. The **Generate Function** button in the **Export** section of the Classification Learner app generates MATLAB code for training a model but does not generate C/C++ code. This example shows how to generate C code from a function that predicts labels using an exported classification model. The example builds a model that predicts the credit rating of a business given various financial ratios, according to these steps:

- 1 Use the credit rating data set in the file `CreditRating_Historical.dat`, which is included with Statistics and Machine Learning Toolbox.
- 2 Reduce the data dimensionality using principal component analysis (PCA).
- 3 Train a set of models that support code generation for label prediction.
- 4 Export the model with the minimum 5-fold, cross-validated classification accuracy.
- 5 Generate C code from an entry-point function that transforms the new predictor data and then predicts corresponding labels using the exported model.

Load Sample Data

Load sample data and import the data into the Classification Learner app. Review the data using scatter plots and remove unnecessary predictors.

Use `readtable` to load the historical credit rating data set in the file `CreditRating_Historical.dat` into a table.

```
creditrating = readtable('CreditRating_Historical.dat');
```

On the **Apps** tab, click **Classification Learner**.

In Classification Learner, on the **Classification Learner** tab, in the **File** section, click **New Session** and select **From Workspace**.

In the New Session dialog box, select the table `creditrating`. All variables, except the one identified as the response, are double-precision numeric vectors. Click **Start Session** to compare classification models based on the 5-fold, cross-validated classification accuracy.

Classification Learner loads the data and plots a scatter plot of the variables `WC_TA` versus `ID`. Because identification numbers are not helpful to display in a plot, choose `RE_TA` for **X** under **Predictors**.

The scatter plot suggests that the two variables can separate the classes AAA, BBB, BB, and CCC fairly well. However, the observations corresponding to the remaining classes are mixed into these classes.

Identification numbers are not helpful for prediction. Therefore, in the **Features** section, click **Feature Selection** and then clear the **ID** check box. You can also remove unnecessary predictors from the beginning by using the check boxes in the New Session dialog box. This example shows how to remove unused predictors for code generation when you have included all predictors.

Enable PCA

Enable PCA to reduce the data dimensionality.

In the **Features** section, click **PCA**, and then select **Enable PCA**. This action applies PCA to the predictor data, and then transforms the data before training the models. Classification Learner uses only components that collectively explain 95% of the variability.

Train Models

Train a set of models that support code generation for label prediction.

Select the following classification models and options, which support code generation for label prediction, and then perform cross-validation (for more details, see “Introduction to Code Generation” on page 31-2). To select each model, in the **Model Type** section, click the **Show more** arrow, and then click the model. After selecting a model and specifying any options, close any open menus, and then click **Train** in the **Training** section.

Models and Options to Select	Description
Under Decision Trees , select All Trees	Classification trees of various complexities
Under Support Vector Machines , select All SVMs	SVMs of various complexities and using various kernels. Complex SVMs require time to fit.
Under Ensemble Classifiers , select Boosted Trees . In the Model Type section, click Advanced . Reduce Maximum number of splits to 5 and increase Number of learners to 100 .	Boosted ensemble of classification trees
Under Ensemble Classifiers , select Bagged Trees . In the Model Type section, click Advanced . Increase Maximum number of splits to 50 and increase Number of learners to 100 .	Random forest of classification trees

After cross-validating each model type, the Data Browser displays each model and its 5-fold, cross-validated classification accuracy, and highlights the model with the best accuracy.

▼ History	
1.1 ☆ Tree Last change: Fine Tree	Accuracy: 67.4% 2/6 features (PCA on)
1.2 ☆ Tree Last change: Medium Tree	Accuracy: 64.9% 2/6 features (PCA on)
1.3 ☆ Tree Last change: Coarse Tree	Accuracy: 56.5% 2/6 features (PCA on)
2.1 ☆ SVM Last change: Linear SVM	Accuracy: 70.6% 2/6 features (PCA on)
2.2 ☆ SVM Last change: Quadratic SVM	Accuracy: 65.2% 2/6 features (PCA on)
2.3 ☆ SVM Last change: Cubic SVM	Accuracy: 49.7% 2/6 features (PCA on)
2.4 ☆ SVM Last change: Fine Gaussian SVM	Accuracy: 71.5% 2/6 features (PCA on)
2.5 ☆ SVM Last change: Medium Gaussian SVM	Accuracy: 69.6% 2/6 features (PCA on)
2.6 ☆ SVM Last change: Coarse Gaussian SVM	Accuracy: 61.2% 2/6 features (PCA on)
3 ☆ Ensemble Last change: Boosted Trees	Accuracy: 67.1% 2/6 features (PCA on)
4 ☆ Ensemble Last change: Bagged Trees	Accuracy: 67.1% 2/6 features (PCA on)

Select the model that yields the maximum 5-fold, cross-validated classification accuracy, which is the error-correcting output codes (ECOC) model of Fine Gaussian SVM learners. With PCA enabled, Classification Learner uses two predictors out of six.

In the **Plots** section, click **Confusion Matrix**.

The model does well distinguishing between A, B, and C classes. However, the model does not do as well distinguishing between particular levels within those groups, the lower B levels in particular.

Export Model to Workspace

Export the model to the MATLAB Workspace and save the model using `saveLearnerForCoder`.

In the **Export** section, click **Export Model**, and then select **Export Compact Model**. Click **OK** in the dialog box.

The structure `trainedModel` appears in the MATLAB Workspace. The field `ClassificationSVM` of `trainedModel` contains the compact model.

At the command line, save the compact model to a file called `ClassificationLearnerModel.mat` in your current folder.

```
saveLearnerForCoder(trainedModel.ClassificationSVM, 'ClassificationLearnerModel')
```

Generate C Code for Prediction

Prediction using the object functions requires a trained model object, but the `-args` option of `codegen` does not accept such objects. Work around this limitation by using `saveLearnerForCoder` and `loadLearnerForCoder`. Save a trained model by using `saveLearnerForCoder`. Then, define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Finally, use `codegen` to generate code for the entry-point function.

Preprocess Data

Preprocess new data in the same way you preprocess the training data.

To preprocess, you need the following three model parameters:

- `removeVars` — Column vector of at most `p` elements identifying indices of variables to remove from the data, where `p` is the number of predictor variables in the raw data
- `pcaCenters` — Row vector of exactly `q` PCA centers
- `pcaCoefficients` — `q`-by-`r` matrix of PCA coefficients, where `r` is at most `q`

Specify the indices of predictor variables that you removed while selecting data using **Feature Selection** in Classification Learner. Extract the PCA statistics from `trainedModel`.

```
removeVars = 1;  
pcaCenters = trainedModel.PCACenters;  
pcaCoefficients = trainedModel.PCACoefficients;
```

Save the model parameters to a file named `ModelParameters.mat` in your current folder.

```
save('ModelParameters.mat', 'removeVars', 'pcaCenters', 'pcaCoefficients');
```

Define Entry-Point Function

An entry-point function is a function you define for code generation. Because you cannot call any function at the top level using `codegen`, you must define an entry-point function that calls code-generation-enabled functions, and then generate C/C++ code for the entry-point function by using `codegen`.

In your current folder, define a function named `mypredictCL.m` that:

- Accepts a numeric matrix (`X`) of raw observations containing the same predictor variables as the ones passed into Classification Learner
- Loads the classification model in `ClassificationLearnerModel.mat` and the model parameters in `ModelParameters.mat`
- Removes the predictor variables corresponding to the indices in `removeVars`
- Transforms the remaining predictor data using the PCA centers (`pcaCenters`) and coefficients (`pcaCoefficients`) estimated by Classification Learner
- Returns predicted labels using the model

```

function label = mypredictCL(X) %#codegen
%MYPREDICTCL Classify credit rating using model exported from
%Classification Learner
% MYPREDICTCL loads trained classification model (SVM) and model
% parameters (removeVars, pcaCenters, and pcaCoefficients), removes the
% columns of the raw matrix of predictor data in X corresponding to the
% indices in removeVars, transforms the resulting matrix using the PCA
% centers in pcaCenters and PCA coefficients in pcaCoefficients, and then
% uses the transformed data to classify credit ratings. X is a numeric
% matrix with n rows and 7 columns. label is an n-by-1 cell array of
% predicted labels.

% Load trained classification model and model parameters
SVM = loadLearnerForCoder('ClassificationLearnerModel');
data = coder.load('ModelParameters');
removeVars = data.removeVars;
pcaCenters = data.pcaCenters;
pcaCoefficients = data.pcaCoefficients;

% Remove unused predictor variables
keepvars = 1:size(X,2);
idx = ~ismember(keepvars,removeVars);
keepvars = keepvars(idx);
XwoID = X(:,keepvars);

% Transform predictors via PCA
Xpca = bsxfun(@minus,XwoID,pcaCenters)*pcaCoefficients;

% Generate label from SVM
label = predict(SVM,Xpca);
end

```

Generate Code

Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Specify variable-size arguments using `coder.typeof` and generate code using the arguments.

Create a double-precision matrix called `x` for code generation using `coder.typeof`. Specify that the number of rows of `x` is arbitrary, but that `x` must have `p` columns.

```

p = size(creditrating,2) - 1;
x = coder.typeof(0,[Inf,p],[1 0]);

```

For more details about specifying variable-size arguments, see “Specify Variable-Size Arguments for Code Generation” on page 31-38.

Generate a MEX function from `mypredictCL.m`. Use the `-args` option to specify `x` as an argument.

```

codegen mypredictCL -args x

```

`codegen` generates the MEX file `mypredictCL_mex.mexw64` in your current folder. The file extension depends on your platform.

Verify Generated Code

Verify that the MEX function returns the expected labels.

Remove the response variable from the original data set, and then randomly draw 15 observations.

```
rng('default'); % For reproducibility
m = 15;
testsampleT = datasample(creditrating(:,1:(end - 1)),m);
```

Predict corresponding labels by using `predictFcn` in the classification model trained by Classification Learner.

```
testLabels = trainedModel.predictFcn(testsampleT);
```

Convert the resulting table to a matrix.

```
testsample = table2array(testsampleT);
```

The columns of `testsample` correspond to the columns of the predictor data loaded by Classification Learner.

Pass the test data to `mypredictCL`. The function `mypredictCL` predicts corresponding labels by using `predict` and the classification model trained by Classification Learner.

```
testLabelsPredict = mypredictCL(testsample);
```

Predict corresponding labels by using the generated MEX function `mypredictCL_mex`.

```
testLabelsMEX = mypredictCL_mex(testsample);
```

Compare the sets of predictions.

```
isequal(testLabels, testLabelsMEX, testLabelsPredict)
```

```
ans =
```

```
    logical
```

```
     1
```

`isequal` returns logical 1 (true) if all the inputs are equal. `predictFcn`, `mypredictCL`, and the MEX function return the same values.

Predict Class Labels Using MATLAB Function Block

This example shows how to add a MATLAB Function block to a Simulink® for label prediction. The MATLAB Function block accepts streaming data, and predicts the label and classification score using a trained, support vector machine (SVM) classification model. For details on using the MATLAB Function block, see “Create Custom Functionality Using MATLAB Function Block” (Simulink).

The `ionosphere` data set, which is included in the Statistics and Machine Learning Toolbox™, contains radar-return qualities (Y) and predictor data (X). Radar returns are either of good quality ('g') or of bad quality ('b').

Load the `ionosphere` data set. Determine the sample size.

```
load ionosphere
n = numel(Y)
```

```
n =
    351
```

The MATLAB Function block cannot return cell arrays. So, convert the response variable to a logical vector whose elements are 1 if the radar returns are good, and 0 otherwise.

```
Y = strcmp(Y, 'g');
```

Suppose that the radar returns are detected in sequence, and you have the first 300 observations, but you have not received the last 51 yet. Partition the data into present and future samples.

```
prsntX = X(1:300,:);
prsntY = Y(1:300);
ftrX = X(301:end,:);
ftrY = Y(301:end);
```

Train an SVM model using all, presently available data. Specify predictor data standardization.

```
Mdl = fitcsvm(prsntX,prsntY,'Standardize',true);
```

`Mdl` is a `ClassificationSVM` model. At the command line, you can use `Mdl` to make predictions for new observations. However, you cannot use `Mdl` as an input argument in a function meant for code generation.

Prepare `Mdl` to be loaded within the function using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl, 'SVMIonosphere');
```

`saveLearnerForCoder` compacts `Mdl`, and then saves it in the MAT-file `SVMIonosphere.mat`.

Define an entry-point function named `svmIonospherePredict.m` that predicts whether a radar return is of good quality. The function should:

- Include the code generation directive `%#codegen` somewhere in the function.
- Accept radar-return predictor data. The data must be commensurate with X except for the number of rows.

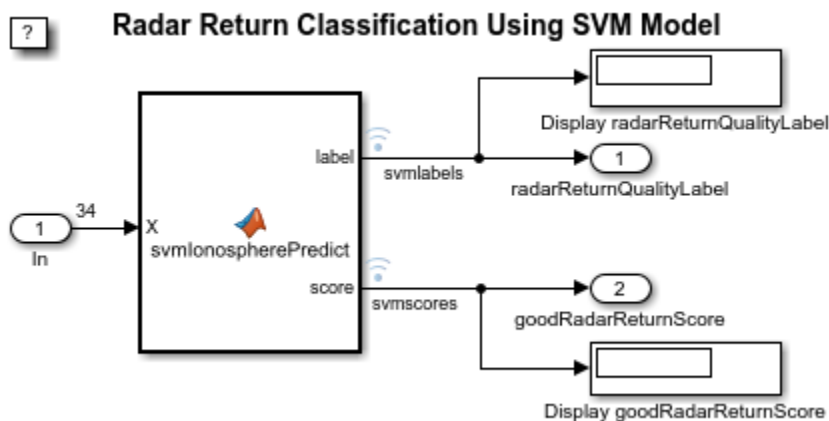

- Load SVMIonosphere.mat using loadLearnerForCoder.
- Return predicted labels and classification scores for predicting the quality of the radar return as good (that is, the positive-class score).

```
function [label,score] = svmIonospherePredict(X) %#codegen
%svmIonospherePredict Predict radar-return quality using SVM model
% svmIonospherePredict predicts labels and estimates classification
% scores of the radar returns in the numeric matrix of predictor data X
% using the compact SVM model in the file SVMIonosphere.mat. Rows of X
% correspond to observations and columns to predictor variables. label
% is the predicted label and score is the confidence measure for
% classifying the radar-return quality as good.
%
% Copyright 2016 The MathWorks Inc.
Mdl = loadLearnerForCoder('SVMIonosphere');
[label,bothscores] = predict(Mdl,X);
score = bothscores(:,2);
end
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function file.

Load the Simulink® model `slexSVMIonospherePredictExample.slx`.

```
SimMdlName = 'slexSVMIonospherePredictExample';
open_system(SimMdlName);
```

The figure displays the Simulink® model. When the input node detects a radar return, it directs that observation into the MATLAB Function block that dispatches to `svmIonospherePredict.m`. After predicting the label and score, the model returns these values to the workspace and displays the values within the model one at a time. When you load `slexSVMIonospherePredictExample.slx`, MATLAB® also loads the data set that it requires called `radarReturnInput`. However, this example shows how to construct the required data set.

The model expects to receive input data as a structure array called `radarReturnInput` containing these fields:

- **time** - The points in time at which the observations enter the model. In the example, the duration includes the integers from 0 though 50. The orientation must correspond to the observations in the predictor data. So, for this example, **time** must be a column vector.
- **signals** - A 1-by-1 structure array describing the input data, and containing the fields **values** and **dimensions**. **values** is a matrix of predictor data. **dimensions** is the number of predictor variables.

Create an appropriate structure array for future radar returns.

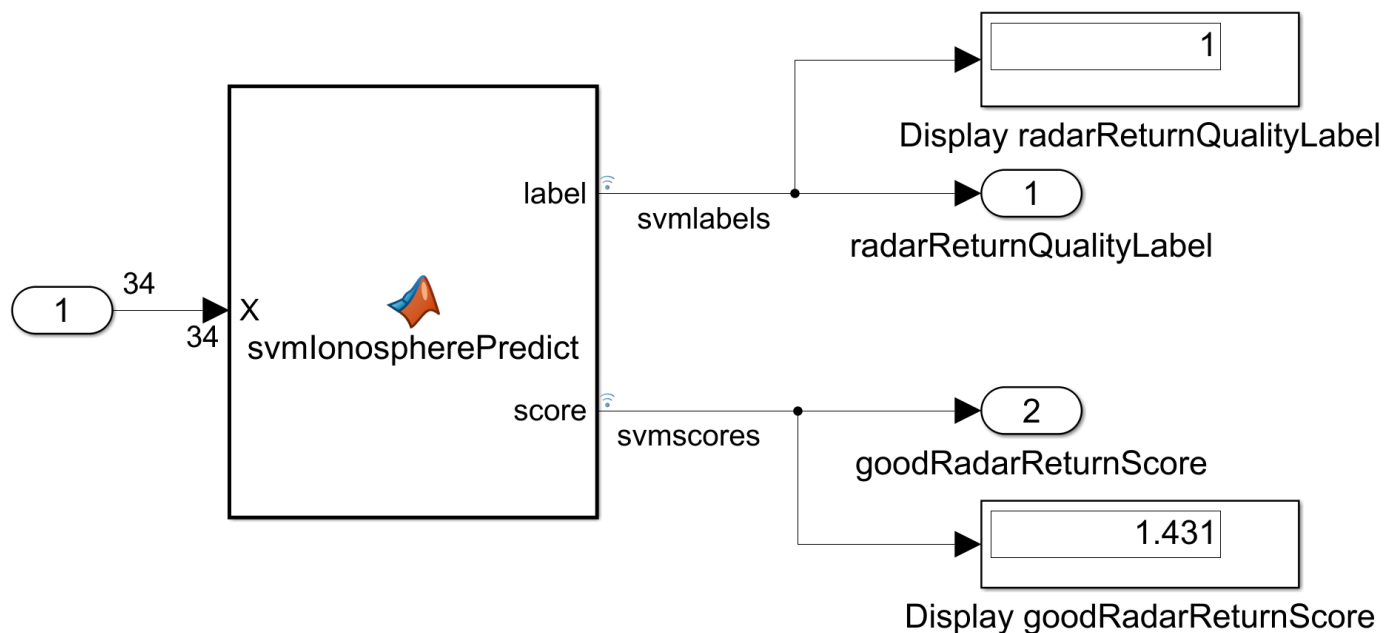

```
radarReturnInput.time = (0:50)';
radarReturnInput.signals(1).values = ftrX;
radarReturnInput.signals(1).dimensions = size(ftrX,2);
```

You can change the name from `radarReturnInput`, and then specify the new name in the model. However, Simulink® expects the structure array to contain the described field names.

Simulate the model using the data held out of training, that is, the data in `radarReturnInput`.

```
sim(SimMdlName);
```

Radar Return Classification Using SVM Model

The figure shows the model after it processes all observations in `radarReturnInput` one at a time. The predicted label of `X(351, :)` is 1 and its positive-class score is 1.431. The variables `tout`, `yout`, and `svmlogsout` appear in the workspace. `yout` and `svmlogsout` are `SimulinkData.Dataset` objects containing the predicted labels and scores. For more details, see “Data Format for Logged Simulation Data” (Simulink).

Extract the simulation data from the simulation log.

```
labelsSL = svmlogsout.getElement(1).Values.Data;
scoresSL = svmlogsout.getElement(2).Values.Data;
```

`labelsSL` is a 51-by-1 numeric vector of predicted labels. `labelsSL(j) = 1` means that the SVM model predicts that radar return `j` in the future sample is of good quality, and 0 means otherwise.

scoresSL is a 51-by-1 numeric vector of positive-class scores, that is, signed distances from the decision boundary. Positive scores correspond to predicted labels of 1, and negative scores correspond to predicted labels of 0.

Predict labels and positive-class scores at the command line using `predict`.

```
[labelCMD,scoresCMD] = predict(Mdl,ftrX);
scoresCMD = scoresCMD(:,2);
```

labelCMD and scoresCMD are commensurate with labelsSL and scoresSL.

Compare the future-sample, positive-class scores returned by `slxSVMIonospherePredictExample` to those returned by calling `predict` at the command line.

```
err = sum((scoresCMD - scoresSL).^2);
err < eps
```

```
ans =
    logical
     1
```

The sum of squared deviations between the sets of scores is negligible.

If you also have a Simulink® Coder™ license, then you can generate C code from `slxSVMIonospherePredictExample.slx` in Simulink® or from the command line using `rtwbuild`. For more details, see “Generate C Code for a Model” (Simulink Coder).

Specify Variable-Size Arguments for Code Generation

This example shows how to specify variable-size input arguments when you generate code for the object functions of classification and regression model objects. Variable-size data is data whose size might change at run time. Specifying variable-size input arguments is convenient when you have data with an unknown size at compile time. This example also describes how to include name-value pair arguments in an entry-point function and how to specify them when generating code.

For more detailed code generation workflow examples, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-9 and “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-16.

Train Classification Model

Load Fisher's iris data set. Convert the labels to a character matrix.

```
load fisheriris
species = char(species);
```

Train a classification tree using the entire data set.

```
Mdl = fitctree(meas,species);
```

Mdl is a ClassificationTree model.

Save Model Using saveLearnerForCoder

Save the trained classification tree to a file named ClassTreeIris.mat in your current folder by using saveLearnerForCoder.

```
MdlName = 'ClassTreeIris';
saveLearnerForCoder(Mdl,MdlName);
```

Define Entry-Point Function

In your current folder, define an entry-point function named mypredictTree.m that does the following:

- Accept measurements with columns corresponding to meas and accept valid name-value pair arguments.
- Load a trained classification tree by using loadLearnerForCoder.
- Predict labels and corresponding scores, node numbers, and class numbers from the loaded classification tree.

You can allow for optional name-value pair arguments by specifying varargin as an input argument. For details, see “Code Generation for Variable Length Argument Lists” (MATLAB Coder).

```
type mypredictTree.m % Display contents of mypredictTree.m file

function [label,score,node,cnum] = mypredictTree(x,savedmdl,varargin) %#codegen
%MYPREDICTTREE Predict iris species using classification tree
% MYPREDICTTREE predicts iris species for the n observations in the
% n-by-4 matrix x using the classification tree stored in the MAT-file
% whose name is in savedmdl, and then returns the predictions in the
% array label. Each row of x contains the lengths and widths of the petal
% and sepal of an iris (see the fisheriris data set). For other output
```

```
% argument descriptions, see the predict reference page.
CompactMdl = loadLearnerForCoder(savedmdl);
[label,score,node,cnum] = predict(CompactMdl,x,varargin{:});
end
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Specify Variable-Size Arguments

Because C and C++ are statically typed languages, you must determine the properties of all variables in an entry-point function at compile time using the `-args` option of `codegen`.

Use `coder.Constant` to specify a compile-time constant input.

```
coder.Constant(v)
```

`coder.Constant(v)` creates a `coder.Constant` type variable whose values are constant, the same as `v`, during code generation.

Use `coder.typeof` to specify a variable-size input.

```
coder.typeof(example_value, size_vector, variable_dims)
```

The values of `example_value`, `size_vector`, and `variable_dims` specify the properties of the input array that the generated code can accept.

- An input array has the same data type as the example values in `example_value`.
- `size_vector` is the array size of an input array if the corresponding `variable_dims` value is `false`.
- `size_vector` is the upper bound of the array size if the corresponding `variable_dims` value is `true`.
- `variable_dims` specifies whether each dimension of the array has a variable size or a fixed size. A value of `true` (logical 1) means that the corresponding dimension has a variable size; a value of `false` (logical 0) means that the corresponding dimension has a fixed size.

The entry-point function `mypredictTree` accepts predictor data, the MAT-file name containing the trained model object, and optional name-value pair arguments. Suppose that you want to generate code that accepts a variable-size array for predictor data and the 'Subtrees' name-value pair argument with a variable-size vector for its value. Then you have four input arguments: predictor data, the MAT-file name, and the name and value of the 'Subtrees' name-value pair argument.

Define a 4-by-1 cell array and assign each input argument type of the entry-point function to each cell.

```
ARGS = cell(4,1);
```

For the first input, use `coder.typeof` to specify that the predictor data variable is double-precision with the same number of columns as the predictor data used in training the model, but that the number of observations (rows) is arbitrary.

```
p = numel(Mdl.PredictorNames);
ARGS{1} = coder.typeof(0,[Inf,p],[1,0]);
```

0 for the `example_value` value implies that the data type is `double` because `double` is the default numeric data type of MATLAB. `[Inf,p]` for the `size_vector` value and `[1,0]` for the `variable_dims` value imply that the size of the first dimension is variable and unbounded, and the size of the second dimension is fixed to be `p`.

The second input is the MAT-file name, which must be a compile-time constant. Use `coder.Constant` to specify the type of the second input.

```
ARGS{2} = coder.Constant(MdlName);
```

The last two inputs are the name and value of the 'Subtrees' name-value pair argument. Names of name-value pair arguments must be compile-time constants.

```
ARGS{3} = coder.Constant('Subtrees');
```

Use `coder.typeof` to specify that the value of 'Subtrees' is a double-precision row vector and that the upper bound of the row vector size is `max(Mdl.PrunedList)`.

```
m = max(Mdl.PruneList);
ARGS{4} = coder.typeof(0,[1,m],[0,1]);
```

Again, 0 for the `example_value` value implies that the data type is `double` because `double` is the default numeric data type of MATLAB. `[1,m]` for the `size_vector` value and `[0,1]` for the `variable_dims` value imply that the size of the first dimension is fixed to be 1, and the size of the second dimension is variable and its upper bound is `m`.

Generate Code Using `codegen`

Generate a MEX function from the entry-point function `mypredictTree` using the cell array `ARGS`, which includes input argument types for `mypredictTree`. Specify the input argument types using the `-args` option. Specify the number of output arguments in the generated entry-point function using the `-nargout` option. The generate code includes the specified number of output arguments in the order in which they occur in the entry-point function definition.

```
codegen mypredictTree -args ARGS -nargout 2
```

`codegen` generates the MEX function `mypredictTree_mex` with a platform-dependent extension in your current folder.

The `predict` function accepts single-precision values, double-precision values, and 'all' for the 'SubTrees' name-value pair argument. However, you can specify only double-precision values when you use the MEX function for prediction because the data type specified by `ARGS{4}` is `double`.

Verify Generated Code

Predict labels for a random selection of 15 values from the training data using the generated MEX function and the subtree at pruning level 1. Compare the labels from the MEX function with those predicted by `predict`.

```
rng('default'); % For reproducibility
Xnew = datasample(meas,15);
[labelMEX,scoreMEX] = mypredictTree_mex(Xnew,MdlName,'Subtrees',1);
[labelPREDICT,scorePREDICT] = predict(Mdl,Xnew,'Subtrees',1);
labelPREDICT
```

```
labelPREDICT = 15x10 char array
    'virginica '
```

```
'virginica '
'setosa    '
'virginica '
'versicolor'
'setosa    '
'setosa    '
'versicolor'
'virginica '
'virginica '
'setosa    '
'virginica '
'virginica '
'versicolor'
'virginica '
```

labelMEX

```
labelMEX = 15x1 cell
    {'virginica' }
    {'virginica' }
    {'setosa'    }
    {'virginica' }
    {'versicolor'}
    {'setosa'    }
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
    {'virginica' }
    {'setosa'    }
    {'virginica' }
    {'virginica' }
    {'versicolor'}
    {'virginica' }
```

The predicted labels are the same as the MEX function labels except for the data type. When the response data type is `char` and `codegen` cannot determine that the value of `Subtrees` is a scalar, then the output from the generated code is a cell array of character vectors.

For the comparison, you can convert `labelsPREDICT` to a cell array and use `isequal`.

```
cell_labelPREDICT = cellstr(labelPREDICT);
verifyLabel = isequal(labelMEX,cell_labelPREDICT)

verifyLabel = logical
    1
```

`isequal` returns logical 1 (true), which means all the inputs are equal.

Compare the second outputs as well. `scoreMex` might include round-off differences compared with `scorePREDICT`. In this case, compare `scoreMEX` and `scorePREDICT`, allowing a small tolerance.

```
find(abs(scorePREDICT-scoreMEX) > 1e-8)

ans =

    0x1 empty double column vector
```

`find` returns an empty vector if the element-wise absolute difference between `scorePREDICT` and `scoreMEX` is not larger than the specified tolerance `1e-8`. The comparison confirms that `scorePREDICT` and `scoreMEX` are equal within the tolerance `1e-8`.

Train SVM Classifier with Categorical Predictors and Generate C/C++ Code

This example shows how to generate code for classifying data using a support vector machine (SVM) model. Train the model using numeric and categorical predictors.

Because code generation does not support categorical predictors, use `dummyvar` to convert categorical predictors to numeric dummy variables before fitting an SVM classifier. When passing new data to your trained model, you must preprocess the data in a similar manner.

Preprocess Data and Train SVM Classifier

Load the `patients` data set. Create a table using the `Diastolic` and `Systolic` numeric variables. Each row of the table corresponds to a different patient.

```
load patients
tbl = table(Diastolic,Systolic);
head(tbl)
```

```
ans=8x2 table
   Diastolic   Systolic
   _____   _____
      93         124
      77         109
      83         125
      75         117
      80         122
      70         121
      88         130
      82         115
```

Convert the `Gender` variable to a categorical variable. The order of the categories in `categoricalGender` is important because it determines the order of the columns in the predictor data. Use `dummyvar` to convert the categorical variable to a matrix of zeros and ones, where a 1 value in the (i, j) th entry indicates that the i th patient belongs to the j th category.

```
categoricalGender = categorical(Gender);
orderGender = categories(categoricalGender)
```

```
orderGender = 2x1 cell
    {'Female'}
    {'Male' }
```

```
dummyGender = dummyvar(categoricalGender);
```

Note: The resulting `dummyGender` matrix is rank deficient. Depending on the type of model you train, this rank deficiency can be problematic. For example, when training linear models, remove the first column of the dummy variables.

Create a table that contains the dummy variable `dummyGender` with the corresponding variable headings. Combine this new table with `tbl`.

```
tblGender = array2table(dummyGender, 'VariableNames', orderGender);
tbl = [tbl tblGender];
head(tbl)
```

```
ans=8x4 table
   Diastolic   Systolic   Female   Male
   _____   _____   _____   _____
      93         124         0         1
      77         109         0         1
      83         125         1         0
      75         117         1         0
      80         122         1         0
      70         121         1         0
      88         130         1         0
      82         115         0         1
```

Convert the `SelfAssessedHealthStatus` variable to a categorical variable. Note the order of the categories in `categoricalHealth`, and convert the variable to a numeric matrix using `dummyvar`.

```
categoricalHealth = categorical(SelfAssessedHealthStatus);
orderHealth = categories(categoricalHealth)
```

```
orderHealth = 4x1 cell
    {'Excellent'}
    {'Fair'      }
    {'Good'     }
    {'Poor'     }
```

```
dummyHealth = dummyvar(categoricalHealth);
```

Create a table that contains `dummyHealth` with the corresponding variable headings. Combine this new table with `tbl`.

```
tblHealth = array2table(dummyHealth, 'VariableNames', orderHealth);
tbl = [tbl tblHealth];
head(tbl)
```

```
ans=8x8 table
   Diastolic   Systolic   Female   Male   Excellent   Fair   Good   Poor
   _____   _____   _____   _____   _____   _____   _____   _____
      93         124         0         1         1         0         0         0
      77         109         0         1         0         1         0         0
      83         125         1         0         0         0         1         0
      75         117         1         0         0         1         0         0
      80         122         1         0         0         0         1         0
      70         121         1         0         0         0         1         0
      88         130         1         0         0         0         1         0
      82         115         0         1         0         0         1         0
```

The third row of `tbl`, for example, corresponds to a patient with these characteristics: diastolic blood pressure of 83, systolic blood pressure of 125, female, and good self-assessed health status.

Because all the values in `tbl` are numeric, you can convert the table to a matrix `X`.

```
X = table2array(tbl);
```

Train an SVM classifier using X. Specify the Smoker variable as the response.

```
Y = Smoker;
Mdl = fitcsvm(X,Y);
```

Generate C/C++ Code

Generate code that loads the SVM classifier, takes new predictor data as an input argument, and then classifies the new data.

Save the SVM classifier to a file using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl, 'SVMClassifier')
```

`saveLearnerForCoder` saves the classifier to the MATLAB® binary file `SVMClassifier.mat` as a structure array in the current folder.

Define the entry-point function `mySVMpredict`, which takes new predictor data as an input argument. Within the function, load the SVM classifier by using `loadLearnerForCoder`, and then pass the loaded classifier to `predict`.

```
type mySVMpredict.m % Display contents of mySVMpredict.m file
```

```
function label = mySVMpredict(X) %#codegen
Mdl = loadLearnerForCoder('SVMClassifier');
label = predict(Mdl,X);
end
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB, then MATLAB opens the example folder. This folder includes the entry-point function file `mySVMpredict.m`.

Generate code for `mySVMpredict` by using `codegen`. Specify the data type and dimensions of the new predictor data by using `coder.typeof` so that the generated code accepts a variable-size array.

```
codegen mySVMpredict -args {coder.typeof(X,[Inf 8],[1 0])}
```

Verify that `mySVMpredict` and the MEX file return the same results for the training data.

```
label = predict(Mdl,X);
mylabel = mySVMpredict(X);
mylabel_mex = mySVMpredict_mex(X);
verifyMEX = isequal(label,mylabel,mylabel_mex)
```

```
verifyMEX = logical
    1
```

Predict Labels for New Data

To predict labels for new data, you must first preprocess the new data. If you run the generated code in the MATLAB environment, you can follow the preprocessing steps described in this section. If you deploy the generated code outside the MATLAB environment, the preprocessing steps can differ. In either case, you must ensure that the new data has the same columns as the training data X.

In this example, take the third, fourth, and fifth patients in the `patients` data set. Preprocess the data for these patients so that the resulting numeric matrix matches the form of the training data.

Convert the categorical variables to dummy variables. Because the new observations might not include values from all categories, you need to specify the same categories as the ones used during training and maintain the same category order. In MATLAB, pass the ordered cell array of category names associated with the corresponding training data variable (in this example, `orderGender` for gender values and `orderHealth` for self-assessed health status values).

```
newcategoricalGender = categorical(Gender(3:5),orderGender);
newdummyGender = dummyvar(newcategoricalGender);
```

```
newcategoricalHealth = categorical(SelfAssessedHealthStatus(3:5),orderHealth);
newdummyHealth = dummyvar(newcategoricalHealth);
```

Combine all the new data into a numeric matrix.

```
newX = [Diastolic(3:5) Systolic(3:5) newdummyGender newdummyHealth]
```

```
newX = 3×8
```

```
    83    125     1     0     0     0     1     0
    75    117     1     0     0     1     0     0
    80    122     1     0     0     0     1     0
```

Note that `newX` corresponds exactly to the third, fourth, and fifth rows of the matrix `X`.

Verify that `mySVMpredict` and the MEX file return the same results for the new data.

```
newlabel = predict(Mdl,newX);
newmylabel = mySVMpredict(newX);
newmylabel_mex = mySVMpredict_mex(newX);
newverifyMEX = isequal(newlabel,newmylabel,newmylabel_mex)
```

```
newverifyMEX = logical
    1
```

System Objects for Classification and Code Generation

This example shows how to generate C code from a MATLAB® System object™ that classifies images of digits by using a trained classification model. This example also shows how to use the System object for classification in Simulink®. The benefit of using System objects over MATLAB function is that System objects are more appropriate for processing large amounts of streaming data. For more details, see “What Are System Objects?” (MATLAB).

This example is based on “Code Generation for Image Classification”, which is an alternative workflow to “Digit Classification Using HOG Features” (Computer Vision Toolbox).

Load Data

Load the `digitimages`.

```
load digitimages.mat
```

`images` is a 28-by-28-by-3000 array of `uint16` integers. Each page is a raster image of a digit. Each element is a pixel intensity. Corresponding labels are in the 3000-by-1 numeric vector `Y`. For more details, enter `Description` at the command line.

Store the number of observations and the number of predictor variables. Create a data partition that specifies to hold out 20% of the data. Extract training and test set indices from the data partition.

```
rng(1); % For reproducibility
n = size(images,3);
p = numel(images(:,:,1));
cvp = cvpartition(n,'Holdout',0.20);
idxTrn = training(cvp);
idxTest = test(cvp);
```

Rescale Data

Rescale the pixel intensities so that they range in the interval [0,1] within each image. Specifically, suppose p_{ij} is pixel intensity j within image i . For image i , rescale all of its pixel intensities by using this formula:

$$\hat{p}_{ij} = \frac{p_{ij} - \min_j(p_{ij})}{\max_j(p_{ij}) - \min_j(p_{ij})}$$

```
X = double(images);

for i = 1:n
    minX = min(min(X(:,:,i)));
    maxX = max(max(X(:,:,i)));
    X(:,:,i) = (X(:,:,i) - minX)/(maxX - minX);
end
```

Reshape Data

For code generation, the predictor data for training must be in a table of numeric variables or a numeric matrix.

Reshape the data to a matrix such that predictor variables correspond to columns and images correspond to rows. Because `reshape` takes elements column-wise, transpose its result.

```
X = reshape(X, [p,n])';
```

Train and Optimize Classification Models

Cross-validate an ECOC model of SVM binary learners and a random forest based on the training observations. Use 5-fold cross-validation.

For the ECOC model, specify predictor standardization and optimize classification error over the ECOC coding design and the SVM box constraint. Explore all combinations of these values:

- For the ECOC coding design, use one-versus-one and one-versus-all.
- For the SVM box constraint, use three logarithmically spaced values from 0.1 to 100 each. For all models, store the 5-fold cross-validated misclassification rates.

```
coding = {'onevsone' 'onevsall'};
boxconstraint = logspace(-1,2,3);
cvLossECOC = nan(numel(coding),numel(boxconstraint)); % For preallocation

for i = 1:numel(coding)
    for j = 1:numel(boxconstraint)
        t = templateSVM('BoxConstraint',boxconstraint(j),'Standardize',true);
        CVMdl = fitcecoc(X(idxTrn,:),Y(idxTrn),'Learners',t,'KFold',5,...
            'Coding',coding{i});
        cvLossECOC(i,j) = kfoldLoss(CVMdl);
        fprintf('cvLossECOC = %f for model using %s coding and box constraint=%f\n',...
            cvLossECOC(i,j),coding{i},boxconstraint(j))
    end
end

cvLossECOC = 0.058333 for model using onevsone coding and box constraint=0.100000
cvLossECOC = 0.057083 for model using onevsone coding and box constraint=3.162278
cvLossECOC = 0.050000 for model using onevsone coding and box constraint=100.000000
cvLossECOC = 0.120417 for model using onevsall coding and box constraint=0.100000
cvLossECOC = 0.121667 for model using onevsall coding and box constraint=3.162278
cvLossECOC = 0.127917 for model using onevsall coding and box constraint=100.000000
```

For the random forest, vary the maximum number of splits by using the values in the sequence $\{3^2, 3^3, \dots, 3^m\}$. m is such that 3^m is no greater than $n - 1$. To reproduce random predictor selections, specify 'Reproducible', true.

```
n = size(X,1);
m = floor(log(n - 1)/log(3));
maxNumSplits = 3.^(2:m);
cvLossRF = nan(numel(maxNumSplits));
for i = 1:numel(maxNumSplits)
    t = templateTree('MaxNumSplits',maxNumSplits(i),'Reproducible',true);
    CVMdl = fitcensemble(X(idxTrn,:),Y(idxTrn),'Method','bag','Learners',t,...
        'KFold',5);
    cvLossRF(i) = kfoldLoss(CVMdl);
    fprintf('cvLossRF = %f for model using %d as the maximum number of splits\n',...
        cvLossRF(i),maxNumSplits(i))
end

cvLossRF = 0.323750 for model using 9 as the maximum number of splits
cvLossRF = 0.198333 for model using 27 as the maximum number of splits
cvLossRF = 0.075417 for model using 81 as the maximum number of splits
cvLossRF = 0.017083 for model using 243 as the maximum number of splits
```

```
cvLossRF = 0.012083 for model using 729 as the maximum number of splits
cvLossRF = 0.012083 for model using 2187 as the maximum number of splits
```

For each algorithm, determine the hyperparameter indices that yield the minimal misclassification rates.

```
minCVLossECOC = min(cvLossECOC(:))

minCVLossECOC = 0.0500

linIdx = find(cvLossECOC == minCVLossECOC,1);
[bestI,bestJ] = ind2sub(size(cvLossECOC),linIdx);
bestCoding = coding{bestI}

bestCoding =
'onevsone'

bestBoxConstraint = boxconstraint(bestJ)

bestBoxConstraint = 100

minCVLossRF = min(cvLossRF(:))

minCVLossRF = 0.0121

linIdx = find(cvLossRF == minCVLossRF,1);
[bestI,bestJ] = ind2sub(size(cvLossRF),linIdx);
bestMNS = maxNumSplits(bestI)

bestMNS = 729
```

The random forest achieves a smaller cross-validated misclassification rate.

Train an ECOC model and a random forest using the training data. Supply the optimal hyperparameter combinations.

```
t = templateSVM('BoxConstraint',bestBoxConstraint,'Standardize',true);
MdLECOE = fitcecoc(X(idxTrn,:),Y(idxTrn),'Learners',t,'Coding',bestCoding);
t = templateTree('MaxNumSplits',bestMNS);
MdLRF = fitcensemble(X(idxTrn,:),Y(idxTrn),'Method','bag','Learners',t);
```

Create a variable for the test sample images and use the trained models to predict test sample labels.

```
testImages = X(idxTest,:);
testLabelsECOC = predict(MdLECOE,testImages);
testLabelsRF = predict(MdLRF,testImages);
```

Save Classification Model to Disk

MdLECOE and MdLRF are predictive classification models, but you must prepare them for code generation. Save MdLECOE and MdLRF to your present working folder using saveLearnerForCoder.

```
saveLearnerForCoder(MdLECOE,'DigitImagesECOC');
saveLearnerForCoder(MdLRF,'DigitImagesRF');
```

Create System Object for Prediction

Create two System objects, one for the ECOC model and the other for the random forest, that:

- Load the previously saved trained model by using `loadLearnerForCoder`.
- Make sequential predictions by the `step` method.
- Enforce no size changes to the input data.
- Enforce double-precision, scalar output.

type `ECOCClassifier.m` % Display contents of `ECOCClassifier.m` file

    end

    function dataout = getOutputDataTypeImpl(~)
        dataout = 'double';
    end

    function sizeout = getOutputSizeImpl(~)
        sizeout = [1 1];
    end
end
end

```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the files used in this example.

For System object basic requirements, see “Define Basic System Objects” (MATLAB).

Define Prediction Functions for Code Generation

Define two MATLAB functions called `predictDigitECOC50.m` and `predictDigitRFS0.m`. The functions:

- Include the code generation directive `%#codegen`.
- Accept image data commensurate with `X`.
- Predict labels using the `ECOCClassifier` and `RFCClassifier` System objects, respectively.
- Return predicted labels.

type `predictDigitECOC50.m` % Display contents of `predictDigitECOC50.m` file

```

function label = predictDigitECOC50(X) %#codegen
%PREDICTDIGITECOC50 Classify digit in image using ECOC Model System object
% PREDICTDIGITECOC50 classifies the 28-by-28 images in the rows of X
% using the compact ECOC model in the System object ECOCClassifier, and
% then returns class labels in label.
classifier = ECOCClassifier;

```

```

label = step(classifier,X);
end

type predictDigitRFS0.m % Display contents of predictDigitRFS0.m file

function label = predictDigitRFS0(X) %#codegen
%PREDICTDIGITRFS0 Classify digit in image using RF Model System object
% PREDICTDIGITRFS0 classifies the 28-by-28 images in the rows of X
% using the compact random forest in the System object RFClassifier, and
% then returns class labels in label.
classifier = RFClassifier;
label = step(classifier,X);
end

```

Compile MATLAB Function to MEX File

Compile the prediction function that achieves better test-sample accuracy to a MEX file by using `codegen`. Specify the test set images by using the `-args` argument.

```

if(minCVLossECOC <= minCVLossRF)
    codegen predictDigitECOC0 -args testImages
else
    codegen predictDigitRFS0 -args testImages
end

```

Verify that the generated MEX file produces the same predictions as the MATLAB function.

```

if(minCVLossECOC <= minCVLossRF)
    mexLabels = predictDigitECOC0_mex(testImages);
    verifyMEX = sum(mexLabels == testLabelsECOC) == numel(testLabelsECOC)
else
    mexLabels = predictDigitRFS0_mex(testImages);
    verifyMEX = sum(mexLabels == testLabelsRF) == numel(testLabelsRF)
end

```

```

verifyMEX = logical
    1

```

`verifyMEX` is 1, which indicates that the predictions made by the generated MEX file and the corresponding MATLAB function are the same.

Predict Labels by Using System Objects in Simulink

Create a video file that displays the test-set images frame-by-frame.

```

v = VideoWriter('testImages.avi','Uncompressed AVI');
v.FrameRate = 1;
open(v);
dim = sqrt(p)*[1 1];
for j = 1:size(testImages,1)
    writeVideo(v,reshape(testImages(j,:),dim));
end
close(v);

```

Define a function called `scalePixelIntensities.m` that converts RGB images to grayscale, and then scales the resulting pixel intensities so that their values are in the interval [0,1].

```

type scalePixelIntensities.m % Display contents of scalePixelIntensities.m file

```

```

function x = scalePixelIntensities(imdat)
%SCALEPIXELINTENSITIES Scales image pixel intensities
% SCALEPIXELINTENSITIES scales the pixel intensities of the image such
% that the result x is a row vector of values in the interval [0,1].
imdat = rgb2gray(imdat);

minimdat = min(min(imdat));
maximdat = max(max(imdat));
x = (imdat - minimdat)/(maximdat - minimdat);
end

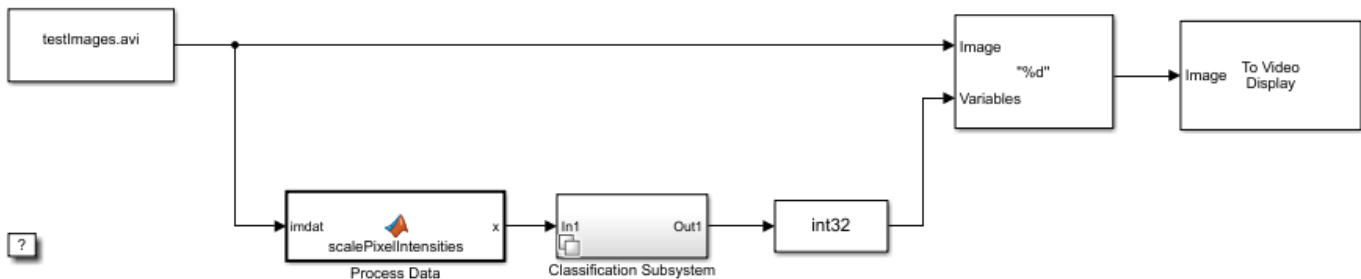

```

Load the Simulink® model `slexClassifyAndDisplayDigitImages.slx`.

```

SimMdlName = 'slexClassifyAndDisplayDigitImages';
open_system(SimMdlName);

```

The figure displays the Simulink® model. At the beginning of simulation, the From Multimedia File block loads the video file of the test-set images. For each image in the video:

- The From Multimedia File block converts and outputs the image to a 28-by-28 matrix of pixel intensities.
- The Process Data block scales the pixel intensities by using `scalePixelIntensities.m`, and outputs a 1-by-784 vector of scaled intensities.
- The Classification Subsystem block predicts labels given the processed image data. The block chooses the System object that minimizes classification error. In this case, the block chooses the random forest. The block outputs a double-precision scalar label.
- The Data Type Conversion block converts the label to an `int32` scalar.
- The Insert Text block embeds the predicted label on the current frame.
- The To Video Display block displays the annotated frame.

Simulate the model.

```

sim(SimMdlName)

```

The model displays all 600 test-set images and its prediction quickly. The last image remains in the video display. You can generate predictions and display them with corresponding images one-by-one by clicking the **Step Forward** button instead.

If you also have a Simulink® Coder™ license, then you can generate C code from `slexClassifyAndDisplayDigitImages.slx` in Simulink® or from the command line using `rtwbuild`. For more details, see “Generate C Code for a Model” (Simulink Coder).

Predict Class Labels Using Stateflow

This example shows how to use a Stateflow® chart for label prediction. The example trains a discriminant analysis model for the Fisher iris data set by using `fitcdiscr`, and defines a function for code generation that loads the trained model and predicts labels for new data. The Stateflow chart in this example accepts streaming data and predicts labels using the function you define.

Fisher's iris data set, which is included in Statistics and Machine Learning Toolbox™, contains species (`species`) and measurements (`meas`) on sepal length, sepal width, petal length, and petal width for 150 iris specimens. The data set contains 50 specimens from each of three species: *setosa*, *versicolor*, and *virginica*.

Load the Fisher iris data set.

```
load fisheriris
```

Convert `species` to an index vector where 1, 2, and 3 correspond to *setosa*, *versicolor*, and *virginica*, respectively.

```
species = grp2idx(species);
```

Partition the data into a training set and a test set.

```
rng('default') % For reproducibility
idx1 = randperm(150,75)';
idx2 = setdiff((1:150)',idx1);
X = meas(idx1,:);
Y = species(idx1,:);
trainX = meas(idx2,:);
trainY = species(idx2,:);
```

Use `trainX` and `trainY` to train a model, and use `X` and `Y` to test the trained model.

Train a quadratic discriminant analysis model.

```
Mdl = fitcdiscr(trainX,trainY,'DiscrimType','quadratic');
```

`Mdl` is a `ClassificationDiscriminant` model. At the command line, you can use `Mdl` to make predictions for new observations. However, you cannot use `Mdl` as an input argument in a function for code generation. Prepare `Mdl` to be loaded within the function by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'DiscrIris');
```

`saveLearnerForCoder` compacts `Mdl` and saves it in the MAT-file `DiscrIris.mat`.

To display the predicted species in the display box of the Stateflow® model, define an enumeration class by using a `classdef` block in the MATLAB file `IrisSpecies.m`.

```
classdef IrisSpecies < Simulink.IntEnumType
    enumeration
        Setosa(1)
        Versicolor(2)
        Virginica(3)
    end
end
```

For details about enumerated data, see “Define Enumerated Data Types” (Stateflow).

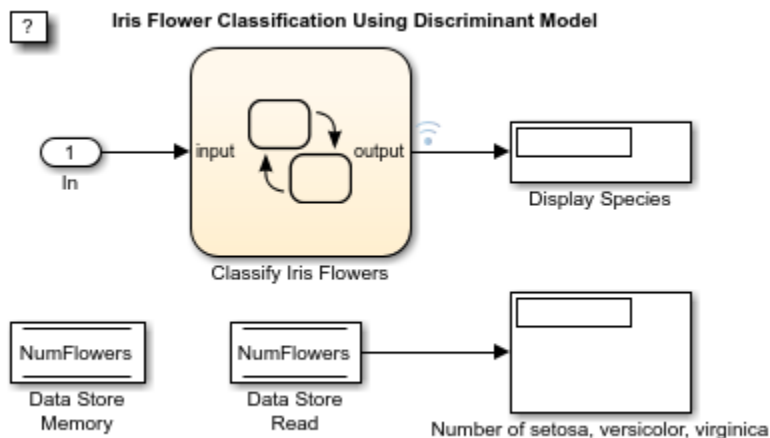

Define a function named `mypredict.m` that predicts the iris species from new measurement data by using the trained model. The function should:

- Include the code generation directive `codegen` somewhere in the function.
- Accept iris measurement data. The data must be consistent with `X` except for the number of rows.
- Load `DiscrIris.mat` using `loadLearnerForCoder`.
- Return predicted iris species.

```
function label = mypredict(X) %codegen
%MPREDICT Predict species of iris flowers using discriminant model
% mypredict predicts species of iris flowers using the compact
% discriminant model in the file DiscrIris.mat. Rows of X correspond to
% observations and columns correspond to predictor variables. label is
% the predicted species.
mdl = loadLearnerForCoder('DiscrIris');
labelTemp = predict(mdl,X);
label = IrisSpecies(labelTemp);
end
```

Open the Simulink® model `sf_countflowers.slx`.

```
sfName = 'sf_countflowers';
open_system(sfName);
```

The figures display the Simulink® model and the flow graph contained in the Stateflow® chart. When the input node detects measurement data, it directs the data into the chart. The chart then predicts a species of iris flower and counts the number of flowers for each species. The chart returns the predicted species to the workspace and displays the species within the model, one at a time. The data store memory block `NumFlowers` stores the number of flowers for each species.

The chart expects to receive input data as a structure array called `fisheririsInput` containing these fields:

- `time` - The points in time at which the observations enter the model. In the example, the duration includes the integers from 0 through 74. The orientation of `time` must correspond to the observations in the predictor data. So, for this example, `time` must be a column vector.
- `signals` - A 1-by-1 structure array describing the input data and containing the fields `values` and `dimensions`. The `values` field is a matrix of predictor data. The `dimensions` field is the number of predictor variables.

Create an appropriate structure array for iris flower measurements.

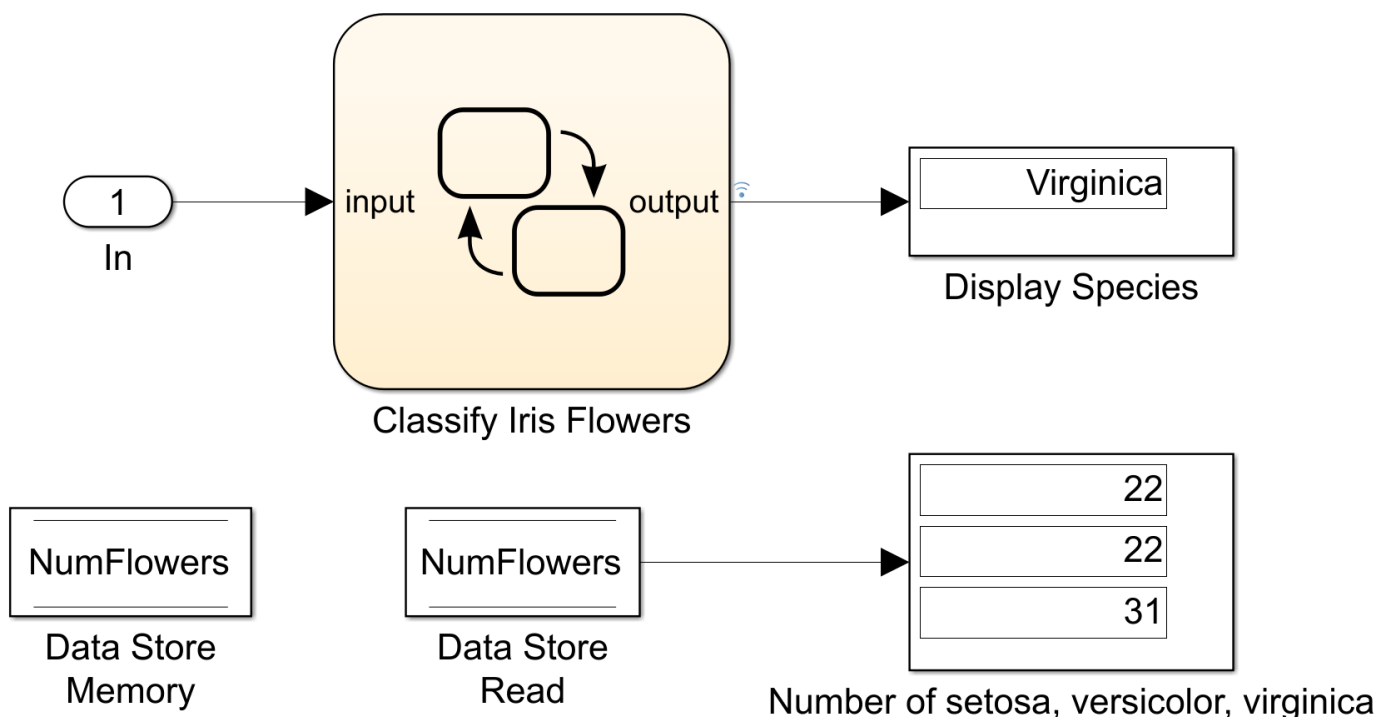

```
fisheririsInput.time = [0:74]';
fisheririsInput.signals.dimensions = 4;
fisheririsInput.signals.values = X;
```

You can change the name from `fisheririsInput`, and then specify the new name in the model. However, Stateflow® expects the structure array to contain the described field names. For more details, see “Loading Data Structures to Root-Level Inputs” (Simulink).

Simulate the model.

```
sim(sfName)
```

Iris Flower Classification Using Discriminant Model

The figure shows the model after it processes all observations in `fisheririsInput`, one at a time. The predicted species of `X(75, :)` is `virginica`. The number of `setosa`, `versicolor`, and `virginica` in `X` is 22, 22, and 31, respectively.

The variable `logout` appears in the workspace. `logout` is a `SimulinkData.Dataset` object containing the predicted species. Extract the predicted species data from the simulation log.

```
labelSF = logout.getElement(1).Values.Data;
```

Predict species at the command line using `predict`.

```
labelCMD = predict(Mdl,X);
```

Compare the predicted species returned by `sf_countflowers` to those returned by calling `predict` at the command line.

```
isequal(labelCMD,labelSF)
```

```
ans =
```

```
    logical
```

```
     1
```

`isequal` returns logical 1 (true) if all the inputs are equal. This comparison confirms that `sf_countflowers` returns the expected results.

If you also have a Simulink® Coder™ license, then you can generate C code from `sf_countflowers.slx` in Simulink® or from the command line using `rtwbuild`. For more details, see “Generate C Code for a Model” (Simulink Coder).

Human Activity Recognition Simulink Model for Smartphone Deployment

This example shows how to prepare a Simulink® model that classifies human activity based on smartphone sensor signals for code generation and smartphone deployment. The example provides two Simulink models that are ready for deployment to an Android device and an iOS device. After you install the required support package for a target device, train the classification model and deploy the Simulink model to the device.

Prerequisites

Simulink support packages are required for the Simulink models in this example.

- Download and Install Simulink Support Package for Android Devices (required for Android deployment)
- Download and Install Simulink Support Package for Apple iOS Devices (required for iOS deployment)

Load Sample Data Set

Load the `humanactivity` data set.

```
load humanactivity
```

The `humanactivity` data set contains 24,075 observations of five different physical human activities: Sitting, Standing, Walking, Running, and Dancing. Each observation has 60 features extracted from acceleration data measured by smartphone accelerometer sensors. The data set contains the following variables:

- `actid` — Response vector containing the activity IDs in integers: 1, 2, 3, 4, and 5 representing Sitting, Standing, Walking, Running, and Dancing, respectively
- `actnames` — Activity names corresponding to the integer activity IDs
- `feat` — Feature matrix of 60 features for 24,075 observations
- `featlabels` — Labels of the 60 features

The Sensor HAR (human activity recognition) App [1] was used to create the `humanactivity` data set. When measuring the raw acceleration data with this app, a person placed a smartphone in a pocket so that the smartphone was upside down and the screen faced toward the person. The software then calibrated the measured raw data accordingly and extracted the 60 features from the calibrated data. For details about the calibration and feature extraction, see [2] and [3], respectively. The Simulink models described later also use the raw acceleration data and include blocks for calibration and feature extraction.

Prepare Data

This example uses 90% of the observations to train a model that classifies the five types of human activities and 10% of the observations to validate the trained model. Use `cvpartition` to specify a 10% holdout for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(actid,'Holdout',0.10);
trainingInds = training(Partition); % Indices for the training set
XTrain = feat(trainingInds,:);
```

```
YTrain = actid(trainingInds);  
testInds = test(Partition); % Indices for the test set  
XTest = feat(testInds,:);  
YTest = actid(testInds);
```

Convert the feature matrix XTrain and the response vector YTrain into a table to load the training data set in the Classification Learner app.

```
tTrain = array2table([XTrain YTrain]);
```

Specify the variable name for each column of the table.

```
tTrain.Properties.VariableNames = [featlabels' 'Activities'];
```

Train Boosted Tree Ensemble Using Classification Learner App

Train a classification model by using the Classification Learner app. To open the Classification Learner app, enter `classificationLearner` at the command line. Alternatively, click the **Apps** tab, and click the arrow at the right of the **Apps** section to open the gallery. Then, under **Machine Learning and Deep Learning**, click **Classification Learner**.

On the **Classification Learner** tab, in the **File** section, click **New Session** and select **From Workspace**.

In the New Session dialog box, click the arrow for **Data Set Variable**, and then select the table `tTrain`. Classification Learner detects the predictors and the response from the table.

Add All Remove All

[How to prepare data](#)

Validation

Cross-Validation
Protects against overfitting by partitioning the data set into folds and estimating accuracy on each fold.

Cross-validation folds: 5 folds

Holdout Validation
Recommended for large data sets.

Percent held out: 25%

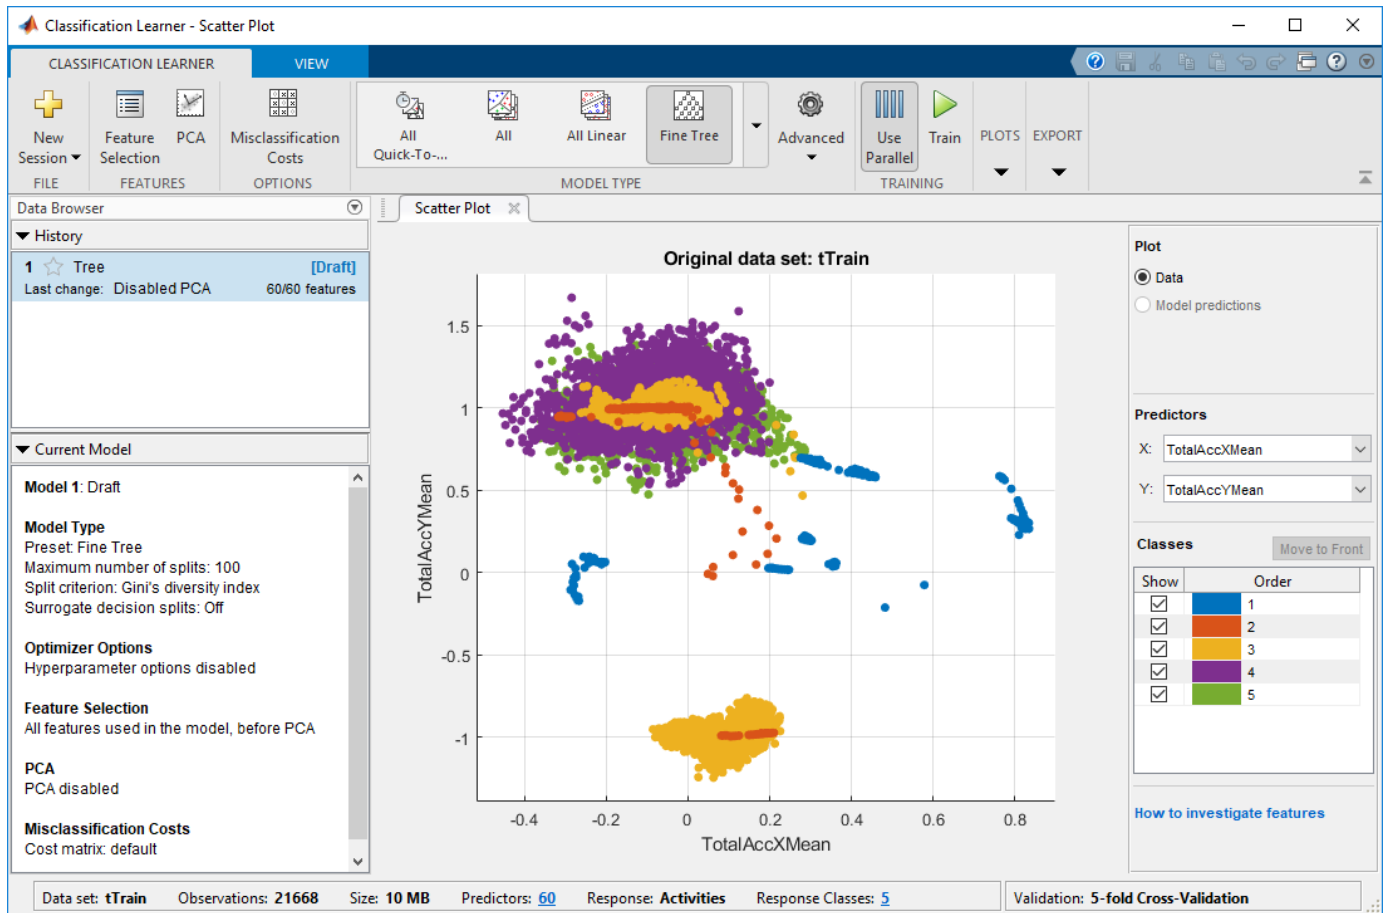

No Validation
No protection against overfitting.

[Read about validation](#)

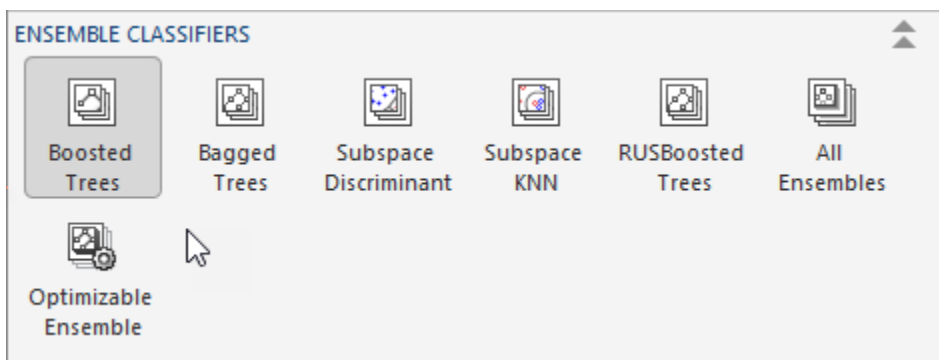

Response variable is numeric. Distinct values will be interpreted as class labels.

Start Session Cancel

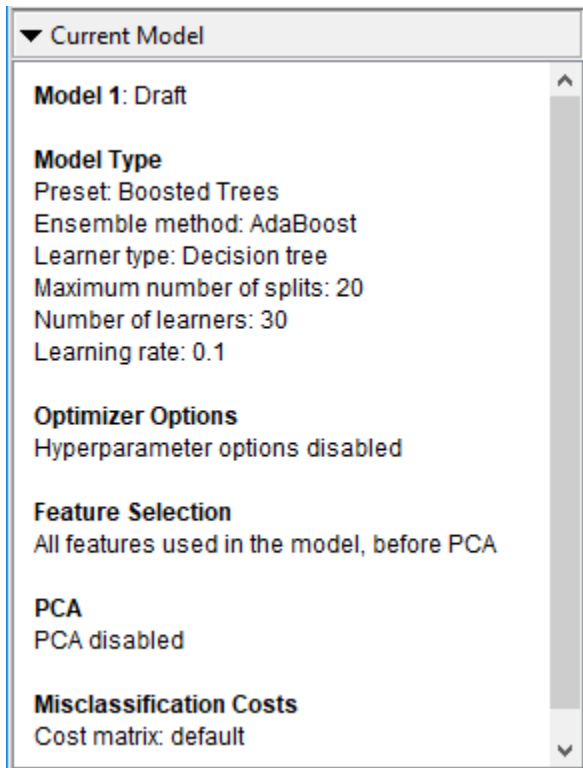

The default option is 5-fold cross-validation, which protects against overfitting. Click **Start Session**. Classification Learner loads the data set and plots a scatter plot of the first two features.

On the **Classification Learner** tab, click the arrow at the right of the **Model Type** section to open the gallery. Then, under **Ensemble Classifiers**, click **Boosted Trees**.

The Current Model pane of the Data Browser displays the default settings of the boosted tree ensemble model.

On the **Classification Learner** tab, in the **Training** section, click **Train**. When the training is complete, the History pane of the Data Browser displays the 5-fold, cross-validated classification accuracy.

On the **Classification Learner** tab, in the **Export** section, click **Export Model**, and then select **Export Compact Model**. Click **OK** in the dialog box. The structure `trainedModel` appears in the MATLAB Workspace. The field `ClassificationEnsemble` of `trainedModel` contains the compact model. Extract the trained model from the structure.

```
classificationEnsemble = trainedModel.ClassificationEnsemble;
```

Train Boosted Tree Ensemble at Command Line

Alternatively, you can train the same classification model at the command line.

```
template = templateTree('MaxNumSplits',20);
classificationEnsemble = fitcensemble(XTrain,YTrain, ...
    'Method','AdaBoostM2', ...
    'NumLearningCycles',30, ...
    'Learners',template, ...
    'LearnRate',0.1, ...
    'ClassNames',[1; 2; 3; 4; 5]);
```

Perform 5-fold cross-validation for `classificationEnsemble` and compute the validation accuracy.

```
partitionedModel = crossval(classificationEnsemble, 'KFold', 5);  
validationAccuracy = 1-kfoldLoss(partitionedModel)  
  
validationAccuracy = 0.9830
```

Evaluate Performance on Test Data

Evaluate performance on the test data set.

```
testAccuracy = 1-loss(classificationEnsemble, XTest, YTest)  
  
testAccuracy = 0.9763
```

The trained model correctly classifies 97.63% of the human activities on the test data set. This result confirms that the trained model does not overfit to the training data set.

Note that the accuracy values can vary slightly depending on your operating system.

Save Trained Model

For code generation including a classification model object, use `saveLearnerForCoder` and `loadLearnerForCoder`.

Save the trained model by using `saveLearnerForCoder`.

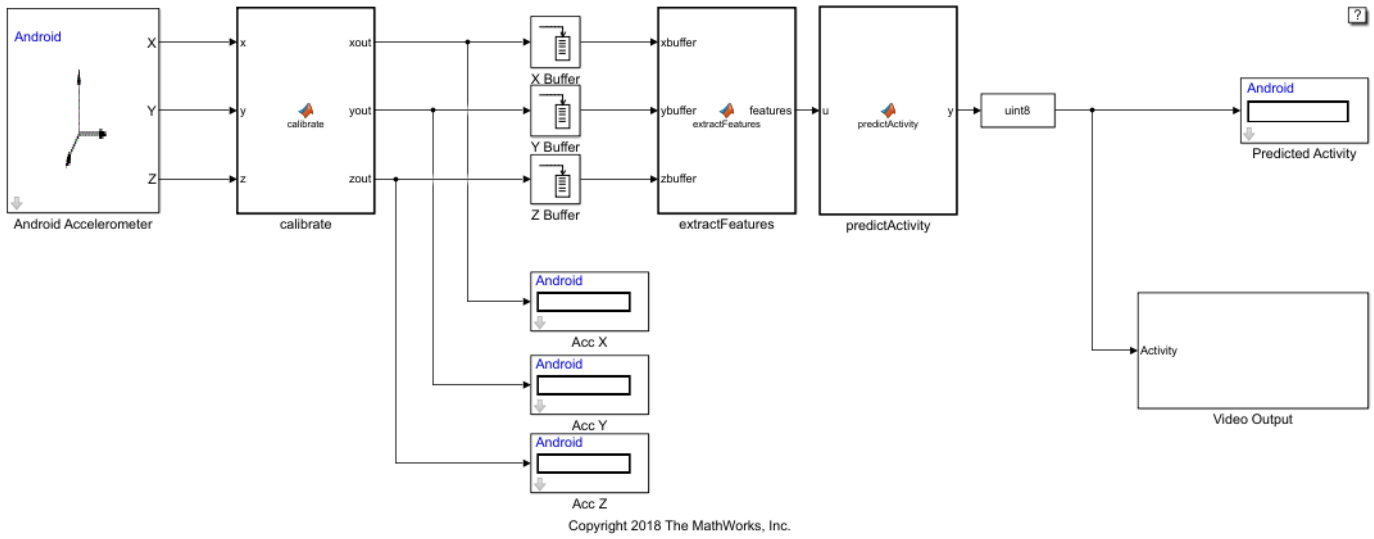

```
saveLearnerForCoder(classificationEnsemble, 'EnsembleModel.mat');
```

The function block **predictActivity** in the Simulink models loads the trained model by using `loadLearnerForCoder` and uses the trained model to classify new data.

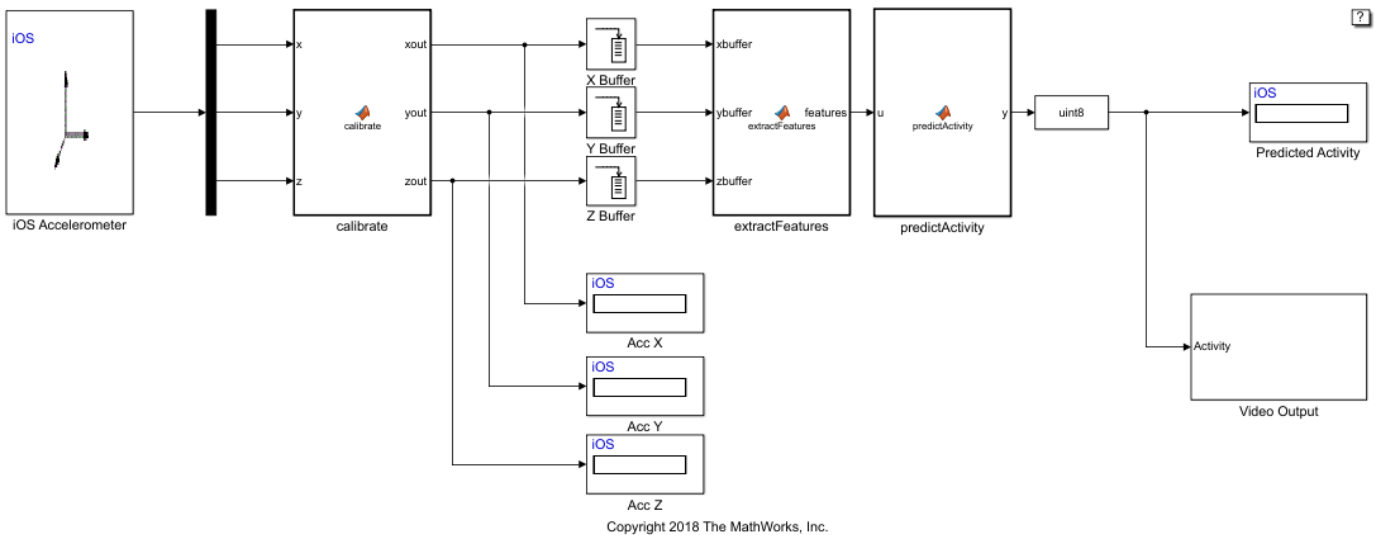

Deploy Simulink Model to Device

Now that you have prepared a classification model, you can open the Simulink model, depending on which type of smartphone you have, and deploy the model to your device. Note that the Simulink model requires the `EnsembleModel.mat` file and the calibration matrix file `slexHARAndroidCalibrationMatrix.mat` or `slexHARiOSCalibrationMatrix.mat`. If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder that includes these calibration matrix files.

Type `slexHARAndroidExample` to open the Simulink model for Android deployment.

Type `slexHARiOSExample` to open the Simulink model for iOS deployment. You can open the model on the Mac OS platform.

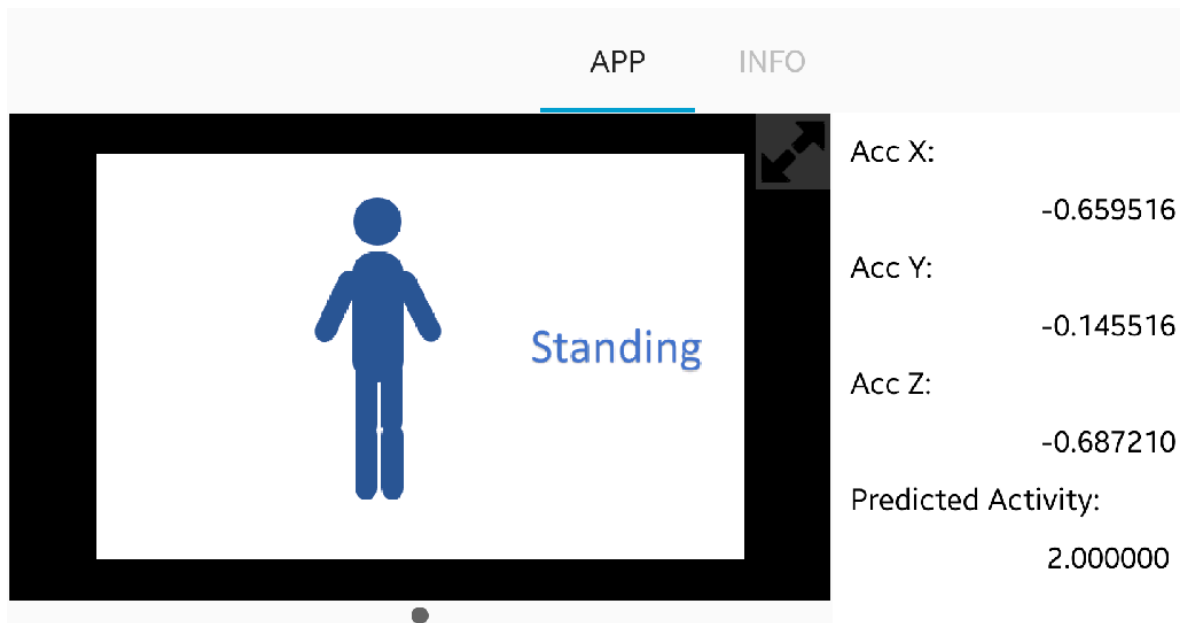

The two Simulink models classify human activity based on acceleration data measured by a smartphone sensor. The models include the following blocks:

- The **Accelerometer** block receives raw acceleration data from accelerometer sensors on the device.
- The **calibrate** block is a MATLAB Function block that calibrates the raw acceleration data. This block uses the calibration matrix in the `slexHARAndroidCalibrationMatrix.mat` file or the `slexHARiOSCalibrationMatrix.mat` file. If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder that includes these files.
- The display blocks **Acc X**, **Acc Y**, and **Acc Z** are connected to the **calibrate** block and display calibrated data points for each axis on the device.

- Each of the **Buffer** blocks, **X Buffer**, **Y Buffer**, and **Z Buffer**, buffers 32 samples of an accelerometer axis with 12 samples of overlap between buffered frames. After collecting 20 samples, each **Buffer** block joins the 20 samples with 12 samples from the previous frame and passes the total 32 samples to the **extractFeatures** block. Each **Buffer** block receives an input sample every 0.1 second and outputs a buffered frame including 32 samples every 2 seconds.
- The **extractFeatures** block is a MATLAB Function block that extracts 60 features from a buffered frame of 32 accelerometer samples. This function block uses DSP System Toolbox™ and Signal Processing Toolbox™.
- The **predictActivity** block is a MATLAB Function block that loads the trained model from the `EnsembleModel.mat` file by using `loadLearnerForCoder` and classifies the user activity using the extracted features. The output is an integer between 1 and 5, corresponding to Sitting, Standing, Walking, Running, and Dancing, respectively.
- The **Predicted Activity** block displays the classified user activity values on the device.
- The **Video Output** subsystem uses a multipoint switch block to choose the corresponding user activity image data to display on the device. The **Convert to RGB** block decomposes the selected image into separate RGB vectors and passes the image to the **Activity Display** block.

To deploy the Simulink model to your device, follow the steps in “Run Model on Android Devices” (Simulink Support Package for Android Devices) or “Run Model on Apple iOS Devices” (Simulink Support Package for Apple iOS Devices). Run the model on your device, place the device in the same way as described earlier for collecting the training data, and try the five activities. The model displays the classified activity accordingly.

To ensure the accuracy of the model, you need to place your device in the same way as described for collecting the training data. If you want to place your device in a different location or orientation, then collect the data in your own way and use your data to train the classification model.

The accuracy of the model can be different from the accuracy of the test data set (test accuracy), depending on the device. To improve the model, you can consider using additional sensors and updating the calibration matrix. Also, you can add another output block for audio feedback to the output subsystem using Audio Toolbox™. Use a ThingSpeak™ write block to publish classified

activities and acceleration data from your device to the Internet of Things. For details, see <https://thingspeak.com/>.

Code Generation for Prediction and Update Using Coder Configurer

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes of model parameters using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the model by using `generateCode`. This requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow for the `predict` and `update` functions using a coder configurer.

This table shows coder configurer objects corresponding to the supported machine learning models.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	<code>ClassificationTreeCoderConfigurer</code>
SVM for one-class and binary classification	<code>ClassificationSVMCoderConfigurer</code>
Linear model for binary classification	<code>ClassificationLinearCoderConfigurer</code>
Multiclass model for SVMs and linear models	<code>ClassificationECOCCoderConfigurer</code>
Binary decision tree for regression	<code>RegressionTreeCoderConfigurer</code>
Support vector machine (SVM) regression	<code>RegressionSVMCoderConfigurer</code>
Linear regression	<code>RegressionLinearCoderConfigurer</code>

For details and examples, see the reference pages for the coder configurer objects.

Code Generation for Probability Distribution Objects

This example shows how to generate code that fits a probability distribution to sample data and evaluates the fitted distribution.

First, define an entry-point function that uses `fitdist` to create a probability distribution object and uses its object functions to evaluate the fitted distribution. Then, generate code for the entry-point function by using `codegen`. An entry-point function can have a probability distribution object as both an input argument and an output argument. Therefore, alternatively, you can define two entry-point functions, one for fitting a distribution and the other for evaluating the fitted distribution. The first entry-point function returns a fitted distribution, and the second entry-point function accepts the fitted distribution as an input argument. This example first describes the workflow with a single entry-point function, and then briefly describes the workflow with two entry-point functions.

`fitdist` supports code generation for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. The supported object functions of the fitted probability distribution objects, created by `fitdist`, are `cdf`, `icdf`, `iqr`, `mean`, `median`, `pdf`, `std`, `truncate`, and `var`.

For more information on code generation, see “General Code Generation Workflow” on page 31-5.

Define Entry-Point Function

Define an entry-point function named `myFitandEvaluate` that takes the sample data, distribution name, truncation limits of the distribution, and data values at which to evaluate the cumulative distribution function (`cdf`) and probability distribution function (`pdf`). Within the entry-point function, fit a probability distribution object to the sample data, truncate the distribution to the specified truncation limits, compute the mean of the truncated distribution, and compute the `cdf` and `pdf` values at the specified data values.

Display the contents of the `myFitandEvaluate.m` file.

```
type myFitandEvaluate.m
```

```
function [pd_truncated,st] = myFitandEvaluate(data,distname,truncation_limits,x) %#codegen
% Fit a probability distribution object to data.
pd = fitdist(data,distname);

% Truncate pd.
pd_truncated = truncate(pd,truncation_limits(1),truncation_limits(2));

% Compute the mean of the truncated pd.
mean_val = mean(pd_truncated);

% Compute the cdf and pdf, evaluated at x.
cdf_val = cdf(pd_truncated,x);
pdf_val = pdf(pd_truncated,x);

% Create a structure array containing the mean, cdf, and pdf values.
st = struct('mean', mean_val,'cdf',cdf_val,'pdf',pdf_val);
end
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function files for this example.

Generate Code

Specify the input argument types of `myFitandEvaluate` using a 4-by-1 cell array. Assign each input argument type of the entry-point function to each cell. Specify the data type and exact input array size by using an example value that represents the set of values with a certain data type and array size.

```
ARGS = cell(4,1);
ARGS{1} = ones(100,1);
ARGS{2} = coder.Constant('Exponential');
ARGS{3} = ones(1,2);
ARGS{4} = ones(10,1);
```

The second input of `myFitandEvaluate` is a distribution name, which is the second input argument of `fitdist`. This argument must be a compile-time constant. Therefore, you specify `ARGS{2}` by using `coder.Constant`.

If you want to specify `ARGS{1}` and `ARGS{3}` as variable-size inputs, use `coder.typeof`. For details, see “General Code Generation Workflow” on page 31-5.

Generate a MEX function from the entry-point function `myFitandEvaluate`. Specify the input argument types using the `-args` option and the cell array `ARGS`.

```
codegen myFitandEvaluate -args ARGS
```

`codegen` generates the MEX function `myFitandEvaluate_mex` with a platform-dependent extension in your current folder.

Verify Generated Code

Pass some data to verify whether `myFitandEvaluate` and `myFitandEvaluate_mex` return the same outputs.

```
rng('default') % For reproducibility
data = exprnd(1,[100,1]); % Exponential random numbers with mean parameter 1
distname = 'Exponential';
truncation_limits = [0,4];
x = (0:9)';
[pd_truncated,st] = myFitandEvaluate(data,distname,truncation_limits,x);
[pd_truncated_mex,st_mex] = myFitandEvaluate_mex(data,distname,truncation_limits,x);
```

Compare the probability distribution objects `pd_truncated` and `pd_truncated_mex`.

```
pd_truncated
```

```
pd_truncated =
    ExponentialDistribution

    Exponential distribution
    mu = 0.917049
    Truncated to the interval [0, 4]
```

```
pd_truncated_mex
```

```
pd_truncated_mex =
    ExponentialDistribution
```

```

Exponential distribution
mu = 0.917049
Truncated to the interval [0, 4]

verifyMEX_pd = isequal(pd_truncated,pd_truncated_mex)

verifyMEX_pd = logical
    1

```

`isequal` returns logical 1 (true), which means `pd_truncated` and `pd_truncated_mex` are equal.

Compare the structure arrays that contain the mean, cdf, and pdf values.

```

verifyMEX_st = isequal(st,st_mex)

verifyMEX_st = logical
    1

```

The comparison confirms that `myFitandEvaluate` and `myFitandEvaluate_mex` return the same outputs. The generated code might not produce the same floating-point numerical results as MATLAB, as described in “Differences Between Generated Code and MATLAB Code” (MATLAB Coder). In that case, compare the values allowing a small tolerance.

Workflow with Two Entry-Point Functions

An entry-point function can have a probability distribution object as both an input argument and an output argument. Therefore, you can define two entry-point functions, one for fitting a distribution and the other for evaluating the fitted distribution. Then generate code for the two entry-point functions.

Define Entry-Point Functions

Define two entry-point functions. The first entry-point function `myFitDist` fits a probability distribution object to the sample data. The second entry-point function `myEvaluateDist` truncates the distribution, computes the mean of the truncated distribution, and computes the cdf and pdf values at the specified data values. `myEvaluateDist` takes the output of `myFitDist` as an input argument.

Display the contents of the `myFitDist.m` and `myEvaluateDist.m` files.

```

type myFitDist.m

function pd = myFitDist(data,dist) %#codegen
% Fit probability distribution object to data.
pd = fitdist(data,dist);
end

type myEvaluateDist.m

function [pd_truncated,st] = myEvaluateDist(pd,truncation_limits,x) %#codegen
% Truncate pd.
pd_truncated = truncate(pd,truncation_limits(1),truncation_limits(2));

% Compute the mean of the truncated pd.
mean_val = mean(pd_truncated);

```

```

% Compute the cdf and pdf, evaluated at x.
cdf_val = cdf(pd_truncated,x);
pdf_val = pdf(pd_truncated,x);

% Create a structure array containing the mean, cdf, and pdf values.
st = struct('mean', mean_val, 'cdf',cdf_val, 'pdf',pdf_val);
end

```

Generate Code

Specify the input argument types of `myFitDist` and `myEvaluateDist`.

```

ARGS_myFitDist = cell(2,1);
ARGS_myFitDist{1} = ones(100,1);
ARGS_myFitDist{2} = coder.Constant('Exponential');

ARGS_myEvaluateDist = cell(3,1);
ARGS_myEvaluateDist{1} = fitdist(exprnd(1,[100,1]), 'Exponential');
ARGS_myEvaluateDist{2} = ones(1,2);
ARGS_myEvaluateDist{3} = ones(10,1);

```

If you do not need to generate a MEX function, then you can specify `ARGS_myEvaluateDist{1}` as `coder.OutputType('myFitdist')`, as described in “Pass an Entry-Point Function Output as an Input” (MATLAB Coder). You cannot use `coder.OutputType` when generating a MEX function, because the data type of the output from `myFitDist` does not match the data type of the input to `myEvaluateDist` in the generated MEX function.

Generate code for the two entry-point functions.

```
codegen -o myFitandEvaluate_mex2 myFitDist -args ARGS_myFitDist myEvaluateDist -args ARGS_myEvaluateDist
```

`codegen` generates the MEX function `myFitandEvaluate_mex2`. For details about generating code for multiple entry-point functions, see “Generate Code for Multiple Entry-Point Functions” (MATLAB Coder).

Verify Generated Code

Verify the generated code.

```

rng('default')
data = exprnd(1,[100,1]);
distname = 'Exponential';
truncation_limits = [0,4];
x = (0:9)';
pd2 = myFitDist(data,distname);
[pd_truncated2,st2] = myEvaluateDist(pd2,truncation_limits,x);
pd_mex2 = myFitandEvaluate_mex2('myFitDist',data,distname);
[pd_truncated_mex2,st_mex2] = myFitandEvaluate_mex2('myEvaluateDist',pd_mex2,truncation_limits,x);
verifyMEX_pd2 = isequal(pd2,pd_mex2)

```

```

verifyMEX_pd2 = logical
    1

```

```

verifyMEX_pd_truncated2 = isequal(pd_truncated2,pd_truncated_mex)

```

```
verifyMEX_pd_truncated2 = logical
    1

verifyMEX_st2 = isequal(st2,st_mex2)

verifyMEX_st2 = logical
    1
```

`isequal` returns logical 1 (true), which means that the entry-point functions and the corresponding MEX functions return the same outputs.

Fixed-Point Code Generation for Prediction of SVM

This example shows how to generate fixed-point C/C++ code for the prediction of a support vector machine (SVM) model. Compared to the general C/C++ code generation workflow, fixed-point code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. You can also optimize the fixed-point data types before generating code.

This flow chart shows the fixed-point code generation workflow.

- 1 Train an SVM model.
- 2 Save the trained model by using `saveLearnerForCoder`.
- 3 Define the fixed-point data types of the variables required for prediction by using the data type function generated by `generateLearnerDataTypeFcn`.
- 4 Define an entry-point function that loads the model by using both `loadLearnerForCoder` and the structure, and then calls the `predict` function.
- 5 (Optional) Optimize the fixed-point data types.
- 6 Generate fixed-point C/C++ code.
- 7 Verify the generated code.

Step 5 is an optional step to improve the performance of the generated fixed-point code. To do so, repeat these two steps until you are satisfied with the code performance:

- 1 Record minimum and maximum values of the variables for prediction by using `buildInstrumentedMex`.
- 2 View the instrumentation results using `showInstrumentationResults`. Then, tune the fixed-point data types (if necessary) to prevent overflow and underflow, and to improve the precision of the fixed-point code.

In this workflow, you define the fixed-point data types by using the data type function generated from `generateLearnerDataTypeFcn`. Separating data types of the variables from the algorithm makes testing simpler. You can programmatically toggle data types between floating-point and fixed-point by using the input argument of the data type function. Also, this workflow is compatible with “Manual Fixed-Point Conversion Workflow” (Fixed-Point Designer).

Preprocess Data

Load the `census1994` data set. This data set consists of demographic data from the US Census Bureau used to predict whether an individual makes over \$50,000 a year.

```
load census1994
```

Consider a model that predicts the salary category of employees given their age, working class, education level, capital gain and loss, and number of working hours per week. Extract the variables of interest and save them using a table.

```
tbl = adultdata(:, {'age', 'education_num', 'capital_gain', 'capital_loss', 'hours_per_week'});
```

Print a summary of the table.

```
summary(tbl)
```

```
Variables:
```

```
age: 32561x1 double
```

```
Values:
```

```
Min      17
Median   37
Max      90
```

```
education_num: 32561x1 double
```

```
Values:
```

```
Min      1
Median   10
Max     16
```

```
capital_gain: 32561x1 double
```

```
Values:
```

```
Min      0
Median    0
Max    99999
```

```
capital_loss: 32561x1 double
```

```
Values:
```

```
Min      0
Median    0
Max    4356
```

```
hours_per_week: 32561x1 double
```

```
Values:
```

```
Min      1
Median   40
Max     99
```

The scales of the variables are not consistent. In this case, you can train a model using a standardized data set by specifying the 'Standardize' name-value pair argument of `fitcsvm`. However, adding the operations for standardization to the fixed-point code can reduce precision and increase memory use. Instead, you can manually standardize the data set, as shown in this example. The example also describes how to check the memory use at the end.

Code generation does not support tables or categorical arrays. So, define the predictor data *X* using a numeric matrix, and define the class labels *Y* using a logical vector. A logical vector uses memory most efficiently in a binary classification problem.

```
X = table2array(tbl);
Y = adultdata.salary == '<=50K';
```

Define the observation weights w .

```
w = adultdata.fnlwgt;
```

The memory use of a trained model increases as the number of support vectors in the model increases. To reduce the number of support vectors, you can increase the box constraint when training by using the 'BoxConstraint' name-value pair argument or use a subsampled representative data set for training. Note that increasing the box constraint can lead to longer training times, and using a subsampled data set can reduce the accuracy of the trained model. In this example, you randomly sample 1000 observations from the data set and use the subsampled data for training.

```
rng('default') % For reproducibility
[X_sampled,idx] = datasample(X,1000,'Replace',false);
Y_sampled = Y(idx);
w_sampled = w(idx);
```

Find the weighted means and standard deviations by training the model using the 'Weight' and 'Standardize' name-value pair arguments.

```
tempMdl = fitcsvm(X_sampled,Y_sampled,'Weight',w_sampled,'KernelFunction','gaussian','Standardize',true);
mu = tempMdl.Mu;
sigma = tempMdl.Sigma;
```

If you do not use the 'Cost', 'Prior', or 'Weight' name-value pair argument for training, then you can find the mean and standard deviation values by using the `zscore` function.

```
[standardizedX_sampled,mu,sigma] = zscore(X_sampled);
```

Standardize the predictor data by using μ and σ .

```
standardizedX = (X-mu)./sigma;
standardizedX_sampled = standardizedX(idx,:);
```

You can use a test data set to validate the trained model and to test an instrumented MEX function. Specify a test data set and standardize the test predictor data by using μ and σ .

```
XTest = table2array(adulttest(:,{'age','education_num','capital_gain','capital_loss','hours_per_week'}));
standardizedXTest = (XTest-mu)./sigma;
YTest = adulttest.salary == '<=50K';
```

Train Model

Train a binary SVM classification model.

```
Mdl = fitcsvm(standardizedX_sampled,Y_sampled,'Weight',w_sampled,'KernelFunction','gaussian');
```

`Mdl` is a `ClassificationSVM` model.

Compute the classification error for the training data set and the test data set.

```
loss(Mdl,standardizedX_sampled,Y_sampled)
```

```
ans = 0.1663
```

```
loss(Mdl,standardizedXTest,YTest)
```

```
ans = 0.1905
```

The SVM classifier misclassifies approximately 17% of the training data and 19% of the test data.

Save Model

Save the SVM classification model to the file `myMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl, 'myMdl');
```

Define Fixed-Point Data Types

Use `generateLearnerDataTypeFcn` to generate a function that defines the fixed-point data types of the variables required for prediction of the SVM model. Use all available predictor data to obtain realistic ranges for the fixed-point data types.

```
generateLearnerDataTypeFcn('myMdl',[standardizedX; standardizedXTest])
```

`generateLearnerDataTypeFcn` generates the `myMdl_datatype` function. Display the contents of `myMdl_datatype.m` by using the `type` function.

```
type myMdl_datatype.m
```

```
function T = myMdl_datatype(dt)
%MYMDL_DATATYPE Define data types for fixed-point code generation
%
% T = MYMDL_DATATYPE(DT) returns the data type structure T, which defines
% data types for the variables required to generate fixed-point C/C++ code
% for prediction of a machine learning model. Each field of T contains a
% fixed-point object returned by fi. The input argument dt specifies the
% DataType property of the fixed-point object. Specify dt as 'Fixed' (default)
% for fixed-point code generation or specify dt as 'Double' to simulate
% floating-point behavior of the fixed-point code.
%
% Use the output structure T as both an input argument of an entry-point
% function and the second input argument of loadLearnerForCoder within the
% entry-point function. For more information, see loadLearnerForCoder.
%
% File: myMdl_datatype.m
% Statistics and Machine Learning Toolbox Version 11.7 (Release R2020a)
% Generated by MATLAB, 29-Feb-2020 10:34:48

if nargin < 1
    dt = 'Fixed';
end

% Set fixed-point math settings
fm = fimath('RoundingMethod','Floor', ...
    'OverflowAction','Wrap', ...
    'ProductMode','FullPrecision', ...
    'MaxProductWordLength',128, ...
    'SumMode','FullPrecision', ...
    'MaxSumWordLength',128);

% Data type for predictor data
T.XDataType = fi([],true,16,11,fm,'DataType',dt);

% Data type for output score
T.ScoreDataType = fi([],true,16,14,fm,'DataType',dt);
```

```

% Internal variables
% Data type of the squared distance dist = (x-sv)^2 for the Gaussian kernel G(x,sv) = exp(-dist)
% where x is the predictor data for an observation and sv is a support vector
T.InnerProductDataType = fi([],true,16,6,fm,'DataType',dt);

end

```

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function file.

The `myMdl_datatype` function uses the default word length (16) and proposes the maximum fraction length to avoid overflows, based on the default word length (16) and safety margin (10%) for each variable.

Create a structure `T` that defines the fixed-point data types by using `myMdl_datatype`.

```

T = myMdl_datatype('Fixed')

T = struct with fields:
    XDataType: [0x0 embedded.fi]
    ScoreDataType: [0x0 embedded.fi]
    InnerProductDataType: [0x0 embedded.fi]

```

The structure `T` includes the fields for the named and internal variables required to run the `predict` function. Each field contains a fixed-point object, returned by `fi`. For example, display the fixed-point data type properties of the predictor data.

`T.XDataType`

```

ans =

[]

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 11

    RoundingMethod: Floor
    OverflowAction: Wrap
    ProductMode: FullPrecision
    MaxProductWordLength: 128
    SumMode: FullPrecision
    MaxSumWordLength: 128

```

For more details about the generated function and the structure, see “Data Type Function” on page 32-2391.

Define Entry-Point Function

Define an entry-point function named `myFixedPointPredict` that does the following:

- Accept the predictor data `X` and the fixed-point data type structure `T`.
- Load a fixed-point version of a trained SVM classification model by using both `loadLearnerForCoder` and the structure `T`.

- Predict labels and scores using the loaded model.

```
function [label,score] = myFixedPointPredict(X,T) %#codegen
Mdl = loadLearnerForCoder('myMdl','DataType',T);
[label,score] = predict(Mdl,X);
end
```

(Optional) Optimize Fixed-Point Data Types

Optimize the fixed-point data types by using `buildInstrumentedMex` and `showInstrumentationResults`. Record minimum and maximum values of all named and internal variables for prediction by using `buildInstrumentedMex`. View the instrumentation results using `showInstrumentationResults`; then, based on the results, tune the fixed-point data type properties of the variables.

Specify Input Argument Types of Entry-Point Function

Specify the input argument types of `myFixedPointPredict` using a 2-by-1 cell array.

```
ARGS = cell(2,1);
```

The first input argument is the predictor data. The `XDataType` field of the structure `T` specifies the fixed-point data type of the predictor data. Convert `X` to the type specified in `T.XDataType` by using the `cast` function.

```
X_fx = cast(standardizedX,'like',T.XDataType);
```

The test data set does not have the same size as the training data set. Specify `ARGS{1}` by using `coder.typeof` so that the MEX function can take variable-size inputs.

```
ARGS{1} = coder.typeof(X_fx,size(standardizedX),[1,0]);
```

The second input argument is the structure `T`, which must be a compile-time constant. Use `coder.Constant` to specify `T` as a constant during code generation.

```
ARGS{2} = coder.Constant(T);
```

Create Instrumented MEX Function

Create an instrumented MEX function by using `buildInstrumentedMex`.

- Specify the input argument types of the entry-point function by using the `-args` option.
- Specify the MEX function name by using the `-o` option.
- Compute a histogram by using the `-histogram` option.
- Allow full code generation support by using the `-coder` option.

```
buildInstrumentedMex myFixedPointPredict -args ARGS -o myFixedPointPredict_instrumented -histogram
```

Test Instrumented MEX Function

Run the instrumented MEX function to record instrumentation results.

```
[labels_fx1,scores_fx1] = myFixedPointPredict_instrumented(X_fx,T);
```

You can run the instrumented MEX function multiple times to record results from various test data sets. Run the instrumented MEX function using `standardizedXTest`.

```
Xtest_fx = cast(standardizedXTest,'like',T.XDataType);
[label_s_fx1_test,scores_fx1_test] = myFixedPointPredict_instrumented(Xtest_fx,T);
```

View Results of Instrumented MEX Function

Call `showInstrumentationResults` to open a report containing the instrumentation results. View the simulation minimum and maximum values, proposed fraction length, percent of current range, and whole number status.

```
showInstrumentationResults('myFixedPointPredict_instrumented')
```

Function: myFixedPointPredict

```

1 function [label, score] = myFixedPointPredict(X,T) %#codegen
2 Mdl = loadLearnerForCoder('myMdl','DataType',T);
3 [label,score] = predict(Mdl,X);
4 end

```

ALL MESSAGES (0)				VARIABLES									
Name	Type	Size	Class	DT Mode	Signed	WL	FL	Percent of Current Range	Always Whole Num	Sim Min	Sim Max		
label	Output	:32561 × 1	logical	-	-	-	-	-	Yes	0	1		
score	Output	:32561 × 2	embedded.fi 	-	Signed	16	14	93	No	-1.856	1.8560		
▲ T	Input	1 × 1	struct 	-	-	-	-	-	No	-	-		
XDataType		0 × 0	embedded.fi 	-	Signed	16	11		No	-	-		
ScoreDataType		0 × 0	embedded.fi 	-	Signed	16	14		No	-	-		
InnerProductDataType		0 × 0	embedded.fi 	-	Signed	16	6		No	-	-		
X	Input	:32561 × 5	embedded.fi 	-	Signed	16	11	87	No	-3.354	13.865		
► Mdl	Local	1 × 1	classreg.learning.coc 	-	-	-	-		No	-	-		

The proposed word lengths and fraction lengths in `X` are the same as those in `XDataType` in the structure `T`.

View the histogram for a variable by clicking  on the **Variables** tab.

The window contains the histogram and dialog panels with information about the variable. For information on this window, see the `NumericTypeScope` reference page.

Clear the results by using `clearInstrumentationResults`.

```
clearInstrumentationResults('myFixedPointPredict_instrumented')
```

Verify Instrumented MEX Function

Compare the outputs from `predict` and `myFixedPointPredict_instrumented`.

```
[labels,scores] = predict(Mdl,standardizedX);
verify_labels1 = isequal(labels,labels_fx1)

verify_labels1 = logical
0
```

`isequal` returns logical 1 (true) if `labels` and `labels_fx1` are equal. If the labels are not equal, you can compute the percentage of incorrectly classified labels as follows.

```
diff_labels1 = sum(strcmp(string(labels_fx1),string(labels))==0)/length(labels_fx1)*100
diff_labels1 = 0.1228
```

Find the maximum of the relative differences between the score outputs.

```
diff_scores1 = max(abs((scores_fx1.double(:,1)-scores(:,1))./scores(:,1)))
diff_scores1 = 68.5186
```

Tune Fixed-Point Data Types

You can tune the fixed-point data types if the recorded results show overflow or underflow, or if you want to improve the precision of the generated code. Modify the fixed-point data types by updating the `myMdl_datatype` function and creating a new structure, and then generate the code using the new structure. To update the `myMdl_datatype` function, you can manually modify the fixed-point data types in the function file (`myMdl_datatype.m`). Or, you can generate the function by using `generateLearnerDataTypeFcn` and specifying a longer word length, as shown in this example. For more details, see “Tips” on page 32-2392.

Generate a new data type function. Specify the word length 32 and the name `myMdl_datatype2` for the generated function.

```
generateLearnerDataTypeFcn('myMdl',[standardizedX; standardizedXTest],'WordLength',32,'OutputFun
```

Display the contents of `myMdl_datatype2.m`.

```
type myMdl_datatype2.m
```

```
function T = myMdl_datatype2(dt)
%MYMDL_DATATYPE2 Define data types for fixed-point code generation
%
% T = MYMDL_DATATYPE2(DT) returns the data type structure T, which defines
% data types for the variables required to generate fixed-point C/C++ code
% for prediction of a machine learning model. Each field of T contains a
% fixed-point object returned by fi. The input argument dt specifies the
% DataType property of the fixed-point object. Specify dt as 'Fixed' (default)
% for fixed-point code generation or specify dt as 'Double' to simulate
% floating-point behavior of the fixed-point code.
%
% Use the output structure T as both an input argument of an entry-point
% function and the second input argument of loadLearnerForCoder within the
% entry-point function. For more information, see loadLearnerForCoder.
%
% File: myMdl_datatype2.m
% Statistics and Machine Learning Toolbox Version 11.7 (Release R2020a)
% Generated by MATLAB, 29-Feb-2020 10:37:18
```

```

if nargin < 1
    dt = 'Fixed';
end

% Set fixed-point math settings
fm = fimath('RoundingMethod','Floor', ...
    'OverflowAction','Wrap', ...
    'ProductMode','FullPrecision', ...
    'MaxProductWordLength',128, ...
    'SumMode','FullPrecision', ...
    'MaxSumWordLength',128);

% Data type for predictor data
T.XDataType = fi([],true,32,27,fm,'DataType',dt);

% Data type for output score
T.ScoreDataType = fi([],true,32,30,fm,'DataType',dt);

% Internal variables
% Data type of the squared distance dist = (x-sv)^2 for the Gaussian kernel G(x,sv) = exp(-dist)
% where x is the predictor data for an observation and sv is a support vector
T.InnerProductDataType = fi([],true,32,22,fm,'DataType',dt);

end

```

The `myMdl_datatype2` function specifies the word length 32 and proposes the maximum fraction length to avoid overflows.

Create a structure `T2` that defines the fixed-point data types by using `myMdl_datatype2`.

```

T2 = myMdl_datatype2('Fixed')

T2 = struct with fields:
    XDataType: [0x0 embedded.fi]
    ScoreDataType: [0x0 embedded.fi]
    InnerProductDataType: [0x0 embedded.fi]

```

Create a new instrumented MEX function, record the results, and view the results by using `buildInstrumentedMex` and `showInstrumentationResults`.

```

X_fx2 = cast(standardizedX,'like',T2.XDataType);
buildInstrumentedMex myFixedPointPredict -args {X_fx2,coder.Constant(T2)} -o myFixedPointPredict_
[labels_fx2,scores_fx2] = myFixedPointPredict_instrumented2(X_fx2,T2);
showInstrumentationResults('myFixedPointPredict_instrumented2')

```

Review the instrumentation report, and then clear the results.

```

clearInstrumentationResults('myFixedPointPredict_instrumented2')

```

Verify `myFixedPointPredict_instrumented2`.

```

verify_labels2 = isequal(labels,labels_fx2)

```

```

verify_labels2 = logical
    0

```

```

diff_labels2 = sum(strcmp(string(labels_fx2),string(labels))==0)/length(labels_fx2)*100
diff_labels2 = 0.0031
diff_scores2 = max(abs((scores_fx2.double(:,1)-scores(:,1))./scores(:,1)))
diff_scores2 = 2.8001

```

The percentage of incorrectly classified labels `diff_labels2` and the relative difference in score values `diff_scores2` are smaller than those from the previous MEX function generated using the default word length (16).

For more details about optimizing fixed-point data types by instrumenting MATLAB® code, see the reference pages `buildInstrumentedMex`, `showInstrumentationResults`, and `clearInstrumentationResults`, and the example “Set Data Types Using Min/Max Instrumentation” (Fixed-Point Designer).

Generate Code

Generate code for the entry-point function using `codegen`. Instead of specifying a variable-size input for a predictor data set, specify a fixed-size input by using `coder.typeof`. If you know the size of the predictor data set that you pass to the generated code, then generating code for a fixed-size input is preferable for the simplicity of the code.

```
codegen myFixedPointPredict -args {coder.typeof(X_fx2,[1,5],[0,0]),coder.Constant(T2)}
```

`codegen` generates the MEX function `myFixedPointPredict_mex` with a platform-dependent extension.

Verify Generated Code

You can verify the `myFixedPointPredict_mex` function in the same way that you verify the instrumented MEX function. See the **Verify Instrumented MEX Function** section for details.

```

[labels_sampled,scores_sampled] = predict(Mdl,standardizedX_sampled);
n = size(standardizedX_sampled,1);
labels_fx = true(n,1);
scores_fx = zeros(n,2);
for i = 1:n
    [labels_fx(i),scores_fx(i,:)] = myFixedPointPredict_mex(X_fx2(idx(i),:),T2);
end
verify_labels = isequal(labels_sampled,labels_fx)

verify_labels = logical
    1

diff_labels = sum(strcmp(string(labels_fx),string(labels_sampled))==0)/length(labels_fx)*100
diff_labels = 0
diff_scores = max(abs((scores_fx(:,1)-scores_sampled(:,1))./scores_sampled(:,1)))
diff_scores = 0.0631

```

Memory Use

A good practice is to manually standardize predictor data before training a model. If you use the 'Standardize' name-value pair argument instead, then the generated fixed-point code includes standardization operations, which can cause loss of precision and increased memory use.

If you generate a static library, you can find the memory use of the generated code by using a code generation report. Specify `-config:lib` to generate a static library, and use the `-report` option to generate a code generation report.

```
codegen myFixedPointPredict -args {coder.typeof(X_fx2,[1,5],[0,0]),coder.Constant(T2)} -o myFixed
```

On the **Summary** tab of the code generation report, click **Code Metrics**. The Function Information section shows the accumulated stack size.

Generate Code to Classify Numeric Data in Table

This example shows how to generate code for classifying numeric data in a table using a binary decision tree.

In the general code generation workflow, you can train a classification or regression model on data in a table, provided that you use only numeric predictor variables. When you create an entry-point function for prediction, you pass a numeric matrix (instead of a table) to `predict`.

Starting in R2020a, you can pass a table to `predict` inside your entry-point function. For more information on table support in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).

Train Classification Model

Load the `patients` data set. Create a table that contains numeric predictors of type `single` and `double` and the response variable `Smoker` of type `logical`. Each row of the table corresponds to a different patient.

```
load patients
Age = single(Age);
Weight = single(Weight);
Tbl = table(Age,Diastolic,Smoker,Systolic,Weight);
```

Train a classification tree using the data in `Tbl`. Notice the predictor names and their order.

```
Mdl = fitctree(Tbl,'Smoker');
Mdl.PredictorNames

ans = 1x4 cell
    {'Age'}    {'Diastolic'}    {'Systolic'}    {'Weight'}
```

Save Model

Save the tree classifier to a file using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'TreeModel');
```

`saveLearnerForCoder` saves the classifier to the MATLAB® binary file `TreeModel.mat` as a structure array in the current folder.

Define Entry-Point Function

Define the entry-point function `predictSmoker`, which takes numeric predictor variables as input arguments. Within the function, load the tree classifier by using `loadLearnerForCoder`, create a table from the input arguments, and then pass the classifier and table to `predict`.

```
type predictSmoker.mlx

function [labels,scores] = predictSmoker(age,diastolic,systolic,weight) %#codegen
%PREDICTSMOKER Label new observations using a trained tree model
% predictSmoker predicts whether patients are smokers (1) or nonsmokers
% (0) based on their age, diastolic blood pressure, systolic blood
% pressure, and weight. The function also provides classification scores
% indicating the likelihood that a predicted label comes from a
% particular class (smoker or nonsmoker).
```

```
mdl = loadLearnerForCoder('TreeModel');
varnames = mdl.PredictorNames;
tbl = table(age,diastolic,systolic,weight,'VariableNames',varnames);
[labels,scores] = predict(mdl,tbl);
end
```

When you create a table inside an entry-point function, you must specify the variable names (for example, by using the 'VariableNames' name-value pair argument of `table`). If your table contains only predictor variables, and the predictors are in the same order as in the table used to train the model, then you can find the predictor variable names in `mdl.PredictorNames`.

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB, then MATLAB opens the example folder. This folder includes the entry-point function file `predictSmoker.mlx`.

Generate Code

Generate code for `predictSmoker` by using `codegen`. Specify the data type and dimensions of the predictor variable input arguments using `coder.typeof`.

- The first input argument of `coder.typeof` specifies the data type of the predictor.
- The second input argument specifies the upper bound on the number of rows (`Inf`) and columns (`1`) in the predictor.
- The third input argument specifies that the number of rows in the predictor can change at run time but the number of columns is fixed.

```
ARGS = cell(4,1);
ARGS{1} = coder.typeof(Age,[Inf 1],[1 0]);
ARGS{2} = coder.typeof(Diastolic,[Inf 1],[1 0]);
ARGS{3} = coder.typeof(Systolic,[Inf 1],[1 0]);
ARGS{4} = coder.typeof(Weight,[Inf 1],[1 0]);
```

```
codegen predictSmoker -args ARGS
```

`codegen` generates the MEX function `predictSmoker_mex` with a platform-dependent extension in your current folder.

Verify Generated Code

Verify that `predict`, `predictSmoker`, and the MEX file return the same results for a random sample of 20 patients.

```
rng('default') % For reproducibility
[newTbl,idx] = datasample(Tbl,20);

[labels1,scores1] = predict(Mdl,newTbl);
[labels2,scores2] = predictSmoker(Age(idx),Diastolic(idx),Systolic(idx),Weight(idx));
[labels3,scores3] = predictSmoker_mex(Age(idx),Diastolic(idx),Systolic(idx),Weight(idx));

verifyMEXlabels = isequal(labels1,labels2,labels3)

verifyMEXlabels = logical
    1

verifyMEXscores = isequal(scores1,scores2,scores3)
```

```
verifyMEXscores = logical  
1
```

Functions

addedvarplot

Create added variable plot using input data

Syntax

```
addedvarplot(X,y,num,inmodel)
addedvarplot(X,y,num,inmodel,stats)
addedvarplot(ax, ___)
```

Description

`addedvarplot(X,y,num,inmodel)` displays an added variable plot using the predictive terms in `X`, the response values in `y`, the added term in column `num` of `X`, and the model with current terms specified by `inmodel`. `X` is an n -by- p matrix of n observations of p predictive terms. `y` is vector of n response values. `num` is a scalar index specifying the column of `X` with the term to be added. `inmodel` is a logical vector of p elements specifying the columns of `X` in the current model. By default, all elements of `inmodel` are `false`.

Note `addedvarplot` automatically includes a constant term in all models. Do not enter a column of 1s directly into `X`.

`addedvarplot(X,y,num,inmodel,stats)` uses the `stats` output from the `stepwisefit` function to improve the efficiency of repeated calls to `addedvarplot`. Otherwise, this syntax is equivalent to the previous syntax.

`addedvarplot(ax, ___)` creates the plot in the axes specified by `ax` instead of the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes. For more information on creating an Axes object, see `axes` and `gca`.

Added variable plots are used to determine the unique effect of adding a new term to a multilinear model. The plot shows the relationship between the part of the response unexplained by terms already in the model and the part of the new term unexplained by terms already in the model. The “unexplained” parts are measured by the residuals of the respective regressions. A scatter of the residuals from the two regressions forms the added variable plot. In addition to the scatter of residuals, the plot produced by `addedvarplot` shows 95% confidence intervals on predictions from the fitted line. The slope of the fitted line is the coefficient that the new term would have if it were added to the model with terms `inmodel`. For more details, see “Added Variable Plot” on page 32-3992.

Added variable plots are sometimes known as partial regression leverage plots.

Examples

Create Added Variable Plot

Load the data in `hald.mat`, which contains observations of the reaction to heat for various cement mixtures.

```
load hald
whos
```

Name	Size	Bytes	Class	Attributes
Description	22x58	2552	char	
hald	13x5	520	double	
heat	13x1	104	double	
ingredients	13x4	416	double	

Create an added variable plot to investigate the effect of adding the third column of ingredients to a model that contains the first two columns.

```
inmodel = [true true false false];
addedvarplot(ingredients,heat,3,inmodel)
```

The wide scatter plot and the low slope of the fitted line are evidence against the statistical significance of adding the third column to the model.

Alternative Functionality

You can create a linear regression model object `LinearModel` by using `fitlm` or `stepwiselm` and use the object function `plotAdded` to create an added variable plot.

A `LinearModel` object provides the object properties and the object functions to investigate a fitted linear regression model. The object properties include information about coefficient estimates,

summary statistics, fitting method, and input data. Use the object functions to predict responses and to modify, evaluate, and visualize the linear regression model.

See Also

`plotAdded` | `stepwise` | `stepwisefit`

Introduced before R2006a

addK

Class: `clustering.evaluation.ClusterCriterion`

Package: `clustering.evaluation`

Evaluate additional numbers of clusters

Syntax

```
eva_out = addK(eva, klist)
```

Description

`eva_out = addK(eva, klist)` returns a clustering evaluation object `eva_out` that contains the evaluation data stored in the input object `eva`, plus additional evaluation data for the proposed number of clusters specified in `klist`.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

klist — Additional numbers of clusters to evaluate

vector of positive integer values

Additional numbers of clusters to evaluate, specified as a vector of positive integer values. If any values in `klist` overlap with clustering solutions already evaluated in the input object `eva`, then `addK` ignores the overlapping values.

Output Arguments

eva_out — Updated clustering evaluation data

clustering evaluation object

Updated clustering evaluation data, returned as a clustering evaluation object. `eva_out` contains data on the proposed clustering solutions included in the input clustering evaluation object `eva`, plus data on the additional proposed numbers of clusters specified in `klist`.

For all clustering evaluation object classes, `addK` updates the `InspectedK` and `CriterionValues` properties to include the proposed clustering solutions specified in `klist` and their corresponding criterion values. `addK` might also update the `OptimalK` and `OptimalY` properties to reflect the new optimal number of clusters and optimal clustering solution.

For certain cluster evaluation objects classes, `addK` might also update the following additional property values:

- For gap evaluation objects — `LogW`, `ExpectedLogW`, `StdLogW`, and `SE`

- For silhouette evaluation objects — `ClusterSilhouettes`

Examples

Evaluate Additional Numbers of Clusters

Create a clustering evaluation object using `evalclusters`, then use `addK` to evaluate additional numbers of clusters.

Load the sample data.

```
load fisheriris
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the Calinski-Harabasz criterion to evaluate proposed solutions of one through five clusters.

```
eva = evalclusters(meas, 'kmeans', 'calinski', 'klist', 1:5)
```

```
eva =
  CalinskiHarabaszEvaluation with properties:

    NumObservations: 150
      InspectedK: [1 2 3 4 5]
  CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279]
      OptimalK: 3
```

The clustering evaluation object `eva` contains data on each proposed clustering solution. The returned value of `OptimalK` indicates that the optimal solution is three clusters.

Evaluate proposed solutions of 6 through 10 clusters using the same criteria. Add these evaluations to the original clustering evaluation object `eva`.

```
eva = addK(eva, 6:10)
```

```
eva =
  CalinskiHarabaszEvaluation with properties:

    NumObservations: 150
      InspectedK: [1 2 3 4 5 6 7 8 9 10]
  CriterionValues: [1x10 double]
      OptimalK: 3
```

The updated values for `InspectedK` and `CriterionValues` show that `eva` now evaluates proposed solutions of 1 through 10 clusters. The `OptimalK` value still equals 3, indicating that three clusters remain the optimal solution.

addlevels

(Not Recommended) Add levels to nominal or ordinal arrays

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

```
B = addlevels(A,newlevels)
```

Description

`B = addlevels(A,newlevels)` adds new levels specified by `newlevels` to the nominal or ordinal array `A`. `addlevels` adds the new levels at the end of the list of possible levels in `A`, but does not modify the value of any element. `B` does not contain elements at the new levels.

Examples

Add Levels To A Nominal Array

Add levels for additional species to Fisher's iris data.

Create a nominal array of the existing species in Fisher's iris data.

```
load fisheriris
species = nominal(species);
getlevels(species)

ans = 1x3 nominal
      setosa      versicolor      virginica
```

Add two additional species.

```
species = addlevels(species,{'spuria','ruthenica'});
getlevels(species)

ans = 1x5 nominal
      setosa      versicolor      virginica      spuria      ruthenica
```

Even though there are new levels, there are no elements in `species` that are in these new levels.

```
sum(species=='spuria')

ans = 0

sum(species=='ruthenica')

ans = 0
```

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

newlevels — Levels to add

string array | cell array of character vectors | 2-D character matrix

Levels to add to the input `nominal` or `ordinal` array, specified as a string array, a cell array of character vectors, or a 2-D character matrix.

Data Types: `char` | `string` | `cell`

Output Arguments

B — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

See Also

`droplevels` | `mergelevels` | `nominal` | `ordinal` | `reorderlevels`

Topics

“Add and Drop Category Levels” on page 2-18

Introduced in R2007a

addlistener

Class: grandstream

Add listener for event

Syntax

```
e1 = addlistener(hsource, 'eventname', callback)
e1 = addlistener(hsource, property, 'eventname', callback)
```

Description

`e1 = addlistener(hsource, 'eventname', callback)` creates a listener for the event named `eventname`, the source of which is handle object `hsource`. If `hsource` is an array of source handles, the listener responds to the named event on any handle in the array. `callback` is a function handle that is invoked when the event is triggered.

`e1 = addlistener(hsource, property, 'eventname', callback)` adds a listener for a property event. `eventname` must be 'PreGet', 'PostGet', 'PreSet', or 'PostSet'. `property` must be either a property name or cell array of property names, or a `meta.property` or array of `meta.property`. The properties must belong to the class of `hsource`. If `hsource` is scalar, `property` can include dynamic properties.

For all forms, `addlistener` returns an `event.listener`. To remove a listener, delete the object returned by `addlistener`. For example, `delete(e1)` calls the handle class `delete` method to remove the listener and delete it from the workspace.

See Also

`delete` | `dynamicprops` | `event.listener` | `events` | `meta.property` | `notify` | `grandstream` | `reset`

anova

Class: GeneralizedLinearMixedModel

Analysis of variance for generalized linear mixed-effects model

Syntax

```
stats = anova(glme)
stats = anova(glme, Name, Value)
```

Description

`stats = anova(glme)` returns a table, `stats`, that contains the results of F -tests to determine if all coefficients representing each fixed-effects term in the generalized linear mixed-effects model `glme` are equal to 0.

`stats = anova(glme, Name, Value)` returns a table, `stats`, using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the method used to compute the approximate denominator degrees of freedom for the F -tests.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

DFMethod — Method for computing approximate denominator degrees of freedom

'residual' (default) | 'none'

Method for computing approximate denominator degrees of freedom to use in the F -test, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

Value	Description
'residual'	The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'none'	All degrees of freedom are set to infinity.

The denominator degrees of freedom for the F -statistic correspond to the column DF2 in the output structure `stats`.

Example: 'DFMethod', 'none'

Output Arguments

stats — Results of *F*-tests for fixed-effects terms

table

Results of *F*-tests for fixed-effects terms, returned as a table with one row for each fixed-effects term in `glme` and the following columns.

Column Name	Description
Term	Name of the fixed-effects term
FStat	<i>F</i> -statistic for the term
DF1	Numerator degrees of freedom for the <i>F</i> -statistic
DF2	Denominator degrees of freedom for the <i>F</i> -statistic
pValue	<i>p</i> -value for the term

Each fixed-effects term is a continuous variable, a grouping variable, or an interaction between two or more continuous or grouping variables. For each fixed-effects term, `anova` performs an *F*-test (marginal test) to determine if all coefficients representing the fixed-effects term are equal to 0.

To perform tests for the type III hypothesis, when fitting the generalized linear mixed-effects model `fitglme`, you must use the 'effects' contrasts for the 'DummyVarCoding' name-value pair argument.

Examples

F-Tests for Fixed Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defect}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log \mu_{ij} = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ...
'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects')
```

```
glme =
Generalized linear mixed-effects model fit by ML
```

```
Model information:
  Number of observations      100
  Fixed effects coefficients    6
  Random effects coefficients  20
  Covariance parameters       1
  Distribution                 Poisson
  Link                         Log
  FitMethod                    Laplace
```

```
Formula:
  defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1 | factory)
```

```
Model fit statistics:
  AIC      BIC      LogLikelihood  Deviance
  416.35   434.58   -201.17      402.35
```

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
{'(Intercept)'} }	1.4689	0.15988	9.1875	94	9.8194e-15
{'newprocess' }	-0.36766	0.17755	-2.0708	94	0.041122
{'time_dev' }	-0.094521	0.82849	-0.11409	94	0.90941
{'temp_dev' }	-0.28317	0.9617	-0.29444	94	0.76907
{'supplier_C' }	-0.071868	0.078024	-0.9211	94	0.35936
{'supplier_B' }	0.071072	0.07739	0.91836	94	0.36078

Lower	Upper
1.1515	1.7864
-0.72019	-0.015134
-1.7395	1.5505
-2.1926	1.6263
-0.22679	0.083051
-0.082588	0.22473

Random effects covariance parameters:

Group: factory (20 Levels)

Name1	Name2	Type	Estimate
{'(Intercept)'} }	{'(Intercept)'} }	{'std'}	0.31381

Group: Error

Name	Estimate
{'sqrt(Dispersion)'} }	1

Perform an *F*-test to determine if all fixed-effects coefficients are equal to 0.

```
stats = anova(glme)
```

```
stats =
```

```
ANOVA marginal tests: DFMethod = 'residual'
```

Term	FStat	DF1	DF2	pValue
{'(Intercept)'} }	84.41	1	94	9.8194e-15
{'newprocess' }	4.2881	1	94	0.041122
{'time_dev' }	0.013016	1	94	0.90941
{'temp_dev' }	0.086696	1	94	0.76907
{'supplier' }	0.59212	2	94	0.5552

The *p*-values for the intercept, `newprocess`, `time_dev`, and `temp_dev` are the same as in the coefficient table of the `glme` display. The small *p*-values for the intercept and `newprocess` indicate that these are significant predictors at the 5% significance level. The large *p*-values for `time_dev` and `temp_dev` indicate that these are not significant predictors at this level.

The *p*-value of 0.5552 for `supplier` measures the combined significance for both coefficients representing the categorical variable `supplier`. This includes the dummy variables `supplier_C` and `supplier_B` as shown in the coefficient table of the `glme` display. The large *p*-value indicates that `supplier` is not a significant predictor at the 5% significance level.

Tips

- For each fixed-effects term, `anova` performs an F -test (marginal test) to determine if all coefficients representing the fixed-effects term are equal to 0.

When fitting a generalized linear mixed-effects (GLME) model using `fitglm` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'):

- If you specify the 'CovarianceMethod' name-value pair argument as 'conditional', then the F -tests are conditional on the estimated covariance parameters.
- If you specify the 'CovarianceMethod' name-value pair as 'JointHessian', then the F -tests account for the uncertainty in estimation of covariance parameters.

When fitting a GLME model using `fitglm` and one of the pseudo likelihood fit methods ('MPL' or 'REML'), `anova` uses the fitted linear mixed effects model from the final pseudo likelihood iteration for inference on fixed effects.

addTerms

Add terms to generalized linear regression model

Syntax

```
NewMdl = addTerms(mdl, terms)
```

Description

`NewMdl = addTerms(mdl, terms)` returns a generalized linear regression model fitted using the input data and settings in `mdl` with the terms `terms` added.

Examples

Add Terms to Generalized Linear Regression Model

Create a generalized linear regression model using one predictor, and then add another predictor.

Generate sample data using Poisson random numbers with two underlying predictors $X(:, 1)$ and $X(:, 2)$.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1), rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data. Include only the first predictor in the model.

```
mdl = fitglm(X,y,'y ~ x1','Distribution','poisson')
```

```
mdl =
Generalized linear regression model:
  log(y) ~ 1 + x1
  Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	2.7784	0.014043	197.85	0
x1	1.1732	0.0033653	348.6	0

100 observations, 98 error degrees of freedom

Dispersion: 1

Chi²-statistic vs. constant model: 1.25e+05, p-value = 0

Add the second predictor to the model.

```
mdl1 = addTerms(mdl, 'x2')
```

```
mdl1 =
Generalized linear regression model:
  log(y) ~ 1 + x1 + x2
  Distribution = Poisson

Estimated Coefficients:

```

	Estimate	SE	tStat	pValue
(Intercept)	1.0405	0.022122	47.034	0
x1	0.9968	0.003362	296.49	0
x2	1.987	0.0063433	313.24	0

```
100 observations, 97 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0
```

Input Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object

Generalized linear regression model, specified as a GeneralizedLinearModel object created using fitglm or stepwiseglm.

terms — Terms to add to regression model

character vector or string scalar formula in Wilkinson notation | *t*-by-*p* terms matrix

Terms to add to the regression model mdl, specified as one of the following:

- Character vector or string scalar formula in “Wilkinson Notation” on page 32-18 representing one or more terms. The variable names in the formula must be valid MATLAB identifiers.
- Terms matrix T of size *t*-by-*p*, where *t* is the number of terms and *p* is the number of predictor variables in mdl. The value of T(*i*, *j*) is the exponent of variable *j* in term *i*.

For example, suppose mdl has three variables A, B, and C in that order. Each row of T represents one term:

- [0 0 0] — Constant term or intercept
- [0 1 0] — B; equivalently, $A^0 * B^1 * C^0$
- [1 0 1] — A*C
- [2 0 0] — A²
- [0 1 2] — B*(C²)

addTerms treats a group of indicator variables for a categorical predictor as a single variable. Therefore, you cannot specify an indicator variable to add to the model. If you specify a categorical predictor to add to the model, addTerms adds a group of indicator variables for the predictor in one step.

Output Arguments

NewMdl — Generalized linear regression model with additional terms

GeneralizedLinearModel object

Generalized linear regression model with additional terms, returned as a GeneralizedLinearModel object. NewMdl is a newly fitted model that uses the input data and settings in mdl with additional terms specified in terms.

To overwrite the input argument mdl, assign the newly fitted model to mdl:

```
mdl = addTerms(mdl, terms);
```

More About

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- – means do not include the next variable.
- : defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- () groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A ^k , where k is a positive integer	A, A ² , ..., A ^k
A + B	A, B
A*B	A, B, A*B
A:B	A*B only
–B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C – A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using –1.

For more details, see “Wilkinson Notation” on page 11-90.

Algorithms

- `addTerms` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `addTerms` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
 - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
 - Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1)*(M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
 - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Alternative Functionality

- Use `stepwiseglm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.
- Use `removeTerms` to remove specific terms from a model.
- Use `step` to optimally improve a model by adding or removing terms.

Topics

“Generalized Linear Models” on page 12-9

Introduced in R2012a

addTerms

Add terms to linear regression model

Syntax

```
NewMdl = addTerms(mdl, terms)
```

Description

`NewMdl = addTerms(mdl, terms)` returns a linear regression model fitted using the input data and settings in `mdl` with the terms `terms` added.

Examples

Add Terms to Linear Regression Model

Create a linear regression model of the `carsmall` data set without any interactions, and then add an interaction term.

Load the `carsmall` data set and create a model of the MPG as a function of weight and model year.

```
load carsmall
tbl = table(MPG, Weight);
tbl.Year = categorical(Model_Year);
mdl = fitlm(tbl, 'MPG ~ Year + Weight^2')
```

```
mdl =
Linear regression model:
    MPG ~ 1 + Weight + Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 2.78

R-squared: 0.885, Adjusted R-Squared: 0.88

F-statistic vs. constant model: 172, p-value = 5.52e-41

The model includes five terms, `Intercept`, `Weight`, `Year_76`, `Year_82`, and `Weight^2`, where `Year_76` and `Year_82` are indicator variables for the categorical variable `Year` that has three distinct values.

Add an interaction term between the `Year` and `Weight` variables to `mdl`.

```
terms = 'Year*Weight';
NewMdl = addTerms(mdl, terms)
```

```
NewMdl =
Linear regression model:
    MPG ~ 1 + Weight*Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.045	6.779	7.0874	3.3967e-10
Weight	-0.012624	0.0041455	-3.0454	0.0030751
Year_76	2.7768	3.0538	0.90931	0.3657
Year_82	16.416	4.9802	3.2962	0.0014196
Weight:Year_76	-0.00020693	0.00092403	-0.22394	0.82333
Weight:Year_82	-0.0032574	0.0018919	-1.7217	0.088673

```
Number of observations: 94, Error degrees of freedom: 87
Root Mean Squared Error: 2.76
R-squared: 0.89, Adjusted R-Squared: 0.882
F-statistic vs. constant model: 117, p-value = 1.88e-39
```

NewMdl includes two additional terms, Weight*Year_76 and Weight*Year_82.

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using fitlm or stepwiselm.

terms — Terms to add to regression model

character vector or string scalar formula in Wilkinson notation | *t*-by-*p* terms matrix

Terms to add to the regression model mdl, specified as one of the following:

- Character vector or string scalar formula in “Wilkinson Notation” on page 32-22 representing one or more terms. The variable names in the formula must be valid MATLAB identifiers.
- Terms matrix T of size *t*-by-*p*, where *t* is the number of terms and *p* is the number of predictor variables in mdl. The value of T(*i*, *j*) is the exponent of variable *j* in term *i*.

For example, suppose mdl has three variables A, B, and C in that order. Each row of T represents one term:

- [0 0 0] — Constant term or intercept
- [0 1 0] — B; equivalently, A⁰ * B¹ * C⁰
- [1 0 1] — A*C
- [2 0 0] — A²
- [0 1 2] — B*(C²)

`addTerms` treats a group of indicator variables for a categorical predictor as a single variable. Therefore, you cannot specify an indicator variable to add to the model. If you specify a categorical predictor to add to the model, `addTerms` adds a group of indicator variables for the predictor in one step. See “Modify Linear Regression Model Using step” on page 32-5210 for an example that describes how to create indicator variables manually and treat each one as a separate variable.

Output Arguments

NewMdl — Linear regression model with additional terms

`LinearModel` object

Linear regression model with additional terms, returned as a `LinearModel` object. `NewMdl` is a newly fitted model that uses the input data and settings in `mdl` with additional terms specified in `terms`.

To overwrite the input argument `mdl`, assign the newly fitted model to `mdl`:

```
mdl = addTerms(mdl, terms);
```

More About

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- `+` means include the next variable.
- `-` means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- `*` defines an interaction and all lower-order terms.
- `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$

Wilkinson Notation	Term in Standard Notation
$A*(B + C)$	A, B, C, A*B, A*C

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

For more details, see “Wilkinson Notation” on page 11-90.

Algorithms

- `addTerms` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `addTerms` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
 - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
 - Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1)*(M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
 - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Alternative Functionality

- Use `stepwiselm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.
- Use `removeTerms` to remove specific terms from a model.
- Use `step` to optimally improve a model by adding or removing terms.

adtest

Anderson-Darling test

Syntax

```
h = adtest(x)
h = adtest(x,Name,Value)
[h,p] = adtest(____)
[h,p,adstat,cv] = adtest(____)
```

Description

`h = adtest(x)` returns a test decision for the null hypothesis that the data in vector `x` is from a population with a normal distribution, using the Anderson-Darling test on page 32-29. The alternative hypothesis is that `x` is not from a population with a normal distribution. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

`h = adtest(x,Name,Value)` returns a test decision for the Anderson-Darling test with additional options specified by one or more name-value pair arguments. For example, you can specify a null distribution other than normal, or select an alternative method for calculating the p -value.

`[h,p] = adtest(____)` also returns the p -value, `p`, of the Anderson-Darling test, using any of the input arguments from the previous syntaxes.

`[h,p,adstat,cv] = adtest(____)` also returns the test statistic, `adstat`, and the critical value, `cv`, for the Anderson-Darling test.

Examples

Anderson-Darling Test for a Normal Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the exam grades come from a normal distribution. You do not need to specify values for the population parameters.

```
[h,p,adstat,cv] = adtest(x)
```

```
h = logical
    0
```

```
p = 0.1854
```

```
adstat = 0.5194
```

```
cv = 0.7470
```

The returned value of $h = 0$ indicates that `adtest` fails to reject the null hypothesis at the default 5% significance level.

Anderson-Darling Test for Extreme Value Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the exam grades come from an extreme value distribution. You do not need to specify values for the population parameters.

```
[h,p] = adtest(x,'Distribution','ev')

h = logical
    0
```

```
p = 0.0714
```

The returned value of $h = 0$ indicates that `adtest` fails to reject the null hypothesis at the default 5% significance level.

Anderson-Darling Test Using Specified Probability Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Create a normal probability distribution object with mean $\mu = 75$ and standard deviation $\sigma = 10$.

```
dist = makedist('normal','mu',75,'sigma',10)

dist =
    NormalDistribution

    Normal distribution
        mu = 75
        sigma = 10
```

Test the null hypothesis that x comes from the hypothesized normal distribution.

```
[h,p] = adtest(x,'Distribution',dist)

h = logical
    0

p = 0.4687
```

The returned value of $h = 0$ indicates that `adtest` fails to reject the null hypothesis at the default 5% significance level.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector. Missing observations in x , indicated by NaN, are ignored.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alpha', 0.01, 'MCTol', 0.01` conducts the hypothesis test at the 1% significance level, and determines the p-value, p , using a Monte Carlo simulation with a maximum Monte Carlo standard error for p of 0.01.

Distribution — Hypothesized distribution

`'norm'` (default) | `'exp'` | `'ev'` | `'logn'` | `'weibull'` | probability distribution object

Hypothesized distribution of data vector x , specified as the comma-separated pair consisting of `'Distribution'` and one of the following.

<code>'norm'</code>	Normal distribution
<code>'exp'</code>	Exponential distribution
<code>'ev'</code>	Extreme value distribution
<code>'logn'</code>	Lognormal distribution
<code>'weibull'</code>	Weibull distribution

In this case, you do not need to specify population parameters. Instead, `adtest` estimates the distribution parameters from the sample data and tests x against a composite hypothesis that it comes from the selected distribution family with parameters unspecified.

Alternatively, you can specify any continuous probability distribution object for the null distribution. In this case, you must specify all the distribution parameters, and `adtest` tests x against a simple hypothesis that it comes from the given distribution with its specified parameters.

Example: `'Distribution', 'exp'`

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

MCTol — Maximum Monte Carlo standard error

positive scalar value

Maximum Monte Carlo standard error on page 32-30 for the p -value, p , specified as the comma-separated pair consisting of 'MCTol' and a positive scalar value. If you use MCTol, `adtest` determines p using a Monte Carlo simulation, and the name-value pair argument `Asymptotic` must have the value `false`.

Example: 'MCTol',0.01

Data Types: single | double

Asymptotic — Method for calculating p -value

false (default) | true

Method for calculating the p -value of the Anderson-Darling test, specified as the comma-separated pair consisting of 'Asymptotic' and either `true` or `false`. If you specify 'true', `adtest` estimates the p -value using the limiting distribution of the Anderson-Darling test statistic. If you specify `false`, `adtest` calculates the p -value based on an analytical formula. For sample sizes greater than 120, the limiting distribution estimate is likely to be more accurate than the small sample size approximation method.

- If you specify a distribution family with unknown parameters for the `Distribution` name-value pair, `Asymptotic` must be `false`.
- If you use MCTol to calculate the p -value using a Monte Carlo simulation, `Asymptotic` must be `false`.

Example: 'Asymptotic',true

Data Types: logical

Output Arguments**h — Hypothesis test result**

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the `Alpha` significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the `Alpha` significance level.

p — p -value

scalar value in the range [0,1]

p -value of the Anderson-Darling test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. p is calculated using one of these methods:

- If the hypothesized distribution is a fully specified probability distribution object, `adtest` calculates p analytically. If 'Asymptotic' is `true`, `adtest` uses the asymptotic distribution of the test statistic. If you specify a value for 'MCTol', `adtest` uses a Monte Carlo simulation.
- If the hypothesized distribution is specified as a distribution family with unknown parameters, `adtest` retrieves the critical value from a table and uses inverse interpolation to determine the p -value. If you specify a value for 'MCTol', `adtest` uses a Monte Carlo simulation.

adstat — Test statistic

scalar value

Test statistic for the Anderson-Darling test, returned as a scalar value.

- If the hypothesized distribution is a fully specified probability distribution object, `adtest` computes `adstat` using specified parameters.
- If the hypothesized distribution is specified as a distribution family with unknown parameters, `adtest` computes `adstat` using parameters estimated from the sample data.

cv — Critical value

scalar value

Critical value for the Anderson-Darling test at the significance level `Alpha`, returned as a scalar value. `adtest` determines `cv` by interpolating into a table based on the specified `Alpha` significance level.

More About**Anderson-Darling Test**

The Anderson-Darling test is commonly used to test whether a data sample comes from a normal distribution. However, it can be used to test for another hypothesized distribution, even if you do not fully specify the distribution parameters. Instead, the test estimates any unknown parameters from the data sample.

The test statistic belongs to the family of quadratic empirical distribution function statistics, which measure the distance between the hypothesized distribution, $F(x)$ and the empirical cdf, $F_n(x)$ as

$$n \int_{-\infty}^{\infty} (F_n(x) - F(x))^2 w(x) dF(x),$$

over the ordered sample values $x_1 < x_2 < \dots < x_n$, where $w(x)$ is a weight function and n is the number of data points in the sample.

The weight function for the Anderson-Darling test is

$$w(x) = [F(x)(1 - F(x))]^{-1},$$

which places greater weight on the observations in the tails of the distribution, thus making the test more sensitive to outliers and better at detecting departure from normality in the tails of the distribution.

The Anderson-Darling test statistic is

$$A_n^2 = -n - \sum_{i=1}^n \frac{2i-1}{n} [\ln(F(X_i)) + \ln(1 - F(X_{n+1-i}))],$$

where $\{X_1 < \dots < X_n\}$ are the ordered sample data points and n is the number of data points in the sample.

In `adtest`, the decision to reject or not reject the null hypothesis is based on comparing the p -value for the hypothesis test with the specified significance level, not on comparing the test statistic with the critical value.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p -value.

The Monte Carlo standard error is calculated as

$$SE = \sqrt{\frac{(\widehat{p})(1 - \widehat{p})}{\text{mcreps}}},$$

where \widehat{p} is the estimated p -value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed.

`adtest` chooses the number of Monte Carlo replications, `mcreps`, large enough to make the Monte Carlo standard error for \widehat{p} less than the value specified for `MCTol`.

Introduced in R2013a

andrewsplot

Andrews plot

Syntax

```
andrewsplot(X)
andrewsplot(X,...,'Standardize',standopt)
andrewsplot(X,...,'Quantile',alpha)
andrewsplot(X,...,'Group',group)
andrewsplot(X,...,'PropName',PropVal,...)
andrewsplot(ax,X,...)
h = andrewsplot(X,...)
```

Description

`andrewsplot(X)` creates an Andrews plot of the multivariate data in the matrix `X`. The rows of `X` correspond to observations, the columns to variables. Andrews plots represent each observation by a function $f(t)$ of a continuous dummy variable t over the interval $[0,1]$. $f(t)$ is defined for the i th observation in `X` as

$$f(t) = X(i, 1)/\sqrt{2} + X(i, 2)\sin(2\pi t) + X(i, 3)\cos(2\pi t) + \dots$$

`andrewsplot` treats NaN values in `X` as missing values and ignores the corresponding rows.

`andrewsplot(X,...,'Standardize',standopt)` creates an Andrews plot where `standopt` is one of the following:

- 'on' — scales each column of `X` to have mean 0 and standard deviation 1 before making the plot.
- 'PCA' — creates an Andrews plot from the principal component scores of `X`, in order of decreasing eigenvalue. (See `pca`.)
- 'PCAStd' — creates an Andrews plot using the standardized principal component scores. (See `pca`.)

`andrewsplot(X,...,'Quantile',alpha)` plots only the median and the `alpha` and $(1 - \alpha)$ quantiles of $f(t)$ at each value of t . This is useful if `X` contains many observations.

`andrewsplot(X,...,'Group',group)` plots the data in different groups with different colors. Groups are defined by `group`, a numeric array containing a group index for each observation. `group` can also be a categorical array, character matrix, string array, or cell array of character vectors containing a group name for each observation.

`andrewsplot(X,...,'PropName',PropVal,...)` sets optional Line object properties to the specified values for all Line objects created by `andrewsplot`. (See Line Properties.)

`andrewsplot(ax,X,...)` uses the plot axes specified in `ax`, an Axes object. (See `axes`.) Specify `ax` as the first input argument followed by any of the input argument combinations in the previous syntaxes.

`h = andrewsplot(X,...)` returns a column vector of handles to the Line objects created by `andrewsplot`, one handle per row of `X`. If you use the 'Quantile' input parameter, `h` contains one

handle for each of the three Line objects created. If you use both the 'Quantile' and the 'Group' input parameters, h contains three handles for each group.

Examples

Create Andrews Plot to Visualize Grouped Data

This example shows how to create an Andrews plot to visualize grouped sample data.

Load the sample data.

```
load fisheriris
```

Create an Andrews plot, grouping the sample data by species.

```
andrewsplot(meas, 'group', species)
```

Create a second, simplified Andrews plot that only displays the median and quartiles of each group.

```
andrewsplot(meas, 'group', species, 'quantile', .25)
```

anova

Package:

Analysis of variance for linear regression model

Syntax

```
tbl = anova mdl
tbl = anova mdl, anovatype
tbl = anova mdl, 'component', sstype
```

Description

`tbl = anova(mdl)` returns a table with component ANOVA statistics.

`tbl = anova(mdl, anovatype)` returns ANOVA statistics of the specified type `anovatype`. For example, specify `anovatype` as `'component'` (default) to return a table with component ANOVA statistics, or specify `anovatype` as `'summary'` to return a table with summary ANOVA statistics.

`tbl = anova(mdl, 'component', sstype)` computes component ANOVA statistics using the specified type of sum of squares.

Examples

Component ANOVA Table

Create a component ANOVA table from a linear regression model of the `hospital` data set.

Load the `hospital` data set and create a model of blood pressure as a function of age and gender.

```
load hospital
tbl = table(hospital.Age, hospital.Sex, hospital.BloodPressure(:,2), ...
    'VariableNames', {'Age', 'Sex', 'BloodPressure'});
tbl.Sex = categorical(tbl.Sex);
mdl = fitlm(tbl, 'BloodPressure ~ Sex + Age^2')
```

```
mdl =
Linear regression model:
    BloodPressure ~ 1 + Age + Sex + Age^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	63.942	19.194	3.3314	0.0012275
Age	0.90673	1.0442	0.86837	0.38736
Sex_Male	3.0019	1.3765	2.1808	0.031643
Age^2	-0.011275	0.013853	-0.81389	0.41772

Number of observations: 100, Error degrees of freedom: 96

Root Mean Squared Error: 6.83
 R-squared: 0.0577, Adjusted R-Squared: 0.0283
 F-statistic vs. constant model: 1.96, p-value = 0.125

Create an ANOVA table of the model.

```
tbl = anova mdl
```

tbl=4x5 table

	SumSq	DF	MeanSq	F	pValue
Age	18.705	1	18.705	0.40055	0.52831
Sex	222.09	1	222.09	4.7558	0.031643
Age^2	30.934	1	30.934	0.66242	0.41772
Error	4483.1	96	46.699		

The table displays the following columns for each term except the constant (intercept) term:

- **SumSq** — Sum of squares explained by the term.
- **DF** — Degrees of freedom. In this example, DF is 1 for each term in the model and $n - p$ for the error term, where n is the number of observations and p is the number of coefficients (including the intercept) in the model. For example, the DF for the error term in this model is $100 - 4 = 96$. If any variable in the model is a categorical variable, the DF for that variable is the number of indicator variables created for its categories (number of categories - 1).
- **MeanSq** — Mean square, defined by $\text{MeanSq} = \text{SumSq}/\text{DF}$. For example, the mean square of the error term, mean squared error (MSE), is $4.4831\text{e}+03/96 = 46.6991$.
- **F** — F -statistic value to test the null hypothesis that the corresponding coefficient is zero, computed by $F = \text{MeanSq}/\text{MSE}$, where MSE is the mean squared error. When the null hypothesis is true, the F -statistic follows the F -distribution. The numerator degrees of freedom is the DF value for the corresponding term, and the denominator degrees of freedom is $n - p$. In this example, each F -statistic follows an $F_{(1,96)}$ -distribution.
- **pValue** — p -value of the F -statistic value. For example, the p -value for **Age** is 0.5283, implying that **Age** is not significant at the 5% significance level given the other terms in the model.

Summary ANOVA Table

Create a summary ANOVA table from a linear regression model of the hospital data set.

Load the `hospital` data set and create a model of blood pressure as a function of age and gender.

```
load hospital
tbl = table(hospital.Age, hospital.Sex, hospital.BloodPressure(:,2), ...
  'VariableNames', {'Age', 'Sex', 'BloodPressure'});
tbl.Sex = categorical(tbl.Sex);
mdl = fitlm(tbl, 'BloodPressure ~ Sex + Age^2')
```

```
mdl =
Linear regression model:
  BloodPressure ~ 1 + Age + Sex + Age^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	63.942	19.194	3.3314	0.0012275
Age	0.90673	1.0442	0.86837	0.38736
Sex_Male	3.0019	1.3765	2.1808	0.031643
Age ²	-0.011275	0.013853	-0.81389	0.41772

Number of observations: 100, Error degrees of freedom: 96
 Root Mean Squared Error: 6.83
 R-squared: 0.0577, Adjusted R-Squared: 0.0283
 F-statistic vs. constant model: 1.96, p-value = 0.125

Create a summary ANOVA table of the model.

```
tbl = anova mdl, 'summary')
```

tbl=7x5 table

	SumSq	DF	MeanSq	F	pValue
Total	4757.8	99	48.059		
Model	274.73	3	91.577	1.961	0.12501
. Linear	243.8	2	121.9	2.6103	0.078726
. Nonlinear	30.934	1	30.934	0.66242	0.41772
Residual	4483.1	96	46.699		
. Lack of fit	1483.1	39	38.028	0.72253	0.85732
. Pure error	3000	57	52.632		

The table displays tests for groups of terms: Total, Model, and Residual.

- **Total** — This row shows the total sum of squares (SumSq), degrees of freedom (DF), and the mean squared error (MeanSq). Note that $\text{MeanSq} = \text{SumSq}/\text{DF}$.
- **Model** — This row includes SumSq, DF, MeanSq, F -statistic value (F), and p -value (pValue). Because this model includes a nonlinear term (Age²), anova partitions the sum of squares (SumSq) of Model into two parts: SumSq explained by the linear terms (Age and Sex) and SumSq explained by the nonlinear term (Age²). The corresponding F -statistic values are for testing the significance of the linear terms and the nonlinear term as separate groups. The nonlinear group consists of the Age² term only, so it has the same p -value as the Age² term in the “Component ANOVA Table” on page 32-34.
- **Residual** — This row includes SumSq, DF, MeanSq, F, and pValue. Because the data set includes replications, anova partitions the residual SumSq into the part for the replications (Pure error) and the rest (Lack of fit). To test the lack of fit, anova computes the F -statistic value by comparing the model residuals to the model-free variance estimate computed on the replications. The F -statistic value shows no evidence of lack of fit.

Linear Regression with Categorical Predictor

Fit a linear regression model that contains a categorical predictor. Reorder the categories of the categorical predictor to control the reference level in the model. Then, use anova to test the significance of the categorical variable.

Model with Categorical Predictor

Load the `carsmall` data set and create a linear regression model of MPG as a function of `Model_Year`. To treat the numeric vector `Model_Year` as a categorical variable, identify the predictor using the `'CategoricalVars'` name-value pair argument.

```
load carsmall
mdl = fitlm(Model_Year,MPG,'CategoricalVars',1,'VarNames',{'Model_Year','MPG'})
```

```
mdl =
Linear regression model:
    MPG ~ 1 + Model_Year
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	17.69	1.0328	17.127	3.2371e-30
Model_Year_76	3.8839	1.4059	2.7625	0.0069402
Model_Year_82	14.02	1.4369	9.7571	8.2164e-16

```
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531, Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

The model formula in the display, `MPG ~ 1 + Model_Year`, corresponds to

$$\text{MPG} = \beta_0 + \beta_1 I_{\text{Year} = 76} + \beta_2 I_{\text{Year} = 82} + \epsilon,$$

where $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$ are indicator variables whose value is one if the value of `Model_Year` is 76 and 82, respectively. The `Model_Year` variable includes three distinct values, which you can check by using the `unique` function.

```
unique(Model_Year)
```

```
ans = 3×1
```

```
70
76
82
```

`fitlm` chooses the smallest value in `Model_Year` as a reference level ('70') and creates two indicator variables $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$. The model includes only two indicator variables because the design matrix becomes rank deficient if the model includes three indicator variables (one for each level) and an intercept term.

Model with Full Indicator Variables

You can interpret the model formula of `mdl` as a model that has three indicator variables without an intercept term:

$$y = \beta_0 I_{x_1 = 70} + (\beta_0 + \beta_1) I_{x_1 = 76} + (\beta_0 + \beta_2) I_{x_2 = 82} + \epsilon.$$

Alternatively, you can create a model that has three indicator variables without an intercept term by manually creating indicator variables and specifying the model formula.

```
temp_Year = dummyvar(categorical(Model_Year));
Model_Year_70 = temp_Year(:,1);
Model_Year_76 = temp_Year(:,2);
Model_Year_82 = temp_Year(:,3);
tbl = table(Model_Year_70,Model_Year_76,Model_Year_82,MPG);
mdl = fitlm(tbl,'MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82 - 1')
```

```
mdl =
Linear regression model:
    MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
Model_Year_70	17.69	1.0328	17.127	3.2371e-30
Model_Year_76	21.574	0.95387	22.617	4.0156e-39
Model_Year_82	31.71	0.99896	31.743	5.2234e-51

```
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
```

Choose Reference Level in Model

You can choose a reference level by modifying the order of categories in a categorical variable. First, create a categorical variable `Year`.

```
Year = categorical(Model_Year);
```

Check the order of categories by using the `categories` function.

```
categories(Year)
ans = 3x1 cell
    {'70'}
    {'76'}
    {'82'}
```

If you use `Year` as a predictor variable, then `fitlm` chooses the first category '70' as a reference level. Reorder `Year` by using the `reordercats` function.

```
Year_reordered = reordercats(Year,{'76','70','82'});
categories(Year_reordered)
```

```
ans = 3x1 cell
    {'76'}
    {'70'}
    {'82'}
```

The first category of `Year_reordered` is '76'. Create a linear regression model of MPG as a function of `Year_reordered`.

```
mdl2 = fitlm(Year_reordered,MPG,'VarNames',{'Model_Year','MPG'})
```

```
mdl2 =
Linear regression model:
  MPG ~ 1 + Model_Year

Estimated Coefficients:
              Estimate      SE      tStat      pValue
-----
(Intercept)    21.574    0.95387    22.617    4.0156e-39
Model_Year_70  -3.8839    1.4059    -2.7625    0.0069402
Model_Year_82   10.136    1.3812     7.3385    8.7634e-11
```

```
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531, Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

`mdl2` uses '76' as a reference level and includes two indicator variables $I_{\text{Year} = 70}$ and $I_{\text{Year} = 82}$.

Evaluate Categorical Predictor

The model display of `mdl2` includes a p -value of each term to test whether or not the corresponding coefficient is equal to zero. Each p -value examines each indicator variable. To examine the categorical variable `Model_Year` as a group of indicator variables, use `anova`. Use the 'components' (default) option to return a component ANOVA table that includes ANOVA statistics for each variable in the model except the constant term.

```
anova(mdl2, 'components')
ans=2x5 table
              SumSq      DF      MeanSq      F      pValue
-----
Model_Year    3190.1      2      1595.1    51.56    1.0694e-15
Error         2815.2     91      30.936
```

The component ANOVA table includes the p -value of the `Model_Year` variable, which is smaller than the p -values of the indicator variables.

Input Arguments

`mdl` — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a `LinearModel` object created by using `fitlm` or `stepwiselm`, or a `CompactLinearModel` object created by using `compact`.

`anovatype` — ANOVA type

'component' (default) | 'summary'

ANOVA type, specified as one of these values:

- 'component' — `anova` returns the table `tbl` with ANOVA statistics for each variable in the model except the constant term.

- 'summary' — anova returns the table tbl with summary ANOVA statistics for grouped variables and the model as a whole.

For details, see the tbl output argument description.

sstype — Sum of squares type

'h' (default) | 1 | 2 | 3

Sum of squares type for each term, specified as one of the values in this table.

Value	Description
1	Type 1 sum of squares — Reduction in residual sum of squares obtained by adding the term to a fit that already includes the preceding terms
2	Type 2 sum of squares — Reduction in residual sum of squares obtained by adding the term to a model that contains all other terms
3	Type 3 sum of squares — Reduction in residual sum of squares obtained by adding the term to a model that contains all other terms, but with their effects constrained to obey the usual “sigma restrictions” that make models estimable
'h'	Hierarchical model — Similar to Type 2, but uses both continuous and categorical factors to determine the hierarchy of terms

The sum of squares for any term is determined by comparing two models. For a model containing main effects but no interactions, the value of sstype influences the computations on unbalanced data only.

Suppose you are fitting a model with two factors and their interaction, and the terms appear in the order A , B , AB . Let $R(\cdot)$ represent the residual sum of squares for the model. So, $R(A, B, AB)$ is the residual sum of squares fitting the whole model, $R(A)$ is the residual sum of squares fitting the main effect of A only, and $R(1)$ is the residual sum of squares fitting the mean only. The three sum of squares types are as follows:

Term	Type 1 Sum of Squares	Type 2 Sum of Squares	Type 3 Sum of Squares
A	$R(1) - R(A)$	$R(B) - R(A, B)$	$R(B, AB) - R(A, B, AB)$
B	$R(A) - R(A, B)$	$R(A) - R(A, B)$	$R(A, AB) - R(A, B, AB)$
AB	$R(A, B) - R(A, B, AB)$	$R(A, B) - R(A, B, AB)$	$R(A, B) - R(A, B, AB)$

The models for Type 3 sum of squares have sigma restrictions imposed. This means, for example, that in fitting $R(B, AB)$, the array of AB effects is constrained to sum to 0 over A for each value of B , and over B for each value of A .

For Type 3 sum of squares:

- If mdl is a CompactLinearModel object and the regression model is nonhierarchical, anova returns an error.
- If mdl is a LinearModel object and the regression model is nonhierarchical, anova refits the model using effects coding whenever it needs to compute a Type 3 sum of squares.

- If the regression model in `mdl` is hierarchical, `anova` computes the results without refitting the model.

`sstype` applies only if `anovatype` is 'component'.

Output Arguments

`tbl` – ANOVA summary statistics table

table

ANOVA summary statistics table, returned as a table.

The contents of `tbl` depend on the ANOVA type specified in `anovatype`.

- If `anovatype` is 'component', then `tbl` contains ANOVA statistics for each variable in the model except the constant (intercept) term. The table includes these columns for each variable:

Column	Description
SumSq	Sum of squares explained by the term, computed depending on <code>sstype</code>
DF	Degrees of freedom <ul style="list-style-type: none"> • DF of a numeric variable is 1. • DF of a categorical variable is the number of indicator variables created for the category (number of categories - 1). Note that <code>tbl</code> contains one row for each categorical variable instead of one row for each indicator variable as in the model display. Use <code>anova</code> to test a categorical variable as a group of indicator variables. • DF of an error term is $n - p$, where n is the number of observations and p is the number of coefficients in the model.
MeanSq	Mean square, defined by $\text{MeanSq} = \text{SumSq}/\text{DF}$ MeanSq for the error term is the mean squared error (MSE).
F	F -statistic value to test the null hypothesis that the corresponding coefficient is zero, computed by $F = \text{MeanSq}/\text{MSE}$ When the null hypothesis is true, the F -statistic follows the F -distribution. The numerator degrees of freedom is the DF value for the corresponding term, and the denominator degrees of freedom is $n - p$.
pValue	p -value of the F -statistic value

For an example, see “Component ANOVA Table” on page 32-34.

- If `anovatype` is 'summary', then `tbl` contains summary statistics of grouped terms for each row. The table includes the same columns as 'component' and these rows:

Row	Description
Total	Total statistics <ul style="list-style-type: none"> • SumSq — Total sum of squares, which is the sum of the squared deviations of the response around its mean • DF — Sum of degrees of freedom of Model and Residual
Model	Statistics for the model as a whole <ul style="list-style-type: none"> • SumSq — Model sum of squares, which is the sum of the squared deviations of the fitted value around the response mean. • F and pValue — These values provide a test of whether the model as a whole fits significantly better than a degenerate model consisting of only a constant term. If mdl includes only linear terms, then anova does not decompose Model into Linear and NonLinear.
Linear	Statistics for linear terms <ul style="list-style-type: none"> • SumSq — Sum of squares for linear terms, which is the difference between the model sum of squares and the sum of squares for nonlinear terms. • F and pValue — These values provide a test of whether the model with only linear terms fits better than a degenerate model consisting of only a constant term. anova uses the mean squared error that is based on the full model to compute this <i>F</i>-value, so the <i>F</i>-value obtained by dropping the nonlinear terms and repeating the test is not the same as the value in this row.
Nonlinear	Statistics for nonlinear terms <ul style="list-style-type: none"> • SumSq — Sum of squares for nonlinear (higher-order or interaction) terms, which is the increase in the residual sum of squares obtained by keeping only the linear terms and dropping all nonlinear terms. • F and pValue — These values provide a test of whether the full model fits significantly better than a smaller model consisting of only the linear terms.

Row	Description
Residual	<p>Statistics for residuals</p> <ul style="list-style-type: none"> • SumSq — Residual sum of squares, which is the sum of the squared residual values • MeanSq — Mean squared error, used to compute the F-statistic values for <code>Model</code>, <code>Linear</code>, and <code>NonLinear</code> <p>If <code>mdl</code> is a full <code>LinearModel</code> object and the sample data contains replications (multiple observations sharing the same predictor values), then <code>anova</code> decomposes the residual sum of squares into a sum of squares for the replicated observations (Lack of fit) and the remaining sum of squares (Pure error).</p>
Lack of fit	<p>Lack-of-fit statistics</p> <ul style="list-style-type: none"> • SumSq — Sum of squares due to lack of fit, which is the difference between the residual sum of squares and the replication sum of squares. • F and pValue — The F-statistic value is the ratio of lack-of-fit MeanSq to pure error MeanSq. The ratio provides a test of bias by measuring whether the variation of the residuals is larger than the variation of the replications. A low p-value implies that adding additional terms to the model can improve the fit.
Pure error	<p>Statistics for pure error</p> <ul style="list-style-type: none"> • SumSq — Replication sum of squares, obtained by finding the sets of points with identical predictor values, computing the sum of squared deviations around the mean within each set, and pooling the computed values • MeanSq — Model-free pure error variance estimate of the response

For an example, see “Summary ANOVA Table” on page 32-35.

Alternative Functionality

More complete ANOVA statistics are available in the `anova1`, `anova2`, and `anova` functions.

Introduced in R2012a

anova

Class: LinearMixedModel

Analysis of variance for linear mixed-effects model

Syntax

```
stats = anova(lme)
stats = anova(lme, Name, Value)
```

Description

`stats = anova(lme)` returns the dataset array `stats` that includes the results of the F -tests for each fixed-effects term in the linear mixed-effects model `lme`.

`stats = anova(lme, Name, Value)` also returns the dataset array `stats` with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

DFMethod — Method for computing approximate degrees of freedom

'residual' (default) | 'satterthwaite' | 'none'

Method for computing approximate degrees of freedom to use in the F -test, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'residual'	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'satterthwaite'	Satterthwaite approximation.
'none'	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod', 'satterthwaite'

Output Arguments

stats — Results of *F*-tests for fixed-effects terms

dataset array

Results of *F*-tests for fixed-effects terms, returned as a dataset array with the following columns.

Term	Name of the fixed effects term
Fstat	<i>F</i> -statistic for the term
DF1	Numerator degrees of freedom for the <i>F</i> -statistic
DF2	Denominator degrees of freedom for the <i>F</i> -statistic
pValue	<i>p</i> -value of the test for the term

There is one row for each fixed-effects term. Each term is a continuous variable, a grouping variable, or an interaction between two or more continuous or grouping variables. For each fixed-effects term, `anova` performs an *F*-test (marginal test) to determine if all coefficients representing the fixed-effects term are 0. To perform tests for the type III hypothesis, you must use the 'effects' contrasts while fitting the linear mixed-effects model.

Examples

F-Tests for Fixed Effects

Load the sample data.

```
load('shift.mat')
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts indicate that the coefficients sum to 0, and `fitlme` creates two contrast-coded variables in the fixed-effects design matrix, $\$X\1 and $\$X\2 , where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

and

$$\text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\text{MorningShift: } QCDev_{im} = \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5,$$

$$\text{EveningShift: } QCDev_{im} = \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \varepsilon_{im},$$

$$\text{NightShift: } QCDev_{im} = \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \varepsilon_{im},$$

where $b \sim N(0, \sigma_b^2)$ and $\varepsilon \sim N(0, \sigma^2)$.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)', ...
'FitMethod', 'REML', 'DummyVarCoding', 'effects')
```

```
lme =
Linear mixed-effects model fit by REML
```

Model information:

Number of observations	15
Fixed effects coefficients	3
Random effects coefficients	5
Covariance parameters	2

Formula:

```
QCDev ~ 1 + Shift + (1 | Operator)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
58.913	61.337	-24.456	48.913

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
{'(Intercept)'} }	3.6525	0.94109	3.8812	12	0.0021832
{'Shift_Evening'}	-0.53293	0.31206	-1.7078	12	0.11339
{'Shift_Morning'}	-0.91973	0.31206	-2.9473	12	0.012206

Lower	Upper
1.6021	5.703
-1.2129	0.14699
-1.5997	-0.23981

Random effects covariance parameters (95% CIs):

Group: Operator (5 Levels)

Name1	Name2	Type	Estimate
{'(Intercept)'} }	{'(Intercept)'} }	{'std'}	2.0457

Lower	Upper
0.98207	4.2612

Group: Error

Name	Estimate	Lower	Upper
{'Res Std'}	0.85462	0.52357	1.395

Perform an F -test to determine if all fixed-effects coefficients are 0.

```
anova(lme)

ans =
ANOVA marginal tests: DFMethod = 'Residual'

Term                FStat    DF1    DF2    pValue
{'(Intercept)'}    15.063     1     12    0.0021832
{'Shift'           }  11.091     2     12    0.0018721
```

The p -value for the constant term, 0.0021832, is the same as in the coefficient table in the `lme` display. The p -value of 0.0018721 for `Shift` measures the combined significance for both coefficients representing `Shift`.

ANOVA for Fixed-Effects in LME Model

Load the sample data.

```
load('fertilizer.mat')
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently. Use the 'effects' contrasts when fitting the data for the type III sum of squares.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)', ...
'DummyVarCoding', 'effects')
```

```
lme =
Linear mixed-effects model fit by ML
```

```
Model information:
  Number of observations      60
  Fixed effects coefficients  20
  Random effects coefficients 18
  Covariance parameters      3
```

```
Formula:
  Yield ~ 1 + Tomato*Fertilizer + (1 | Soil) + (1 | Soil:Tomato)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
522.57	570.74	-238.29	476.57

```

The p -value for the constant term, $5.9086e-30$, is the same as in the coefficient table in the `lme` display. The p -values of 0.00018935 , $1.0024e-14$, and 0.19804 for `Tomato`, `Fertilizer`, and `Tomato:Fertilizer` represent the combined significance for all tomato coefficients, fertilizer coefficients, and coefficients representing the interaction between the tomato and fertilizer, respectively. The p -value of 0.19804 indicates that the interaction between tomato and fertilizer is not significant.

Satterthwaite Approximation for Degrees of Freedom

Load the sample data.

```
load('weight.mat')
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit the model using the 'effects' contrasts.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)',...
'DummyVarCoding','effects')
```

lme =
Linear mixed-effects model fit by ML

Model information:

Number of observations	120
Fixed effects coefficients	9
Random effects coefficients	40
Covariance parameters	4

Formula:

$$y \sim 1 + \text{InitialWeight} + \text{Program} * \text{Week} + (1 + \text{Week} \mid \text{Subject})$$

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
-22.981	13.257	24.49	-48.981

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF

{'Program_C:Week' }	0.0049357	0.058417	0.084492	111

pValue	Lower	Upper
0.0019549	0.28951	1.2529
0.022863	0.00045067	0.0059252
0.17323	-0.26945	0.0491
0.0023402	0.091195	0.41003
0.077424	-0.3029	0.016031
4.1099e-08	0.13198	0.26564
0.66198	-0.14136	0.090149
0.82212	-0.10259	0.12892
0.93282	-0.11082	0.12069

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate
{'(Intercept)'} }	{'(Intercept)'} }	{'std' }	0.18407
{'Week' }	{'(Intercept)'} }	{'corr' }	0.66841
{'Week' }	{'Week' }	{'std' }	0.15033

Lower	Upper
0.12281	0.27587
0.21076	0.88573
0.11004	0.20537

Group: Error

Name	Estimate	Lower	Upper
{'Res Std' }	0.10261	0.087882	0.11981

The p -values 0.022863 and 4.1099e-08 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they are significant.

Perform an F-test that all fixed-effects coefficients are zero.

```
anova(lme)

ans =
ANOVA marginal tests: DFMethod = 'Residual'

Term                FStat    DF1    DF2    pValue
{'(Intercept)'}    10.065     1    111    0.0019549
{'InitialWeight'}   5.326     1    111    0.022863
{'Program'}         3.6798     3    111    0.014286
{'Week'}            34.747     1    111    4.1099e-08
{'Program:Week'}    0.066648   3    111    0.97748
```

The p -values for the constant term, initial weight, and week are the same as in the coefficient table in the previous lme output display. The p -value of 0.014286 for Program represents the combined significance for all program coefficients. Similarly, the p -value for the interaction between program and week (Program:Week) measures the combined significance for all coefficients representing this interaction.

Now, use the Satterthwaite method to compute the degrees of freedom.

```
anova(lme, 'DFMethod', 'satterthwaite')

ans =
ANOVA marginal tests: DFMethod = 'Satterthwaite'

Term                FStat    DF1    DF2    pValue
{'(Intercept)'}    10.065     1    20.445    0.004695
{'InitialWeight'}   5.326     1     20    0.031827
{'Program'}         3.6798     3    19.14    0.030233
{'Week'}            34.747     1     20    9.1346e-06
{'Program:Week'}    0.066648   3     20    0.97697
```

The Satterthwaite method produces smaller denominator degrees of freedom and slightly larger p -values.

Tips

- For each fixed-effects term, anova performs an F -test (marginal test), that all coefficients representing the fixed-effects term are 0. To perform tests for type III hypotheses, you must set the 'DummyVarCoding' name-value pair argument to 'effects' contrasts while fitting your linear mixed-effects model.

LinearMixedModel | fitlme | fitlmematrix

anova1

One-way analysis of variance

Syntax

```
p = anova1(y)
p = anova1(y,group)
p = anova1(y,group,displayopt)
[p,tbl] = anova1(____)
[p,tbl,stats] = anova1(____)
```

Description

`p = anova1(y)` performs one-way ANOVA on page 9-3 for the sample data `y` and returns the p -value. `anova1` treats each column of `y` as a separate group. The function tests the hypothesis that the samples in the columns of `y` are drawn from populations with the same mean against the alternative hypothesis that the population means are not all the same. The function also displays the box plot on page 32-63 for each group in `y` and the standard ANOVA table (`tbl`).

`p = anova1(y,group)` performs one-way ANOVA for the sample data `y`, grouped by `group`.

`p = anova1(y,group,displayopt)` enables the ANOVA table and box plot displays when `displayopt` is 'on' (default) and suppresses the displays when `displayopt` is 'off'.

`[p,tbl] = anova1(____)` returns the ANOVA table (including column and row labels) in the cell array `tbl` using any of the input argument combinations in the previous syntaxes. To copy a text version of the ANOVA table to the clipboard, select **Edit > Copy Text** from the ANOVA table figure.

`[p,tbl,stats] = anova1(____)` returns a structure, `stats`, which you can use to perform a multiple comparison test on page 9-18. A multiple comparison test enables you to determine which pairs of group means are significantly different. To perform this test, use `multcompare`, providing the `stats` structure as an input argument.

Examples

One-Way ANOVA

Create sample data matrix `y` with columns that are constants, plus random normal disturbances with mean 0 and standard deviation 1.

```
y = meshgrid(1:5);
rng default; % For reproducibility
y = y + normrnd(0,1,5,5)
```

`y = 5×5`

1.5377	0.6923	1.6501	3.7950	5.6715
2.8339	1.5664	6.0349	3.8759	3.7925
-1.2588	2.3426	3.7254	5.4897	5.7172

```

1.8622  5.5784  2.9369  5.4090  6.6302
1.3188  4.7694  3.7147  5.4172  5.4889

```

Perform one-way ANOVA.

```
p = anova1(y)
```

ANOVA Table					
Source	SS	df	MS	F	Prob>F
Columns	53.7238	4	13.4309	6.05	0.0023
Error	44.408	20	2.2204		
Total	98.1318	24			

```
p = 0.0023
```

The ANOVA table shows the between-groups variation (Columns) and within-groups variation (Error). SS is the sum of squares, and df is the degrees of freedom. The total degrees of freedom is total number of observations minus one, which is $25 - 1 = 24$. The between-groups degrees of freedom is number of groups minus one, which is $5 - 1 = 4$. The within-groups degrees of freedom is total degrees of freedom minus the between groups degrees of freedom, which is $24 - 4 = 20$.

MS is the mean squared error, which is SS/df for each source of variation. The F -statistic is the ratio of the mean squared errors ($13.4309/2.2204$). The p -value is the probability that the test statistic can

take a value greater than the value of the computed test statistic, i.e., $P(F > 6.05)$. The small p -value of 0.0023 indicates that differences between column means are significant.

Compare Beam Strength Using One-Way ANOVA

Input the sample data.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];
alloy = {'st', 'st', 'st', 'st', 'st', 'st', 'st', 'st', ...
        'al1', 'al1', 'al1', 'al1', 'al1', 'al1', ...
        'al2', 'al2', 'al2', 'al2', 'al2', 'al2'};
```

The data are from a study of the strength of structural beams in Hogg (1987). The vector `strength` measures deflections of beams in thousandths of an inch under 3000 pounds of force. The vector `alloy` identifies each beam as steel ('st'), alloy 1 ('al1'), or alloy 2 ('al2'). Although `alloy` is sorted in this example, grouping variables do not need to be sorted.

Test the null hypothesis that the steel beams are equal in strength to the beams made of the two more expensive alloys. Turn the figure display off and return the ANOVA results in a cell array.

```
[p,tbl] = anova1(strength,alloy,'off')
```

```
p = 1.5264e-04
```

```
tbl=4x6 cell array
Columns 1 through 5
```

{'Source' }	{'SS' }	{'df' }	{'MS' }	{'F' }
{'Groups' }	{[184.8000]}	{[2]}	{[92.4000]}	{[15.4000]}
{'Error' }	{[102.0000]}	{[17]}	{[6.0000]}	{0x0 double}
{'Total' }	{[286.8000]}	{[19]}	{0x0 double}	{0x0 double}

```
Column 6
```

{'Prob>F' }
{[1.5264e-04]}
{0x0 double }
{0x0 double }

The total degrees of freedom is total number of observations minus one, which is $20 - 1 = 19$. The between-groups degrees of freedom is number of groups minus one, which is $3 - 1 = 2$. The within-groups degrees of freedom is total degrees of freedom minus the between groups degrees of freedom, which is $19 - 2 = 17$.

MS is the mean squared error, which is SS/df for each source of variation. The F -statistic is the ratio of the mean squared errors. The p -value is the probability that the test statistic can take a value greater than or equal to the value of the test statistic. The p -value of $1.5264e-04$ suggests rejection of the null hypothesis.

You can retrieve the values in the ANOVA table by indexing into the cell array. Save the F -statistic value and the p -value in the new variables `Fstat` and `pvalue`.

```
Fstat = tbl{2,5}
```

```
Fstat = 15.4000
pvalue = tbl{2,6}
pvalue = 1.5264e-04
```

Multiple Comparisons for One-Way ANOVA

Input the sample data.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];
alloy = {'st', 'st', 'st', 'st', 'st', 'st', 'st', 'st', 'st', ...
         'al1', 'al1', 'al1', 'al1', 'al1', 'al1', 'al1', ...
         'al2', 'al2', 'al2', 'al2', 'al2', 'al2'};
```

The data are from a study of the strength of structural beams in Hogg (1987). The vector `strength` measures deflections of beams in thousandths of an inch under 3000 pounds of force. The vector `alloy` identifies each beam as steel (`st`), alloy 1 (`al1`), or alloy 2 (`al2`). Although `alloy` is sorted in this example, grouping variables do not need to be sorted.

Perform one-way ANOVA using `anova1`. Return the structure `stats`, which contains the statistics `multcompare` needs for performing “Multiple Comparisons” on page 9-18.

```
[~,~,stats] = anova1(strength,alloy);
```

ANOVA Table					
Source	SS	df	MS	F	Prob>F
Groups	184.8	2	92.4	15.4	0.0002
Error	102	17	6		
Total	286.8	19			

The small p -value of 0.0002 suggests that the strength of the beams is not the same.

Perform a multiple comparison of the mean strength of the beams.

```
[c,~,~,gnames] = multcompare(stats);
```

Display the comparison results with the corresponding group names.

```
[gnames(c(:,1)), gnames(c(:,2)), num2cell(c(:,3:6))]  
  
ans=3x6 cell array  
Columns 1 through 5  
  
    {'st' }    {'al1' }    {[ 3.6064]}    {[ 7]}    {[10.3936]}  
    {'st' }    {'al2' }    {[ 1.6064]}    {[ 5]}    {[ 8.3936]}  
    {'al1' }    {'al2' }    {[ -5.6280]}    {[ -2]}    {[ 1.6280]}  
  
Column 6  
  
    {[1.6831e-04]}  
    {[ 0.0040]}  
    {[ 0.3560]}
```

The first two columns show the pair of groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for the 95% confidence intervals of the true difference of means. The sixth column shows the p -value for a hypothesis that the true difference of means for the corresponding groups is equal to zero.

The first two rows show that both comparisons involving the first group (steel) have confidence intervals that do not include zero. Because the corresponding p -values (1.6831e-04 and 0.0040, respectively) are small, those differences are significant.

The third row shows that the differences in strength between the two alloys is not significant. A 95% confidence interval for the difference is [-5.6,1.6], so you cannot reject the hypothesis that the true difference is zero. The corresponding p -value of 0.3560 in the sixth column confirms this result.

In the figure, the blue bar represents the comparison interval for mean material strength for steel. The red bars represent the comparison intervals for the mean material strength for alloy 1 and alloy 2. Neither of the red bars overlap with the blue bar, which indicates that the mean material strength for steel is significantly different from that of alloy 1 and alloy 2. To confirm the significant difference by clicking the bars that represent alloy 1 and 2.

Input Arguments

y — sample data

vector | matrix

Sample data, specified as a vector or matrix.

- If y is a vector, you must specify the `group` input argument. Each element in `group` represents a group name of the corresponding element in y . The `anova1` function treats the y values corresponding to the same value of `group` as part of the same group. Use this design when groups have different numbers of elements (unbalanced ANOVA).

$$y = [y_1 \ y_2 \ y_3 \ y_4 \ y_5 \ \dots \ y_N]$$

↑ ↑ ↑ ↑ ↑ ↑

$$g = \{ 'A', 'A', 'C', 'B', 'B', \dots, 'D' \}$$

- If y is a matrix and you do not specify `group`, then `anova1` treats each column of y as a separate group. In this design, the function evaluates whether the population means of the columns are equal. Use this design when each group has the same number of elements (balanced ANOVA).

$$Y = \begin{matrix} & \begin{matrix} \text{group 1} \\ \downarrow \\ y_{11} & y_{12} & \dots & y_{1k} \\ y_{21} & y_{22} & \dots & y_{2k} \\ \vdots & \vdots & & \\ \vdots & \vdots & & \\ y_{n1} & y_{n2} & \dots & y_{nk} \end{matrix} & \end{matrix}$$

- If y is a matrix and you specify `group`, then each element in `group` represents a group name for the corresponding column in y . The `anova1` function treats the columns that have the same group name as part of the same group.

$$Y = \begin{bmatrix} Y_{11} & Y_{12} & Y_{13} & Y_{14} & \cdots & Y_{1k} \\ Y_{21} & Y_{22} & Y_{23} & Y_{24} & \cdots & Y_{2k} \\ \vdots & \vdots & \vdots & \vdots & & \\ \vdots & \vdots & \vdots & \vdots & & \\ Y_{n1} & Y_{n2} & Y_{n3} & Y_{n4} & \cdots & Y_{nk} \end{bmatrix}$$

 $group = \{ 'Red', 'Black', 'Red', 'Yellow', \dots, 'Black' \}$

Note `anova1` ignores any NaN values in `y`. Also, if `group` contains empty or NaN values, `anova1` ignores the corresponding observations in `y`. The `anova1` function performs balanced ANOVA if each group has the same number of observations after the function disregards empty or NaN values. Otherwise, `anova1` performs unbalanced ANOVA.

Data Types: `single` | `double`

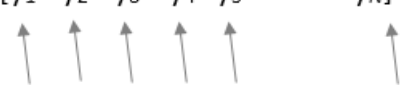

group — Grouping variable

numeric vector | logical vector | categorical vector | character array | string array | cell array of character vectors

Grouping variable containing group names, specified as a numeric vector, logical vector, categorical vector, character array, string array, or cell array of character vectors.

- If `y` is a vector, then each element in `group` represents a group name of the corresponding element in `y`. The `anova1` function treats the `y` values corresponding to the same value of `group` as part of the same group.

$$Y = [y_1 \ y_2 \ y_3 \ y_4 \ y_5 \ \dots \ y_N]$$

 $g = \{ 'A', 'A', 'C', 'B', 'B', \dots, 'D' \}$

N is the total number of observations.

- If `y` is a matrix, then each element in `group` represents a group name for the corresponding column in `y`. The `anova1` function treats the columns of `y` that have the same group name as part of the same group.

$$Y = \begin{bmatrix} Y_{11} & Y_{12} & Y_{13} & Y_{14} & \cdots & Y_{1k} \\ Y_{21} & Y_{22} & Y_{23} & Y_{24} & \cdots & Y_{2k} \\ \vdots & \vdots & \vdots & \vdots & & \\ \vdots & \vdots & \vdots & \vdots & & \\ Y_{n1} & Y_{n2} & Y_{n3} & Y_{n4} & \cdots & Y_{nk} \end{bmatrix}$$

`group = {'Red', 'Black', 'Red', 'Yellow', . . . , 'Black'}`

If you do not want to specify group names for the matrix sample data `y`, enter an empty array (`[]`) or omit this argument. In this case, `anova1` treats each column of `y` as a separate group.

If `group` contains empty or NaN values, `anova1` ignores the corresponding observations in `y`.

For more information on grouping variables, see “Grouping Variables” on page 2-45.

Example: `'group', [1,2,1,3,1, . . . ,3,1]` when `y` is a vector with observations categorized into groups 1, 2, and 3

Example: `'group', {'white', 'red', 'white', 'black', 'red'}` when `y` is a matrix with five columns categorized into groups red, white, and black

Data Types: `single` | `double` | `logical` | `categorical` | `char` | `string` | `cell`

displayopt — Indicator to display ANOVA table and box plot

`'on'` (default) | `'off'`

Indicator to display the ANOVA table and box plot, specified as `'on'` or `'off'`. When `displayopt` is `'off'`, `anova1` returns the output arguments, only. It does not display the standard ANOVA table and box plot.

Example: `p = anova(x,group,'off')`

Output Arguments

p — *p*-value for the *F*-test

scalar value

p-value for the *F*-test, returned as a scalar value. *p*-value is the probability that the *F*-statistic can take a value larger than the computed test-statistic value. `anova1` tests the null hypothesis that all group means are equal to each other against the alternative hypothesis that at least one group mean is different from the others. The function derives the *p*-value from the cdf of the *F*-distribution.

A *p*-value that is smaller than the significance level indicates that at least one of the sample means is significantly different from the others. Common significance levels are 0.05 or 0.01.

tbl — ANOVA table

cell array

ANOVA table, returned as a cell array. `tbl` has six columns.

Column	Definition
source	The source of the variability.
SS	The sum of squares due to each source.
df	The degrees of freedom associated with each source. Suppose N is the total number of observations and k is the number of groups. Then, $N - k$ is the within-groups degrees of freedom (Error), $k - 1$ is the between-groups degrees of freedom (Columns), and $N - 1$ is the total degrees of freedom. $N - 1 = (N - k) + (k - 1)$
MS	The mean squares for each source, which is the ratio SS/df .
F	F -statistic, which is the ratio of the mean squares.
Prob>F	The p -value, which is the probability that the F -statistic can take a value larger than the computed test-statistic value. <code>anova1</code> derives this probability from the cdf of F -distribution.

The rows of the ANOVA table show the variability in the data that is divided by the source.

Row	Definition
Groups	Variability due to the differences among the group means (variability <i>between</i> groups)
Error	Variability due to the differences between the data in each group and the group mean (variability <i>within</i> groups)
Total	Total variability

stats — Statistics for multiple comparison tests

structure

Statistics for multiple comparison tests on page 9-18, returned as a structure with the fields described in this table.

Field name	Definition
gnames	Names of the groups
n	Number of observations in each group
source	Source of the <code>stats</code> output
means	Estimated values of the means
df	Error (within-groups) degrees of freedom ($N - k$, where N is the total number of observations and k is the number of groups)
s	Square root of the mean squared error

More About

Box Plot

`anova1` returns a box plot of the observations for each group in `y`. Box plots provide a visual comparison of the group location parameters.

On each box, the central mark is the median (2nd quantile, q_2) and the edges of the box are the 25th and 75th percentiles (1st and 3rd quantiles, q_1 and q_3 , respectively). The whiskers extend to the most extreme data points that are not considered outliers. The outliers are plotted individually using the '+' symbol. The extremes of the whiskers correspond to $q_3 + 1.5 \times (q_3 - q_1)$ and $q_1 - 1.5 \times (q_3 - q_1)$.

Box plots include notches for the comparison of the median values. Two medians are significantly different at the 5% significance level if their intervals, represented by notches, do not overlap. This test is different from the F -test that ANOVA performs; however, large differences in the center lines of the boxes correspond to a large F -statistic value and correspondingly a small p -value. The extremes of the notches correspond to $q_2 - 1.57(q_3 - q_1)/\sqrt{n}$ and $q_2 + 1.57(q_3 - q_1)/\sqrt{n}$, where n is the number of observations without any NaN values.

For more information about box plots, see 'Whisker' and 'Notch' of `boxplot`.

Topics

“Perform One-Way ANOVA” on page 9-5

“One-Way ANOVA” on page 9-3

“Multiple Comparisons” on page 9-18

Introduced before R2006a

anova2

Two-way analysis of variance

Syntax

```
p = anova2(y, reps)
p = anova2(y, reps, displayopt)
[p, tbl] = anova2( ___ )
[p, tbl, stats] = anova2( ___ )
```

Description

`anova2` performs two-way analysis of variance (ANOVA) with balanced designs. To perform two-way ANOVA with unbalanced designs, see `anovan`.

`p = anova2(y, reps)` returns the p -values for a balanced two-way ANOVA for comparing the means of two or more columns and two or more rows of the observations in `y`.

`reps` is the number of replicates for each combination of factor groups, which must be constant, indicating a balanced design. For unbalanced designs, use `anovan`. The `anova2` function tests the main effects for column and row factors and their interaction effect. To test the interaction effect, `reps` must be greater than 1.

`anova2` also displays the standard ANOVA table.

`p = anova2(y, reps, displayopt)` enables the ANOVA table display when `displayopt` is 'on' (default) and suppresses the display when `displayopt` is 'off'.

`[p, tbl] = anova2(___)` returns the ANOVA table (including column and row labels) in cell array `tbl`. To copy a text version of the ANOVA table to the clipboard, select **Edit > Copy Text** menu.

`[p, tbl, stats] = anova2(___)` returns a `stats` structure, which you can use to perform a multiple comparison test on page 9-18. A multiple comparison test enables you to determine which pairs of group means are significantly different. To perform this test, use `multcompare`, providing the `stats` structure as input.

Examples

Two-Way ANOVA

Load the sample data.

```
load popcorn
popcorn
```

```
popcorn = 6×3
```

```
    5.5000    4.5000    3.5000
    5.5000    4.5000    4.0000
    6.0000    4.0000    3.0000
```

```

6.5000    5.0000    4.0000
7.0000    5.5000    5.0000
7.0000    5.0000    4.5000

```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands, Gourmet, National, and Generic, respectively. The rows are popper types, oil and air. In the study, researchers popped a batch of each brand three times with each popper, that is, the number of replications is 3. The first three rows correspond to the oil popper, and the last three rows correspond to the air popper. The response values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Save the ANOVA table in the cell array `tbl` for easy access to results.

```
[p,tbl] = anova2(popcorn,3);
```

ANOVA Table					
Source	SS	df	MS	F	Prob>F
Columns	15.75	2	7.875	56.7	0
Rows	4.5	1	4.5	32.4	0.0001
Interaction	0.0833	2	0.04167	0.3	0.7462
Error	1.6667	12	0.13889		
Total	22	17			

The column `Prob>F` shows the p -values for the three brands of popcorn (0.0000), the two popper types (0.0001), and the interaction between brand and popper type (0.7462). These values indicate that popcorn brand and popper type affect the yield of popcorn, but there is no evidence of an interaction effect of the two.

Display the cell array containing the ANOVA table.

```
tbl
```

```
tbl=6x6 cell array
Columns 1 through 5
```

```

{'Source'      } {'SS'      } {'df'} {'MS'      } {'F'      }
{'Columns'    } {[15.7500]} {[ 2]} {[ 7.8750]} {[ 56.7000]}
{'Rows'       } {[ 4.5000]} {[ 1]} {[ 4.5000]} {[ 32.4000]}
{'Interaction'} {[ 0.0833]} {[ 2]} {[ 0.0417]} {[ 0.3000]}
{'Error'      } {[ 1.6667]} {[12]} {[ 0.1389]} {0x0 double}
{'Total'     } {[      22]} {[17]} {0x0 double} {0x0 double}

```

```
Column 6
```

```

{'Prob>F'     }
{[7.6790e-07]}
{[1.0037e-04]}
{[ 0.7462]}
{0x0 double }
{0x0 double }

```

Store the F -statistic for the factors and factor interaction in separate variables.

```

Fbrands = tbl{2,5}
Fbrands = 56.7000
Fpoppertype = tbl{3,5}
Fpoppertype = 32.4000
Finteraction = tbl{4,5}
Finteraction = 0.3000

```

Multiple Comparisons for Two-Way ANOVA

Load the sample data.

```

load popcorn
popcorn
popcorn = 6x3
  5.5000  4.5000  3.5000
  5.5000  4.5000  4.0000
  6.0000  4.0000  3.0000
  6.5000  5.0000  4.0000
  7.0000  5.5000  5.0000
  7.0000  5.0000  4.5000

```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper types oil and air. In the study, researchers popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Also compute the statistics that you need to perform a multiple comparison test on the main effects.

```

[~,~,stats] = anova2(popcorn,3,'off')
stats = struct with fields:
  source: 'anova2'
  sigmasq: 0.1389
  colmeans: [6.2500 4.7500 4]
  coln: 6
  rowmeans: [4.5000 5.5000]
  rown: 9
  inter: 1
  pval: 0.7462
  df: 12

```

The `stats` structure includes

- The mean squared error (`sigmasq`)
- The estimates of the mean yield for each popcorn brand (`colmeans`)

- The number of observations for each popcorn brand (`coln`)
- The estimate of the mean yield for each popper type (`rowmeans`)
- The number of observations for each popper type (`rown`)
- The number of interactions (`inter`)
- The p -value that shows the significance level of the interaction term (`pval`)
- The error degrees of freedom (`df`).

Perform a multiple comparison test to see if the popcorn yield differs between pairs of popcorn brands (columns).

```
c = multcompare(stats)
```

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.

```
c = 3×6
```

1.0000	2.0000	0.9260	1.5000	2.0740	0.0000
1.0000	3.0000	1.6760	2.2500	2.8240	0.0000
2.0000	3.0000	0.1760	0.7500	1.3240	0.0116

The first two columns of `c` show the groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for 95% confidence intervals for the true mean difference. The sixth column contains the p -

value for a hypothesis test that the corresponding mean difference is equal to zero. All p -values (0, 0, and 0.0116) are very small, which indicates that the popcorn yield differs across all three brands.

The figure shows the multiple comparison of the means. By default, the group 1 mean is highlighted and the comparison interval is in blue. Because the comparison intervals for the other two groups do not intersect with the intervals for the group 1 mean, they are highlighted in red. This lack of intersection indicates that both means are different than group 1 mean. Select other group means to confirm that all group means are significantly different from each other.

Perform a multiple comparison test to see the popcorn yield differs between the two popper types (rows).

```
c = multcompare(stats, 'Estimate', 'row')
```

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.

```
c = 1x6
```

```
1.0000    2.0000   -1.3828   -1.0000   -0.6172    0.0001
```

The small p -value of 0.0001 indicates that the popcorn yield differs between the two popper types (air and oil). The figure shows the same results. The disjoint comparison intervals indicate that the group means are significantly different from each other.

Input Arguments

y — Sample data

matrix

Sample data, specified as a matrix. The columns correspond to groups of one factor, and the rows correspond to the groups of the other factor and the replications. Replications are the measurements or observations for each combination of groups (levels) of the row and column factor. For example, in the following data the row factor *A* has three levels, column factor *B* has two levels, and there are two replications (`reps = 2`). The subscripts indicate row, column, and replication, respectively.

$$\begin{array}{cc}
 B = 1 & B = 2 \\
 \left[\begin{array}{cc}
 Y_{111} & Y_{121} \\
 Y_{112} & Y_{122} \\
 Y_{211} & Y_{221} \\
 Y_{212} & Y_{222} \\
 Y_{311} & Y_{321} \\
 Y_{312} & Y_{322}
 \end{array} \right] & \begin{array}{l}
 \} A = 1 \\
 \} A = 2 \\
 \} A = 3
 \end{array}
 \end{array}$$

Data Types: `single` | `double`

reps — Number of replications

1 (default) | an integer number

Number of replications for each combination of groups, specified as an integer number. For example, the following data has two replications (`reps = 2`) for each group combination of row factor *A* and column factor *B*.

$$\begin{array}{cc}
 B = 1 & B = 2 \\
 \left[\begin{array}{cc}
 Y_{111} & Y_{121} \\
 Y_{112} & Y_{122} \\
 Y_{211} & Y_{221} \\
 Y_{212} & Y_{222} \\
 Y_{311} & Y_{321} \\
 Y_{312} & Y_{322}
 \end{array} \right] & \begin{array}{l}
 \} A = 1 \\
 \} A = 2 \\
 \} A = 3
 \end{array}
 \end{array}$$

- When `reps` is 1 (default), `anova2` returns two *p*-values in vector `p`:
 - The *p*-value for the null hypothesis that all samples from factor *B* (i.e., all column samples in `y`) are drawn from the same population.
 - The *p*-value for the null hypothesis, that all samples from factor *A* (i.e., all row samples in `y`) are drawn from the same population.
- When `reps` is greater than 1, `anova2` also returns the *p*-value for the null hypothesis that factors *A* and *B* have no interaction (i.e., the effects due to factors *A* and *B* are *additive*).

Example: `p = anova(y, 3)` specifies that each combination of groups (levels) has three replications.

Data Types: `single` | `double`

displayopt – Indicator to display the ANOVA table

'on' (default) | 'off'

Indicator to display the ANOVA table as a figure, specified as 'on' or 'off'.

Output Arguments**p** – *p*-value

scalar value

p-value for the *F*-test, returned as a scalar value. A small *p*-value indicates that the results are statistically significant. Common significance levels are 0.05 or 0.01. For example:

- A sufficiently small *p*-value for the null hypothesis for group means of row factor *A* suggests that at least one row-sample mean is significantly different from the other row-sample means; i.e., there is a main effect due to factor *A*.
- A sufficiently small *p*-value for the null hypothesis for group (level) means of column factor *B* suggests that at least one column-sample mean is significantly different from the other column-sample means; i.e., there is a main effect due to factor *B*.
- A sufficiently small *p*-value for combinations of groups (levels) of factors *A* and *B* suggests that there is an interaction between factors *A* and *B*.

tbl – ANOVA table

cell array

ANOVA table, returned as a cell array. `tbl` has six columns.

Column name	Definition
source	Source of the variability.
SS	Sum of squares due to each source.
df	Degrees of freedom associated with each source.
MS	Mean squares for each source, which is the ratio SS/df .
F	<i>F</i> -statistic, which is the ratio of the mean squares.
Prob>F	<i>p</i> -value, which is the probability that the <i>F</i> -statistic can take a value larger than the computed test-statistic value. <code>anova2</code> derives this probability from the cdf of the <i>F</i> -distribution.

The rows of the ANOVA table show the variability in the data, divided by the source into three or four parts, depending on the value of `reps`.

Row	Definition
Columns	Variability due to the differences among the column means
Rows	Variability due to the differences among the row means

Row	Definition
Interaction	Variability due to the interaction between rows and columns (if <code>reps</code> is greater than its default value of 1)
Error	Remaining variability not explained by any systematic source

Data Types: cell

stats — Statistics for multiple comparison test

structure

Statistics for multiple comparisons tests on page 9-18, returned as a structure. Use `multcompare` to perform multiple comparison tests, supplying `stats` as an input argument. `stats` has nine fields.

Field	Definition
<code>source</code>	Source of the <code>stats</code> output
<code>sigmasq</code>	Mean squared error
<code>colmeans</code>	Estimated values of the column means
<code>coln</code>	Number of observations for each group in columns
<code>rowmeans</code>	Estimated values of the row means
<code>rown</code>	Number of observations for each group in rows
<code>inter</code>	Number of interactions
<code>pval</code>	p -value for the interaction term
<code>df</code>	Error degrees of freedom $(reps - 1) * r * c$ where <code>reps</code> is the number of replications and <code>c</code> and <code>r</code> are the number of groups in factors, respectively.

Data Types: struct

Introduced before R2006a

anovan

N-way analysis of variance

Syntax

```
p = anovan(y,group)
p = anovan(y,group,Name,Value)
[p,tbl] = anovan(____)
[p,tbl,stats] = anovan(____)
[p,tbl,stats,terms] = anovan(____)
```

Description

`p = anovan(y,group)` returns a vector of p -values, one per term, for multiway (n -way) analysis of variance (ANOVA) for testing the effects of multiple factors on the mean of the vector y .

`anovan` also displays a figure showing the standard ANOVA table.

`p = anovan(y,group,Name,Value)` returns a vector of p -values for multiway (n -way) ANOVA using additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which predictor variable is continuous, if any, or the type of sum of squares to use.

`[p,tbl] = anovan(____)` returns the ANOVA table (including factor labels) in cell array `tbl` for any of the input arguments specified in the previous syntaxes. Copy a text version of the ANOVA table to the clipboard by using the `Copy Text` item on the **Edit** menu.

`[p,tbl,stats] = anovan(____)` returns a `stats` structure that you can use to perform a multiple comparison test on page 9-18, which enables you to determine which pairs of group means are significantly different. You can perform such a test using the `multcompare` function by providing the `stats` structure as input.

`[p,tbl,stats,terms] = anovan(____)` returns the main and interaction terms used in the ANOVA computations in `terms`.

Examples

Three-Way ANOVA

Load the sample data.

```
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';
g1 = [1 2 1 2 1 2 1 2];
g2 = {'hi';'hi';'lo';'lo';'hi';'hi';'lo';'lo'};
g3 = {'may';'may';'may';'may';'june';'june';'june';'june'};
```

y is the response vector and $g1$, $g2$, and $g3$ are the grouping variables (factors). Each factor has two levels, and every observation in y is identified by a combination of factor levels. For example,

observation $y(1)$ is associated with level 1 of factor g_1 , level 'hi' of factor g_2 , and level 'may' of factor g_3 . Similarly, observation $y(6)$ is associated with level 2 of factor g_1 , level 'hi' of factor g_2 , and level 'june' of factor g_3 .

Test if the response is the same for all factor levels.

```
p = anovan(y, {g1, g2, g3})
```

Analysis of Variance					
Source	Sum Sq.	d. f.	Mean Sq.	F	Prob>F
X1	3.781	1	3.781	0.82	0.4174
X2	199.001	1	199.001	42.95	0.0028
X3	0.061	1	0.061	0.01	0.914
Error	18.535	4	4.634		
Total	221.379	7			

Constrained (Type III) sums of squares.

```
p = 3×1
```

```
0.4174
0.0028
0.9140
```

In the ANOVA table, X1, X2, and X3 correspond to the factors g_1 , g_2 , and g_3 , respectively. The p -value 0.4174 indicates that the mean responses for levels 1 and 2 of the factor g_1 are not significantly different. Similarly, the p -value 0.914 indicates that the mean responses for levels 'may' and 'june', of the factor g_3 are not significantly different. However, the p -value 0.0028 is small enough to conclude that the mean responses are significantly different for the two levels, 'hi' and 'lo' of the factor g_2 . By default, `anovan` computes p -values just for the three main effects.

Test the two-factor interactions. This time specify the variable names.

```
p = anovan(y, {g1 g2 g3}, 'model', 'interaction', 'varnames', {'g1', 'g2', 'g3'})
```

Analysis of Variance					
Source	Sum Sq.	d. f.	Mean Sq.	F	Prob>F
g1	3.781	1	3.781	336.11	0.0347
g2	199.001	1	199.001	17689	0.0048
g3	0.061	1	0.061	5.44	0.2578
g1*g2	18.301	1	18.301	1626.78	0.0158
g1*g3	0.211	1	0.211	18.78	0.1444
g2*g3	0.011	1	0.011	1	0.5
Error	0.011	1	0.011		
Total	221.379	7			

Constrained (Type III) sums of squares.

```
p = 6×1
```

```

0.0347
0.0048
0.2578
0.0158
0.1444
0.5000

```

The interaction terms are represented by $g1*g2$, $g1*g3$, and $g2*g3$ in the ANOVA table. The first three entries of p are the p -values for the main effects. The last three entries are the p -values for the two-way interactions. The p -value of 0.0158 indicates that the interaction between $g1$ and $g2$ is significant. The p -values of 0.1444 and 0.5 indicate that the corresponding interactions are not significant.

Two-Way ANOVA for Unbalanced Design

Load the sample data.

```
load carbig
```

The data has measurements on 406 cars. The variable `org` shows where the cars were made and `when` shows when in the year the cars were manufactured.

Study how the mileage depends on when and where the cars were made. Also include the two-way interactions in the model.

```
p = anovan(MPG, {org when}, 'model', 2, 'varnames', {'origin', 'mfg date'})
```

Analysis of Variance					
Source	Sum Sq.	d. f.	Mean Sq.	F	Prob>F
origin	5727.2	2	2863.58	115.09	0
mfg date	4710.3	2	2355.15	94.65	0
origin*mfg date	120.5	4	30.12	1.21	0.3059
Error	9679.1	389	24.88		
Total	24252.6	397			

Constrained (Type III) sums of squares.

```
p = 3x1
```

```

0.0000
0.0000
0.3059

```

The `'model', 2` name-value pair argument represents the two-way interactions. The p -value for the interaction term, 0.3059, is not small, indicating little evidence that the effect of the time of manufacture (`mfg date`) depends on where the car was made (`origin`). The main effects of origin and manufacturing date, however, are significant, both p -values are 0.

Multiple Comparisons for Three-Way ANOVA

Load the sample data.

```
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';
g1 = [1 2 1 2 1 2 1 2];
g2 = {'hi'; 'hi'; 'lo'; 'lo'; 'hi'; 'hi'; 'lo'; 'lo'};
g3 = {'may'; 'may'; 'may'; 'may'; 'june'; 'june'; 'june'; 'june'};
```

y is the response vector and $g1$, $g2$, and $g3$ are the grouping variables (factors). Each factor has two levels, and every observation in y is identified by a combination of factor levels. For example, observation $y(1)$ is associated with level 1 of factor $g1$, level 'hi' of factor $g2$, and level 'may' of factor $g3$. Similarly, observation $y(6)$ is associated with level 2 of factor $g1$, level 'hi' of factor $g2$, and level 'june' of factor $g3$.

Test if the response is the same for all factor levels. Also compute the statistics required for multiple comparison tests.

```
[~,~,stats] = anovan(y,{g1 g2 g3},'model','interaction',...
    'varnames',{'g1','g2','g3'});
```

Analysis of Variance					
Source	Sum Sq.	d. f.	Mean Sq.	F	Prob>F
g1	3.781	1	3.781	336.11	0.0347
g2	199.001	1	199.001	17689	0.0048
g3	0.061	1	0.061	5.44	0.2578
g1*g2	18.301	1	18.301	1626.78	0.0158
g1*g3	0.211	1	0.211	18.78	0.1444
g2*g3	0.011	1	0.011	1	0.5
Error	0.011	1	0.011		
Total	221.379	7			

Constrained (Type III) sums of squares.

The p -value of 0.2578 indicates that the mean responses for levels 'may' and 'june' of factor $g3$ are not significantly different. The p -value of 0.0347 indicates that the mean responses for levels 1 and 2 of factor $g1$ are significantly different. Similarly, the p -value of 0.0048 indicates that the mean responses for levels 'hi' and 'lo' of factor $g2$ are significantly different.

Perform multiple comparison tests to find out which groups of the factors $g1$ and $g2$ are significantly different.

```
results = multcompare(stats,'Dimension',[1 2])
```

results = 6×6

1.0000	2.0000	-6.8604	-4.4000	-1.9396	0.0280
1.0000	3.0000	4.4896	6.9500	9.4104	0.0177
1.0000	4.0000	6.1396	8.6000	11.0604	0.0143
2.0000	3.0000	8.8896	11.3500	13.8104	0.0108
2.0000	4.0000	10.5396	13.0000	15.4604	0.0095
3.0000	4.0000	-0.8104	1.6500	4.1104	0.0745

`multcompare` compares the combinations of groups (levels) of the two grouping variables, `g1` and `g2`. In the `results` matrix, the number 1 corresponds to the combination of level 1 of `g1` and level `hi` of `g2`, the number 2 corresponds to the combination of level 2 of `g1` and level `hi` of `g2`. Similarly, the number 3 corresponds to the combination of level 1 of `g1` and level `lo` of `g2`, and the number 4 corresponds to the combination of level 2 of `g1` and level `lo` of `g2`. The last column of the matrix contains the p -values.

For example, the first row of the matrix shows that the combination of level 1 of `g1` and level `hi` of `g2` has the same mean response values as the combination of level 2 of `g1` and level `hi` of `g2`. The p -value corresponding to this test is 0.0280, which indicates that the mean responses are significantly different. You can also see this result in the figure. The blue bar shows the comparison interval for the mean response for the combination of level 1 of `g1` and level `hi` of `g2`. The red bars are the comparison intervals for the mean response for other group combinations. None of the red bars overlap with the blue bar, which means the mean response for the combination of level 1 of `g1` and level `hi` of `g2` is significantly different from the mean response for other group combinations.

You can test the other groups by clicking on the corresponding comparison interval for the group. The bar you click on turns to blue. The bars for the groups that are significantly different are red. The bars for the groups that are not significantly different are gray. For example, if you click on the comparison interval for the combination of level 1 of `g1` and level 1o of `g2`, the comparison interval for the combination of level 2 of `g1` and level 1o of `g2` overlaps, and is therefore gray. Conversely, the other comparison intervals are red, indicating significant difference.

Input Arguments

y — Sample data

numeric vector

Sample data, specified as a numeric vector.

Data Types: `single` | `double`

group — Grouping variables

cell array

Grouping variables, i.e. the factors and factor levels of the observations in `y`, specified as a cell array. Each of the cells in `group` contains a list of factor levels identifying the observations in `y` with respect to one of the factors. The list within each cell can be a categorical array, numeric vector, character matrix, string array, or single-column cell array of character vectors, and must have the same number of elements as `y`.

$$\begin{array}{cccccccc}
 y & = & [& y_1, & y_2, & y_3, & y_4, & y_5, & \dots, & y_N &] \\
 & & & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & & \uparrow & \\
 g1 & = & \{ & 'A', & 'A', & 'C', & 'B', & 'B', & \dots, & 'D' & \} \\
 g2 & = & [& 1 & 2 & 1 & 3 & 1 & \dots, & 2 &] \\
 g3 & = & \{ & 'hi', & 'mid', & 'low', & 'mid', & 'hi', & \dots, & 'low' & \}
 \end{array}$$

By default, `anovan` treats all grouping variables as fixed effects.

For example, in a study you want to investigate the effects of gender, school, and the education method on the academic success of elementary school students, then you can specify the grouping variables as follows.

Example: `{'Gender','School','Method'}`

Data Types: `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'alpha', 0.01, 'model', 'interaction', 'sstype', 2` specifies `anovan` to compute the 99% confidence bounds and p-values for the main effects and two-way interactions using type II sum of squares.

alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level for confidence bounds, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

Example: 'alpha', 0.01 corresponds to 99% confidence intervals

Data Types: single | double

continuous — Indicator for continuous predictors

vector of indices

Indicator for continuous predictors, representing which grouping variables should be treated as continuous predictors rather than as categorical predictors, specified as the comma-separated pair consisting of 'continuous' and a vector of indices.

For example, if there are three grouping variables and second one is continuous, then you can specify as follows.

Example: 'continuous', [2]

Data Types: single | double

display — Indicator to display ANOVA table

'on' (default) | 'off'

Indicator to display ANOVA table, specified as the comma-separated pair consisting of 'display' and 'on' or 'off'. When `displayopt` is 'off', `anovan` only returns the output arguments, and does not display the standard ANOVA table as a figure.

Example: 'display', 'off'

model — Type of the model

'linear' (default) | 'interaction' | 'full' | integer value | terms matrix

Type of the model, specified as the comma-separated pair consisting of 'model' and one of the following:

- 'linear' — The default 'linear' model computes only the p -values for the null hypotheses on the N main effects.
- 'interaction' — The 'interaction' model computes the p -values for null hypotheses on the N main effects and the $\binom{N}{2}$ two-factor interactions.
- 'full' — The 'full' model computes the p -values for null hypotheses on the N main effects and interactions at all levels.
- An integer — For an integer value of k , ($k \leq N$) for model type, `anovan` computes all interaction levels through the k th level. For example, the value 3 means main effects plus two- and three-factor interactions. The values $k = 1$ and $k = 2$ are equivalent to the 'linear' and 'interaction' specifications, respectively. The value $k = N$ is equivalent to the 'full' specification.
- Terms matrix — A matrix of term definitions having the same form as the input to the `x2fx` function. All entries must be 0 or 1 (no higher powers).

For more precise control over the main and interaction terms that `anovan` computes, you can specify a matrix containing one row for each main or interaction term to include in the ANOVA model. Each row defines one term using a vector of N zeros and ones. The table below illustrates the coding for a 3-factor ANOVA for factors A , B , and C .

Matrix Row	ANOVA Term
[1 0 0]	Main term <i>A</i>
[0 1 0]	Main term <i>B</i>
[0 0 1]	Main term <i>C</i>
[1 1 0]	Interaction term <i>AB</i>
[1 0 1]	Interaction term <i>AC</i>
[0 1 1]	Interaction term <i>BC</i>
[1 1 1]	Interaction term <i>ABC</i>

For example, if there are three factors *A*, *B*, and *C*, and 'model', [0 1 0;0 0 1;0 1 1], then anovan tests for the main effects *B* and *C*, and the interaction effect *BC*, respectively.

A simple way to generate the terms matrix is to modify the terms output, which codes the terms in the current model using the format described above. If anovan returns [0 1 0;0 0 1;0 1 1] for terms, for example, and there is no significant interaction *BC*, then you can recompute ANOVA on just the main effects *B* and *C* by specifying [0 1 0;0 0 1] for model.

Example: 'model', [0 1 0;0 0 1;0 1 1]

Example: 'model', 'interaction'

Data Types: char | string | single | double

nested — Nesting relationships

matrix of 0's and 1's

Nesting relationships among the grouping variables, specified as the comma-separated pair consisting of 'nested' and a matrix *M* of 0's and 1's, i.e. $M(i,j) = 1$ if variable *i* is nested in variable *j*.

You cannot specify nesting in a continuous variable.

For example, if there are two grouping variables District and School, where School is nested in District, then you can express this relationship as follows.

Example: 'nested', [0 0;1 0]

Data Types: single | double

random — Indicator for random variables

vector of indices

Indicator for random variables, representing which grouping variables are random, specified as the comma-separated pair consisting of 'random' and a vector of indices. By default, anovan treats all grouping variables as fixed.

anovan treats an interaction term as random if any of the variables in the interaction term is random.

Example: 'random', [3]

Data Types: single | double

sstype — Type of sum of squares

3 (default) | 1 | 2 | 'h'

Type of sum squares, specified as the comma-separated pair consisting of 'sstype' and the following:

- 1 — Type I sum of squares. The reduction in residual sum of squares obtained by adding that term to a fit that already includes the terms listed before it.
- 2 — Type II sum of squares. The reduction in residual sum of squares obtained by adding that term to a model consisting of all other terms that do not contain the term in question.
- 3 — Type III sum of squares. The reduction in residual sum of squares obtained by adding that term to a model containing all other terms, but with their effects constrained to obey the usual “sigma restrictions” that make models estimable.
- 'h' — Hierarchical model. Similar to type 2, but with continuous as well as categorical factors used to determine the hierarchy of terms.

The sum of squares for any term is determined by comparing two models. For a model containing main effects but no interactions, the value of sstype influences the computations on unbalanced data only.

Suppose you are fitting a model with two factors and their interaction, and the terms appear in the order A , B , AB . Let $R(\cdot)$ represent the residual sum of squares for the model. So, $R(A, B, AB)$ is the residual sum of squares fitting the whole model, $R(A)$ is the residual sum of squares fitting the main effect of A only, and $R(1)$ is the residual sum of squares fitting the mean only. The three sum of squares types are as follows:

Term	Type 1 Sum of Squares	Type 2 Sum of Squares	Type 3 Sum of Squares
A	$R(1) - R(A)$	$R(B) - R(A, B)$	$R(B, AB) - R(A, B, AB)$
B	$R(A) - R(A, B)$	$R(A) - R(A, B)$	$R(A, AB) - R(A, B, AB)$
AB	$R(A, B) - R(A, B, AB)$	$R(A, B) - R(A, B, AB)$	$R(A, B) - R(A, B, AB)$

The models for Type 3 sum of squares have sigma restrictions imposed. This means, for example, that in fitting $R(B, AB)$, the array of AB effects is constrained to sum to 0 over A for each value of B , and over B for each value of A .

Example: 'sstype', 'h'

Data Types: single | double | char | string

varnames — Names of grouping variables

X_1, X_2, \dots, X_N (default) | character matrix | string array | cell array of character vectors

Names of grouping variables, specified as the comma-separating pair consisting of 'varnames' and a character matrix, a string array, or a cell array of character vectors.

Example: 'varnames', {'Gender', 'City'}

Data Types: char | string | cell

Output Arguments

p — p-values

vector

p-values, returned as a vector.

Output vector p contains p -values for the null hypotheses on the N main effects and any interaction terms specified. Element $p(1)$ contains the p -value for the null hypotheses that samples at all levels of factor A are drawn from the same population; element $p(2)$ contains the p -value for the null hypotheses that samples at all levels of factor B are drawn from the same population; and so on.

For example, if there are three factors A , B , and C , and 'model', $[0\ 1\ 0; 0\ 0\ 1; 0\ 1\ 1]$, then the output vector p contains the p -values for the null hypotheses on the main effects B and C and the interaction effect BC , respectively.

A sufficiently small p -value corresponding to a factor suggests that at least one group mean is significantly different from the other group means; that is, there is a main effect due to that factor. It is common to declare a result significant if the p -value is less than 0.05 or 0.01.

tbl – ANOVA table

cell array

ANOVA table, returned as a cell array. The ANOVA table has seven columns:

Column name	Definition
source	Source of the variability.
SS	Sum of squares due to each source.
df	Degrees of freedom associated with each source.
MS	Mean squares for each source, which is the ratio SS/df .
Singular?	Indication of whether the term is singular.
F	F -statistic, which is the ratio of the mean squares.
Prob>F	The p -values, which is the probability that the F -statistic can take a value larger than a computed test-statistic value. <code>anovan</code> derives these probabilities from the cdf of F -distribution.

The ANOVA table also contains the following columns if at least one of the grouping variables is specified as random using the name-value pair argument `random`:

Column name	Definition
Type	Type of each source; 'fixed' for a fixed effect or 'random' for a random effect.
Expected MS	Text representation of the expected value for the mean square. $Q(\text{source})$ represents a quadratic function of source and $V(\text{source})$ represents the variance of source .
MS denom	Denominator of the F -statistic.
d.f. denom	Degrees of freedom for the denominator of the F -statistic.
Denom. defn.	Text representation of the denominator of the F -statistic. $MS(\text{source})$ represents the mean square of source .

Column name	Definition
Var. est.	Variance component estimate.
Var. lower bnd	Lower bound of the 95% confidence interval for the variance component estimate.
Var. upper bnd	Upper bound of the 95% confidence interval for the variance component estimate.

stats – Statistics

structure

Statistics to use in a multiple comparison test on page 9-18 using the `multcompare` function, returned as a structure.

`anovan` evaluates the hypothesis that the different groups (levels) of a factor (or more generally, a term) have the same effect, against the alternative that they do not all have the same effect. Sometimes it is preferable to perform a test to determine which pairs of levels are significantly different, and which are not. Use the `multcompare` function to perform such tests by supplying the `stats` structure as input.

The `stats` structure contains the fields listed below, in addition to a number of other fields required for doing multiple comparisons using the `multcompare` function:

Field	Description
<code>coeffs</code>	Estimated coefficients
<code>coeffnames</code>	Name of term for each coefficient
<code>vars</code>	Matrix of grouping variable values for each term
<code>resid</code>	Residuals from the fitted model

The `stats` structure also contains the following fields if at least one of the grouping variables is specified as random using the name-value pair argument `random`:

Field	Description
<code>ems</code>	Expected mean squares
<code>denom</code>	Denominator definition
<code>rtnames</code>	Names of random terms
<code>varest</code>	Variance component estimates (one per random term)
<code>varci</code>	Confidence intervals for variance components

terms – Main and interaction terms

matrix

Main and interaction terms, returned as a matrix. The terms are encoded in the output matrix `terms` using the same format described above for input `model`. When you specify `model` itself in this format, the matrix returned in `terms` is identical.

Introduced before R2006a

anova

Class: RepeatedMeasuresModel

Analysis of variance for between-subject effects

Syntax

```
anovatbl = anova(rm)
anovatbl = anova(rm, 'WithinModel', WM)
```

Description

`anovatbl = anova(rm)` returns the analysis of variance results for the repeated measures model `rm`.

`anovatbl = anova(rm, 'WithinModel', WM)` returns the analysis of variance results it performs using the response or responses specified by the within-subject model `WM`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

WM — Within-subject model

'separatemeans' (default) | 'orthogonalcontrasts' | character vector or string scalar defining a model specification | r -by- nc matrix specifying nc contrasts

Within-subject model, specified as one of the following:

- 'separatemeans' — The response is the average of the repeated measures (average across the within-subject model).
- 'orthogonalcontrasts' — This is valid when the within-subject model has a single numeric factor T . Responses are the average, the slope of centered T , and, in general, all orthogonal contrasts for a polynomial up to $T^{(p-1)}$, where p is the number of rows in the within-subject model. `anova` multiplies Y , the response you use in the repeated measures model `rm` by the orthogonal contrasts, and uses the columns of the resulting product matrix as the responses.

`anova` computes the orthogonal contrasts for T using the Q factor of a QR factorization on page 32-88 of the Vandermonde matrix on page 32-88.

- A character vector or string scalar that defines a model specification in the within-subject factors. Responses are defined by the terms in that model. `anova` multiplies Y , the response matrix you use in the repeated measures model `rm` by the terms of the model, and uses the columns of the result as the responses.

For example, if there is a Time factor and 'Time' is the model specification, then `anova` uses two terms, the constant and the uncentered Time term. The default is '1' to perform on the average response.

- An r -by- nc matrix, C , specifying nc contrasts among the r repeated measures. If Y represents the matrix of repeated measures you use in the repeated measures model `rm`, then the output `tbl` contains a separate analysis of variance for each column of $Y*C$.

The `anova` table contains a separate univariate analysis of variance results for each response.

Example: `'WithinModel', 'Time'`

Example: `'WithinModel', 'orthogonalcontrasts'`

Output Arguments

`anovatbl` — Results of analysis of variance

table

Results of analysis of variance for between-subject effects, returned as a table. This includes all terms on the between-subjects model and the following columns.

Column Name	Definition
Within	Within-subject factors
Between	Between-subject factors
SumSq	Sum of squares
DF	Degrees of freedom
MeanSq	Mean squared error
F	F -statistic
pValue	p -value corresponding to the F -statistic

Examples

Analysis of Variance for Average Response

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas);
```

Perform analysis of variance.

```
anova(rm)
```

```
ans=3x7 table
```

	Within	Between	SumSq	DF	MeanSq	F	pValue
Constant		constant	7201.7	1	7201.7	19650	2.0735e-158
Constant		species	309.61	2	154.8	422.39	1.1517e-61
Constant		Error	53.875	147	0.36649		

There are 150 observations and 3 species. The degrees of freedom for species is $3 - 1 = 2$, and for error it is $150 - 3 = 147$. The small p -value of $1.1517e-61$ indicates that the measurements differ significantly according to species.

Panel Data

Load the sample panel data.

```
load('panelData.mat');
```

The dataset array, `panelData`, contains yearly observations on eight cities for 6 years. The first variable, `Growth`, measures economic growth (the response variable). The second and third variables are city and year indicators, respectively. The last variable, `Employ`, measures employment (the predictor variable). This is simulated data.

Store the data in a table array and define city as a nominal variable.

```
t = table(panelData.Growth, panelData.City, panelData.Year, ...
    'VariableNames', {'Growth', 'City', 'Year'});
```

Convert the data in a proper format to do repeated measures analysis.

```
t = unstack(t, 'Growth', 'Year', 'NewDataVariableNames', ...
    {'year1', 'year2', 'year3', 'year4', 'year5', 'year6'});
```

Add the mean employment level over the years as a predictor variable to the table `t`.

```
t(:,8) = table(grpstats(panelData.Employ, panelData.City));
t.Properties.VariableNames{'Var8'} = 'meanEmploy';
```

Define the within-subjects variable.

```
Year = [1 2 3 4 5 6]';
```

Fit a repeated measures model, where the growth figures over the 6 years are the responses and the mean employment is the predictor variable.

```
rm = fitrm(t, 'year1-year6 ~ meanEmploy', 'WithinDesign', Year);
```

Perform analysis of variance.

```
anovatbl = anova(rm, 'WithinModel', Year)
```

```
anovatbl=3x7 table
```

Within	Between	SumSq	DF	MeanSq	F	pValue
Contrast1	constant	588.17	1	588.17	0.038495	0.85093
Contrast1	meanEmploy	3.7064e+05	1	3.7064e+05	24.258	0.0026428
Contrast1	Error	91675	6	15279		

Longitudinal Data

Load the sample data.

```
load('longitudinalData.mat');
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to do repeated measures analysis.

```
t = table(Gender, Y(:,1), Y(:,2), Y(:,3), Y(:,4), Y(:,5), ...
'VariableNames', {'Gender', 't0', 't2', 't4', 't6', 't8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t, 't0-t8 ~ Gender', 'WithinDesign', Time);
```

Perform analysis of variance.

```
anovatbl = anova(rm)
```

```
anovatbl=3x7 table
```

Within	Between	SumSq	DF	MeanSq	F	pValue
Constant	constant	54702	1	54702	1079.2	1.1897e-14
Constant	Gender	2251.7	1	2251.7	44.425	1.0693e-05
Constant	Error	709.6	14	50.685		

There are 2 genders and 16 observations, so the degrees of freedom for gender is $(2 - 1) = 1$ and for error it is $(16 - 2) * (2 - 1) = 14$. The small p -value of $1.0693e-05$ indicates that there is a significant effect of gender on blood pressure.

Repeat analysis of variance using orthogonal contrasts.

```
anovatbl = anova(rm, 'WithinModel', 'orthogonalcontrasts')
```

```
anovatbl=15x7 table
```

Within	Between	SumSq	DF	MeanSq	F	pValue

More About

Vandermonde Matrix

Vandermonde matrix is the matrix where columns are the powers of the vector a , that is, $V(i,j) = a(i)^{n-j}$, where n is the length of a .

QR Factorization

QR factorization of an m -by- n matrix A is the factorization that matrix into the product $A = Q^*R$, where R is an m -by- n upper triangular matrix and Q is an m -by- m unitary matrix.

“Model Specification for Repeated Measures Models” on page 9-54

ansaribradley

Ansari-Bradley test

Syntax

```
h = ansaribradley(x,y)
h = ansaribradley(x,y,Name,Value)
[h,p] = ansaribradley(____)
[h,p,stats] = ansaribradley(____)
```

Description

`h = ansaribradley(x,y)` returns a test decision for the null hypothesis that the data in vectors `x` and `y` comes from the same distribution, using the Ansari-Bradley test on page 32-92. The alternative hypothesis is that the data in `x` and `y` comes from distributions with the same median and shape but different dispersions (e.g., variances). The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

`h = ansaribradley(x,y,Name,Value)` returns a test decision for the Ansari-Bradley test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level, conduct a one-sided test, or use a normal approximation to calculate the value of the test statistic.

`[h,p] = ansaribradley(____)` also returns the *p*-value, `p`, of the test, using any of the input arguments in the previous syntaxes.

`[h,p,stats] = ansaribradley(____)` also returns the structure `stats` containing information about the test statistic.

Examples

Ansari-Bradley Test for Equal Variances

Load the sample data. Create data vectors of miles per gallon (MPG) measurements for the model years 1982 and 1976.

```
load carsmall
x = MPG(Model_Year==82);
y = MPG(Model_Year==76);
```

Test the null hypothesis that the miles per gallon measured in cars from 1982 and 1976 have equal variances.

```
[h,p,stats] = ansaribradley(x,y)

h = 0

p = 0.8426

stats = struct with fields:
    W: 526.9000
```

```
Wstar: 0.1986
```

The returned value of `h = 0` indicates that `ansaribradley` does not reject the null hypothesis at the default 5% significance level.

Ansari-Bradley One-Sided Hypothesis Test

Load the sample data. Create data vectors of miles per gallon (MPG) measurements for the model years 1982 and 1976.

```
load carsmall
x = MPG(Model_Year==82);
y = MPG(Model_Year==76);
```

Test the null hypothesis that the miles per gallon measured in cars from 1982 and 1976 have equal variances, against the alternative hypothesis that the variance of cars from 1982 is greater than that of cars from 1976.

```
[h,p,stats] = ansaribradley(x,y,'Tail','right')
```

```
h = 0
```

```
p = 0.5787
```

```
stats = struct with fields:
    W: 526.9000
    Wstar: 0.1986
```

The returned value of `h = 0` indicates that `ansaribradley` does not reject the null hypothesis that the variance in miles per gallon is the same for the two model years, when the alternative is that the variance of cars from 1982 is greater than that of cars from 1976.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` and `y` are specified as vectors, they do not need to be the same length.
- If `x` and `y` are specified as matrices, they must have the same number of columns. `ansaribradley` performs separate tests along each column and returns a vector of results.
- If `x` and `y` are specified as multidimensional arrays on page 32-93, `ansaribradley` works along the first nonsingleton dimension on page 32-93. `x` and `y` must have the same size along all remaining dimensions.

Data Types: `single` | `double`

y — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If x and y are specified as vectors, they do not need to be the same length.
- If x and y are specified as matrices, they must have the same number of columns. `ansaribradley` performs separate tests along each column and returns a vector of results.
- If x and y are specified as multidimensional arrays on page 32-93, `ansaribradley` works along the first nonsingleton dimension on page 32-93. x and y must have the same size along all remaining dimensions.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01` specifies a right-tailed hypothesis test at the 1% significance level.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim', 1` tests the column means, while `'Dim', 2` tests the row means.

Example: `'Dim', 2`

Data Types: `single` | `double`

Tail — Type of alternative hypothesis

`'both'` (default) | `'left'` | `'right'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

<code>'both'</code>	Test the alternative hypothesis that the dispersion parameters of x and y are not equal.
<code>'right'</code>	Test the alternative hypothesis that the dispersion parameter of x is greater than that of y .
<code>'left'</code>	Test the alternative hypothesis that the dispersion parameter of x is less than that of y .

Example: `'Tail', 'right'`

Method — Computation method

'exact' | 'approximate'

Computation method for the test statistic, specified as the comma-separated pair consisting of 'Method' and one of the following.

'exact'	Compute p using an exact calculation of the distribution of the test statistic W . This is the default if n , the total number of rows in x and y , is 25 or less. Note that n is computed before any NaN values (representing missing data) are removed.
'approximate'	Compute p using a normal approximation for the statistic W^* . This is the default if n , the total number of rows in x and y , is greater than 25.

Example: 'Method', 'exact'

Output Arguments**h — Hypothesis test result**

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the α significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the α significance level.

p — p-value

scalar value in the range [0,1]

p -value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

stats — Test statistics

structure

Test statistics for the Ansari-Bradley test, returned as a structure containing:

- W — Value of the test statistic, which is the sum of the Ansari-Bradley ranks for the x sample.
- W_{star} — Approximate normal statistic W^* .

More About**Ansari-Bradley Test**

The Ansari-Bradley test is a nonparametric alternative to the two-sample F -test of equal variances. It does not require the assumption that x and y come from normal distributions. The dispersion of a distribution is generally measured by its variance or standard deviation, but the Ansari-Bradley test can be used with samples from distributions that do not have finite variances.

This test requires that the samples have equal medians. Under that assumption, and if the distributions of the samples are continuous and identical, the test is independent of the distributions. If the samples do not have the same medians, the results can be misleading. In that case, Ansari and

Bradley recommend subtracting the median, but then the distribution of the resulting test under the null hypothesis is no longer independent of the common distribution of x and y . If you want to perform the tests with medians subtracted, you should subtract the medians from x and y before calling `ansaribradley`.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if x is a 1-by-3-by-4 array, then x is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if x is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of x .

Introduced before R2006a

aoctool

Interactive analysis of covariance

Syntax

```
aoctool(x,y,group)
aoctool(x,y,group,alpha)
aoctool(x,y,group,alpha,xname,yname,gname)
aoctool(x,y,group,alpha,xname,yname,gname,displayopt)
aoctool(x,y,group,alpha,xname,yname,gname,displayopt,model)
h = aoctool(...)
[h,atab,ctab] = aoctool(...)
[h,atab,ctab,stats] = aoctool(...)
```

Description

`aoctool(x,y,group)` fits a separate line to the column vectors, `x` and `y`, for each group defined by the values in the array `group`. `group` may be a categorical variable, numeric vector, character array, string array, or cell array of character vectors. These types of models are known as one-way analysis of covariance (ANOCOVA) models. The output consists of three figures:

- An interactive graph of the data and prediction curves
- An ANOVA table
- A table of parameter estimates

You can use the figures to change models and to test different parts of the model. More information about interactive use of the `aoctool` function appears in “Analysis of Covariance Tool” on page 9-39.

`aoctool(x,y,group,alpha)` determines the confidence levels of the prediction intervals. The confidence level is $100(1-\alpha)\%$. The default value of `alpha` is 0.05.

`aoctool(x,y,group,alpha,xname,yname,gname)` specifies the name to use for the `x`, `y`, and `g` variables in the graph and tables. If you enter simple variable names for the `x`, `y`, and `g` arguments, the `aoctool` function uses those names. If you enter an expression for one of these arguments, you can specify a name to use in place of that expression by supplying these arguments. For example, if you enter `m(:,2)` as the `x` argument, you might choose to enter `'Col 2'` as the `xname` argument.

`aoctool(x,y,group,alpha,xname,yname,gname,displayopt)` enables the graph and table displays when `displayopt` is `'on'` (default) and suppresses those displays when `displayopt` is `'off'`.

`aoctool(x,y,group,alpha,xname,yname,gname,displayopt,model)` specifies the initial model to fit. The value of `model` can be any of the following:

- `'same mean'` — Fit a single mean, ignoring grouping
- `'separate means'` — Fit a separate mean to each group
- `'same line'` — Fit a single line, ignoring grouping
- `'parallel lines'` — Fit a separate line to each group, but constrain the lines to be parallel

- 'separate lines' — Fit a separate line to each group, with no constraints

`h = aoctool(...)` returns a vector of handles to the line objects in the plot.

`[h,atab,ctab] = aoctool(...)` returns cell arrays containing the entries in ANOVA table (`atab`) and the table of coefficient estimates (`ctab`). (You can copy a text version of either table to the clipboard by using the Copy Text item on the **Edit** menu.)

`[h,atab,ctab,stats] = aoctool(...)` returns a `stats` structure that you can use to perform a follow-up multiple comparison test. The ANOVA table output includes tests of the hypotheses that the slopes or intercepts are all the same, against a general alternative that they are not all the same. Sometimes it is preferable to perform a test to determine which pairs of values are significantly different, and which are not. You can use the `multcompare` function to perform such tests by supplying the `stats` structure as input. You can test either the slopes, the intercepts, or population marginal means (the heights of the curves at the mean `x` value).

Examples

This example illustrates how to fit different models non-interactively. After loading the smaller car data set and fitting a separate-slopes model, you can examine the coefficient estimates.

```
load carsmall
[h,a,c,s] = aoctool(Weight,MPG,Model_Year,0.05,...
    '','','','off','separate lines');
c(:,1:2)
ans =
    'Term'      'Estimate'
    'Intercept' [45.97983716833132]
    ' 70'       [-8.58050531454973]
    ' 76'       [-3.89017396094922]
    ' 82'       [12.47067927549897]
    'Slope'     [-0.00780212907455]
    ' 70'       [ 0.00195840368824]
    ' 76'       [ 0.00113831038418]
    ' 82'       [-0.00309671407243]
```

Roughly speaking, the lines relating MPG to Weight have an intercept close to 45.98 and a slope close to -0.0078. Each group's coefficients are offset from these values somewhat. For instance, the intercept for the cars made in 1970 is $45.98 - 8.58 = 37.40$.

Next, try a fit using parallel lines. (The ANOVA table shows that the parallel-lines fit is significantly worse than the separate-lines fit.)

```
[h,a,c,s] = aoctool(Weight,MPG,Model_Year,0.05,...
    '','','','off','parallel lines');
c(:,1:2)
ans =
    'Term'      'Estimate'
    'Intercept' [43.38984085130596]
    ' 70'       [-3.27948192983761]
    ' 76'       [-1.35036234809006]
    ' 82'       [ 4.62984427792768]
    'Slope'     [-0.00664751826198]
```

Again, there are different intercepts for each group, but this time the slopes are constrained to be the same.

Introduced before R2006a

append

Class: TreeBagger

Append new trees to ensemble

Syntax

```
B = append(B, other)
```

Description

`B = append(B, other)` appends the trees from the `other` ensemble to those in `B`. This method checks for consistency of the `X` and `Y` properties of the two ensembles, as well as consistency of their compact objects and out-of-bag indices, before appending the trees. The output ensemble `B` takes training parameters such as `FBoot`, `Prior`, `Cost`, and `other` from the `B` input. There is no attempt to check if these training parameters are consistent between the two objects.

See Also

`combine`

barttest

Bartlett's test

Syntax

```
ndim = barttest(x,alpha)
[ndim,prob,chisquare] = barttest(x,alpha)
```

Description

`ndim = barttest(x,alpha)` returns the number of dimensions necessary to explain the nonrandom variation in the data matrix `x` at the `alpha` significance level.

`[ndim,prob,chisquare] = barttest(x,alpha)` also returns the significance values for the hypothesis tests `prob`, and the χ^2 values associated with the tests `chisquare`.

Examples

Determine Dimensions Needed to Explain Nonrandom Data Variation

Generate a 20-by-6 matrix of random numbers from a multivariate normal distribution with mean `mu = [0 0]` and covariance `sigma = [1 0.99; 0.99 1]`.

```
rng default % for reproducibility
mu = [0 0];
sigma = [1 0.99; 0.99 1];
X = mvnrnd(mu,sigma,20); % columns 1 and 2
X(:,3:4) = mvnrnd(mu,sigma,20); % columns 3 and 4
X(:,5:6) = mvnrnd(mu,sigma,20); % columns 5 and 6
```

Determine the number of dimensions necessary to explain the nonrandom variation in data matrix `X`. Report the significance values for the hypothesis tests.

```
[ndim, prob] = barttest(X,0.05)
```

```
ndim = 3
```

```
prob = 5×1
```

```
0.0000
0.0000
0.0000
0.5148
0.3370
```

The returned value of `ndim` indicates that three dimensions are necessary to explain the nonrandom variation in `X`.

Input Arguments

x — Input data

matrix of scalar values

Input data, specified as a matrix of scalar values.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1).

Example: 0.1

Data Types: `single` | `double`

Output Arguments

ndim — Number of dimensions

positive integer value

Number of dimensions, returned as a positive integer value. The dimension is determined by a series of hypothesis tests. The test for `ndim = 1` tests the hypothesis that the variances of the data values along each principal component are equal, the test for `ndim = 2` tests the hypothesis that the variances along the second through last components are equal, and so on. The null hypothesis is that the number of dimensions is equal to the number of the largest unequal eigenvalues of the covariance matrix of `x`.

prob — Significance value

vector of scalar values in the range (0,1)

Significance value for the hypothesis tests, returned as a vector of scalar values in the range (0,1). Each element in `prob` corresponds to an element of `chisquare`.

chisquare — Test statistics

vector of scalar values

Test statistics for each dimension's hypothesis test, returned as a vector of scalar values.

BayesianOptimization

Bayesian optimization results

Description

A `BayesianOptimization` object contains the results of a Bayesian optimization. It is the output of `bayesopt` or a fit function that accepts the `OptimizeHyperparameters` name-value pair such as `fitcdiscr`. In addition, a `BayesianOptimization` object contains data for each iteration of `bayesopt` that can be accessed by a plot function or an output function.

Creation

Create a `BayesianOptimization` object using the `bayesopt` function or a fit function with the `OptimizeHyperparameters` name-value pair.

Properties

Problem Definition Properties

ObjectiveFcn — ObjectiveFcn argument used by bayesopt

function handle

This property is read-only.

ObjectiveFcn argument used by `bayesopt`, returned as a function handle.

- If you call `bayesopt` directly, `ObjectiveFcn` is the `bayesopt` objective function argument.
- If you call a fit function containing the 'OptimizeHyperparameters' name-value pair argument, `ObjectiveFcn` is a function handle that returns the misclassification rate for classification or returns the logarithm of one plus the cross-validation loss for regression, measured by five-fold cross-validation.

Data Types: `function_handle`

VariableDescriptions — VariableDescriptions argument that bayesopt used

vector of `optimizableVariable` objects

This property is read-only.

`VariableDescriptions` argument that `bayesopt` used, returned as a vector of `optimizableVariable` objects.

- If you called `bayesopt` directly, `VariableDescriptions` is the `bayesopt` variable description argument.
- If you called a fit function with the `OptimizeHyperparameters` name-value pair, `VariableDescriptions` is the vector of hyperparameters.

Options — Options that bayesopt used

structure

This property is read-only.

Options that bayesopt used, returned as a structure.

- If you called bayesopt directly, Options is the options used in bayesopt, which are the name-value pairs See bayesopt “Input Arguments” on page 32-124.
- If you called a fit function with the OptimizeHyperparameters name-value pair, Options are the default bayesopt options, modified by the HyperparameterOptimizationOptions name-value pair.

Options is a read-only structure containing the following fields.

Option Name	Meaning
AcquisitionFunctionName	Acquisition function name. See “Acquisition Function Types” on page 10-3.
IsObjectiveDeterministic	true means the objective function is deterministic, false otherwise.
ExplorationRatio	Used only when AcquisitionFunctionName is 'expected-improvement-plus' or 'expected-improvement-per-second-plus'. See “Plus” on page 10-5.
MaxObjectiveEvaluations	Objective function evaluation limit.
MaxTime	Time limit.
XConstraintFcn	Deterministic constraints on variables. See “Deterministic Constraints — XConstraintFcn” on page 10-38.
ConditionalVariableFcn	Conditional variable constraints. See “Conditional Constraints — ConditionalVariableFcn” on page 10-39.
NumCoupledConstraints	Number of coupled constraints. See “Coupled Constraints” on page 10-40.
CoupledConstraintTolerances	Coupled constraint tolerances. See “Coupled Constraints” on page 10-40.
AreCoupledConstraintsDeterministic	Logical vector specifying whether each coupled constraint is deterministic.
Verbose	Command-line display level.
OutputFcn	Function called after each iteration. See “Bayesian Optimization Output Functions” on page 10-19.
SaveVariableName	Variable name for the @assignInBase output function.
SaveFileName	File name for the @saveToFile output function.

Option Name	Meaning
PlotFcn	Plot function called after each iteration. See “Bayesian Optimization Plot Functions” on page 10-11
InitialX	Points where bayesopt evaluated the objective function.
InitialObjective	Objective function values at InitialX.
InitialConstraintViolations	Coupled constraint function values at InitialX.
InitialErrorValues	Error values at InitialX.
InitialObjectiveEvaluationTimes	Objective function evaluation times at InitialX.
InitialIterationTimes	Time for each iteration, including objective function evaluation and other computations.

Data Types: struct

Solution Properties

MinObjective — Minimum observed value of objective function

real scalar

This property is read-only.

Minimum observed value of objective function, returned as a real scalar. When there are coupled constraints or evaluation errors, this value is the minimum over all observed points that are feasible according to the final constraint and Error models.

Data Types: double

XAtMinObjective — Observed point with minimum objective function value

1-by-D table

This property is read-only.

Observed point with minimum objective function value, returned as a 1-by-D table, where D is the number of variables.

Data Types: table

MinEstimatedObjective — Minimum estimated value of objective function

real scalar

This property is read-only.

Minimum estimated value of objective function, returned as a real scalar. MinEstimatedObjective uses the final objective model.

MinEstimatedObjective is the same as the CriterionValue result of bestPoint with default criterion.

Data Types: double

XAtMinEstimatedObjective — Point with minimum estimated objective function value

1-by-D table

This property is read-only.

Point with minimum estimated objective function value, returned as a 1-by-D table, where D is the number of variables. `XAtMinEstimatedObjective` uses the final objective model.

Data Types: `table`

NumObjectiveEvaluations – Number of objective function evaluations

positive integer

This property is read-only.

Number of objective function evaluations, returned as a positive integer. This includes the initial evaluations to form a posterior model as well as evaluation during the optimization iterations.

Data Types: `double`

TotalElapsedTime – Total elapsed time of optimization in seconds

positive scalar

This property is read-only.

Total elapsed time of optimization in seconds, returned as a positive scalar.

Data Types: `double`

NextPoint – Next point to evaluate if optimization continues

1-by-D table

This property is read-only.

Next point to evaluate if optimization continues, returned as a 1-by-D table, where D is the number of variables.

Data Types: `table`

Trace Properties

XTrace – Points where the objective function was evaluated

T-by-D table

This property is read-only.

Points where the objective function was evaluated, returned as a T-by-D table, where T is the number of evaluation points and D is the number of variables.

Data Types: `table`

ObjectiveTrace – Objective function values

column vector of length T

This property is read-only.

Objective function values, returned as a column vector of length T, where T is the number of evaluation points. `ObjectiveTrace` contains the history of objective function evaluations.

Data Types: `double`

ObjectiveEvaluationTimeTrace — Objective function evaluation times

column vector of length T

This property is read-only.

Objective function evaluation times, returned as a column vector of length T, where T is the number of evaluation points. `ObjectiveEvaluationTimeTrace` includes the time in evaluating coupled constraints, because the objective function computes these constraints.

Data Types: `double`**IterationTimeTrace — Iteration times**

column vector of length T

This property is read-only.

Iteration times, returned as a column vector of length T, where T is the number of evaluation points. `IterationTimeTrace` includes both objective function evaluation time and other overhead.

Data Types: `double`**ConstraintsTrace — Coupled constraint values**

T-by-K array

This property is read-only.

Coupled constraint values, returned as a T-by-K array, where T is the number of evaluation points and K is the number of coupled constraints.

Data Types: `double`**ErrorTrace — Error indications**

column vector of length T of -1 or 1 entries

This property is read-only.

Error indications, returned as a column vector of length T of -1 or 1 entries, where T is the number of evaluation points. Each 1 entry indicates that the objective function errored or returned NaN on the corresponding point in `XTrace`. Each -1 entry indicates that the objective function value was computed.

Data Types: `double`**FeasibilityTrace — Feasibility indications**

logical column vector of length T

This property is read-only.

Feasibility indications, returned as a logical column vector of length T, where T is the number of evaluation points. Each 1 entry indicates that the final constraint model predicts feasibility at the corresponding point in `XTrace`.

Data Types: `logical`**FeasibilityProbabilityTrace — Probability that evaluation point is feasible**

column vector of length T

This property is read-only.

Probability that evaluation point is feasible, returned as a column vector of length T , where T is the number of evaluation points. The probabilities come from the final constraint model, including the error constraint model, on the corresponding points in `XTrace`.

Data Types: `double`

IndexOfMinimumTrace — Which evaluation gave minimum feasible objective

column vector of integer indices of length T

This property is read-only.

Which evaluation gave minimum feasible objective, returned as a column vector of integer indices of length T , where T is the number of evaluation points. Feasibility is determined with respect to the constraint models that existed at each iteration, including the error constraint model.

Data Types: `double`

ObjectiveMinimumTrace — Minimum observed objective

column vector of length T

This property is read-only.

Minimum observed objective, returned as a column vector of integer indices of length T , where T is the number of evaluation points.

Data Types: `double`

EstimatedObjectiveMinimumTrace — Minimum estimated objective

column vector of length T

This property is read-only.

Minimum estimated objective, returned as a column vector of integer indices of length T , where T is the number of evaluation points. The estimated objective at each iteration is determined with respect to the objective model that existed at that iteration.

Data Types: `double`

UserDataTrace — Auxiliary data from the objective function

cell array of length T

This property is read-only.

Auxiliary data from the objective function, returned as a cell array of length T , where T is the number of evaluation points. Each entry in the cell array is the `UserData` returned in the third output of the objective function.

Data Types: `cell`

Object Functions

<code>bestPoint</code>	Best point in a Bayesian optimization according to a criterion
<code>plot</code>	Plot Bayesian optimization results
<code>predictConstraints</code>	Predict coupled constraint violations at a set of points
<code>predictError</code>	Predict error value at a set of points
<code>predictObjective</code>	Predict objective function at a set of points
<code>predictObjectiveEvaluationTime</code>	Predict objective function run times at a set of points

resume

Resume a Bayesian optimization

Examples

Create a BayesianOptimization Object Using bayesopt

This example shows how to create a `BayesianOptimization` object by using `bayesopt` to minimize cross-validation loss.

Optimize hyperparameters of a KNN classifier for the `ionosphere` data, that is, find KNN hyperparameters that minimize the cross-validation loss. Have `bayesopt` minimize over the following hyperparameters:

- Nearest-neighborhood sizes from 1 to 30
- Distance functions 'chebychev', 'euclidean', and 'minkowski'.

For reproducibility, set the random seed, set the partition, and set the `AcquisitionFunctionName` option to 'expected-improvement-plus'. To suppress iterative display, set 'Verbose' to 0. Pass the partition `c` and fitting data `X` and `Y` to the objective function `fun` by creating `fun` as an anonymous function that incorporates this data. See “Parameterizing Functions” (MATLAB).

```
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
results = bayesopt(fun,[num,dst],'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus')
```

results =

BayesianOptimization with properties:

```

    ObjectiveFcn: [function_handle]
    VariableDescriptions: [1x2 optimizableVariable]
    Options: [1x1 struct]
    MinObjective: 0.1197
    XAtMinObjective: [1x2 table]
    MinEstimatedObjective: 0.1213
    XAtMinEstimatedObjective: [1x2 table]
    NumObjectiveEvaluations: 30
    TotalElapsedTime: 130.1401
    NextPoint: [1x2 table]
    XTrace: [30x2 table]
    ObjectiveTrace: [30x1 double]
    ConstraintsTrace: []
    UserDataTrace: {30x1 cell}
    ObjectiveEvaluationTimeTrace: [30x1 double]
    IterationTimeTrace: [30x1 double]
    ErrorTrace: [30x1 double]
    FeasibilityTrace: [30x1 logical]
    FeasibilityProbabilityTrace: [30x1 double]
    IndexOfMinimumTrace: [30x1 double]
    ObjectiveMinimumTrace: [30x1 double]
    EstimatedObjectiveMinimumTrace: [30x1 double]

```

Create a BayesianOptimization Object Using a Fit Function

This example shows how to minimize the cross-validation loss in the `ionosphere` data using Bayesian optimization of an SVM classifier.

Load the data.

```
load ionosphere
```

Optimize the classification using the 'auto' parameters.

```
rng default % For reproducibility
Mdl = fitcsvm(X,Y,'OptimizeHyperparameters','auto')
```

Topics

“Bayesian Optimization Workflow” on page 10-25

Introduced in R2016b

bayesopt

Select optimal machine learning hyperparameters using Bayesian optimization

Syntax

```
results = bayesopt(fun,vars)
results = bayesopt(fun,vars,Name,Value)
```

Description

`results = bayesopt(fun,vars)` attempts to find values of `vars` that minimize `fun(vars)`.

Note To include extra parameters in an objective function, see “Parameterizing Functions” (MATLAB).

`results = bayesopt(fun,vars,Name,Value)` modifies the optimization process according to the `Name,Value` arguments.

Examples

Create a BayesianOptimization Object Using bayesopt

This example shows how to create a `BayesianOptimization` object by using `bayesopt` to minimize cross-validation loss.

Optimize hyperparameters of a KNN classifier for the `ionosphere` data, that is, find KNN hyperparameters that minimize the cross-validation loss. Have `bayesopt` minimize over the following hyperparameters:

- Nearest-neighborhood sizes from 1 to 30
- Distance functions 'chebychev', 'euclidean', and 'minkowski'.

For reproducibility, set the random seed, set the partition, and set the `AcquisitionFunctionName` option to 'expected-improvement-plus'. To suppress iterative display, set 'Verbose' to 0. Pass the partition `c` and fitting data `X` and `Y` to the objective function `fun` by creating `fun` as an anonymous function that incorporates this data. See “Parameterizing Functions” (MATLAB).

```
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
results = bayesopt(fun,[num,dst],'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus')
```

results =

```

Bayesian Optimization with Coupled Constraints

A coupled constraint is one that can be evaluated only by evaluating the objective function. In this case, the objective function is the cross-validated loss of an SVM model. The coupled constraint is that the number of support vectors is no more than 100. The model details are in “Optimize a Cross-Validated SVM Classifier Using bayesopt” on page 10-45.

Create the data for classification.

```
rng default
grnpop = mvnrnd([1,0],eye(2),10);
redpop = mvnrnd([0,1],eye(2),10);
redpts = zeros(100,2);
grnpts = redpts;
for i = 1:100
    grnpts(i,:) = mvnrnd(grnpop(randi(10),:),eye(2)*0.02);
    redpts(i,:) = mvnrnd(redpop(randi(10),:),eye(2)*0.02);
end
cdata = [grnpts;redpts];
grp = ones(200,1);
grp(101:200) = -1;
c = cvpartition(200,'KFold',10);
sigma = optimizableVariable('sigma',[1e-5,1e5],'Transform','log');
box = optimizableVariable('box',[1e-5,1e5],'Transform','log');
```

The objective function is the cross-validation loss of the SVM model for partition c. The coupled constraint is the number of support vectors minus 100.5. This ensures that 100 support vectors give a negative constraint value, but 101 support vectors give a positive value. The model has 200 data points, so the coupled constraint values range from -99.5 (there is always at least one support vector) to 99.5. Positive values mean the constraint is not satisfied.

```
function [objective,constraint] = mysvmfun(x,cdata,grp,c)
SVMModel = fitsvm(cdata,grp,'KernelFunction','rbf',...
    'BoxConstraint',x.box,...
    'KernelScale',x.sigma);
cvModel = crossval(SVMModel,'CVPartition',c);
objective = kfoldLoss(cvModel);
constraint = sum(SVMModel.IsSupportVector)-100.5;
```

Pass the partition c and fitting data cdata and grp to the objective function fun by creating fun as an anonymous function that incorporates this data. See “Parameterizing Functions” (MATLAB).

```
fun = @(x)mysvmfun(x,cdata,grp,c);
```

Set the NumCoupledConstraints to 1 so the optimizer knows that there is a coupled constraint. Set options to plot the constraint model.

```
results = bayesopt(fun,[sigma,box],'IsObjectiveDeterministic',true,...
    'NumCoupledConstraints',1,'PlotFcn',...
    {@plotMinObjective,@plotConstraintModels},...
    'AcquisitionFunctionName','expected-improvement-plus','Verbose',0);
```

Constraint 1 model

Most points lead to an infeasible number of support vectors.

Parallel Bayesian Optimization

Improve the speed of a Bayesian optimization by using parallel objective function evaluation.

Prepare variables and the objective function for Bayesian optimization.

The objective function is the cross-validation error rate for the ionosphere data, a binary classification problem. Use `fitcsvm` as the classifier, with `BoxConstraint` and `KernelScale` as the parameters to optimize.

```
load ionosphere
box = optimizableVariable('box',[1e-4,1e3],'Transform','log');
kern = optimizableVariable('kern',[1e-4,1e3],'Transform','log');
vars = [box,kern];
fun = @(vars)kfoldLoss(fitcsvm(X,Y,'BoxConstraint',vars.box,'KernelScale',vars.kern,...
    'Kfold',5));
```

Search for the parameters that give the lowest cross-validation error by using parallel Bayesian optimization.

```
results = bayesopt(fun,vars,'UseParallel',true);
```

```
Copying objective function to workers...
Done copying objective function to workers.
```

Optimization completed.
 MaxObjectiveEvaluations of 30 reached.
 Total function evaluations: 30
 Total elapsed time: 48.2085 seconds.
 Total objective function evaluation time: 128.3472

Best observed feasible point:
 box kern

_____	_____
0.0015925	0.0050225

Observed objective function value = 0.10826
 Estimated objective function value = 0.10846
 Function evaluation time = 4.0711

Best estimated feasible point (according to models):
 box kern

_____	_____
0.0015925	0.0050225

Estimated objective function value = 0.10846
 Estimated function evaluation time = 2.8307

Return the best feasible point in the Bayesian model results by using the `bestPoint` function. Use the default criterion `min-visited-upper-confidence-interval`, which determines the best feasible point as the visited point that minimizes an upper confidence interval on the objective function value.

```
zbest = bestPoint(results)
```

```
zbest=1x2 table
      box      kern
-----
0.0015925  0.0050225
```

The table `zbest` contains the optimal estimated values for the `'BoxConstraint'` and `'KernelScale'` name-value pair arguments. Use these values to train a new optimized classifier.

```
Mdl = fitcsvm(X,Y,'BoxConstraint',zbest.box,'KernelScale',zbest.kern);
```

Observe that the optimal parameters are in `Mdl`.

```
Mdl.BoxConstraints(1)
```

```
ans = 0.0016
```

```
Mdl.KernelParameters.Scale
```

```
ans = 0.0050
```

Input Arguments

fun — Objective function

function handle | `parallel.pool.Constant` whose Value is a function handle

Objective function, specified as a function handle or, when the `UseParallel` name-value pair is true, a `parallel.pool.Constant` whose Value is a function handle. Typically, `fun` returns a measure of loss (such as a misclassification error) for a machine learning model that has tunable hyperparameters to control its training. `fun` has these signatures:

```
objective = fun(x)
% or
[objective,constraints] = fun(x)
% or
[objective,constraints,UserData] = fun(x)
```

`fun` accepts `x`, a 1-by-D table of variable values, and returns `objective`, a real scalar representing the objective function value `fun(x)`.

Optionally, `fun` also returns:

- `constraints`, a real vector of coupled constraint violations. For a definition, see “Coupled Constraints” on page 32-132. `constraint(j) > 0` means constraint `j` is violated. `constraint(j) < 0` means constraint `j` is satisfied.
- `UserData`, an entity of any type (such as a scalar, matrix, structure, or object). For an example of a custom plot function that uses `UserData`, see “Create a Custom Plot Function” on page 10-12.

For details about using `parallel.pool.Constant` with `bayesopt`, see “Placing the Objective Function on Workers” on page 10-8.

Example: `@objfun`

Data Types: `function_handle`

vars — Variable descriptions

vector of `optimizableVariable` objects defining the hyperparameters to be tuned

Variable descriptions, specified as a vector of `optimizableVariable` objects defining the hyperparameters to be tuned.

Example: `[X1,X2]`, where `X1` and `X2` are `optimizableVariable` objects

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `results = bayesopt(fun,vars,'AcquisitionFunctionName','expected-improvement-plus')`

Algorithm Control

AcquisitionFunctionName — Function to choose next evaluation point

'expected-improvement-per-second-plus' (default) | 'expected-improvement' | 'expected-improvement-plus' | 'expected-improvement-per-second' | 'lower-confidence-bound' | 'probability-of-improvement'

Function to choose next evaluation point, specified as one of the listed choices.

Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.

Example: `'AcquisitionFunctionName','expected-improvement-per-second'`

IsObjectiveDeterministic — Specify deterministic objective function

false (default) | true

Specify deterministic objective function, specified as `false` or `true`. If `fun` is stochastic (that is, `fun(x)` can return different values for the same `x`), then set `IsObjectiveDeterministic` to `false`. In this case, `bayesopt` estimates a noise level during optimization.

Example: `'IsObjectiveDeterministic',true`

Data Types: `logical`

ExplorationRatio — Propensity to explore

0.5 (default) | positive real

Propensity to explore, specified as a positive real. Applies to the `'expected-improvement-plus'` and `'expected-improvement-per-second-plus'` acquisition functions. See “Plus” on page 10-5.

Example: `'ExplorationRatio',0.2`

Data Types: double

GPAciveSetSize — Fit Gaussian Process model to GPAciveSetSize or fewer points

300 (default) | positive integer

Fit Gaussian Process model to GPAciveSetSize or fewer points, specified as a positive integer. When `bayesopt` has visited more than GPAciveSetSize points, subsequent iterations that use a GP model fit the model to GPAciveSetSize points. `bayesopt` chooses points uniformly at random without replacement among visited points. Using fewer points leads to faster GP model fitting, at the expense of possibly less accurate fitting.

Example: 'GPAciveSetSize',80

Data Types: double

UseParallel — Compute in parallel

false (default) | true

Compute in parallel, specified as `false` (do not compute in parallel) or `true` (compute in parallel). `bayesopt` performs parallel objective function evaluations concurrently on parallel workers. For algorithmic details, see “Parallel Bayesian Optimization” on page 10-7.

Example: 'UseParallel',true

Data Types: logical

ParallelMethod — Imputation method for parallel worker objective function values

'clipped-model-prediction' (default) | 'model-prediction' | 'max-observed' | 'min-observed'

Imputation method for parallel worker objective function values, specified as 'clipped-model-prediction', 'model-prediction', 'max-observed', or 'min-observed'. To generate a new point to evaluate, `bayesopt` fits a Gaussian process to all points, including the points being evaluated on workers. To fit the process, `bayesopt` imputes objective function values for the points that are currently on workers. `ParallelMethod` specifies the method used for imputation.

- 'clipped-model-prediction' — Impute the maximum of these quantities:
 - Mean Gaussian process prediction at the point x
 - Minimum observed objective function among feasible points visited
 - Minimum model prediction among all feasible points
- 'model-prediction' — Impute the mean Gaussian process prediction at the point x .
- 'max-observed' — Impute the maximum observed objective function value among feasible points.
- 'min-observed' — Impute the minimum observed objective function value among feasible points.

Example: 'ParallelMethod','max-observed'

MinWorkerUtilization — Tolerance on number of active parallel workers

$\text{floor}(0.8 * N_{\text{workers}})$ (default) | positive integer

Tolerance on the number of active parallel workers, specified as a positive integer. After `bayesopt` assigns a point to evaluate, and before it computes a new point to assign, it checks whether fewer than `MinWorkerUtilization` workers are active. If so, `bayesopt` assigns random points within

bounds to all available workers. Otherwise, `bayesopt` calculates the best point for one worker. `bayesopt` creates random points much faster than fitted points, so this behavior leads to higher utilization of workers, at the cost of possibly poorer points. For details, see “Parallel Bayesian Optimization” on page 10-7.

Example: `'MinWorkerUtilization',3`

Data Types: `double`

Starting and Stopping

MaxObjectiveEvaluations — Objective function evaluation limit

30 (default) | positive integer

Objective function evaluation limit, specified as a positive integer.

Example: `'MaxObjectiveEvaluations',60`

Data Types: `double`

MaxTime — Time limit

Inf (default) | positive real

Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`.

Run time can exceed `MaxTime` because `bayesopt` does not interrupt function evaluations.

Example: `'MaxTime',3600`

Data Types: `double`

NumSeedPoints — Number of initial evaluation points

4 (default) | positive integer

Number of initial evaluation points, specified as a positive integer. `bayesopt` chooses these points randomly within the variable bounds, according to the setting of the `Transform` setting for each variable (uniform for `'none'`, logarithmically spaced for `'log'`).

Example: `'NumSeedPoints',10`

Data Types: `double`

Constraints

XConstraintFcn — Deterministic constraints on variables

[] (default) | function handle

Deterministic constraints on variables, specified as a function handle.

For details, see “Deterministic Constraints — XConstraintFcn” on page 10-38.

Example: `'XConstraintFcn',@xconstraint`

Data Types: `function_handle`

ConditionalVariableFcn — Conditional variable constraints

[] (default) | function handle

Conditional variable constraints, specified as a function handle.

For details, see “Conditional Constraints — ConditionalVariableFcn” on page 10-39.

Example: 'ConditionalVariableFcn',@condfun

Data Types: function_handle

NumCoupledConstraints — Number of coupled constraints

0 (default) | positive integer

Number of coupled constraints, specified as a positive integer. For details, see “Coupled Constraints” on page 10-40.

Note NumCoupledConstraints is required when you have coupled constraints.

Example: 'NumCoupledConstraints',3

Data Types: double

AreCoupledConstraintsDeterministic — Indication of whether coupled constraints are deterministic

true for all coupled constraints (default) | logical vector

Indication of whether coupled constraints are deterministic, specified as a logical vector of length NumCoupledConstraints. For details, see “Coupled Constraints” on page 10-40.

Example: 'AreCoupledConstraintsDeterministic',[true,false,true]

Data Types: logical

Reports, Plots, and Halting

Verbose — Command-line display level

1 (default) | 0 | 2

Command-line display level, specified as 0, 1, or 2.

- 0 — No command-line display.
- 1 — At each iteration, display the iteration number, result report (see the next paragraph), objective function model, objective function evaluation time, best (lowest) observed objective function value, best (lowest) estimated objective function value, and the observed constraint values (if any). When optimizing in parallel, the display also includes a column showing the number of active workers, counted after assigning a job to the next worker.

The result report for each iteration is one of the following:

- **Accept** — The objective function returns a finite value, and all constraints are satisfied.
- **Best** — Constraints are satisfied, and the objective function returns the lowest value among feasible points.
- **Error** — The objective function returns a value that is not a finite real scalar.
- **Infeas** — At least one constraint is violated.
- 2 — Same as 1, adding diagnostic information such as time to select the next point, model fitting time, indication that “plus” acquisition functions declare overexploiting, and parallel workers are being assigned to random points due to low parallel utilization.

Example: 'Verbose',2

Data Types: double

OutputFcn — Function called after each iteration

{ } (default) | function handle | cell array of function handles

Function called after each iteration, specified as a function handle or cell array of function handles. An output function can halt the solver, and can perform arbitrary calculations, including creating variables or plotting. Specify several output functions using a cell array of function handles.

There are two built-in output functions:

- **@assignInBase** — Constructs a `BayesianOptimization` instance at each iteration and assigns it to a variable in the base workspace. Choose a variable name using the `SaveVariableName` name-value pair.
- **@saveToFile** — Constructs a `BayesianOptimization` instance at each iteration and saves it to a file in the current folder. Choose a file name using the `SaveFileName` name-value pair.

You can write your own output functions. For details, see “Bayesian Optimization Output Functions” on page 10-19.

Example: `'OutputFcn',{@saveToFile @myOutputFunction}`

Data Types: cell | function_handle

SaveFileName — File name for the @saveToFile output function

'BayesoptResults.mat' (default) | character vector | string scalar

File name for the `@saveToFile` output function, specified as a character vector or string scalar. The file name can include a path, such as `'../optimizations/September2.mat'`.

Example: `'SaveFileName','September2.mat'`

Data Types: char | string

SaveVariableName — Variable name for the @assignInBase output function

'BayesoptResults' (default) | character vector | string scalar

Variable name for the `@assignInBase` output function, specified as a character vector or string scalar.

Example: `'SaveVariableName','September2Results'`

Data Types: char | string

PlotFcn — Plot function called after each iteration

{@plotObjectiveModel,@plotMinObjective} (default) | 'all' | function handle | cell array of function handles

Plot function called after each iteration, specified as `'all'`, a function handle, or a cell array of function handles. A plot function can halt the solver, and can perform arbitrary calculations, including creating variables, in addition to plotting.

Specify no plot function as `[]`.

`'all'` calls all built-in plot functions. Specify several plot functions using a cell array of function handles.

The built-in plot functions appear in the following tables.

Model Plots — Apply When $D \leq 2$	Description
@plotAcquisitionFunction	Plot the acquisition function surface.
@plotConstraintModels	Plot each constraint model surface. Negative values indicate feasible points. Also plot a $P(\text{feasible})$ surface. Also plot the error model, if it exists, which ranges from -1 to 1 . Negative values mean that the model probably does not error, positive values mean that it probably does error. The model is: Plotted error = $2 * \text{Probability}(\text{error}) - 1$.
@plotObjectiveEvaluationTimeModel	Plot the objective function evaluation time model surface.
@plotObjectiveModel	Plot the fun model surface, the estimated location of the minimum, and the location of the next proposed point to evaluate. For one-dimensional problems, plot envelopes one credible interval above and below the mean function, and envelopes one noise standard deviation above and below the mean.

Trace Plots — Apply to All D	Description
@plotObjective	Plot each observed function value versus the number of function evaluations.
@plotObjectiveEvaluationTime	Plot each observed function evaluation run time versus the number of function evaluations.
@plotMinObjective	Plot the minimum observed and estimated function values versus the number of function evaluations.
@plotElapsedTime	Plot three curves: the total elapsed time of the optimization, the total function evaluation time, and the total modeling and point selection time, all versus the number of function evaluations.

You can write your own plot functions. For details, see “Bayesian Optimization Plot Functions” on page 10-11.

Note When there are coupled constraints, iterative display and plot functions can give counterintuitive results such as:

- A *minimum objective* plot can increase.
- The optimization can declare a problem infeasible even when it showed an earlier feasible point.

The reason for this behavior is that the decision about whether a point is feasible can change as the optimization progresses. `bayesopt` determines feasibility with respect to its constraint model, and this model changes as `bayesopt` evaluates points. So a “minimum objective” plot can increase when the minimal point is later deemed infeasible, and the iterative display can show a feasible point that is later deemed infeasible.

Example: 'PlotFcn', 'all'

Data Types: char | string | cell | function_handle

Initialization

InitialX — Initial evaluation points

NumSeedPoints-by-D random initial points within bounds (default) | N-by-D table

Initial evaluation points, specified as an N-by-D table, where N is the number of evaluation points, and D is the number of variables.

Note If only InitialX is provided, it is interpreted as initial points to evaluate. The objective function is evaluated at InitialX.

If any other initialization parameters are also provided, InitialX is interpreted as prior function evaluation data. The objective function is not evaluated. Any missing values are set to NaN.

Data Types: table

InitialObjective — Objective values corresponding to InitialX

[] (default) | length-N vector

Objective values corresponding to InitialX, specified as a length-N vector, where N is the number of evaluation points.

Example: 'InitialObjective', [17; -3; -12.5]

Data Types: double

InitialConstraintViolations — Constraint violations of coupled constraints

[] (default) | N-by-K matrix

Constraint violations of coupled constraints, specified as an N-by-K matrix, where N is the number of evaluation points and K is the number of coupled constraints. For details, see “Coupled Constraints” on page 10-40.

Data Types: double

InitialErrorValues — Errors for InitialX

[] (default) | length-N vector with entries -1 or 1

Errors for InitialX, specified as a length-N vector with entries -1 or 1, where N is the number of evaluation points. Specify -1 for no error, and 1 for an error.

Example: 'InitialErrorValues', [-1, -1, -1, -1, 1]

Data Types: double

InitialUserData — Initial data corresponding to InitialX

[] (default) | length-N cell vector

Initial data corresponding to InitialX, specified as a length-N cell vector, where N is the number of evaluation points.

Example: 'InitialUserData', {2, 3, -1}

Data Types: cell

InitialObjectiveEvaluationTimes — Evaluation times of objective function at `InitialX`
 [] (default) | length-N vector

Evaluation times of objective function at `InitialX`, specified as a length-N vector, where N is the number of evaluation points. Time is measured in seconds.

Data Types: double

InitialIterationTimes — Times for the first N iterations
 {} (default) | length-N vector

Times for the first N iterations, specified as a length-N vector, where N is the number of evaluation points. Time is measured in seconds.

Data Types: double

Output Arguments

results — Bayesian optimization results
 BayesianOptimization object

Bayesian optimization results, returned as a BayesianOptimization object.

More About

Coupled Constraints

Coupled constraints are those constraints whose value comes from the objective function calculation. See “Coupled Constraints” on page 10-40.

Tips

- Bayesian optimization is not reproducible if one of these conditions exists:
 - You specify an acquisition function whose name includes `per-second`, such as `'expected-improvement-per-second'`. The `per-second` modifier indicates that optimization depends on the run time of the objective function. For more details, see “Acquisition Function Types” on page 10-3.
 - You specify to run Bayesian optimization in parallel. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For more details, see “Parallel Bayesian Optimization” on page 10-7.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

Set the `'UseParallel', true` name-value pair argument in the call to this function.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

bbdesign

Box-Behnken design

Syntax

```
dBB = bbdesign(n)
[dBB,blocks] = bbdesign(n)
[...] = bbdesign(n,param,val)
```

Description

`dBB = bbdesign(n)` generates a Box-Behnken design for n factors. n must be an integer 3 or larger. The output matrix `dBB` is m -by- n , where m is the number of runs in the design. Each row represents one run, with settings for all factors represented in the columns. Factor values are normalized so that the cube points take values between -1 and 1.

`[dBB,blocks] = bbdesign(n)` requests a blocked design. The output `blocks` is an m -by-1 vector of block numbers for each run. Blocks indicate runs that are to be measured under similar conditions to minimize the effect of inter-block differences on the parameter estimates.

`[...] = bbdesign(n,param,val)` specifies one or more optional parameter/value pairs for the design. The following table lists valid parameter/value pairs.

Parameter	Description	Values
'center'	Number of center points.	Integer. The default depends on n .
'blocksize'	Maximum number of points per block.	Integer. The default is <code>Inf</code> .

Examples

The following creates a 3-factor Box-Behnken design:

```
dBB = bbdesign(3)
dBB =
    -1    -1     0
    -1     1     0
     1    -1     0
     1     1     0
    -1     0    -1
    -1     0     1
     1     0    -1
     1     0     1
     0    -1    -1
     0    -1     1
     0     1    -1
     0     1     1
     0     0     0
     0     0     0
     0     0     0
```

The center point is run 3 times to allow for a more uniform estimate of the prediction variance over the entire design space.

Visualize the design as follows:

```
plot3(dBB(:,1),dBB(:,2),dBB(:,3),'ro',...
      'MarkerFaceColor','b')
X = [1 -1 -1 -1 1 -1 -1 -1 1 1 -1 -1; ...
     1 1 1 -1 1 1 1 -1 1 1 -1 -1];
Y = [-1 -1 1 -1 -1 -1 1 -1 1 -1 1 -1; ...
     1 -1 1 1 1 -1 1 1 1 -1 1 -1];
Z = [1 1 1 1 -1 -1 -1 -1 -1 -1 -1 -1; ...
     1 1 1 1 -1 -1 -1 -1 1 1 1 1];
line(X,Y,Z,'Color','b')
axis square equal
```

bestPoint

Best point in a Bayesian optimization according to a criterion

Syntax

```
x = bestPoint(results)
x = bestPoint(results,Name,Value)
[x,CriterionValue] = bestPoint(____)
[x,CriterionValue,iteration] = bestPoint(____)
```

Description

`x = bestPoint(results)` returns the best feasible point in the Bayesian model `results` according to the default criterion `'min-visited-upper-confidence-interval'`.

`x = bestPoint(results,Name,Value)` modifies the best point using name-value pairs.

`[x,CriterionValue] = bestPoint(____)`, for any previous syntax, also returns the value of the criterion at `x`.

`[x,CriterionValue,iteration] = bestPoint(____)` also returns the iteration number at which the best point was returned. Applies when the `Criterion` name-value pair is `'min-observed'`, `'min-visited-mean'`, or the default `'min-visited-upper-confidence-interval'`.

Examples

Best Point of an Optimized KNN Classifier

This example shows how to obtain the best point of an optimized classifier.

Optimize a KNN classifier for the `ionosphere` data, meaning find parameters that minimize the cross-validation loss. Minimize over nearest-neighborhood sizes from 1 to 30, and over the distance functions `'chebychev'`, `'euclidean'`, and `'minkowski'`.

For reproducibility, set the random seed, and set the `AcquisitionFunctionName` option to `'expected-improvement-plus'`.

```
load ionosphere
rng(11)
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
results = bayesopt(fun,[num,dst],'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus');
```

Obtain the best point according to the default 'min-visited-upper-confidence-interval' criterion.

```
x = bestPoint(results)
```

```
x=1×2 table
```

n	dst
1	chebychev

The lowest estimated cross-validation loss occurs for one nearest neighbor and 'chebychev' distance.

Careful examination of the objective function model plot shows a point with two nearest neighbors and 'chebychev' distance that has a lower objective function value. Find this point using a different criterion.

```
x = bestPoint(results, 'Criterion', 'min-observed')
```

```
x=1×2 table
```

n	dst
2	chebychev

Also find the minimum observed objective function value, and the iteration number at which it was observed.

```
[x,CriterionValue,iteration] = bestPoint(results,'Criterion','min-observed')
```

```
x=1x2 table
      n      dst
      -      -
      2      chebychev
```

```
CriterionValue = 0.1054
```

```
iteration = 21
```

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `x = bestPoint(results,'Criterion','min-observed')`

Criterion — Best point criterion

'min-visited-upper-confidence-interval' (default) | 'min-observed' | 'min-mean' | 'min-upper-confidence-interval' | 'min-visited-mean'

Best point criterion, specified as the comma-separated pair consisting of 'Criterion' and a criterion name. The names are case-insensitive, do not require - characters, and require only enough characters to make the name uniquely distinguishable.

Criterion Name	Meaning
'min-observed'	x is the feasible point with minimum observed objective.
'min-mean'	x is the feasible point where the objective model mean is minimized.
'min-upper-confidence-interval'	x is the feasible point minimizing an upper confidence interval of the objective model. See alpha.
'min-visited-mean'	x is the feasible point where the objective model mean is minimized among the visited points.
'min-visited-upper-confidence-interval'	x is the feasible point minimizing an upper confidence interval of the objective model among the visited points. See alpha.

Example: 'Criterion','min-visited-mean'

alpha — Probability that modeled objective mean exceeds CriterionValue

0.01 (default) | scalar between 0 and 1

Probability that the modeled objective mean exceeds CriterionValue, specified as the comma-separated pair consisting of 'alpha' and a scalar between 0 and 1. alpha relates to the 'min-upper-confidence-interval' and 'min-visited-upper-confidence-interval' Criterion values. The definition for the upper confidence interval is the value Y where

$$P(\text{mean}_Q(\text{fun}(x)) > Y) = \text{alpha},$$

where fun is the objective function, and the mean is calculated with respect to the posterior distribution Q.

Example: 'alpha', 0.05

Data Types: double

Output Arguments**x — Best point**

1-by-D table

Best point, returned as a 1-by-D table, where D is the number of variables. The meaning of “best” is with respect to Criterion.

CriterionValue — Value of criterion

real scalar

Value of criterion, returned as a real scalar. The value depends on the setting of the Criterion name-value pair, which has a default value of 'min-visited-upper-confidence-interval'.

Criterion Name	Meaning
'min-observed'	Minimum observed objective.
'min-mean'	Minimum of model mean.
'min-upper-confidence-interval'	Value Y satisfying the equation $P(\text{mean}_Q(\text{fun}(x)) > Y) = \text{alpha}$.
'min-visited-mean'	Minimum of observed model mean.
'min-visited-upper-confidence-interval'	Value Y satisfying the equation $P(\text{mean}_Q(\text{fun}(x)) > Y) = \text{alpha}$ among observed points.

iteration — Iteration number at which best point was observed

positive integer

Iteration number at which best point was observed, returned as a positive integer. The best point is defined by CriterionValue.

Introduced in R2016b

betacdf

Beta cumulative distribution function

Syntax

```
p = betacdf(x,a,b)
p = betacdf(x,a,b,'upper')
```

Description

`p = betacdf(x,a,b)` returns the beta cdf at each of the values in `x` using the corresponding parameters in `a` and `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `a` and `b` must all be positive, and the values in `x` must lie on the interval `[0,1]`.

`p = betacdf(x,a,b,'upper')` returns the complement of the beta cdf at each of the values in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The beta cdf for a given value `x` and given pair of parameters `a` and `b` is

$$p = F(x|a,b) = \frac{1}{B(a,b)} \int_0^x t^{a-1} (1-t)^{b-1} dt$$

where $B(\cdot)$ is the Beta function.

Examples

Compute Beta Distribution CDF

Compute the cdf for a beta distribution with parameters `a = 2` and `b = 2`.

```
x = 0.1:0.2:0.9;
a = 2;
b = 2;
p = betacdf(x,a,b)
```

```
p = 1x5
```

```
    0.0280    0.2160    0.5000    0.7840    0.9720
```

```
a = [1 2 3];
p = betacdf(0.5,a,a)
```

```
p = 1x3
```

```
    0.5000    0.5000    0.5000
```

betafit

Beta parameter estimates

Syntax

```
phat = betafit(data)
[phat,pci] = betafit(data,alpha)
```

Description

`phat = betafit(data)` computes the maximum likelihood estimates of the beta distribution parameters a and b from the data in the vector `data` and returns a column vector containing the a and b estimates, where the beta cdf is given by

$$F(x|a,b) = \frac{1}{B(a,b)} \int_0^x t^{a-1}(1-t)^{b-1} dt$$

and $B(\cdot)$ is the Beta function. The elements of `data` must lie in the open interval $(0, 1)$, where the beta distribution is defined. However, it is sometimes also necessary to fit a beta distribution to data that include exact zeros or ones. For such data, the beta likelihood function is unbounded, and standard maximum likelihood estimation is not possible. In that case, `betafit` maximizes a modified likelihood that incorporates the zeros or ones by treating them as if they were values that have been left-censored at `sqrt(realmin)` or right-censored at `1-eps/2`, respectively.

`[phat,pci] = betafit(data,alpha)` returns confidence intervals on the a and b parameters in the 2-by-2 matrix `pci`. The first column of the matrix contains the lower and upper confidence bounds for parameter a , and the second column contains the confidence bounds for parameter b . The optional input argument `alpha` is a value in the range $[0, 1]$ specifying the width of the confidence intervals. By default, `alpha` is `0.05`, which corresponds to 95% confidence intervals. The confidence intervals are based on a normal approximation for the distribution of the logs of the parameter estimates.

Examples

This example generates 100 beta distributed observations. The true a and b parameters are 4 and 3, respectively. Compare these to the values returned in `p` by the beta fit. Note that the columns of `ci` both bracket the true parameters.

```
data = betarnd(4,3,100,1);
[p,ci] = betafit(data,0.01)
p =
    5.5328    3.8097
ci =
    3.6538    2.6197
    8.3781    5.5402
```

Topics

“Beta Distribution” on page B-6

Introduced before R2006a

betainv

Beta inverse cumulative distribution function

Syntax

`X = betainv(P,A,B)`

Description

`X = betainv(P,A,B)` computes the inverse of the beta cdf with parameters specified by `A` and `B` for the corresponding probabilities in `P`. `P`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `A` and `B` must all be positive, and the values in `P` must lie on the interval $[0, 1]$.

The inverse beta cdf for a given probability p and a given pair of parameters a and b is

$$x = F^{-1}(p|a, b) = \{x: F(x|a, b) = p\}$$

where

$$p = F(x|a, b) = \frac{1}{B(a, b)} \int_0^x t^{a-1} (1-t)^{b-1} dt$$

and $B(\cdot)$ is the Beta function. Each element of output `X` is the value whose cumulative probability under the beta cdf defined by the corresponding parameters in `A` and `B` is specified by the corresponding value in `P`.

Examples

```
p = [0.01 0.5 0.99];
x = betainv(p,10,5)
x =
    0.3726    0.6742    0.8981
```

According to this result, for a beta cdf with $a = 10$ and $b = 5$, a value less than or equal to 0.3726 occurs with probability 0.01. Similarly, values less than or equal to 0.6742 and 0.8981 occur with respective probabilities 0.5 and 0.99.

Algorithms

The `betainv` function uses Newton's method with modifications to constrain steps to the allowable range for x , i.e., $[0, 1]$.

Topics

“Beta Distribution” on page B-6

Introduced before R2006a

betalike

Beta negative log-likelihood

Syntax

```
nlogL = betalike(params,data)
[nlogL,AVAR] = betalike(params,data)
```

Description

`nlogL = betalike(params,data)` returns the negative of the beta log-likelihood function for the beta parameters a and b specified in vector `params` and the observations specified in the column vector `data`.

The elements of `data` must lie in the open interval $(0, 1)$, where the beta distribution is defined. However, it is sometimes also necessary to fit a beta distribution to data that include exact zeros or ones. For such data, the beta likelihood function is unbounded, and standard maximum likelihood estimation is not possible. In that case, `betalike` computes a modified likelihood that incorporates the zeros or ones by treating them as if they were values that have been left-censored at $\sqrt{\text{realmin}}$ or right-censored at $1-\text{eps}/2$, respectively.

`[nlogL,AVAR] = betalike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates if the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`betalike` is a utility function for maximum likelihood estimation of the beta distribution. The likelihood assumes that all the elements in the data sample are mutually independent. Since `betalike` returns the negative beta log-likelihood function, minimizing `betalike` using `fminsearch` is the same as maximizing the likelihood.

Examples

This example continues the `betafit` example, which calculates estimates of the beta parameters for some randomly generated beta distributed data.

```
r = betarnd(4,3,100,1);
[nlogl,AVAR] = betalike(betafit(r),r)
nlogl =

    -27.5996
```

```
AVAR =

    0.2783    0.1316
    0.1316    0.0867
```

Extended Capabilities

Topics

“Beta Distribution” on page B-6

Introduced before R2006a

betapdf

Beta probability density function

Syntax

`Y = betapdf(X,A,B)`

Description

`Y = betapdf(X,A,B)` computes the beta pdf at each of the values in `X` using the corresponding parameters in `A` and `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions of the other inputs. The parameters in `A` and `B` must all be positive, and the values in `X` must lie on the interval $[0, 1]$.

The beta probability density function for a given value x and given pair of parameters a and b is

$$y = f(x|a,b) = \frac{1}{B(a,b)} x^{a-1} (1-x)^{b-1} I_{[0,1]}(x)$$

where $B(\cdot)$ is the Beta function. The uniform distribution on $(0, 1)$ is a degenerate case of the beta pdf where $a = 1$ and $b = 1$.

A *likelihood function* is the pdf viewed as a function of the parameters. Maximum likelihood estimators (MLEs) are the values of the parameters that maximize the likelihood function for a fixed value of x .

Examples

```
a = [0.5 1; 2 4]
a =
    0.5000    1.0000
    2.0000    4.0000
y = betapdf(0.5,a,a)
y =
    0.6366    1.0000
    1.5000    2.1875
```

betarnd

Beta random numbers

Syntax

```
R = betarnd(A,B)
R = betarnd(A,B,m,n,...)
R = betarnd(A,B,[m,n,...])
```

Description

`R = betarnd(A,B)` generates random numbers from the beta distribution with parameters specified by `A` and `B`. `A` and `B` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `A` or `B` is expanded to a constant array with the same dimensions as the other input.

`R = betarnd(A,B,m,n,...)` or `R = betarnd(A,B,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the beta distribution with parameters `A` and `B`. `A` and `B` can each be scalars or arrays of the same size as `R`.

Examples

```
a = [1 1;2 2];
b = [1 2;1 2];
```

```
r = betarnd(a,b)
r =
    0.6987    0.6139
    0.9102    0.8067
```

```
r = betarnd(10,10,[1 5])
r =

```

```
r = betarnd(4,2,2,3)
r =
    0.3943    0.6101    0.5768
    0.5990    0.2760    0.5474
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.

- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

betastat

Beta mean and variance

Syntax

```
[M,V] = betastat(A,B)
```

Description

`[M,V] = betastat(A,B)`, with $A > 0$ and $B > 0$, returns the mean of and variance for the beta distribution with parameters specified by A and B . A and B can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of M and V . A scalar input for A or B is expanded to a constant array with the same dimensions as the other input.

The mean of the beta distribution with parameters a and b is $a/(a + b)$ and the variance is

$$\frac{ab}{(a + b + 1)(a + b)^2}$$

Examples

If parameters a and b are equal, the mean is $1/2$.

```
a = 1:6;
[m,v] = betastat(a,a)
m =
    0.5000    0.5000    0.5000    0.5000    0.5000    0.5000
v =
    0.0833    0.0500    0.0357    0.0278    0.0227    0.0192
```

binocdf

Binomial cumulative distribution function

Syntax

```
y = binocdf(x,n,p)
y = binocdf(x,n,p,'upper')
```

Description

`y = binocdf(x,n,p)` computes a binomial cumulative distribution function at each of the values in `x` using the corresponding number of trials in `n` and the probability of success for each trial in `p`.

`x`, `n`, and `p` can be vectors, matrices, or multidimensional arrays of the same size. Alternatively, one or more arguments can be scalars. The `binocdf` function expands scalar inputs to constant arrays with the same dimensions as the other inputs.

`y = binocdf(x,n,p,'upper')` returns the complement of the binomial cumulative distribution function at each value in `x`, using an algorithm that computes the extreme upper tail probabilities more accurately than the default algorithm.

Examples

Compute and Plot Binomial Cumulative Distribution Function

Compute and plot the binomial cumulative distribution function for the specified range of integer values, number of trials, and probability of success for each trial.

A baseball team plays 100 games in a season and has a 50-50 chance of winning each game. Find the probability of the team winning more than 55 games in a season.

```
format long
1 - binocdf(55,100,0.5)
```

```
ans =
    0.135626512036917
```

Find the probability of the team winning between 50 and 55 games in a season.

```
binocdf(55,100,0.5) - binocdf(49,100,0.5)
```

```
ans =
    0.404168106656672
```

Compute the probabilities of the team winning more than 55 games in a season if the chance of winning each game ranges from 10% to 90%.

```
chance = 0.1:0.05:0.9;
y = 1 - binocdf(55,100,chance);
```

Plot the results.

```
scatter(chance,y)
grid on
```

Compute Extreme Upper Tail Probabilities

Compute the complement of the binomial cumulative distribution function with more accurate upper tail probabilities.

A baseball team plays 100 games in a season and has a 50-50 chance of winning each game. Find the probability of the team winning more than 95 games in a season.

```
format long
1 - binocdf(95,100,0.5)
```

```
ans =
    0
```

This result shows that the probability is so close to 1 (within `eps`) that subtracting it from 1 gives 0. To approximate the extreme upper tail probabilities better, compute the complement of the binomial cumulative distribution function directly instead of computing the difference.

```
binocdf(95,100,0.5,'upper')
```

```
ans =  
    3.224844447881779e-24
```

Alternatively, use the `binopdf` function to find the probabilities of the team winning 96, 97, 98, 99, and 100 games in a season. Find the sum of these probabilities by using the `sum` function.

```
sum(binopdf(96:100,100,0.5),'all')  
  
ans =  
    3.224844447881779e-24
```

Input Arguments

x — Values at which to evaluate binomial cdf

integer from interval $[0 \ n]$ | array of integers from interval $[0 \ n]$

Values at which to evaluate the binomial cdf, specified as an integer or an array of integers. All values of x must belong to the interval $[0 \ n]$, where n is the number of trials.

Example: `[0 1 3 4]`

Data Types: `single` | `double`

n — Number of trials

positive integer | array of positive integers

Number of trials, specified as a positive integer or an array of positive integers.

Example: `[10 20 50 100]`

Data Types: `single` | `double`

p — Probability of success for each trial

scalar value from interval $[0 \ 1]$ | array of scalar values from interval $[0 \ 1]$

Probability of success for each trial, specified as a scalar value or an array of scalar values. All values of p must belong to the interval $[0 \ 1]$.

Example: `[0.01 0.1 0.5 0.7]`

Data Types: `single` | `double`

Output Arguments

y — Binomial cdf values

scalar value | array of scalar values

Binomial cdf values, returned as a scalar value or an array of scalar values. Each element in y is the binomial cdf value of the distribution evaluated at the corresponding element in x .

Data Types: `single` | `double`

More About

Binomial Cumulative Distribution Function

The binomial cumulative distribution function lets you obtain the probability of observing less than or equal to x successes in n trials, with the probability p of success on a single trial.

The binomial cumulative distribution function for a given value x and a given pair of parameters n and p is

$$y = F(x | n, p) = \sum_{i=0}^x \binom{n}{i} p^i (1-p)^{(n-i)} I_{(0,1,\dots,n)}(i).$$

The resulting value y is the probability of observing up to x successes in n independent trials, where the probability of success in any given trial is p . The indicator function $I_{(0,1,\dots,n)}(i)$ ensures that x only adopts values of $0,1,\dots,n$.

Alternative Functionality

- `binocdf` is a function specific to binomial distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, specify the probability distribution name and its parameters. Alternatively, create a `BinomialDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `binocdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Topics

“Binomial Distribution” on page B-10

Introduced before R2006a

binofit

Binomial parameter estimates

Syntax

```
phat = binofit(x,n)
[phat,pci] = binofit(x,n)
[phat,pci] = binofit(x,n,alpha)
```

Description

`phat = binofit(x,n)` returns a maximum likelihood estimate of the probability of success in a given binomial trial based on the number of successes, `x`, observed in `n` independent trials. If `x = (x(1), x(2), ... x(k))` is a vector, `binofit` returns a vector of the same size as `x` whose `i`th entry is the parameter estimate for `x(i)`. All `k` estimates are independent of each other. If `n = (n(1), n(2), ..., n(k))` is a vector of the same size as `x`, the binomial fit, `binofit`, returns a vector whose `i`th entry is the parameter estimate based on the number of successes `x(i)` in `n(i)` independent trials. A scalar value for `x` or `n` is expanded to the same size as the other input.

`[phat,pci] = binofit(x,n)` returns the probability estimate, `phat`, and the 95% confidence intervals, `pci`. `binofit` uses the Clopper-Pearson method to calculate confidence intervals.

`[phat,pci] = binofit(x,n,alpha)` returns the $100(1 - \alpha)\%$ confidence intervals. For example, `alpha = 0.01` yields 99% confidence intervals.

Note `binofit` behaves differently than other Statistics and Machine Learning Toolbox functions that compute parameter estimates, in that it returns independent estimates for each entry of `x`. By comparison, `expfit` returns a single parameter estimate based on all the entries of `x`.

Unlike most other distribution fitting functions, the `binofit` function treats its input `x` vector as a collection of measurements from separate samples. If you want to treat `x` as a single sample and compute a single parameter estimate for it, you can use `binofit(sum(x),sum(n))` when `n` is a vector, and `binofit(sum(X),N*length(X))` when `n` is a scalar.

Examples

This example generates a binomial sample of 100 elements, where the probability of success in a given trial is 0.6, and then estimates this probability from the outcomes in the sample.

```
r = binornd(100,0.6);
[phat,pci] = binofit(r,100)
phat =
    0.5800
pci =
    0.4771    0.6780
```

The 95% confidence interval, `pci`, contains the true value, 0.6.

Topics

“Binomial Distribution” on page B-10

Introduced before R2006a

binoinv

Binomial inverse cumulative distribution function

Syntax

```
X = binoinv(Y,N,P)
```

Description

`X = binoinv(Y,N,P)` returns the smallest integer X such that the binomial cdf evaluated at X is equal to or exceeds Y . You can think of Y as the probability of observing X successes in N independent trials where P is the probability of success in each trial. Each X is a positive integer less than or equal to N .

Y , N , and P can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in N must be positive integers, and the values in both P and Y must lie on the interval $[0\ 1]$.

Examples

If a baseball team has a 50-50 chance of winning any game, what is a reasonable range of games this team might win over a season of 162 games?

```
binoinv([0.05 0.95],162,0.5)
ans =
    71    91
```

This result means that in 90% of baseball seasons, a .500 team should win between 71 and 91 games.

binopdf

Binomial probability density function

Syntax

```
y = binopdf(x,n,p)
```

Description

`y = binopdf(x,n,p)` computes the binomial probability density function at each of the values in `x` using the corresponding number of trials in `n` and probability of success for each trial in `p`.

`x`, `n`, and `p` can be vectors, matrices, or multidimensional arrays of the same size. Alternatively, one or more arguments can be scalars. The `binopdf` function expands scalar inputs to constant arrays with the same dimensions as the other inputs.

Examples

Compute and Plot Binomial Probability Density Function

Compute and plot the binomial probability density function for the specified range of integer values, number of trials, and probability of success for each trial.

In one day, a quality assurance inspector tests 200 circuit boards. 2% of the boards have defects. Compute the probability that the inspector will find no defective boards on any given day.

```
binopdf(0,200,0.02)
```

```
ans = 0.0176
```

Compute the binomial probability density function values at each value from 0 to 200. These values correspond to the probabilities that the inspector will find 0, 1, 2, ..., 200 defective boards on any given day.

```
defects = 0:200;  
y = binopdf(defects,200,.02);
```

Plot the resulting binomial probability values.

```
plot(defects,y)
```

Compute the most likely number of defective boards that the inspector finds in a day.

```
[x,i] = max(y);
defects(i)
```

```
ans = 4
```

Input Arguments

x — Values at which to evaluate binomial pdf

integer from interval $[0 \ n]$ | array of integers from interval $[0 \ n]$

Values at which to evaluate the binomial pdf, specified as an integer or an array of integers. All values of x must belong to the interval $[0 \ n]$, where n is the number of trials.

Example: `[0,1,3,4]`

Data Types: `single` | `double`

n — Number of trials

positive integer | array of positive integers

Number of trials, specified as a positive integer or an array of positive integers.

Example: `[10,20,50,100]`

Data Types: `single` | `double`

p – Probability of success for each trial

scalar value from interval [0 1] | array of scalar values from interval [0 1]

Probability of success for each trial, specified as a scalar value or an array of scalar values. All values of p must belong to the interval [0 1].

Example: [0.01,0.1,0.5,0.7]

Data Types: single | double

Output Arguments**y – Binomial pdf values**

scalar value | array of scalar values

Binomial pdf values, returned as a scalar value or array of scalar values. Each element in y is the binomial pdf value of the distribution evaluated at the corresponding element in x .

Data Types: single | double

More About**Binomial Probability Density Function**

The binomial probability density function lets you obtain the probability of observing exactly x successes in n trials, with the probability p of success on a single trial.

The binomial probability density function for a given value x and given pair of parameters n and p is

$$y = f(x | n, p) = \binom{n}{x} p^x q^{(n-x)} I_{(0,1,\dots,n)}(x)$$

where $q = 1 - p$. The resulting value y is the probability of observing exactly x successes in n independent trials, where the probability of success in any given trial is p . The indicator function $I_{(0,1,\dots,n)}(x)$ ensures that x only adopts values of 0, 1, ..., n .

Alternative Functionality

- `binopdf` is a function specific to binomial distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, specify the probability distribution name and its parameters. Alternatively, create a `BinomialDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `binopdf` is faster than the generic function `pdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

binornd

Random numbers from binomial distribution

Syntax

```
r = binornd(n,p)
r = binornd(n,p,sz1,...,szN)
r = binornd(n,p,sz)
```

Description

`r = binornd(n,p)` generates random numbers from the binomial distribution specified by the number of trials `n` and the probability of success for each trial `p`.

`n` and `p` can be vectors, matrices, or multidimensional arrays of the same size. Alternatively, one or more arguments can be scalars. The `binornd` function expands scalar inputs to constant arrays with the same dimensions as the other inputs. The function returns a vector, matrix, or multidimensional array `r` of the same size as `n` and `p`.

`r = binornd(n,p,sz1,...,szN)` generates an array of random numbers from the binomial distribution with the scalar parameters `n` and `p`, where `sz1, ..., szN` indicates the size of each dimension.

`r = binornd(n,p,sz)` generates an array of random numbers from the binomial distribution with the scalar parameters `n` and `p`, where vector `sz` specifies `size(r)`.

Examples

Array of Random Numbers from Several Binomial Distributions

Generate an array of random numbers from the binomial distributions. For each distribution, you specify the number of trials and the probability of success for each trial.

Specify the numbers of trials.

```
n = 10:10:60
n = 1×6
    10    20    30    40    50    60
```

Specify the probabilities of success for each trial.

```
p = 1./n
p = 1×6
    0.1000    0.0500    0.0333    0.0250    0.0200    0.0167
```

Generate random numbers from the binomial distributions.

```
r = binornd(n,p)
```

```
r = 1×6
```

```
    0    1    1    0    1    1
```

Array of Random Numbers from One Binomial Distribution

Generate an array of random numbers from one binomial distribution. Here, the distribution parameters *n* and *p* are scalars.

Use the `binornd` function to generate random numbers from the binomial distribution with 100 trials, where the probability of success in each trial is 0.2. The function returns one number.

```
r_scalar = binornd(100,0.2)
```

```
r_scalar = 20
```

Generate a 2-by-3 array of random numbers from the same distribution by specifying the required array dimensions.

```
r_array = binornd(100,0.2,2,3)
```

```
r_array = 2×3
```

```
    18    23    20  
    18    24    23
```

Alternatively, specify the required array dimensions as a vector.

```
r_array = binornd(100,0.2,[2 3])
```

```
r_array = 2×3
```

```
    21    21    20  
    26    18    23
```

Input Arguments

n — Number of trials

positive integer | array of positive integers

Number of trials, specified as a positive integer or an array of positive integers.

Example: [10 20 50 100]

Data Types: single | double

p — Probability of success for each trial

scalar value | array of scalar values

Probability of success for each trial, specified as a scalar value or an array of scalar values. All values of p must belong to the interval $[0 \ 1]$.

Example: `[0.01 0.1 0.5 0.7]`

Data Types: `single` | `double`

sz1, ..., szN — Size of each dimension (as separate arguments)

integers

Size of each dimension, specified as separate arguments of integers. For example, specifying `5,3,2` generates a 5-by-3-by-2 array of random numbers from the binomial probability distribution.

If either n or p is an array, then the specified dimensions $sz1, \dots, szN$ must match the common dimensions of n and p after any necessary scalar expansion. The default values of $sz1, \dots, szN$ are the common dimensions.

- If you specify a single value $sz1$, then r is a square matrix of size $sz1$ -by- $sz1$.
- If the size of any dimension is 0 or negative, then r is an empty array.
- Beyond the second dimension, `binornd` ignores trailing dimensions with a size of 1. For example, `binornd(n,p,3,1,1,1)` produces a 3-by-1 vector of random numbers.

Example: `5,3,2`

Data Types: `single` | `double`

sz — Size of each dimension (as a row vector)

row vector of integers

Size of each dimension, specified as a row vector of integers. For example, specifying `[5 3 2]` generates a 5-by-3-by-2 array of random numbers from the binomial probability distribution.

If either n or p is an array, then the specified dimensions sz must match the common dimensions of n and p after any necessary scalar expansion. The default values of sz are the common dimensions.

- If you specify a single value $[sz1]$, then r is a square matrix of size $sz1$ -by- $sz1$.
- If the size of any dimension is 0 or negative, then r is an empty array.
- Beyond the second dimension, `binornd` ignores trailing dimensions with a size of 1. For example, `binornd(n,p,[3 1 1 1])` produces a 3-by-1 vector of random numbers.

Example: `[5 3 2]`

Data Types: `single` | `double`

Output Arguments

r — Random numbers from binomial distribution

scalar value | array of scalar values

Random numbers from the binomial distribution, returned as a scalar value or an array of scalar values.

Data Types: `single` | `double`

Alternative Functionality

- `binornd` is a function specific to binomial distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, specify the probability distribution name and its parameters. Alternatively, create a `BinomialDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `binornd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB in these two cases:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Distributed Arrays

Partition large arrays across the combined memory of your cluster using Parallel Computing Toolbox™.

This function fully supports distributed arrays. For more information, see “Run MATLAB Functions with Distributed Arrays” (Parallel Computing Toolbox).

binostat

Binomial mean and variance

Syntax

```
[M,V] = binostat(N,P)
```

Description

`[M,V] = binostat(N,P)` returns the mean of and variance for the binomial distribution with parameters specified by the number of trials, `N`, and probability of success for each trial, `P`. `N` and `P` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `M` and `V`. A scalar input for `N` or `P` is expanded to a constant array with the same dimensions as the other input.

The mean of the binomial distribution with parameters n and p is np . The variance is npq , where $q = 1 - p$.

Examples

```
n = logspace(1,5,5)
n =
    10    100   1000  10000 100000

[m,v] = binostat(n,1./n)
m =
    1    1    1    1    1
v =
    0.9000  0.9900  0.9990  0.9999  1.0000

[m,v] = binostat(n,1/2)
m =
    5    50   500  5000 50000
v =
    1.0e+04 *
    0.0003  0.0025  0.0250  0.2500  2.5000
```

binScatterPlot

Scatter plot of bins for tall arrays

Syntax

```
binScatterPlot(X,Y)
binScatterPlot(X,Y,nbins)
binScatterPlot(X,Y,Xedges,Yedges)
binScatterPlot(X,Y,Name,Value)
h = binScatterPlot( ___ )
```

Description

`binScatterPlot(X,Y)` creates a binned scatter plot of the data in `X` and `Y`. The `binScatterPlot` function uses an automatic binning algorithm that returns bins with a uniform area, chosen to cover the range of elements in `X` and `Y` and reveal the underlying shape of the distribution.

`binScatterPlot(X,Y,nbins)` specifies the number of bins to use in each dimension.

`binScatterPlot(X,Y,Xedges,Yedges)` specifies the edges of the bins in each dimension using the vectors `Xedges` and `Yedges`.

`binScatterPlot(X,Y,Name,Value)` specifies additional options with one or more name-value pair arguments using any of the previous syntaxes. For example, you can specify `'Color'` and a valid color option to change the color theme of the plot, or `'Gamma'` with a positive scalar to adjust the level of detail.

`h = binScatterPlot(___)` returns a `Histogram2` object. Use this object to inspect properties of the plot.

Examples

Binned Scatter Plot of Normally-Distributed Random Data

Create two tall vectors of random data. Create a binned scatter plot for the data.

```
X = tall(randn(1e5,1));
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
Y = tall(randn(1e5,1));
```

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

```
binScatterPlot(X,Y)
```

```

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 12 sec
Evaluation completed in 20 sec
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 2.9 sec
Evaluation completed in 3.6 sec

```

The resulting figure contains a slider to adjust the level of detail in the image.

Specify Number of Scatter Plot Bins

Specify a scalar value as the third input argument to use the same number of bins in each dimension, or a two-element vector to use a different number of bins in each dimension.

Plot a binned scatter plot of random data sorted into 100 bins in each dimension.

```
X = tall(randn(1e5,1));
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
Y = tall(randn(1e5,1));
```

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example

using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

```
binScatterPlot(X,Y,100)
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 12 sec
Evaluation completed in 16 sec
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 3.4 sec
Evaluation completed in 4.4 sec
```

Use 20 bins in the x-dimension and continue to use 100 bins in the y-dimension.

```
binScatterPlot(X,Y,[20 100])
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 3.1 sec
Evaluation completed in 5.4 sec
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 3.8 sec
Evaluation completed in 4.5 sec
```

Specify Bin Edges for Scatter Plot

Plot a binned scatter plot of random data with specific bin edges. Use bin edges of Inf and $-\text{Inf}$ to capture outliers.

Create a binned scatter plot with 100 bin edges between $[-2 \ 2]$ in each dimension. The data outside the specified bin edges is not included in the plot.

```
X = tall(randn(1e5,1));
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
Y = tall(randn(1e5,1));
```

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

```
Xedges = linspace(-2,2);
Yedges = linspace(-2,2);
binScatterPlot(X,Y,Xedges,Yedges)
```

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 14 sec
Evaluation completed in 19 sec

Use coarse bins extending to infinity on the edges of the plot to capture outliers.

```
Xedges = [-Inf linspace(-2,2) Inf];  
Yedges = [-Inf linspace(-2,2) Inf];  
binScatterPlot(X,Y,Xedges,Yedges)
```

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 2.6 sec
Evaluation completed in 3.5 sec

Adjust Plot Color Theme

Plot a binned scatter plot of random data, specifying 'Color' as 'c'.

```
X = tall(randn(1e5,1));
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
Y = tall(randn(1e5,1));
```

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

```
binScatterPlot(X,Y,'Color','c')
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 7.7 sec
Evaluation completed in 12 sec
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 1.5 sec
Evaluation completed in 1.9 sec
```

Input Arguments

X, Y — Data to distribute among bins (as separate arguments)

tall vectors | tall matrices | tall multidimensional arrays

Data to distribute among bins, specified as separate arguments of tall vectors, matrices, or multidimensional arrays. X and Y must be the same size. If X and Y are not vectors, then `binScatterPlot` treats them as single column vectors, `X(:)` and `Y(:)`.

Corresponding elements in X and Y specify the x and y coordinates of 2-D data points, `[X(k), Y(k)]`. The underlying data types of X and Y can be different, but `binScatterPlot` concatenates these inputs into a single N-by-2 tall matrix of the dominant underlying data type.

`binScatterPlot` ignores all NaN values. Similarly, `binScatterPlot` ignores Inf and -Inf values, unless the bin edges explicitly specify Inf or -Inf as a bin edge.

Note If X or Y contain integers of type `int64` or `uint64` that are larger than `flintmax`, then it is recommended that you explicitly specify the bin edges. `binScatterPlot` automatically bins the input data using double precision, which lacks integer precision for numbers greater than `flintmax`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

nbins — Number of bins in each dimension

scalar | vector

Number of bins in each dimension, specified as a positive scalar integer or two-element vector of positive integers. If you do not specify `nbins`, then `binScatterPlot` automatically calculates how many bins to use based on the values in `X` and `Y`.

- If `nbins` is a scalar, then `binScatterPlot` uses that many bins in each dimension.
- If `nbins` is a vector, then `nbins(1)` specifies the number of bins in the x-dimension and `nbins(2)` specifies the number of bins in the y-dimension.

Example: `binScatterPlot(X,Y,20)` uses 20 bins in each dimension.

Example: `binScatterPlot(X,Y,[10 20])` uses 10 bins in the x-dimension and 20 bins in the y-dimension.

Xedges — Bin edges in x-dimension

vector

Bin edges in x-dimension, specified as a vector. `Xedges(1)` is the first edge of the first bin in the x-dimension, and `Xedges(end)` is the outer edge of the last bin.

The value `[X(k),Y(k)]` is in the `(i,j)`th bin if `Xedges(i) ≤ X(k) < Xedges(i+1)` **and** `Yedges(j) ≤ Y(k) < Yedges(j+1)`. The last bins in each dimension also include the last (outer) edge. For example, `[X(k),Y(k)]` falls into the `i`th bin in the last row if `Xedges(end-1) ≤ X(k) ≤ Xedges(end)` **and** `Yedges(i) ≤ Y(k) < Yedges(i+1)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Yedges — Bin edges in y-dimension

vector

Bin edges in y-dimension, specified as a vector. `Yedges(1)` is the first edge of the first bin in the y-dimension, and `Yedges(end)` is the outer edge of the last bin.

The value `[X(k),Y(k)]` is in the `(i,j)`th bin if `Xedges(i) ≤ X(k) < Xedges(i+1)` **and** `Yedges(j) ≤ Y(k) < Yedges(j+1)`. The last bins in each dimension also include the last (outer) edge. For example, `[X(k),Y(k)]` falls into the `i`th bin in the last row if `Xedges(end-1) ≤ X(k) ≤ Xedges(end)` **and** `Yedges(i) ≤ Y(k) < Yedges(i+1)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `binScatterPlot(X,Y,'BinWidth',[5 10])`

BinMethod — Binning algorithm

'auto' (default) | 'scott' | 'integers'

Binning algorithm, specified as the comma-separated pair consisting of 'BinMethod' and one of these values.

Value	Description
'auto'	The default 'auto' algorithm uses a maximum of 100 bins and chooses a bin width to cover the data range and reveal the shape of the underlying distribution.
'scott'	Scott's rule is optimal if the data is close to being jointly normally distributed. This rule is appropriate for most other distributions, as well. It uses a bin size of $[3.5 * \text{std}(X) * \text{numel}(X)^{-1/4}, 3.5 * \text{std}(Y) * \text{numel}(Y)^{-1/4}]$.
'integers'	The integer rule is useful with integer data, as it creates a bin for each integer. It uses a bin width of 1 and places bin edges halfway between integers. To avoid accidentally creating too many bins, you can use this rule to create a limit of 65536 bins (2^{16}). If the data range is greater than 65536, then the integer rule uses wider bins instead.

Note The BinMethod property of the resulting Histogram2 object always has a value of 'manual'.

BinWidth — Width of bins in each dimension

scalar | vector

Width of bins in each dimension, specified as the comma-separated pair consisting of 'BinWidth' and a scalar or two-element vector of positive integers, [xWidth yWidth]. A scalar value indicates the same bin width for each dimension.

If you specify BinWidth, then binScatterPlot can use a maximum of 1024 bins (2^{10}) along each dimension. If instead the specified bin width requires more bins, then binScatterPlot uses a larger bin width corresponding to the maximum number of bins.

Example: binScatterPlot(X,Y, 'BinWidth', [5 10]) uses bins with size 5 in the x-dimension and size 10 in the y-dimension.

Color — Plot color theme

'b' (default) | 'y' | 'm' | 'c' | 'r' | 'g' | 'k'

Plot color theme, specified as the comma-separated pair consisting of 'Color' and one of these options.

Option	Description
'b'	Blue
'm'	Magenta
'c'	Cyan
'r'	Red
'g'	Green

Option	Description
'y'	Yellow
'k'	Black

Gamma — Gamma correction

1 (default) | positive scalar

Gamma correction, specified as the comma-separated pair consisting of 'Gamma' and a positive scalar. Use this option to adjust the brightness and color intensity to affect the amount of detail in the image.

- $\text{gamma} < 1$ — As gamma decreases, the shading of bins with smaller bin counts becomes progressively darker, including more detail in the image.
- $\text{gamma} > 1$ — As gamma increases, the shading of bins with smaller bin counts becomes progressively lighter, removing detail from the image.
- The default value of 1 does not apply any correction to the display.

XBinLimits — Bin limits in x-dimension

vector

Bin limits in x-dimension, specified as the comma-separated pair consisting of 'XBinLimits' and a two-element vector, [xbmin,xbmax]. The vector indicates the first and last bin edges in the x-dimension.

binScatterPlot only plots data that falls within the bin limits inclusively, `Data(Data(:,1)>=xbmin & Data(:,1)<=xbmax)`.

YBinLimits — Bin limits in y-dimension

vector

Bin limits in y-dimension, specified as the comma-separated pair consisting of 'YBinLimits' and a two-element vector, [ybmin,ybmax]. The vector indicates the first and last bin edges in the y-dimension.

binScatterPlot only plots data that falls within the bin limits inclusively, `Data(Data(:,2)>=ybmin & Data(:,2)<=ybmax)`.

Output Arguments

h — Binned scatter plot

Histogram2 object

Binned scatter plot, returned as a Histogram2 object. For more information, see Histogram2 Properties.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

biplot

Biplot

Syntax

```
biplot(coefs)
biplot(coefs,Name,Value)
```

```
biplot(ax, ___)
```

```
h = biplot(___)
```

Description

`biplot(coefs)` creates a biplot of the coefficients in the matrix `coefs`. The biplot is 2-D if `coefs` has two columns or 3-D if it has three columns. The axes in the biplot represent the columns of `coefs`, and the vectors in the biplot represent the rows of `coefs` (the observed variables).

`biplot(coefs,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify `'Positive'`, `'true'` to restrict the biplot to the positive quadrant (in 2-D) or octant (in 3-D).

`biplot(ax, ___)` uses the plot axes specified by the Axes object `ax`. Specify `ax` as the first input argument followed by any of the input argument combinations in the previous syntaxes.

`h = biplot(___)` returns a column vector of handles to the graphics objects created by `biplot`. Use `h` to query and modify properties of specific graphics objects. For more information, see Graphics Object Properties (MATLAB).

Examples

Biplot of Coefficients and Scores

Create a biplot of the first three principal component coefficients, the observations, and the observed variables for the `carsmall` data set.

Load the sample data.

```
load carsmall
```

Create a matrix consisting of the variables `Acceleration`, `Displacement`, `Horsepower`, `MPG`, and `Weight`. Delete rows in the matrix that have missing values.

```
X = [Acceleration Displacement Horsepower MPG Weight];
X = rmmissing(X);
```

Standardize `X` and perform a principal component analysis.

```
Z = zscore(X); % Standardized data
[coefs,score] = pca(Z);
```

The 5-by-5 matrix `coefs` contains the principal component coefficients (one column for each principal component). The matrix `score` contains the principal component scores (the observations).

Create a biplot of the first three principal component coefficients. The axes of the biplot represent the columns of `coefs`, and the vectors in the biplot represent the rows of `coefs`.

```
biplot(coefs(:,1:3))
```

Create a more detailed biplot by labeling each variable and plotting the observations in the space of the first three principal components.

```
vbls = {'Accel','Disp','HP','MPG','Wgt'}; % Labels for the variables
biplot(coefs(:,1:3),'Scores',score(:,1:3),'VarLabels',vbls);
```

Specify Axes for Biplot

Load the `fisheriris` data set, standardize the flower measurements in `meas`, and perform a principal component analysis.

```
load fisheriris
Z = zscore(meas);
[coefs,scores] = pca(Z);
```

Create a figure with two subplots and return the Axes objects as `ax1` and `ax2`. Create a biplot in each set of axes by referring to the corresponding Axes object. In the top subplot, display a biplot using the first two principal components. In the bottom subplot, display a biplot using the third and fourth principal components. Specify the x-axis and y-axis limits by passing the corresponding Axes objects to the `xlim` and `ylim` functions. Change the x-axis and y-axis labels in the bottom plot by passing `ax2` to `xlabel` and `ylabel`.

```
figure('Units','normalized','Position',[0.3 0.3 0.3 0.5])
variables = {'SepalLength','SepalWidth','PetalLength','PetalWidth'};
ax1 = subplot(2,1,1); % Top subplot
biplot(ax1,coefs(:,1:2),'Scores',scores(:,1:2),'VarLabels',variables);
xlim(ax1,[-1 1])
ylim(ax1,[-1 1])

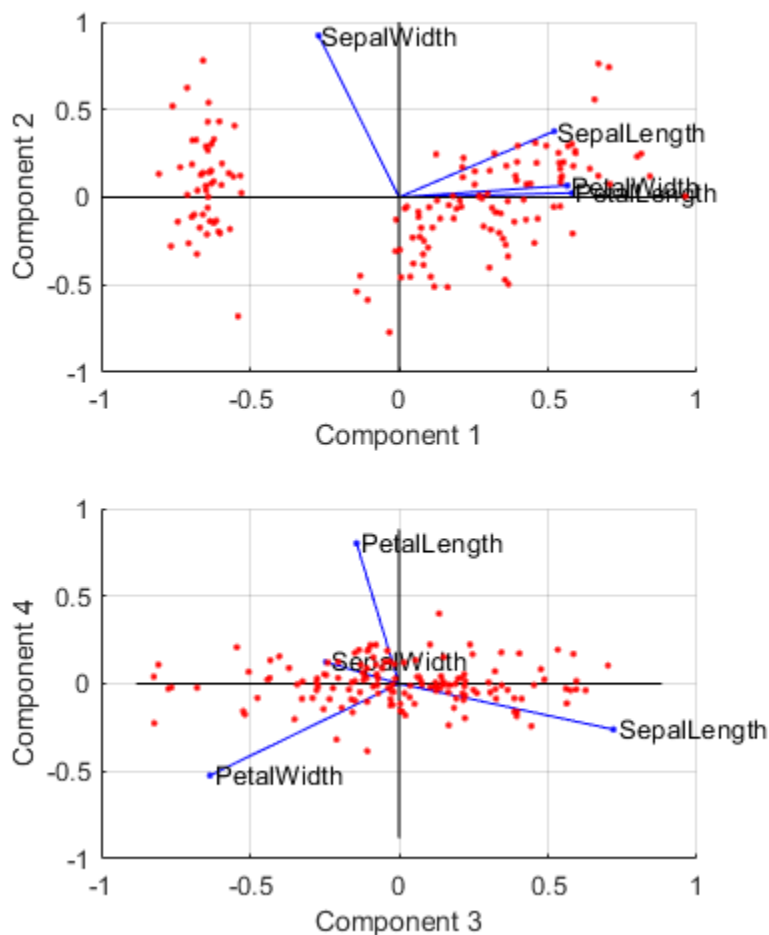

ax2 = subplot(2,1,2); % Bottom subplot
```

```

biplot(ax2,coefs(:,3:4),'Scores',scores(:,3:4),'VarLabels',variables);
xlim(ax2,[-1 1])
ylim(ax2,[-1 1])
xlabel(ax2,'Component 3')
ylabel(ax2,'Component 4')

```

Modify Biplot Properties

Control the appearance of a biplot by specifying supported line property names and values, and by using handles to the graphics objects created by `biplot`.

Load the sample data.

```
load carsmall
```

Create a matrix consisting of the variables Acceleration, Displacement, and MPG. Delete rows in the matrix that have missing values.

```
X = [Acceleration Displacement MPG];
X = rmmissing(X);
```

Standardize X and perform a principal component analysis.

```
Z = zscore(X); % Standardized data
[coefs,score] = pca(Z);
```

The 3-by-3 matrix `coefs` contains the principal component coefficients (one column for each principal component). The matrix `score` contains the principal component scores (the observations).

Create a biplot of the observations in the space of the first two principal components. Use the default properties for the biplot.

```
h = biplot(coefs(:,1:2), 'Scores', score(:,1:2));
```

`h` is a vector of handles to graphics objects. You can modify the properties of the line objects returned by `biplot`.

Label the three variables for easy identification. Specify circles as the marker symbol and blue as the line color for all line objects.

```
vbls = {'Accel', 'Disp', 'MPG'}; % Array of variable labels
h1 = biplot(coefs(:,1:2), 'Scores', score(:,1:2), ...
    'Color', 'b', 'Marker', 'o', 'VarLabels', vbls);
```

`h1` is a vector of handles to graphics objects. View the first few elements of `h1`.

```
h1(1:10) % First ten object handles
```

```
ans =
  10x1 graphics array:

  Line      (varline)
  Line      (varline)
  Line      (varline)
  Line      (varmarker)
  Line      (varmarker)
  Line      (varmarker)
  Text      (varlabel)
  Text      (varlabel)
  Text      (varlabel)
  Line      (obsmarker)
```

The handles for the variable labels (`h1(7:9)`) are text. Therefore, the settings specified for the line properties do not affect these labels.

Create another biplot of the observations in the space of the first two principal components, and label the three variables for easy identification.

```
h2 = biplot(coefs(:,1:2), 'Scores', score(:,1:2), 'VarLabels', vbls);
```

`h2` is a vector of handles to graphics objects. View the first few elements of `h2`.

```
h2(1:10) % First ten object handles
```

```
ans =
  10x1 graphics array:

  Line      (varline)
  Line      (varline)
  Line      (varline)
  Line      (varmarker)
  Line      (varmarker)
  Line      (varmarker)
  Text      (varlabel)
  Text      (varlabel)
  Text      (varlabel)
  Line      (obsmarker)
```

`h2` contains 104 object handles.

- The first three handles (`h(1:3)`) correspond to line handles for the three variables.
- Handles `h(4:6)` correspond to marker handles for the three variables.
- Handles `h(7:9)` correspond to text handles for the three variables.
- The next 94 handles correspond to line handles for the observations.

- The last handle corresponds to a line handle for the axis lines.

Modify specific properties of the biplot by using handles to the graphics objects.

Change the line color of the variables (vectors).

```
for k = 1:3
    h2(k).Color = 'r'; % Specify red as the line color
end
```

Modify the font of the variable labels.

```
for k = 7:9
    h2(k).FontWeight = 'bold'; % Specify bold font
end
```

Change the color of the observation markers.

```
for k = 10:103
    h2(k).MarkerEdgeColor = 'k'; % Specify black color for the observations
end
```

Input Arguments

coefs — Coefficients

matrix

Coefficients, specified as a matrix that has two or three columns. If `coefs` has two columns, then the biplot is 2-D; if `coefs` has three columns, then the biplot is 3-D. The columns of `coefs` usually contain principal component coefficients created with `pca` or `pcacov`, or factor loadings estimated with `factoran`. The axes in the biplot represent columns of `coefs`, and the vectors in the biplot represent rows of `coefs` (the observed variables).

Data Types: `single` | `double`

ax — Axes for plot

Axes object

Axes for the plot, specified as an Axes object. If you do not specify `ax`, then `biplot` creates the plot using the current axes. For more information on creating an Axes object, see `axes`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `biplot(coefs, 'VarLabels', varlabels)` labels each vector (variable) with the text in the array `varlabels`.

Scores — Scores

matrix

Scores, specified as the comma-separated pair consisting of `'Scores'` and a matrix with the same number of columns as `coefs`. `Scores` usually contains principal component scores created with `pca` or factor scores estimated with `factoran`. The `biplot` function represents each row of `Scores` (the observations) as points and each row of `coefs` (the observed variables) as vectors.

Example: `'Scores', score(:, 1:3)`

Data Types: `single` | `double`

VarLabels — Variable labels

character array | string array | cell array

Variable labels, specified as the comma-separated pair consisting of `'VarLabels'` and a character array, string array, or cell array. `biplot` labels each vector (observed variable) with the text in the array.

Example: `'VarLabels', varlabels`

Data Types: `char` | `string` | `cell`

ObsLabels — Observation labels

character array | string array | cell array

Observation labels, specified as the comma-separated pair consisting of `'ObsLabels'` and a character array, string array, or cell array. `biplot` uses the text in the array as observation names when displaying data cursors.

Example: `'ObsLabels', obslabels`

Data Types: `char` | `string` | `cell`

Positive — Indicator for plotting in positive coordinates

`false` (default) | `true`

Indicator for plotting in the positive coordinates, specified as the comma-separated pair consisting of 'Positive' and one of these logical values.

Value	Description
false	Creates the biplot over the range $\pm \max(\text{coefs}(:))$ for all coordinates (default)
true	Restricts the biplot to the positive quadrant (in 2-D) or octant (in 3-D)

Example: 'Positive', true

Data Types: logical

PropertyName — Property name

supported line property value

Property name, specified as the comma-separated pair consisting of a property name and its associated value for one or more supported Line Properties. These properties are the names and values for all primitive line graphics objects created by `biplot`. The specified property names control the appearance and behavior of the graphics objects.

Example: 'Marker', 'square', 'MarkerSize', 10

Output Arguments

h — Handles to graphics objects

column vector

Handles to the graphics objects created by `biplot`, returned as a column vector. The vector contains handles in this order:

- 1 Handles corresponding to variables (line handles first, followed by marker handles then text handles)
- 2 Handles corresponding to observations (marker handles first, followed by text handles)
- 3 Handles corresponding to the axis lines

You can use the handles to query and modify properties of specific graphics objects. See Graphics Object Handles (MATLAB) and Graphics Arrays (MATLAB) for more details.

Algorithms

A biplot allows you to visualize the magnitude and sign of each variable's contribution to the first two or three principal components, and to represent each observation in terms of those components. The `biplot` function:

- Imposes a sign convention, forcing the element with the largest magnitude in each column of `coefs` to be positive. This action flips some of the vectors in `coefs` to the opposite direction, but often makes the plot easier to read. Interpretation of the plot is unaffected, because changing the sign of a coefficient vector does not change its meaning.
- Scales the scores so that they fit on the plot. That is, the function divides each score by the maximum absolute value of all scores, and multiplies by the maximum coefficient length of `coefs`. Then `biplot` changes the sign of the score coordinates according to the sign convention for the coefficients.

bootci

Bootstrap confidence interval

Syntax

```
ci = bootci(nboot,bootfun,...)
ci = bootci(nboot,{bootfun,...},'alpha',alpha)
ci = bootci(nboot,{bootfun,...},...,'type',type)
ci = bootci(nboot,{bootfun,...},...,'type','student','nbootstd',nbootstd)
ci = bootci(nboot,{bootfun,...},...,'type','student','stderr',stderr)
ci = bootci(nboot,{bootfun,...},...,'Weights',weights)
ci = bootci(nboot,{bootfun,...},...,'Options',options)
[ci,bootstat] = bootci(...)
```

Description

`ci = bootci(nboot,bootfun,...)` computes the 95% bootstrap confidence interval of the statistic computed by the function `bootfun`. `nboot` is a positive integer indicating the number of bootstrap samples used in the computation. `bootfun` is a function handle specified with `@`. The third and later input arguments to `bootci` are data (scalars, column vectors, or matrices) that are used to create inputs to `bootfun`. `bootci` creates each bootstrap sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `bootfun` unchanged.

If `bootfun` returns a scalar, `ci` is a vector containing the lower and upper bounds of the confidence interval. If `bootfun` returns a vector of length m , `ci` is an array of size 2-by- m , where `ci(1,:)` are lower bounds and `ci(2,:)` are upper bounds. If `bootfun` returns an array of size m -by- n -by- p -by-..., `ci` is an array of size 2-by- m -by- n -by- p -by-..., where `ci(1,:,:,:,...)` is an array of lower bounds and `ci(2,:,:,:,...)` is an array of upper bounds.

`ci = bootci(nboot,{bootfun,...},'alpha',alpha)` computes the $100*(1-\alpha)$ bootstrap confidence interval of the statistic defined by the function `bootfun`. `bootfun` and the data that `bootci` passes to it are contained in a single cell array. `alpha` is a scalar between 0 and 1. The default value of `alpha` is 0.05.

`ci = bootci(nboot,{bootfun,...},...,'type',type)` computes the bootstrap confidence interval of the statistic defined by the function `bootfun`. `type` is the confidence interval type, chosen from among the following:

- 'norm' or 'normal' — Normal approximated interval with bootstrapped bias and standard error.
- 'per' or 'percentile' — Basic percentile method.
- 'cper' or 'corrected percentile' — Bias corrected percentile method.
- 'bca' — Bias corrected and accelerated percentile method. This is the default.
- 'stud' or 'student' — Studentized confidence interval.

`ci = bootci(nboot,{bootfun,...},...,'type','student','nbootstd',nbootstd)` computes the studentized bootstrap confidence interval of the statistic defined by the function `bootfun`. The standard error of the bootstrap statistics is estimated using bootstrap, with `nbootstd` bootstrap data samples. `nbootstd` is a positive integer value. The default value of `nbootstd` is 100.

`ci = bootci(nboot,{bootfun,...},..., 'type','student','stderr',stderr)` computes the studentized bootstrap confidence interval of statistics defined by the function `bootfun`. The standard error of the bootstrap statistics is evaluated by the function `stderr`. `stderr` is a function handle. `stderr` takes the same arguments as `bootfun` and returns the standard error of the statistic computed by `bootfun`.

`ci = bootci(nboot,{bootfun,...},..., 'Weights',weights)` specifies observation weights. `weights` must be a vector of non-negative numbers with at least one positive element. The number of elements in `weights` must be equal to the number of rows in non-scalar input arguments to `bootfun`. To obtain one bootstrap replicate, `bootstrp` samples N out of N with replacement using these weights as multinomial sampling probabilities.

`ci = bootci(nboot,{bootfun,...},..., 'Options',options)` specifies options that govern the computation of bootstrap iterations. One option requests that `bootci` perform bootstrap iterations using multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to be used in bootstrap resampling. This argument is a struct that you can create with a call to `statset`. You can retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are:

- `'UseParallel'` — If `true` and if a `parpool` of the Parallel Computing Toolbox is open, compute bootstrap iterations in parallel. If the Parallel Computing Toolbox is not installed, or a `parpool` is not open, computation occurs in serial mode. Default is `false`, or serial computation.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
- `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `bootci` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
 - `UseParallel` is `true`
 - `UseSubstreams` is `false`

In that case, use a cell array the same size as the Parallel pool.

`[ci,bootstat] = bootci(...)` also returns the bootstrapped statistic computed for each of the `nboot` bootstrap replicate samples. Each row of `bootstat` contains the results of applying `bootfun` to one bootstrap sample. If `bootfun` returns a matrix or array, then this output is converted to a row vector for storage in `bootstat`.

Examples

Compute the confidence interval for the capability index in statistical process control:

```
y = normrnd(1,1,30,1);           % Simulated process data
LSL = -3; USL = 3;              % Process specifications
capable = @(x)(USL-LSL)./(6* std(x)); % Process capability
ci = bootci(2000,capable,y)      % BCa confidence interval
ci =
    0.8122
    1.2657

sci = bootci(2000,{capable,y},'type','student') % Studentized ci
sci =
    0.7739
    1.2707
```

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2006a

bootstrap

Bootstrap sampling

Syntax

```
bootstat = bootstrap(nboot,bootfun,d)
bootstat = bootstrap(nboot,bootfun,d1,...,dN)
bootstat = bootstrap( ___,Name,Value)
[bootstat,bootsam] = bootstrap( ___ )
```

Description

`bootstat = bootstrap(nboot,bootfun,d)` draws `nboot` bootstrap data samples from `d`, computes statistics on each sample using the function `bootfun`, and returns the results in `bootstat`. The `bootstrap` function creates each bootstrap sample by sampling with replacement from the rows of `d`. Each row of the output argument `bootstat` contains the results of applying `bootfun` to one bootstrap sample.

`bootstat = bootstrap(nboot,bootfun,d1,...,dN)` draws `nboot` bootstrap samples from the data in `d1,...,dN`. The nonscalar data arguments in `d1,...,dN` must have the same number of rows, `n`. The `bootstrap` function creates each bootstrap sample by sampling with replacement from the indices `1:n` and selecting the corresponding rows of the nonscalar `d1,...,dN`. The function passes the sample of nonscalar data and the unchanged scalar data arguments in `d1,...,dN` to `bootfun`.

`bootstat = bootstrap(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can add observation weights to your data or compute bootstrap iterations in parallel.

`[bootstat,bootsam] = bootstrap(___)` also returns `bootsam`, an `n-by-nboot` matrix of bootstrap sample indices, where `n` is the number of rows in the original, nonscalar data. Each column in `bootsam` corresponds to one bootstrap sample and contains the row indices of the values drawn from the nonscalar data to create that sample.

To get the bootstrap sample indices without applying a function to the samples, set `bootfun` to empty (`[]`).

Examples

Estimate Density of Bootstrapped Statistic

Estimate the kernel density of bootstrapped means.

Generate 100 random numbers from the exponential distribution with mean 5.

```
rng('default') % For reproducibility
y = exprnd(5,100,1);
```

Compute a sample of 100 bootstrapped means of random samples taken from the vector `y`.

```
m = bootstrp(100,@mean,y);
```

Plot an estimate of the density of the bootstrapped means.

```
[fi,xi] = ksdensity(m);
plot(xi,fi)
```

Bootstrapping Multiple Statistics

Compute and plot the means and standard deviations of 100 bootstrap samples.

Generate 100 random numbers from the exponential distribution with mean 5.

```
rng('default') % For reproducibility
y = exprnd(5,100,1);
```

Compute a sample of 100 bootstrapped means and standard deviations of random samples taken from the vector y.

```
stats = bootstrp(100,@(x)[mean(x) std(x)],y);
```

Plot the bootstrap estimate pairs.

```
plot(stats(:,1),stats(:,2),'o')
xlabel('Mean')
ylabel('Standard Deviation')
```

Bootstrap Samples of Observations

Take bootstrap samples of patient data, compute the mean measurements for each data sample, and visualize the results.

Load the `patients` data set. Create the matrix `patientData` containing age, weight, and height measurements. Each row of `patientData` corresponds to one patient.

```
load patients
patientData = [Age Weight Height];
```

Create 200 bootstrap data samples from the data in `patientData`. To create each sample, randomly select with replacement 100 rows (that is, `size(patientData,1)`) from the rows in `patientData`. For each sample, calculate the mean age, weight, and height measurements. Each row of `bootstat` contains the three mean measurements for one bootstrap sample.

```
rng('default') % For reproducibility
bootstat = bootstrp(200,@mean,patientData);
```

Visualize the mean measurements for all 200 bootstrap data samples. Note that bootstrap samples with greater mean weights tend to have greater mean heights.

```
scatter3(bootstat(:,1),bootstat(:,2),bootstat(:,3))
xlabel('Mean Age')
```

```

ylabel('Mean Weight')
zlabel('Mean Height')

view([-75 10])

```

Bootstrapping Correlation Coefficient Standard Error

Compute a correlation coefficient standard error using bootstrap resampling of the sample data.

Load the `lawdata` data set, which contains the LSAT score and law school GPA for 15 students.

```

load lawdata
rng('default') % For reproducibility
size(lsat)

```

```

ans = 1×2
    15     1

```

```

size(gpa)
ans = 1×2
    15     1

```

Create 1000 data samples by resampling the 15 data points, and compute the correlation between the two variables for each data sample.

```
[bootstat,bootsam] = bootstrp(1000,@corr,lsat,gpa);
```

Display the first 5 bootstrapped correlation coefficients.

```
bootstat(1:5,:)
```

```
ans = 5×1
```

```
0.9874
0.4918
0.5459
0.8458
0.8959
```

Display the indices of the data selected for the first 5 bootstrap samples.

```
bootsam(:,1:5)
```

```
ans = 15×5
```

```
13     3    11     8    12
14     7     1     7     4
 2    14     5    10     8
14    12     1    11    11
10    15     2    12    14
 2    10    13     5    15
 5     1    11    11     9
 9    13     5    10     3
15    15    15     3     3
15    11     1     2     4
  :
```

Create a histogram that shows the variation of the correlation coefficient across all the bootstrap samples.

```
histogram(bootstat)
```

The sample minimum is positive, indicating that the relationship between LSAT score and GPA is not accidental.

Finally, compute a bootstrap standard of error for the estimated correlation coefficient.

```
se = std(bootstat)
```

```
se = 0.1285
```

Compare Bootstrap Samples with Different Observation Weights

Compare bootstrap samples with different observation weights. Create a custom function that computes statistics for each sample.

Create 50 bootstrap samples from the numbers 1 through 6. To create each sample, `bootstrap` randomly chooses with replacement from the numbers 1 through 6, six times. This process is similar to rolling a die six times. For each sample, the custom function `countfun` (shown at the end of this example) counts the number of 1s in the sample.

```
rng('default') %For reproducibility
counts = bootstrap(50,@countfun,1:6);
```

Note: If you use the live script file for this example, the `countfun` function is already included at the end of the file. Otherwise, you need to create this function at the end of your `.m` file or add it as a file on the MATLAB® path.

Create 50 bootstrap samples from the numbers 1 through 6, but assign different weights to the numbers. Each time `bootstrap` randomly chooses from the numbers 1 through 6, the probability of choosing a 1 is 0.5, the probability of choosing a 2 is 0.1, and so on. Again, `countfun` counts the number of 1s in each sample.

```
weights = [0.5 0.1 0.1 0.1 0.1 0.1];
weightedCounts = bootstrap(50,@countfun,1:6,'Weights',weights);
```

Compare the two sets of bootstrap samples by using histograms.

```
histogram(counts)
hold on
histogram(weightedCounts)
legend
xlabel('Number of 1s in Sample')
ylabel('Number of Samples')
hold off
```

The two sets of bootstrap samples have different distributions; in particular, the samples in the second set tend to contain more 1s. For example, of the 50 samples in the first set, only two samples contain more than two 1s. By contrast, of the 50 samples in the second set (with observation weights), $12 + 14 + 4 + 2 = 32$ samples contain more than two 1s.

This code creates the function `countfun`.

```
function numberofones = countfun(sample)
numberofones = sum(sample == 1);
end
```

Bootstrapping Regression Model

Estimate the standard errors for a coefficient vector in a linear regression by bootstrapping the residuals.

Note: This example uses `regress`, which is useful when you simply need the coefficient estimates or residuals of a regression model and you need to repeat fitting a model multiple times, as in the case of bootstrapping. If you need to investigate a fitted regression model further, create a linear regression model object by using `fitlm`.

Load the sample data.

```
load hald
```

Perform a linear regression, and compute the residuals.

```
x = [ones(size(heat)),ingredients];
y = heat;
b = regress(y,x);
yfit = x*b;
resid = y - yfit;
```

Estimate the standard errors by bootstrapping the residuals.

```
se = std(bootstrp(1000,@(bootr)regress(yfit+bootr,x),resid))
```

```
se = 1×5
```

```
56.1752    0.5940    0.5815    0.5989    0.5691
```

Input Arguments

nboot — Number of bootstrap samples

positive integer scalar

Number of bootstrap samples to draw, specified as a positive integer scalar. To create each bootstrap sample, `bootstrp` randomly selects with replacement `n` out of the `n` rows of (nonscalar) data in `d` or `d1, ..., dN`.

Example: 100

Data Types: `single` | `double`

bootfun — Function to apply to each sample

function handle

Function to apply to each sample, specified as a function handle. The function can be a custom or built-in function. You must specify `bootfun` with the `@` symbol.

For an example that uses a custom function, see “Compare Bootstrap Samples with Different Observation Weights” on page 32-201.

Example: `@mean`

Data Types: `function_handle`

d — Data to sample from

`column vector` | `matrix`

Data to sample from, specified as a column vector or matrix. The `n` rows of `d` correspond to observations. If you use multiple data input arguments `d1, . . . , dN`, then all nonscalar arguments must have the same number of rows.

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `bootstrp(4,@mean,1:2,'Weights',[0.4 0.6])` specifies to draw four bootstrap samples from the values 1 and 2 and take the mean of each sample. For each draw, the probability of getting a 1 is 0.4, and the probability of getting a 2 is 0.6.

Weights — Observation weights

`ones(n,1)/n` (default) | `nonnegative vector`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a nonnegative vector with at least one positive element. The number of elements in `Weights` must be equal to the number of rows `n` in the data `d` or `d1, . . . , dN`. To obtain one bootstrap sample, `bootstrp` randomly selects with replacement `n` out of `n` rows of data using the weights as multinomial sampling probabilities.

Data Types: `single` | `double`

Options — Options for computing in parallel and setting random numbers

`structure`

Options for computing bootstrap iterations in parallel and setting random numbers during the bootstrap sampling, specified as the comma-separated pair consisting of `'Options'` and a structure. Create the `Options` structure with `statset`. This table lists the option fields and their values.

Field Name	Value	Default
<code>UseParallel</code>	Set this value to <code>true</code> to compute bootstrap iterations in parallel.	<code>false</code>
<code>UseSubstreams</code>	Set this value to <code>true</code> to run computations in parallel in a reproducible manner. To compute reproducibly, set <code>Streams</code> to a type that allows substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code> .	<code>false</code>

Field Name	Value	Default
Streams	Specify this value as a <code>RandStream</code> object or cell array of such objects. Use a single object except when the <code>UseParallel</code> value is true and the <code>UseSubstreams</code> value is false. In that case, use a cell array that has the same size as the parallel pool.	If you do not specify <code>Streams</code> , then <code>bootstrap</code> uses the default stream or streams.

Note You need Parallel Computing Toolbox to run computations in parallel.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

Output Arguments

bootstat — Bootstrap sample statistics

column vector | matrix

Bootstrap sample statistics, returned as a column vector or matrix with `n` rows. The `i`th row of `bootstat` corresponds to the results of applying `bootfun` to the `i`th bootstrap sample. If `bootfun` returns a matrix or array, then the `bootstrap` function first converts this output to a row vector before storing it in `bootstat`.

bootsam — Bootstrap sample indices

numeric matrix

Bootstrap sample indices, returned as an `n`-by-`nboot` numeric matrix, where `n` is the number of rows in the original, nonscalar data. Each column in `bootsam` corresponds to one bootstrap sample and contains the row indices of the values drawn from the nonscalar data to create that sample.

For example, if each data input argument in `d1, ..., dN` contains 16 values, and `nboot = 4`, then `bootsam` is a 16-by-4 matrix. The first column contains the indices of the 16 values drawn from `d1, ..., dN` for the first bootstrap sample, the second column contains the indices for the second bootstrap sample, and so on. The bootstrap indices are the same for all input data sets `d1, ..., dN`.

Tips

- To get the bootstrap sample indices `bootsam` without applying a function to the samples, set `bootfun` to empty (`[]`).

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

`RandStream` | `bootci` | `histogram` | `ksdensity` | `parfor` | `random` | `randsample` | `statget` | `statset`

Introduced before R2006a

boxplot

Visualize summary statistics with box plot

Syntax

```
boxplot(x)  
boxplot(x,g)
```

```
boxplot(ax, ___ )
```

```
boxplot( ___ ,Name,Value)
```

Description

`boxplot(x)` creates a box plot of the data in `x`. If `x` is a vector, `boxplot` plots one box. If `x` is a matrix, `boxplot` plots one box for each column of `x`.

On each box, the central mark indicates the median, and the bottom and top edges of the box indicate the 25th and 75th percentiles, respectively. The whiskers extend to the most extreme data points not considered outliers, and the outliers are plotted individually using the '+' symbol.

`boxplot(x,g)` creates a box plot using one or more grouping variables contained in `g`. `boxplot` produces a separate box for each set of `x` values that share the same `g` value or values.

`boxplot(ax, ___)` creates a box plot using the axes specified by the axes graphic object `ax`, using any of the previous syntaxes.

`boxplot(___ ,Name,Value)` creates a box plot with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the box style or order.

Examples

Create a Box Plot

Load the sample data.

```
load carsmall
```

Create a box plot of the miles per gallon (MPG) measurements. Add a title and label the axes.

```
boxplot(MPG)  
xlabel('All Vehicles')  
ylabel('Miles per Gallon (MPG)')  
title('Miles per Gallon for All Vehicles')
```

The boxplot shows that the median miles per gallon for all vehicles in the sample data is approximately 24. The minimum value is about 9, and the maximum value is about 44.

Create Box Plots for Grouped Data

Load the sample data.

```
load carsmall
```

Create a box plot of the miles per gallon (MPG) measurements from the sample data, grouped by the vehicles' country of origin (Origin). Add a title and label the axes.

```
boxplot(MPG,Origin)
title('Miles per Gallon by Vehicle Origin')
xlabel('Country of Origin')
ylabel('Miles per Gallon (MPG)')
```

Each box visually represents the MPG data for cars from the specified country. Italy's "box" appears as a single line because the sample data contains only one observation for this group.

Create Notched Box Plots

Generate two sets of sample data. The first sample, x_1 , contains random numbers generated from a normal distribution with $\mu = 5$ and $\sigma = 1$. The second sample, x_2 , contains random numbers generated from a normal distribution with $\mu = 6$ and $\sigma = 1$.

```
rng default % For reproducibility
x1 = normrnd(5,1,100,1);
x2 = normrnd(6,1,100,1);
```

Create notched box plots of x_1 and x_2 . Label each box with its corresponding μ value.

```
figure
boxplot([x1,x2], 'Notch', 'on', 'Labels', {'mu = 5', 'mu = 6'})
title('Compare Random Data from Different Distributions')
```

The boxplot shows that the difference between the medians of the two groups is approximately 1. Since the notches in the box plot do not overlap, you can conclude, with 95% confidence, that the true medians do differ.

The following figure shows the box plot for the same data with the maximum whisker length specified as 1.0 times the interquartile range. Data points beyond the whiskers are displayed using +.

```
figure
boxplot([x1,x2], 'Notch', 'on', 'Labels', {'mu = 5', 'mu = 6'}, 'Whisker', 1)
title('Compare Random Data from Different Distributions')
```

With the smaller whiskers, `boxplot` displays more data points as outliers.

Create Compact Box Plots

Create a 100-by-25 matrix of random numbers generated from a standard normal distribution to use as sample data.

```
rng default % For reproducibility
x = randn(100,25);
```

Create two box plots for the data in `x` on the same figure. Use the default formatting for the top plot, and compact formatting for the bottom plot.

```
figure
```

```
subplot(2,1,1)
boxplot(x)
```

```
subplot(2,1,2)
boxplot(x, 'PlotStyle', 'compact')
```

Each plot presents the same data, but the compact formatting may improve readability for plots with many boxes.

Box Plots for Vectors of Varying Length

Create box plots for data vectors of varying length by using a grouping variable.

Randomly generate three column vectors of varying length: one of length 5, one of length 10, and one of length 15. Combine the data into a single column vector of length 30.

```
rng('default') % For reproducibility
x1 = rand(5,1);
x2 = rand(10,1);
x3 = rand(15,1);
x = [x1; x2; x3];
```

Create a grouping variable that assigns the same value to rows that correspond to the same vector in `x`. For example, the first five rows of `g` have the same value, `First`, because the first five rows of `x` all come from the same vector, `x1`.

```
g1 = repmat({'First'},5,1);
g2 = repmat({'Second'},10,1);
g3 = repmat({'Third'},15,1);
g = [g1; g2; g3];
```

Create the box plots.

```
boxplot(x,g)
```

Input Arguments

x — Input data

numeric vector | numeric matrix

Input data, specified as a numeric vector or numeric matrix. If `x` is a vector, `boxplot` plots one box. If `x` is a matrix, `boxplot` plots one box for each column of `x`.

On each box, the central mark indicates the median, and the bottom and top edges of the box indicate the 25th and 75th percentiles, respectively. The whiskers extend to the most extreme data points not considered outliers, and the outliers are plotted individually using the '+' symbol.

Data Types: `single` | `double`

g — Grouping variables

numeric vector | character array | string array | cell array | categorical array

Grouping variables, specified as a numeric vector, character array, string array, cell array, or categorical array. You can specify multiple grouping variables in `g` by using a cell array of these variable types or a matrix. If you specify multiple grouping variables, they must all be the same length.

If `x` is a vector, then the grouping variables must contain one row for each element of `x`. If `x` is a matrix, then the grouping variables must contain one row for each column of `x`. Groups that contain a missing value (NaN), an empty character vector, an empty or `<missing>` string, or an `<undefined>` value in a grouping variable are omitted, and are not counted in the number of groups considered by other parameters.

By default, `boxplot` sorts character and string grouping variables in the order they initially appear in the data, categorical grouping variables by the order of their levels, and numeric grouping variables in numeric order. To control the order of groups, do one of the following:

- Use categorical variables in `g` and specify the order of their levels.
- Use the `'GroupOrder'` name-value pair argument.
- Pre-sort your data.

Data Types: `single` | `double` | `char` | `string` | `cell` | `categorical`

ax — Axes on which to plot

axes graphic object

Axes on which to plot, specified as an axes graphic object. If you do not specify `ax`, then `boxplot` creates the plot using the current axis. For more information on creating an axes graphic object, see `axes` and `Axes`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Notch', 'on', 'Labels', {'mu = 5', 'mu = 6'}` creates a notched box plot and labels the two boxes `mu = 5` and `mu = 6`, from left to right

Box Appearance

BoxStyle — Box style

`'outline'` | `'filled'`

Box style, specified as the comma-separated pair consisting of `'BoxStyle'` and one of the following.

Name	Value
<code>'outline'</code>	Plot boxes using an unfilled box with dashed whiskers. This is the default if <code>'PlotStyle'</code> is <code>'traditional'</code> .
<code>'filled'</code>	Plot boxes using a narrow filled box with lines for whiskers. This is the default if <code>'PlotStyle'</code> is <code>'compact'</code> .

Example: `'BoxStyle', 'filled'`

Colors — Box colors

RGB triplet | character vector or string scalar of color names

Box colors, specified as the comma-separated pair consisting of `'Colors'` and an RGB triplet, character vector, or string scalar. An RGB triplet is a three-element row vector whose elements

specify the intensities of the red, green, and blue components of the color, respectively. Each intensity must be in the range [0,1].

The following table lists the available color characters and their equivalent RGB triplet values.

Long Name	Short Name	RGB Triplet
Yellow	'y'	[1 1 0]
Magenta	'm'	[1 0 1]
Cyan	'c'	[0 1 1]
Red	'r'	[1 0 0]
Green	'g'	[0 1 0]
Blue	'b'	[0 0 1]
White	'w'	[1 1 1]
Black	'k'	[0 0 0]

You can specify multiple colors either as a character vector or string scalar of color names (for example, 'rgbm') or a three-column matrix of RGB values. The sequence is replicated or truncated as required, so for example, 'rb' gives boxes that alternate red and blue.

If you do not specify the name-value pair 'ColorGroup', then boxplot uses the same color scheme for all boxes. If you do specify 'ColorGroup', then the default is a modified hsv colormap.

Example: 'Colors', 'rgbm'

MedianStyle — Median style

'line' | 'target'

Median style, specified as the comma-separated pair consisting of 'MedianStyle' and one of the following.

Name	Value
'line'	Draw a line to represent the median in each box. This is the default when 'PlotStyle' is 'traditional'.
'target'	Draw a black dot inside a white circle to represent the median in each box. This is the default when 'PlotStyle' is 'compact'.

Example: 'MedianStyle', 'target'

Notch — Marker for comparison intervals

'off' (default) | 'on' | 'marker'

Marker for comparison intervals, specified as the comma-separated pair consisting of 'Notch' and one of the following.

Name	Value
'off'	Omit comparison intervals from box display.

Name	Value
'on'	If 'PlotStyle' is 'traditional', draw comparison intervals using notches. If 'PlotStyle' is 'compact', draw comparison intervals using triangular markers.
'marker'	Draw comparison intervals using triangular markers.

Two medians are significantly different at the 5% significance level if their intervals do not overlap. `boxplot` represents interval endpoints using the extremes of the notches or the centers of the triangular markers. The notch extremes correspond to $q_2 - 1.57(q_3 - q_1)/\sqrt{n}$ and $q_2 + 1.57(q_3 - q_1)/\sqrt{n}$, where q_2 is the median (50th percentile), q_1 and q_3 are the 25th and 75th percentiles, respectively, and n is the number of observations without any NaN values. If the sample size is small, the notches might extend beyond the end of the box.

Example: 'Notch', 'on'

OutlierSize – Marker size for outliers

positive numeric value

Marker size for outliers, specified as the comma-separated pair consisting of 'OutlierSize' and a positive numeric value. The specified value represents the marker size in points.

If 'PlotStyle' is 'traditional', then the default value for OutlierSize is 6. If 'PlotStyle' is 'compact', then the default value for OutlierSize is 4.

Example: 'OutlierSize', 8

Data Types: single | double

PlotStyle – Plot style

'traditional' (default) | 'compact'

Plot style, specified as the comma-separated pair consisting of 'PlotStyle' and one of the following.

Name	Value
'traditional'	Plot boxes using a traditional box style.
'compact'	Plot boxes using a smaller box style designed for plots with many groups. This style changes the defaults for some other parameters.

Example: 'PlotStyle', 'compact'

Symbol – Symbol and color for outliers

line specification

Symbol and color for outliers, specified as the comma-separated pair consisting of 'Symbol' and a line specification. See the `LineStyle` parameter in `plot` for available line specifications.

If 'PlotStyle' is 'traditional', then the default value is 'r+', which plots each outlier using a red '+' symbol.

If 'PlotStyle' is 'compact', then the default value is 'o', which plots each outlier using an 'o' symbol in the same color as the corresponding box.

If you omit the symbol, then the outliers appear invisible. If you omit the color, then the outliers appear in the same color as the box.

Example: 'kx'

Widths — Box width

numeric scalar | numeric vector

Box width, specified as the comma-separated pair consisting of 'Widths' and a numeric scalar or numeric vector. If the number of boxes is not equal to the number of width values specified, then the list of values is replicated or truncated as necessary.

This name-value pair argument does not alter the spacing between boxes. Therefore, if you specify a large value for 'Widths', the boxes might overlap.

The default box width is equal to half of the minimum separation between boxes, which is 0.5 when the 'Positions' name-value pair argument takes its default value.

Example: 'Widths',0.3

Data Types: single | double

Group Appearance

ColorGroup — Grouping variable for box color change

[] (default) | numeric vector | character array | string array | cell array | categorical array

Grouping variable for box color change, specified as the comma-separated pair consisting of 'ColorGroup' and a grouping variable. The grouping variable is a numeric vector, character array, string array, cell array, or categorical array. The box color changes when the specified grouping variable changes. The default value [] indicates that the box color does not change based on the group.

Data Types: single | double | char | string | cell | categorical

FactorDirection — Order of factors on plot

'data' (default) | 'list' | 'auto'

Order of factors on plot, specified as the comma-separated pair consisting of 'FactorDirection' and one of the following.

Name	Value
'data'	Factors appear with the first value next to the plot origin.
'list'	Factors appear left-to-right if on the x-axis, or top-to-bottom if on the y-axis.
'auto'	If the grouping variables are numeric, then boxplot uses 'data'. If the grouping variables are character arrays, string arrays, cell arrays, or categorical arrays, then boxplot uses 'list'.

FullFactors — Plot all group factors

'off' (default) | 'on'

Plot all group factors, specified as the comma-separated pair consisting of 'FullFactors' and either 'off' or 'on'. If 'off', then `boxplot` plots one box for each unique row of grouping variables. If 'on', then `boxplot` plots one box for each possible combination of grouping variable values, including combinations that do not appear in the data.

Example: 'FullFactors', 'on'

FactorGap — Distance between different grouping factors

[] | positive numeric value | vector of positive numeric values | 'auto'

Distance between different grouping factors, specified as the comma-separated pair consisting of 'FactorGap' and a positive numeric value, a vector of positive numeric values, or 'auto'. If you specify a vector, then the vector length must be less than or equal to the number of grouping variables.

'FactorGap' represents the distance of the gap between different factors of a grouping variable, expressed as a percentage of the width of the plot. For example, if you specify [3,1], then the gap is three percent of the width of the plot between groups with different values of the first grouping variable, and one percent between groups with the same value of the first grouping variable but different values for the second.

If you specify 'auto', then `boxplot` selects a gap distance automatically. The value [] indicates no change in gap size between different factors.

If 'PlotStyle' is 'traditional', then the default value for FactorGap is []. If 'PlotStyle' is 'compact', then the default value is 'auto'.

Example: 'FactorGap', [3,1]

Data Types: single | double | char | string

FactorSeparator — Separation between grouping factors

[] | positive integer | vector of positive integers | 'auto'

Separation between grouping factors, specified as the comma-separated pair consisting of 'FactorSeparator' and a positive integer or a vector of positive integers, or 'auto'. If you specify a vector, then the length of the vector should be less than or equal to the number of grouping variables. The integer values must be in the range [1,G], where G is the number of grouping variables.

'FactorSeparator' specifies which factors should have their values separated by a grid line. For example, [1,2] adds a separator line when the first or second grouping variable changes value.

If 'PlotStyle' is 'traditional', then the default value for FactorSeparator is []. If 'PlotStyle' is 'compact', then the default value is 'auto'.

Example: 'FactorSeparator', [1,2]

Data Types: single | double | char | string

GroupOrder — Plotting order of groups

[] (default) | string array | cell array

Plotting order of groups, specified as the comma-separated pair consisting of 'GroupOrder' and a string array or cell array containing the names of the grouping variables. If you have multiple

grouping variables, separate values with a comma. You can also use categorical arrays as grouping variables to control the order of the boxes. The default value `[]` does not reorder the boxes.

Data Types: `string` | `cell`

Data Limits and Maximum Distances

DataLim — Extreme data limits

`[-Inf, Inf]` (default) | two-element numeric vector

Extreme data limits, specified as the comma-separated pair consisting of `'DataLim'` and a two-element numeric vector containing the lower and upper limits, respectively. The values specified for `'DataLim'` are used by `'ExtremeMode'` to determine which data points are extreme.

Data Types: `single` | `double`

ExtremeMode — Handling method for extreme data

`'clip'` (default) | `'compress'`

Handling method for extreme data, specified as the comma-separated pair consisting of `'ExtremeMode'` and one of the following.

Name	Value
<code>'clip'</code>	If any data values fall outside the limits specified by <code>'DataLim'</code> , then <code>boxplot</code> displays these values at <code>DataLim</code> on the plot.
<code>'compress'</code>	If any data values fall outside the limits specified by <code>'DataLim'</code> , then <code>boxplot</code> displays these values evenly distributed in a region just outside <code>DataLim</code> , retaining the relative order of the points.

If any data points lie outside the limit specified by `'DataLim'`, then the limit is marked with a dotted line. If any data points are compressed, then two gray lines mark the compression region. Values at `-Inf` or `Inf` can be clipped or compressed, but `NaN` values do not appear on the plot. Box notches are drawn to scale and may extend beyond the bounds if the median is inside the limit. Box notches are not drawn if the median is outside the limits.

Example: `'ExtremeMode', 'compress'`

Jitter — Maximum outlier displacement distance

numeric value

Maximum outlier displacement distance, specified as the comma-separated pair consisting of `'Jitter'` and a numeric value. `Jitter` is the maximum distance to displace outliers along the factor axis by a uniform random amount, in order to make duplicate points visible. If you specify `'Jitter'` equal to 1, then the jitter regions just touch between the closest adjacent groups.

If `'PlotStyle'` is `'traditional'`, then the default value for `Jitter` is 0. If `'PlotStyle'` is `'compact'`, then the default value is 0.5.

Example: `'Jitter', 1`

Data Types: `single` | `double`

Whisker — Maximum whisker length

1.5 (default) | positive numeric value

Maximum whisker length, specified as the comma-separated pair consisting of 'Whisker' and a positive numeric value.

`boxplot` draws points as outliers if they are greater than $q_3 + w \times (q_3 - q_1)$ or less than $q_1 - w \times (q_3 - q_1)$, where w is the maximum whisker length, and q_1 and q_3 are the 25th and 75th percentiles of the sample data, respectively.

The default value for 'Whisker' corresponds to approximately $\pm 2.7\sigma$ and 99.3 percent coverage if the data are normally distributed. The plotted whisker extends to the *adjacent value*, which is the most extreme data value that is not an outlier.

Specify 'Whisker' as 0 to give no whiskers and to make every point outside of q_1 and q_3 an outlier.

Example: 'Whisker',0

Data Types: single | double

Plot Appearance**Labels — Box labels**

character array | string array | cell array | numeric vector | numeric matrix

Box labels, specified as the comma-separated pair consisting of 'Labels' and a character array, string array, cell array, or numeric vector containing the box label names. Specify one label per x value or one label per group. To specify multiple label variables, use a numeric matrix or a cell array containing any of the accepted data types.

To remove labels from a plot, use the following command: `set(gca, 'XTickLabel', {' '})`.

Data Types: char | string | cell | single | double

LabelOrientation — Label orientation

'inline' | 'horizontal'

Label orientation, specified as the comma-separated pair consisting of 'LabelOrientation' and one of the following.

Name	Value
'inline'	Rotate box labels to be vertical. This is the default when 'PlotStyle' is 'compact'.
'horizontal'	Leave box labels horizontal. This is the default when 'PlotStyle' is 'traditional'.

If the labels are on the y axis, then both settings leave the labels horizontal.

Example: 'LabelOrientation', 'inline'

LabelVerbosity — Labels to display on plot

'all' | 'minor' | 'majorminor'

Labels to display on plot, specified as the comma-separated pair consisting of LabelVerbosity and one of the following.

Name	Value
'all'	Display a label for every value of a grouping variable. This is the default when 'PlotStyle' is 'traditional'.
'minor'	For any grouping variable, display the value corresponding to box j only if that value differs from the value corresponding to box $(j - 1)$.
'majorminor'	For any grouping variable $g(:, i)$, display the value corresponding to box j , only if that value differs from the value of $g(:, i)$ corresponding to box $(j - 1)$, or if the condition above holds for at least one of the grouping variables $g(:, 1), \dots, g(:, i-1)$. This is the default when 'PlotStyle' is 'compact'.

Example: 'LabelVerbosity', 'minor'

Orientation — Plot orientation

'vertical' (default) | 'horizontal'

Plot orientation, specified as the comma-separated pair consisting of Orientation and one of the following.

Name	Value
'vertical'	Plot x on the y -axis.
'horizontal'	Plot x on the x -axis.

Example: 'horizontal'

Positions — Box positions

numeric vector

Box positions, specified as the comma-separated pair consisting of 'Positions' and a numeric vector containing one entry for each group or x value. The default is $1:NumGroups$, where $NumGroups$ is the number of groups.

Data Types: single | double

Tips

- `boxplot` creates a visual representation of the data, but does not return numeric values. To calculate the relevant summary statistics for the sample data, use the following functions:
 - `min` — Find the minimum value in the sample data.
 - `max` — Find the maximum value in the sample data.
 - `median` — Find the median value in the sample data.
 - `quantile` — Find the quantile values in the sample data.
 - `grpstats` — Calculate summary statistics for the sample data, organized by group.

- You can see data values and group names using the data cursor (MATLAB) in the figure window. The cursor shows the original values of any points affected by the `dataLim` parameter. You can label the group to which an outlier belongs using the `gname` function.
- To modify graphics properties of a box plot component, use `findobj` with the `Tag` property to find the component's handle. `Tag` values for box plot components depend on parameter settings, and are listed in the following table.

Parameter Settings	Tag Values
All settings	<ul style="list-style-type: none"> • 'Box' • 'Outliers'
When 'PlotStyle' is 'traditional'	<ul style="list-style-type: none"> • 'Median' • 'Upper Whisker' • 'Lower Whisker' • 'Upper Adjacent Value' • 'Lower Adjacent Value'
When 'PlotStyle' is 'compact'	<ul style="list-style-type: none"> • 'Whisker' • 'MedianOuter' • 'MedianInner'
When 'Notch' is 'marker'	<ul style="list-style-type: none"> • 'NotchLo' • 'NotchHi'

Alternative Functionality

You can also create a `BoxChart` object by using the `boxchart` function. Although `boxchart` does not include all the functionality of `boxplot`, it has some advantages. Unlike `boxplot`, the `boxchart` function:

- Allows for categorical rulers along the group axis
- Provides the option of a legend
- Works well with the `hold on` command
- Has an improved visual design that helps you see notches more easily

To control the appearance and behavior of the object, change the `BoxChart` Properties.

Introduced before R2006a

boundary

Piecewise distribution boundaries

Syntax

```
[p,q] = boundary(pd)
[p,q] = boundary(pd,j)
```

Description

`[p,q] = boundary(pd)` returns the boundary points between segments in `pd`, the piecewise distribution. `p` is a vector of the cumulative probabilities at the boundaries, and `q` is a vector of the corresponding quantiles.

`[p,q] = boundary(pd,j)` returns boundary values of the `j`th boundary.

Examples

Boundaries in `paretotails` Object

Generate a sample data set and create a `paretotails` object by fitting a piecewise distribution with Pareto tails to the generated data. Find the boundary points between segments in a `paretotails` object by using the object function `boundary`.

Generate a sample data set containing 20% outliers.

```
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and generalized Pareto distributions (GPDs) for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)

pd =
Piecewise distribution with 3 segments
  -Inf < x < -1.33251   (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
 -1.33251 < x < 1.80149 (0.1 < p < 0.9): interpolated empirical cdf
  1.80149 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Return the boundary values between the piecewise segments by using the `boundary` function.

```
[p,q] = boundary(pd)

p = 2×1
```

```
0.1000
0.9000
```

```
q = 2×1
```

```
-1.3325
 1.8015
```

The values in `p` are the cumulative probabilities at the boundaries, and the values in `q` are the corresponding quantiles.

Plot the cdf of the `paretotails` object and mark the boundary points on the figure.

```
xi = sort(x);
plot(xi,cdf(pd,xi))
hold on
plot(q,p,'ro')
legend('Pareto Tails Object','Boundary Points','Location','best')
hold off
```

Input Arguments

pd — Piecewise distribution with Pareto tails
`paretotails` object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

j – Boundary index

positive integer

Boundary index indicating which boundary to return, specified as a positive integer.

Data Types: `single` | `double`

Output Arguments**p – Cumulative probability at boundary**

numeric vector of range $(0, 1)$ values

Cumulative probability at each boundary, returned as a numeric vector of range $(0, 1)$ values.

q – Quantile at boundary

numeric vector

Quantile at each boundary, returned as a numeric vector.

CalinskiHarabaszEvaluation

Package: clustering.evaluation

Superclasses: clustering.evaluation.ClusterCriterion

Calinski-Harabasz criterion clustering evaluation object

Description

CalinskiHarabaszEvaluation is an object consisting of sample data, clustering data, and Calinski-Harabasz criterion values used to evaluate the optimal number of clusters. Create a Calinski-Harabasz criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x,clust,'CalinskiHarabasz')` creates a Calinski-Harabasz criterion clustering evaluation object.

`eva = evalclusters(x,clust,'CalinskiHarabasz',Name,Value)` creates a Calinski-Harabasz criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in <code>x</code> using the <code>kmeans</code> clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in <code>x</code> using the <code>clusterdata</code> agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in <code>x</code> using the <code>gmdistribution</code> Gaussian mixture distribution algorithm, with 'SharedCov' set to <code>true</code> and 'Replicates' set to 5.

If `criterion` is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric n -by- K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `criterion` is `'CalinskiHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a n -by- K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the j th clustering solution.

Data Types: `single` | `double` | `char` | `string` | `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'KList', [1:6]` specifies to test 1, 2, 3, 4, 5, and 6 clusters to find the optimal number.

KList — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name or a function handle. When `criterion` is `'gap'`, `clust` must be a character vector, a string scalar, or a function handle, and you must specify `KList`.

Example: `'KList', [1:6]`

Data Types: `single` | `double`

Properties

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

CriterionValues

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

Distance

Distance metric used for clustering data, stored as a valid distance metric name.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

NumObservations

Number of observations in the data matrix `X`, minus the number of missing (NaN) values in `X`, stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

X

Data used for clustering, stored as a matrix of numerical values.

Methods**Inherited Methods**

<code>addK</code>	Evaluate additional numbers of clusters
<code>plot</code>	Plot clustering evaluation object criterion values
<code>compact</code>	Compact clustering evaluation object

Examples**Evaluate the Clustering Solution Using Calinski-Harabasz Criterion**

Evaluate the optimal number of clusters using the Calinski-Harabasz clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion. Cluster the data using `kmeans`.

```

rng('default'); % For reproducibility
eva = evalclusters(meas, 'kmeans', 'CalinskiHarabasz', 'KList', [1:6])

eva =
  CalinskiHarabaszEvaluation with properties:

    NumObservations: 150
      InspectedK: [1 2 3 4 5 6]
    CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]
      OptimalK: 3

```

The `OptimalK` value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

Plot the Calinski-Harabasz criterion values for each number of clusters tested.

```

figure;
plot(eva);

```

The plot shows that the highest Calinski-Harabasz value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```

PetalLength = meas(:,3);
PetalWidth = meas(:,4);

```

```

ClusterGroup = eva.OptimalY;
figure;
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbg','xod');

```

The plot shows cluster 3 in the lower-left corner, completely separated from the other two clusters. Cluster 3 contains flowers with the smallest petal widths and lengths. Cluster 1 is in the upper-right corner, and contains flowers with the largest petal widths and lengths. Cluster 2 is near the center of the plot, and contains flowers with measurements between these two extremes.

More About

Calinski-Harabasz Criterion

The Calinski-Harabasz criterion is sometimes called the variance ratio criterion (VRC). The Calinski-Harabasz index is defined as

$$VRC_k = \frac{SS_B}{SS_W} \times \frac{(N - k)}{(k - 1)},$$

where SS_B is the overall between-cluster variance, SS_W is the overall within-cluster variance, k is the number of clusters, and N is the number of observations.

The overall between-cluster variance SS_B is defined as

$$SS_B = \sum_{i=1}^k n_i \|m_i - m\|^2,$$

where k is the number of clusters, n_i is the number of observations in cluster i , m_i is the centroid of cluster i , m is the overall mean of the sample data, and $\|m_i - m\|$ is the L^2 norm (Euclidean distance) between the two vectors.

The overall within-cluster variance SS_W is defined as

$$SS_W = \sum_{i=1}^k \sum_{x \in c_i} \|x - m_i\|^2,$$

where k is the number of clusters, x is a data point, c_i is the i th cluster, m_i is the centroid of cluster i , and $\|x - m_i\|$ is the L^2 norm (Euclidean distance) between the two vectors.

Well-defined clusters have a large between-cluster variance (SS_B) and a small within-cluster variance (SS_W). The larger the VRC_k ratio, the better the data partition. To determine the optimal number of clusters, maximize VRC_k with respect to k . The optimal number of clusters is the solution with the highest Calinski-Harabasz index value.

The Calinski-Harabasz criterion is best suited for k -means clustering solutions with squared Euclidean distances.

Property Attributes (MATLAB)

candexch

D-optimal design from candidate set using row exchanges

Syntax

```
rlist = candexch(C,nrows)
rlist = candexch(C,nrows,Name,Value)
```

Description

`rlist = candexch(C,nrows)` uses a row-exchange algorithm to select a *D*-optimal design from the candidate set *C*.

`rlist = candexch(C,nrows,Name,Value)` generates a *D*-optimal design with additional options specified by one or more *Name, Value* pair arguments.

Input Arguments

C

N-by-*P* matrix containing the values of *P* model terms at each of *N* points.

Default:

nrows

The desired number of rows in the design.

Name-Value Pair Arguments

Specify optional comma-separated pairs of *Name, Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside quotes. You can specify several name and value pair arguments in any order as *Name1, Value1, . . . , NameN, ValueN*.

display

When 'on', displays iteration number. Disable the display by setting to 'off'.

Default: 'on', except when the `UseParallel` option is `true`

init

nrows-by-*P* matrix giving an initial design.

Default: A random subset of the rows of *C*

maxiter

Maximum number of iterations, a positive integer.

Default: 10

options

A structure that specifies whether to run in parallel, and specifies the random stream or streams. This option requires Parallel Computing Toolbox.

Create the options structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
- `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `candexch` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
 - `UseParallel` is `true`
 - `UseSubstreams` is `false`

In that case, use a cell array the same size as the Parallel pool.

Default: []

start

An `nobs-by-p` matrix of factor settings, specifying a set of `nobs` fixed design points to include in the design. `candexch` finds `nrows` additional rows to add to the `start` design. The parameter provides the same functionality as the `daugment` function, using a row-exchange algorithm rather than a coordinate-exchange algorithm.

Default: []

tries

Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first.

Default: 1

Output Arguments**rlist**

Vector of length `nrows` listing the selected rows.

Examples

This example shows how to generate a *D*-optimal design when there is a restriction on the candidate set, so the `rowexch` function isn't appropriate.

```
F = (fullfact([5 5 5])-1)/4; % factor settings in unit cube
T = sum(F,2)<=1.51;        % find rows matching a restriction
F = F(T,:);               % take only those rows
C = [ones(size(F,1),1) F F.^2];
```

```

                                % compute model terms including
                                % a constant and all squared terms
R = candexch(C,12);             % find a D-optimal 12-point subset
X = F(R,:);                     % get factor settings

```

Algorithms

candexch selects a starting design X at random, and uses a row-exchange algorithm to iteratively replace rows of X by rows of C in an attempt to improve the determinant of $X' * X$.

Alternatives

The rowexch function also generates D -optimal designs using a row-exchange algorithm, but it automatically generates a candidate set that is appropriate for a specified model. The daugment function augments a set of fixed design points using a coordinate-exchange algorithm; the 'start' parameter provides the same functionality using the row exchange algorithm.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced before R2006a

candgen

Candidate set generation

Syntax

```
dC = candgen(nfactors, 'model')
[dC, C] = candgen(nfactors, 'model')
[...] = candgen(nfactors, 'model', 'Name', value)
```

Description

`dC = candgen(nfactors, 'model')` generates a candidate set `dC` of treatments appropriate for estimating the parameters in the `model` with `nfactors` factors. `dC` has `nfactors` columns and one row for each candidate treatment. `model` is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

Alternatively, `model` can be a matrix specifying polynomial terms of arbitrary order. In this case, `model` should have one column for each factor and one row for each term in the model. The entries in any row of `model` are powers for the factors in the columns. For example, if a model has factors `X1`, `X2`, and `X3`, then a row `[0 1 2]` in `model` specifies the term $(X1.^0) .* (X2.^1) .* (X3.^2)$. A row of all zeros in `model` specifies a constant term, which can be omitted.

`[dC, C] = candgen(nfactors, 'model')` also returns the design matrix `C` evaluated at the treatments in `dC`. The order of the columns of `C` for a full quadratic model with n terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ..., n
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n - 1$, n)
- 4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Pass `C` to `candexch` to generate a D -optimal design using a coordinate-exchange algorithm.

`[...] = candgen(nfactors, 'model', 'Name', value)` specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify `Name` inside single quotes.

Name	Value
bounds	Lower and upper bounds for each factor, specified as a 2-by- <code>nfactors</code> matrix. Alternatively, this value can be a cell array containing <code>nfactors</code> elements, each element specifying the vector of allowable values for the corresponding factor.

Name	Value
categorical	Indices of categorical predictors.
levels	Vector of number of levels for each factor.

Note The `rowexch` function automatically generates a candidate set using `candgen`, and then creates a D -optimal design from that candidate set using `candexch`. Call `candexch` separately to specify your own candidate set to the row-exchange algorithm.

Examples

The following example uses `rowexch` to generate a five-run design for a two-factor pure quadratic model using a candidate set that is produced internally:

```
dRE1 = rowexch(2,5,'purequadratic','tries',10)
dRE1 =
    -1     1
     0     0
     1    -1
     1     0
     1     1
```

The same thing can be done using `candgen` and `candexch` in sequence:

```
[dC,C] = candgen(2,'purequadratic') % Candidate set, C
dC =
    -1    -1
     0    -1
     1    -1
    -1     0
     0     0
     1     0
    -1     1
     0     1
     1     1
C =
     1    -1    -1     1     1
     1     0    -1     0     1
     1     1    -1     1     1
     1    -1     0     1     0
     1     0     0     0     0
     1     1     0     1     0
     1    -1     1     1     1
     1     0     1     0     1
     1     1     1     1     1
treatments = candexch(C,5,'tries',10) % Find D-opt subset
treatments =
     2
     1
     7
     3
     4
dRE2 = dC(treatments,:) % Display design
dRE2 =
     0    -1
```

```
-1 -1  
-1 1  
1 -1  
-1 0
```

canoncorr

Canonical correlation

Syntax

```
[A,B] = canoncorr(X,Y)
[A,B,r] = canoncorr(X,Y)
[A,B,r,U,V] = canoncorr(X,Y)
[A,B,r,U,V,stats] = canoncorr(X,Y)
```

Description

`[A,B] = canoncorr(X,Y)` computes the sample canonical coefficients for the data matrices `X` and `Y`.

`[A,B,r] = canoncorr(X,Y)` also returns `r`, a vector of the sample canonical correlations.

`[A,B,r,U,V] = canoncorr(X,Y)` also returns `U` and `V`, matrices of the canonical scores for `X` and `Y`, respectively.

`[A,B,r,U,V,stats] = canoncorr(X,Y)` also returns `stats`, a structure containing information related to testing the sequence of hypotheses that the remaining correlations are all zero.

Examples

Compute Sample Canonical Correlation

Perform canonical correlation analysis for a sample data set.

The data set `carbig` contains measurements for 406 cars from the years 1970 to 1982.

Load the sample data.

```
load carbig;
data = [Displacement Horsepower Weight Acceleration MPG];
```

Define `X` as the matrix of displacement, horsepower, and weight observations, and `Y` as the matrix of acceleration and MPG observations. Omit rows with insufficient data.

```
nans = sum(isnan(data),2) > 0;
X = data(~nans,1:3);
Y = data(~nans,4:5);
```

Compute the sample canonical correlation.

```
[A,B,r,U,V] = canoncorr(X,Y);
```

View the output of `A` to determine the linear combinations of displacement, horsepower, and weight that make up the canonical variables of `X`.

`A`

```
A = 3×2
    0.0025    0.0048
    0.0202    0.0409
   -0.0000   -0.0027
```

$A(3,1)$ is displayed as -0.000 because it is very small. Display $A(3,1)$ separately.

```
A(3,1)
ans = -2.4737e-05
```

The first canonical variable of X is $u1 = 0.0025*Disp + 0.0202*HP - 0.000025*Wgt.$

The second canonical variable of X is $u2 = 0.0048*Disp + 0.0409*HP - 0.0027*Wgt.$

View the output of B to determine the linear combinations of acceleration and MPG that make up the canonical variables of Y.

```
B
B = 2×2
   -0.1666   -0.3637
   -0.0916    0.1078
```

The first canonical variable of Y is $v1 = -0.1666*Acce1 - 0.0916*MPG.$

The second canonical variable of Y is $v2 = -0.3637*Acce1 + 0.1078*MPG.$

Plot the scores of the canonical variables of X and Y against each other.

```
t = tiledlayout(2,2);
title(t,'Canonical Scores of X vs Canonical Scores of Y')
xlabel(t,'Canonical Variables of X')
ylabel(t,'Canonical Variables of Y')
t.TileSpacing = 'compact';

nexttile
plot(U(:,1),V(:,1),'.')
xlabel('u1')
ylabel('v1')

nexttile
plot(U(:,2),V(:,1),'.')
xlabel('u2')
ylabel('v1')

nexttile
plot(U(:,1),V(:,2),'.')
xlabel('u1')
ylabel('v2')

nexttile
plot(U(:,2),V(:,2),'.')
xlabel('u2')
ylabel('v2')
```

The pairs of canonical variables $\{u_i, v_i\}$ are ordered from the strongest to weakest correlation, with all other pairs independent.

Return the correlation coefficient of the variables u1 and v1.

`r(1)`

`ans = 0.8782`

Input Arguments

X — Input matrix

matrix

Input matrix, specified as an n -by- d_1 matrix. The rows of X correspond to observations, and the columns correspond to variables.

Data Types: single | double

Y — Input matrix

matrix

Input matrix, specified as an n -by- d_2 matrix where X is an n -by- d_1 matrix. The rows of Y correspond to observations, and the columns correspond to variables.

Data Types: single | double

Output Arguments

A — Sample canonical coefficients for X variables

matrix

Sample canonical coefficients for the variables in X , returned as a d_1 -by- d matrix, where $d = \min(\text{rank}(X), \text{rank}(Y))$.

The j th column of A contains the linear combination of variables that makes up the j th canonical variable for X .

If X is less than full rank, `canoncorr` gives a warning and returns zeros in the rows of A corresponding to dependent columns of X .

B — Sample canonical coefficients for Y variables

matrix

Sample canonical coefficients for the variables in Y , returned as a d_2 -by- d matrix, where $d = \min(\text{rank}(X), \text{rank}(Y))$.

The j th column of B contains the linear combination of variables that makes up the j th canonical variable for Y .

If Y is less than full rank, `canoncorr` gives a warning and returns zeros in the rows of B corresponding to dependent columns of Y .

r — Sample canonical correlations

vector

Sample canonical correlations, returned as a 1-by- d vector, where $d = \min(\text{rank}(X), \text{rank}(Y))$.

The j th element of r is the correlation between the j th columns of U and V .

U — Canonical scores for the X variables

matrix

Canonical scores for the variables in X , returned as an n -by- d matrix, where X is an n -by- d_1 matrix and $d = \min(\text{rank}(X), \text{rank}(Y))$.

V — Canonical scores for the Y variables

matrix

Canonical scores for the variables in Y , returned as an n -by- d matrix, where Y is an n -by- d_2 matrix and $d = \min(\text{rank}(X), \text{rank}(Y))$.

stats — Hypothesis test information

structure

Hypothesis test information, returned as a structure. This information relates to the sequence of d null hypotheses $H_0^{(k)}$ that the $(k+1)$ st through d th correlations are all zero for $k=1, \dots, d-1$, and $d = \min(\text{rank}(X), \text{rank}(Y))$.

The fields of `stats` are 1-by- d vectors with elements corresponding to the values of k .

Field	Description
Wilks	Wilks' lambda (likelihood ratio) statistic
df1	Degrees of freedom for the chi-squared statistic, and the numerator degrees of freedom for the F statistic
df2	Denominator degrees of freedom for the F statistic
F	Rao's approximate F statistic for $H_0^{(k)}$
pF	Right-tail significance level for F
chisq	Bartlett's approximate chi-squared statistic for $H_0^{(k)}$ with Lawley's modification
pChisq	Right-tail significance level for chisq

stats has two other fields (dfe and p), which are equal to df1 and pChisq, respectively, and exist for historical reasons.

Data Types: struct

More About

Canonical Correlation Analysis

The canonical scores of the data matrices X and Y are defined as

$$U_i = Xa_i$$

$$V_i = Yb_i$$

where a_i and b_i maximize the Pearson correlation coefficient $\rho(U_i, V_i)$ subject to being uncorrelated to all previous canonical scores and scaled so that U_i and V_i have zero mean and unit variance.

The canonical coefficients of X and Y are the matrices A and B with columns a_i and b_i , respectively.

The canonical variables of X and Y are the linear combinations of the columns of X and Y given by the canonical coefficients in A and B respectively.

The canonical correlations are the values $\rho(U_i, V_i)$ measuring the correlation of each pair of canonical variables of X and Y .

Algorithms

canoncorr computes A , B , and r using qr and svd. canoncorr computes U and V as $U = (X - \text{mean}(X)) * A$ and $V = (Y - \text{mean}(Y)) * B$.

capability

Process capability indices

Syntax

```
S = capability(data,specs)
```

Description

`S = capability(data,specs)` estimates capability indices for measurements in `data` given the specifications in `specs`. `data` can be either a vector or a matrix of measurements. If `data` is a matrix, indices are computed for the columns. `specs` can be either a two-element vector of the form `[L,U]` containing lower and upper specification limits, or (if `data` is a matrix) a two-row matrix with the same number of columns as `data`. If there is no lower bound, use `-Inf` as the first element of `specs`. If there is no upper bound, use `Inf` as the second element of `specs`.

The output `S` is a structure with the following fields:

- `mu` — Sample mean
- `sigma` — Sample standard deviation
- `P` — Estimated probability of being within limits
- `Pl` — Estimated probability of being below `L`
- `Pu` — Estimated probability of being above `U`
- `Cp` — $(U-L)/(6*\sigma)$
- `Cpl` — $(\mu-L)/(3.*\sigma)$
- `Cpu` — $(U-\mu)/(3.*\sigma)$
- `Cpk` — $\min(C_{pl},C_{pu})$

Indices are computed under the assumption that data values are independent samples from a normal population with constant mean and variance.

Indices divide a “specification width” (between specification limits) by a “process width” (between control limits). Higher ratios indicate a process with fewer measurements outside of specification.

Examples

Compute Capability Indices

Simulate a sample from a process with a mean of 3 and a standard deviation of 0.005.

```
rng default; % for reproducibility
data = normrnd(3,0.005,100,1);
```

Compute capability indices if the process has an upper specification limit of 3.01 and a lower specification limit of 2.99.

```
S = capability(data,[2.99 3.01])
```

```
S = struct with fields:
  mu: 3.0006
  sigma: 0.0058
  P: 0.9129
  Pl: 0.0339
  Pu: 0.0532
  Cp: 0.5735
  Cpl: 0.6088
  Cpu: 0.5382
  Cpk: 0.5382
```

Visualize the specification and process widths.

```
capaplot(data,[2.99 3.01]);
grid on
```

capaplot | histfit

Introduced in R2006b

capaplot

Process capability plot

Syntax

```
p = capaplot(data,specs)
[p,h] = capaplot(data,specs)
```

Description

`p = capaplot(data,specs)` estimates the mean and variance for the observations in input vector `data`, and plots the pdf of the resulting T distribution. The observations in `data` are assumed to be normally distributed. The output, `p`, is the probability that a new observation from the estimated distribution will fall within the range specified by the two-element vector `specs`. The portion of the distribution between the lower and upper bounds specified in `specs` is shaded in the plot.

`[p,h] = capaplot(data,specs)` additionally returns handles to the plot elements in `h`.

`capaplot` treats NaN values in `data` as missing, and ignores them.

Examples

Create a Process Capability Plot

Randomly generate sample data from a normal process with a mean of 3 and a standard deviation of 0.005.

```
rng default; % For reproducibility
data = normrnd(3,0.005,100,1);
```

Compute capability indices if the process has an upper specification limit of 3.01 and a lower specification limit of 2.99.

```
S = capability(data,[2.99 3.01])
```

```
S = struct with fields:
    mu: 3.0006
    sigma: 0.0058
    P: 0.9129
    Pl: 0.0339
    Pu: 0.0532
    Cp: 0.5735
    Cpl: 0.6088
    Cpu: 0.5382
    Cpk: 0.5382
```

Visualize the specification and process widths.

```
capaplot(data,[2.99 3.01]);
grid on
```

capability | histfit

Introduced before R2006a

caseread

Read case names from file

Syntax

```
names = caseread(filename)
names = caseread
```

Description

`names = caseread(filename)` reads the contents of `filename` and returns a character array `names`. The `caseread` function treats each line of the file as a separate case name. Specify `filename` as either the name of a file in the current folder or the complete path name of a file.

`filename` can have one of the following file extensions:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsm`, or `.xlsx` for Excel spreadsheet files

`names = caseread` opens the Select File to Open dialog box so that you can interactively select the file to read.

Examples

Write and Read Case Names

Create a character array of case names representing months.

```
months = char('January','February', ...
             'March','April','May');
```

Write the names to a file named `months.dat`. View the contents of the file by using the `type` function.

```
casewrite(months,'months.dat')
type months.dat
```

```
January
February
March
April
May
```

Read the names in the `months.dat` file.

```
names = caseread('months.dat')
```

```
names = 5x8 char array
    'January '
    'February'
    'March   '
```

```
'April'
'May'
```

Input Arguments

filename — Name of file to read

character vector | string scalar

Name of the file to read, specified as a character vector or string scalar.

Depending on the location of the file, `filename` has one of these forms.

Location of File	Form
Current folder or folder on the MATLAB path	Specify the name of the file in <code>filename</code> . Example: <code>'myTextFile.csv'</code>
Folder that is not the current folder or a folder on the MATLAB path	Specify the full or relative path name in <code>filename</code> . Example: <code>'C:\myFolder\myTextFile.csv'</code>

Example: `'months.dat'`

Data Types: `char` | `string`

Alternative Functionality

Instead of using `casewrite` and `caseread` with character arrays, consider using `writecell` and `readcell` with cell arrays. For example:

```
months = {'January'; 'February'; 'March'; 'April'; 'May'};
writecell(months, 'months.dat')
names = readcell('months.dat')
```

`names =`

5×1 cell array

```
{'January' }
{'February'}
{'March' }
{'April' }
{'May' }
```

See Also

`casewrite` | `gname` | `readcell` | `readtable` | `writecell` | `writetable`

Introduced before R2006a

casewrite

Write case names to file

Syntax

```
casewrite(strmat,filename)
casewrite(strmat)
```

Description

`casewrite(strmat,filename)` writes the contents of the character array or string column vector `strmat` to a file `filename`. Each row of `strmat` represents one case name, and `casewrite` writes each name to a separate line in `filename`. Specify `filename` as either a file name (to write the file to the current folder) or a complete path name (to write the file to a different folder).

`filename` can have one of the following file extensions:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xslm`, or `.xlsx` for Excel spreadsheet files

`casewrite(strmat)` opens the Select File to Write dialog box so that you can interactively specify the file to write.

Examples

Write and Read Case Names

Create a character array of case names representing months.

```
months = char('January','February', ...
             'March','April','May');
```

Write the names to a file named `months.dat`. View the contents of the file by using the `type` function.

```
casewrite(months,'months.dat')
type months.dat
```

```
January
February
March
April
May
```

Read the names in the `months.dat` file.

```
names = caseread('months.dat')
```

```
names = 5x8 char array
    'January '
    'February'
```

```
'March'
'April'
'May'
```

Input Arguments

strmat — Case names

character array | string column vector

Case names, specified as a character array or string column vector. Each row of `strmat` corresponds to a case name and becomes a line in `filename`.

Data Types: `char` | `string`

filename — Name of file to write

character vector | string scalar

Name of the file to write, specified as a character vector or string scalar.

Depending on the location you are writing to, `filename` has one of these forms.

Location of File	Form
Current folder	Specify the name of the file in <code>filename</code> . Example: <code>'myTextFile.csv'</code>
Folder that is different from the current folder	Specify the full or relative path name in <code>filename</code> . Example: <code>'C:\myFolder\myTextFile.csv'</code>

Example: `'months.dat'`

Data Types: `char` | `string`

Alternative Functionality

Instead of using `casewrite` and `caseread` with character arrays, consider using `writecell` and `readcell` with cell arrays. For example:

```
months = {'January'; 'February'; 'March'; 'April'; 'May'};
writecell(months, 'months.dat')
names = readcell('months.dat')
```

`names =`

5×1 cell array

```
{'January' }
{'February'}
{'March' }
{'April' }
{'May' }
```

Introduced before R2006a

DaviesBouldinEvaluation

Package: clustering.evaluation

Superclasses: clustering.evaluation.ClusterCriterion

Davies-Bouldin criterion clustering evaluation object

Description

DaviesBouldinEvaluation is an object consisting of sample data, clustering data, and Davies-Bouldin criterion values used to evaluate the optimal number of clusters. Create a Davies-Bouldin criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x, clust, 'DaviesBouldin')` creates a Davies-Bouldin criterion clustering evaluation object.

`eva = evalclusters(x, clust, 'DaviesBouldin', Name, Value)` creates a Davies-Bouldin criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in <code>x</code> using the <code>kmeans</code> clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in <code>x</code> using the <code>clusterdata</code> agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in <code>x</code> using the <code>gmdistribution</code> Gaussian mixture distribution algorithm, with 'SharedCov' set to <code>true</code> and 'Replicates' set to 5.

If `criterion` is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form `C = clustfun(DATA, K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric n -by- K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `criterion` is `'CalinskiHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a n -by- K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the j th clustering solution.

Data Types: `single` | `double` | `char` | `string` | `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'KList', [1:5]` specifies to test 1, 2, 3, 4, and 5 clusters to find the optimal number.

KList — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name or a function handle. When `criterion` is `'gap'`, `clust` must be a character vector, a string scalar, or a function handle, and you must specify `KList`.

Example: `'KList', [1:6]`

Data Types: `single` | `double`

Properties

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

CriterionValues

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

NumObservations

Number of observations in the data matrix `X`, minus the number of missing (NaN) values in `X`, stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

X

Data used for clustering, stored as a matrix of numerical values.

Methods**Inherited Methods**

<code>addK</code>	Evaluate additional numbers of clusters
<code>plot</code>	Plot clustering evaluation object criterion values
<code>compact</code>	Compact clustering evaluation object

Examples**Evaluate the Clustering Solution Using Davies-Bouldin Criterion**

Evaluate the optimal number of clusters using the Davies-Bouldin clustering evaluation criterion.

Generate sample data containing random numbers from three multivariate distributions with different parameter values.

```
rng('default'); % For reproducibility
mu1 = [2 2];
sigma1 = [0.9 -0.0255; -0.0255 0.9];

mu2 = [5 5];
sigma2 = [0.5 0 ; 0 0.3];

mu3 = [-2, -2];
sigma3 = [1 0 ; 0 0.9];

N = 200;

X = [mvnrnd(mu1,sigma1,N);...
```

```
mvnrnd(mu2,sigma2,N);...
mvnrnd(mu3,sigma3,N)];
```

Evaluate the optimal number of clusters using the Davies-Bouldin criterion. Cluster the data using `kmeans`.

```
E = evalclusters(X,'kmeans','DaviesBouldin','klist',[1:6])
```

```
E =
```

```
DaviesBouldinEvaluation with properties:
```

```
NumObservations: 600
InspectedK: [1 2 3 4 5 6]
CriterionValues: [NaN 0.4663 0.4454 0.8316 1.0444 0.9236]
OptimalK: 3
```

The `OptimalK` value indicates that, based on the Davies-Bouldin criterion, the optimal number of clusters is three.

Plot the Davies-Bouldin criterion values for each number of clusters tested.

```
figure;
plot(E)
```

The plot shows that the lowest Davies-Bouldin value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to visually examine the suggested clusters.

```
figure;
gscatter(X(:,1),X(:,2),E.OptimalY,'rbg','xod')
```

The plot shows three distinct clusters within the data: Cluster 1 is in the lower-left corner, cluster 2 is in the upper-right corner, and cluster 3 is near the center of the plot.

More About

Davies-Bouldin Criterion

The Davies-Bouldin criterion is based on a ratio of within-cluster and between-cluster distances. The Davies-Bouldin index is defined as

$$DB = \frac{1}{k} \sum_{i=1}^k \max_{j \neq i} \{D_{i,j}\},$$

where $D_{i,j}$ is the within-to-between cluster distance ratio for the i th and j th clusters. In mathematical terms,

$$D_{i,j} = \frac{(\bar{d}_i + \bar{d}_j)}{d_{i,j}}.$$

\bar{d}_i is the average distance between each point in the i th cluster and the centroid of the i th cluster. \bar{d}_j is the average distance between each point in the j th cluster and the centroid of the j th cluster. $d_{i,j}$ is the Euclidean distance between the centroids of the i th and j th clusters.

The maximum value of $D_{i,j}$ represents the worst-case within-to-between cluster ratio for cluster i . The optimal clustering solution has the smallest Davies-Bouldin index value.

[Property Attributes \(MATLAB\)](#)

cat

Class: dataset

(Not Recommended) Concatenate dataset arrays

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
ds = cat(dim, ds1, ds2, ...)
```

Description

`ds = cat(dim, ds1, ds2, ...)` concatenates the dataset arrays `ds1`, `ds2`, ... along dimension `dim` by calling the `dataset/horzcat` or `dataset/vertcat` method. `dim` must be 1 or 2.

See Also

`horzcat` | `vertcat`

cdf

Cumulative distribution function for Gaussian mixture distribution

Syntax

```
y = cdf(gm,X)
```

Description

`y = cdf(gm,X)` returns the cumulative distribution function (cdf) of the Gaussian mixture distribution `gm`, evaluated at the values in `X`.

Examples

Compute cdf Values

Create a `gmdistribution` object and compute its cdf values.

Define the distribution parameters (means and covariances) of a two-component bivariate Gaussian mixture distribution.

```
mu = [1 2;-3 -5];  
sigma = [1 1]; % shared diagonal covariance matrix
```

Create a `gmdistribution` object by using the `gmdistribution` function. By default, the function creates an equal proportion mixture.

```
gm = gmdistribution(mu,sigma)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
```

```
Component 1:
```

```
Mixing proportion: 0.500000
```

```
Mean:      1      2
```

```
Component 2:
```

```
Mixing proportion: 0.500000
```

```
Mean:     -3     -5
```

Compute the cdf values of `gm`.

```
X = [0 0;1 2;3 3;5 3];
```

```
cdf(gm,X)
```

```
ans = 4×1
```

```
    0.5011
```

```
    0.6250
```

```
    0.9111
```

```
    0.9207
```

Plot cdf

Create a `gmdistribution` object and plot its cdf.

Define the distribution parameters (means, covariances, and mixing proportions) of two bivariate Gaussian mixture components.

```
p = [0.4 0.6];           % Mixing proportions
mu = [1 2;-3 -5];      % Means
sigma = cat(3,[2 .5],[1 1]) % Covariances 1-by-2-by-2 array

sigma =
sigma(:,:,1) =

    2.0000    0.5000

sigma(:,:,2) =

    1    1
```

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1,:,i)` contains the diagonal elements of the covariance matrix of component `i`.

Create a `gmdistribution` object by using the `gmdistribution` function.

```
gm = gmdistribution(mu,sigma,p)

gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.400000
Mean:    1    2

Component 2:
Mixing proportion: 0.600000
Mean:   -3   -5
```

Plot the cdf of the Gaussian mixture distribution by using `fsurf`.

```
fsurf(@(x,y)reshape(cdf(gm,[x(:) y(:)]),size(x)),-10 10)
```

Input Arguments

gm — Gaussian mixture distribution

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

X — Values at which to evaluate cdf

n -by- m numeric matrix

Values at which to evaluate the cdf, specified as an n -by- m numeric matrix, where n is the number of observations and m is the number of variables in each observation.

Data Types: `single` | `double`

Output Arguments

y — cdf values

n -by-1 numeric vector

cdf values of the Gaussian mixture distribution `gm`, evaluated at `X`, returned as an n -by-1 numeric vector, where n is the number of observations in `X`.

ccdesign

Central composite design

Syntax

```
dCC = ccdesign(n)
[dCC,blocks] = ccdesign(n)
[...] = ccdesign(n,'Name',value)
```

Description

`dCC = ccdesign(n)` generates a central composite design for n factors. n must be an integer 2 or larger. The output matrix `dCC` is m -by- n , where m is the number of runs in the design. Each row represents one run, with settings for all factors represented in the columns. Factor values are normalized so that the cube points take values between -1 and 1.

`[dCC,blocks] = ccdesign(n)` requests a blocked design. The output `blocks` is an m -by-1 vector of block numbers for each run. Blocks indicate runs that are to be measured under similar conditions to minimize the effect of inter-block differences on the parameter estimates.

`[...] = ccdesign(n,'Name',value)` specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify *Name* in single quotes.

Parameter	Description	Values	Value Description
center	Number of center points.	Integer	Number of center points to include.
		'uniform'	Select number of center points to give uniform precision.
		'orthogonal'	Select number of center points to give an orthogonal design. This is the default.
fraction	Fraction of full-factorial cube, expressed as an exponent of 1/2.	0	Whole design. Default when $n \leq 4$.
		1	1/2 fraction. Default when $4 < n \leq 7$ or $n > 11$.
		2	1/4 fraction. Default when $7 < n \leq 9$.
		3	1/8 fraction. Default when $n = 10$.
		4	1/16 fraction. Default when $n = 11$.
type	Type of CCD.	'circumscribed'	Circumscribed (CCC). This is the default.

Parameter	Description	Values	Value Description
		'inscribed'	Inscribed (CCI).
		'faced'	Faced (CCF).
blocksize	Maximum number of points per block.	Integer	The default is Inf.

Examples

Two-Factor Central Composite Design

Create a 2-factor central composite design.

```
dCC = ccdesign(2, 'type', 'circumscribed')
```

```
dCC = 16×2
```

```
-1.0000 -1.0000
-1.0000  1.0000
 1.0000 -1.0000
 1.0000  1.0000
-1.4142     0
 1.4142     0
     0 -1.4142
     0  1.4142
     0     0
     0     0
     :
```

The center point is run 8 times to reduce the correlations among the coefficient estimates.

Visualize the design.

```
plot(dCC(:,1),dCC(:,2), 'ro', 'MarkerFaceColor', 'b')
X = [1 -1 -1 -1; 1 1 1 -1];
Y = [-1 -1 1 -1; 1 -1 1 1];
line(X,Y, 'Color', 'b')
axis square equal
```

`bbdesign`

Introduced before R2006a

cdf

Package: prob

Cumulative distribution function

Syntax

```
y = cdf('name', x, A)
y = cdf('name', x, A, B)
y = cdf('name', x, A, B, C)
y = cdf('name', x, A, B, C, D)

y = cdf(pd, x)

y = cdf(____, 'upper')
```

Description

`y = cdf('name', x, A)` returns the cumulative distribution function (cdf) for the one-parameter distribution family specified by 'name' and the distribution parameter A, evaluated at the values in x.

`y = cdf('name', x, A, B)` returns the cdf for the two-parameter distribution family specified by 'name' and the distribution parameters A and B, evaluated at the values in x.

`y = cdf('name', x, A, B, C)` returns the cdf for the three-parameter distribution family specified by 'name' and the distribution parameters A, B, and C, evaluated at the values in x.

`y = cdf('name', x, A, B, C, D)` returns the cdf for the four-parameter distribution family specified by 'name' and the distribution parameters A, B, C, and D, evaluated at the values in x.

`y = cdf(pd, x)` returns the cdf of the probability distribution object pd, evaluated at the values in x.

`y = cdf(____, 'upper')` returns the complement of the cdf using an algorithm that more accurately computes the extreme upper-tail probabilities. 'upper' can follow any of the input arguments in the previous syntaxes.

Examples

Compute Normal Distribution cdf

Create a standard normal distribution object with the mean, μ , equal to 0 and the standard deviation, σ , equal to 1.

```
mu = 0;
sigma = 1;
pd = makedist('Normal', 'mu', mu, 'sigma', sigma);
```

Define the input vector x to contain the values at which to calculate the cdf.

```
x = [-2, -1, 0, 1, 2];
```

Compute the cdf values for the standard normal distribution at the values in x .

```
y = cdf(pd,x)
```

```
y = 1x5
```

```
    0.0228    0.1587    0.5000    0.8413    0.9772
```

Each value in y corresponds to a value in the input vector x . For example, at the value x equal to 1, the corresponding cdf value y is equal to 0.8413.

Alternatively, you can compute the same cdf values without creating a probability distribution object. Use the `cdf` function, and specify a standard normal distribution using the same parameter values for μ and σ .

```
y2 = cdf('Normal',x,mu,sigma)
```

```
y2 = 1x5
```

```
    0.0228    0.1587    0.5000    0.8413    0.9772
```

The cdf values are the same as those computed using the probability distribution object.

Compute Poisson Distribution cdf

Create a Poisson distribution object with the rate parameter, λ , equal to 2.

```
lambda = 2;
```

```
pd = makedist('Poisson','lambda',lambda);
```

Define the input vector x to contain the values at which to calculate the cdf.

```
x = [0,1,2,3,4];
```

Compute the cdf values for the Poisson distribution at the values in x .

```
y = cdf(pd,x)
```

```
y = 1x5
```

```
    0.1353    0.4060    0.6767    0.8571    0.9473
```

Each value in y corresponds to a value in the input vector x . For example, at the value x equal to 3, the corresponding cdf value y is equal to 0.8571.

Alternatively, you can compute the same cdf values without creating a probability distribution object. Use the `cdf` function, and specify a Poisson distribution using the same value for the rate parameter, λ .

```
y2 = cdf('Poisson',x,lambda)
```

```
y2 = 1x5
    0.1353    0.4060    0.6767    0.8571    0.9473
```

The cdf values are the same as those computed using the probability distribution object.

Plot Standard Normal Distribution cdf

Create a standard normal distribution object.

```
pd = makedist('Normal')
pd =
  NormalDistribution

  Normal distribution
      mu = 0
      sigma = 1
```

Specify the x values and compute the cdf.

```
x = -3:.1:3;
p = cdf(pd,x);
```

Plot the cdf of the standard normal distribution.

```
plot(x,p)
```

Plot Gamma Distribution cdf

Create three gamma distribution objects. The first uses the default parameter values. The second specifies $a = 1$ and $b = 2$. The third specifies $a = 2$ and $b = 1$.

```
pd_gamma = makedist('Gamma')
```

```
pd_gamma =  
GammaDistribution  
  
Gamma distribution  
a = 1  
b = 1
```

```
pd_12 = makedist('Gamma','a',1,'b',2)
```

```
pd_12 =  
GammaDistribution  
  
Gamma distribution  
a = 1  
b = 2
```

```
pd_21 = makedist('Gamma','a',2,'b',1)
```

```
pd_21 =  
    GammaDistribution  
  
    Gamma distribution  
    a = 2  
    b = 1
```

Specify the x values and compute the cdf for each distribution.

```
x = 0:.1:5;  
cdf_gamma = cdf(pd_gamma,x);  
cdf_12 = cdf(pd_12,x);  
cdf_21 = cdf(pd_21,x);
```

Create a plot to visualize how the cdf of the gamma distribution changes when you specify different values for the shape parameters a and b.

```
figure;  
J = plot(x,cdf_gamma);  
hold on;  
K = plot(x,cdf_12,'r--');  
L = plot(x,cdf_21,'k-.');  
set(J,'LineWidth',2);  
set(K,'LineWidth',2);  
legend([J K L], 'a = 1, b = 1', 'a = 1, b = 2', 'a = 2, b = 1', 'Location', 'southeast');  
hold off;
```

Fit Pareto Tails to t Distribution and Compute the cdf

Fit Pareto tails to a t distribution at cumulative probabilities 0.1 and 0.9.

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
```

```
p = 2×1
    0.1000
    0.9000
```

```
q = 2×1
   -1.8487
    2.0766
```

Compute the cdf at the values in q.

```
cdf(obj,q)
ans = 2×1
    0.1000
    0.9000
```

Input Arguments**'name' — Probability distribution name**

character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

Example: 'Normal'

x — Values at which to evaluate cdf

scalar value | array of scalar values

Values at which to evaluate the cdf, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Example: [0.1,0.25,0.5,0.75,0.9]

Data Types: single | double

A — First probability distribution parameter

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A, B, C, and D are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

B — Second probability distribution parameter

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A, B, C, and D are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

C — Third probability distribution parameter

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A, B, C, and D are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

D — Fourth probability distribution parameter

scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A, B, C, and D are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.

Function or App	Description
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.
<code>paretotails</code>	Create a piecewise distribution object that has generalized Pareto distributions in the tails.

Output Arguments

y — cdf values

scalar value | array of scalar values

cdf values, returned as a scalar value or an array of scalar values. **y** is the same size as **x** after any necessary scalar expansion. Each element in **y** is the cdf value of the distribution, specified by the corresponding elements in the distribution parameters (A, B, C, and D) or the probability distribution object (**pd**), evaluated at the corresponding element in **x**.

Alternative Functionality

- `cdf` is a generic function that accepts either a distribution by its name 'name' or a probability distribution object `pd`. It is faster to use a distribution-specific function, such as `normcdf` for the normal distribution and `binocdf` for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-13.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument 'name' must be a compile-time constant. For example, to use the normal distribution, include `coder.Constant('Normal')` in the `-args` value of `codegen`.
- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see “Code Generation for Probability Distribution Objects” on page 31-70.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

cdfplot

Empirical cumulative distribution function (cdf) plot

Syntax

```
cdfplot(x)
h = cdfplot(x)
[h,stats] = cdfplot(x)
```

Description

`cdfplot(x)` creates an empirical cumulative distribution function (cdf) plot for the data in `x`. For a value t in `x`, the empirical cdf $F(t)$ is the proportion of the values in `x` less than or equal to t .

`h = cdfplot(x)` returns a handle of the empirical cdf plot line object. Use `h` to query or modify properties of the object after you create it. For a list of properties, see [Line Properties](#).

`[h,stats] = cdfplot(x)` also returns a structure including summary statistics for the data in `x`.

Examples

Compare Empirical cdf to Theoretical cdf

Plot the empirical cdf of a sample data set and compare it to the theoretical cdf of the underlying distribution of the sample data set. In practice, a theoretical cdf can be unknown.

Generate a random sample data set from the extreme value distribution with a location parameter of 0 and a scale parameter of 3.

```
rng('default') % For reproducibility
y = evrnd(0,3,100,1);
```

Plot the empirical cdf of the sample data set and the theoretical cdf on the same figure.

```
cdfplot(y)
hold on
x = linspace(min(y),max(y));
plot(x,evcdf(x,0,3))
legend('Empirical CDF','Theoretical CDF','Location','best')
hold off
```

The plot shows the similarity between the empirical cdf and the theoretical cdf.

Alternatively, you can use the `ecdf` function. The `ecdf` function also plots the 95% confidence intervals estimated by using Greenwood's Formula. For details, see "Greenwood's Formula" on page 32-1147.

```
ecdf(y, 'Bounds', 'on')
hold on
plot(x, ecdf(x, 0, 3))
grid on
title('Empirical CDF')
legend('Empirical CDF', 'Lower Confidence Bound', 'Upper Confidence Bound', 'Theoretical CDF', 'Local')
hold off
```

Test for Standard Normal Distribution

Perform the one-sample Kolmogorov-Smirnov test by using `kstest`. Confirm the test decision by visually comparing the empirical cumulative distribution function (cdf) to the standard normal cdf.

Load the `examgrades` data set. Create a vector containing the first column of the exam grade data.

```
load examgrades
test1 = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector, because `kstest` tests for a standard normal distribution by default.

```
x = (test1-75)/10;
h = kstest(x)
```

```
h = logical
    0
```

The returned value of `h = 0` indicates that `kstest` fails to reject the null hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```

cdfplot(x)
hold on
x_values = linspace(min(x),max(x));
plot(x_values,normcdf(x_values,0,1),'r-')
legend('Empirical CDF','Standard Normal CDF','Location','best')

```

The figure shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

Input Arguments

x — Input data

numeric vector

Input data, specified as a numeric vector.

Data Types: `single` | `double`

Output Arguments

h — Handle of plot line object

chart line object

Handle of the empirical cdf plot line object, returned as a chart line object. Use `h` to query or modify properties of the object after you create it. For a list of properties, see [Line Properties](#).

stats — Summary statistics

structure

Summary statistics for the data in `x`, returned as a structure with the following fields:

Field	Description
<code>min</code>	Minimum value
<code>max</code>	Maximum value
<code>mean</code>	Sample mean
<code>median</code>	Sample median (50th percentile)
<code>std</code>	Sample standard deviation

Tips

- `cdfplot` is useful for examining the distribution of a sample data set. You can overlay a theoretical cdf on the same plot of `cdfplot` to compare the empirical distribution of the sample to the theoretical distribution. For an example, see “Compare Empirical cdf to Theoretical cdf” on page 32-280.
- The `kstest`, `kstest2`, and `lillietest` functions compute test statistics derived from an empirical cdf. `cdfplot` is useful in helping you to understand the output from these functions. For an example, see “Test for Standard Normal Distribution” on page 32-282.

Alternative Functionality

You can use the `ecdf` function to find the empirical cdf values and create an empirical cdf plot. The `ecdf` function enables you to indicate censored data and compute the confidence bounds for the estimated cdf values.

Introduced before R2006a

cell2dataset

(Not Recommended) Convert cell array to dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = cell2dataset(C)
ds = cell2dataset(C,Name,Value)
```

Description

`ds = cell2dataset(C)` converts a cell array to a `dataset` array.

`ds = cell2dataset(C,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

Examples

Convert Cell Array to Dataset Array

Convert a cell array to a dataset array using the default options.

Create a cell array to convert.

```
C = {'Name', 'Gender', 'SystolicBP', 'DiastolicBP';
     'CLARK', 'M', 124, 93;
     'BROWN', 'F', 122, 80;
     'MARTIN', 'M', 130, 92}
```

```
C=4x4 cell array
    {'Name' }    {'Gender' }    {'SystolicBP' }    {'DiastolicBP' }
    {'CLARK' }    {'M' }    {[ 124]}    {[ 93]}
    {'BROWN' }    {'F' }    {[ 122]}    {[ 80]}
    {'MARTIN' }    {'M' }    {[ 130]}    {[ 92]}
```

Convert the cell array to a dataset array.

```
ds = cell2dataset(C)

ds =
    Name          Gender          SystolicBP          DiastolicBP
    {'CLARK' }    {'M' }          124                 93
    {'BROWN' }    {'F' }          122                 80
    {'MARTIN' }    {'M' }          130                 92
```

The first row of `C` become the variable names in the output dataset array, `ds`.

Create a Dataset Array with Multicolumn Variables

Convert a cell array to a dataset array containing multicolumn variables.

Create a cell array to convert.

```
C = {'Name','Gender','SystolicBP','DiastolicBP';
     'CLARK','M',124,93;
     'BROWN','F',122,80;
     'MARTIN','M',130,92}
```

```
C=4x4 cell array
     {'Name' }      {'Gender' }      {'SystolicBP' }      {'DiastolicBP' }
     {'CLARK' }    {'M' }      {[ 124]}      {[ 93]}
     {'BROWN' }    {'F' }      {[ 122]}      {[ 80]}
     {'MARTIN' }   {'M' }      {[ 130]}      {[ 92]}
```

Convert the cell array to a dataset array, combining the systolic and diastolic blood pressure measurements into one variable named `BloodPressure`.

```
ds = cell2dataset(C, 'NumCols', [1,1,2]);
ds.Properties.VarNames{3} = 'BloodPressure';
ds
```

```
ds =
     Name      Gender      BloodPressure
     {'CLARK' }    {'M' }      124      93
     {'BROWN' }    {'F' }      122      80
     {'MARTIN' }   {'M' }      130      92
```

The output dataset array has three observations and three variables.

Input Arguments

C — Input cell array

cell array

Input cell array to convert to a dataset array, specified as an M -by- N cell array. Each column of `C` becomes a variable in the output dataset array, `ds`. By default, `cell2dataset` assumes that the first row of `C` contains variable names.

Data Types: `cell` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'ReadVarNames', false, 'ReadObsNames', true` specifies that the first row of the cell array does not contain variable names, but the first column contains observation names.

ReadVarNames — Indicator for whether or not to read variable names

true (default) | false

Indicator for whether or not to read variable names from the first row of the input cell array, specified as the comma-separated pair consisting of 'ReadVarNames' and either true or false. The default value is true, unless variable names are specified using the name-value pair argument VarNames. When ReadVarNames is false, cell2dataset creates default variable names if you do not provide any.

Example: 'ReadVarNames', false

VarNames — Variable names for output dataset array

string array | cell array of character vectors

Variable names for the output dataset array, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors. You must provide a variable name for each variable in ds. The names must be valid MATLAB identifiers, and must be unique.

Example: 'VarNames', {'myVar1', 'myVar2', 'myVar3'}

ReadObsNames — Indicator for whether or not to read observation names

false (default) | true

Indicator for whether or not to read observation names from the input cell array, specified as the comma-separated pair consisting of 'ReadObsNames' and either true or false. When ReadObsNames has the value true, cell2dataset creates observation names in ds using the first column of C, and sets ds.Properties.DimNames equal to {C{1,1}, 'Variables'}.

Example: 'ReadObsNames', true

ObsNames — Observation names for output dataset array

string array | cell array of character vectors

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a string array or cell array of character vectors. The names do not need to be valid MATLAB identifiers, but they must be unique.

NumCols — Number of columns for each variable

vector of nonnegative integers

Number of columns for each variable in ds, specified as the comma-separated pair consisting of 'NumCols' and a vector of nonnegative integers. When the number of columns for a variable is greater than one, cell2dataset combines multiple columns in C into a single variable in ds. The vector you assign to NumCols must sum to size(C,2), or size(C,1) of ReadObsNames is equal to true.

For example, to convert a cell array with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as 'NumCols', [1,1,3,1,2].

Output Arguments**ds — Output dataset array**

dataset array

Output dataset array, returned by default with a variable for each column of C, an observation for each row of C (except for the first row), and variable names corresponding to the first row of C.

- If you set `ReadVarNames` equal to `false` (or specify `VarNames`), then there is an observation in `ds` for each row of `C`, and `cell2dataset` creates default variable names (or uses the names in `VarNames`).
- If you set `ReadObsNames` equal to `true`, then `cell2dataset` uses the first column of `C` as observation names.
- If you specify `NumCols`, then the number of variables in `ds` is equal to the length of the specified vector of column numbers.

“Dataset Arrays” on page 2-112

Introduced in R2012b

cellstr

Class: dataset

(Not Recommended) Create cell array of character vectors from dataset array

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

B = cellstr(A)
B = cellstr(A, VARS)

Description

B = cellstr(A) returns the contents of the dataset A, converted to a cell array of character vectors. The variables in the dataset must support the conversion and must have compatible sizes.

B = cellstr(A, VARS) returns the contents of the dataset variables specified by VARS. VARS is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

See Also

double | replacedata

chi2cdf

Chi-square cumulative distribution function

Syntax

```
p = chi2cdf(x,nu)
p = chi2cdf(x,nu,'upper')
```

Description

`p = chi2cdf(x,nu)` returns the cumulative distribution function (cdf) of the chi-square distribution with degrees of freedom `nu`, evaluated at the values in `x`.

`p = chi2cdf(x,nu,'upper')` returns the complement of the cdf, evaluated at the values in `x` with degrees of freedom `nu`, using an algorithm that more accurately computes the extreme upper-tail probabilities than subtracting the lower tail value from 1.

Examples

Compute Chi-Square cdf

Compute the probability that an observation from the chi-square distribution with 5 degrees of freedom is in the interval `[0 3]`.

```
p1 = chi2cdf(3,5)
p1 = 0.3000
```

Compute the probability that an observation from the chi-square distributions with degrees of freedom 1 through 5 is in the interval `[0 3]`.

```
p2 = chi2cdf(3,1:5)
p2 = 1×5
    0.9167    0.7769    0.6084    0.4422    0.3000
```

The mean of the chi-square distribution is equal to the degrees of freedom. Compute the probability that an observation is in the interval `[0 nu]` for degrees of freedom 1 through 6.

```
nu = 1:6;
x = nu;
p3 = chi2cdf(x,nu)
p3 = 1×6
    0.6827    0.6321    0.6084    0.5940    0.5841    0.5768
```

As the degrees of freedom increase, the probability that an observation from a chi-square distribution with degrees of freedom `nu` is less than the mean value approaches 0.5.

Complementary cdf (Tail Distribution)

Determine the probability that an observation from the chi-square distribution with 3 degrees of freedom is in on the interval `[100 Inf]`.

```
p1 = 1 - chi2cdf(100,3)
```

```
p1 = 0
```

`chi2cdf(100,3)` is nearly 1, so `p1` becomes 0. Specify `'upper'` so that `chi2cdf` computes the extreme upper-tail probabilities more accurately.

```
p2 = chi2cdf(100,3,'upper')
```

```
p2 = 1.5542e-21
```

Input Arguments

x — Values at which to evaluate cdf

nonnegative scalar value | array of nonnegative scalar values

Values at which to evaluate the cdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2cdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: `[3 4 7 9]`

Data Types: `single` | `double`

nu — Degrees of freedom

positive scalar value | array of positive scalar values

Degrees of freedom for the chi-square distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2cdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: `[9 19 49 99]`

Data Types: `single` | `double`

Output Arguments

p — cdf values

scalar value | array of scalar values

cdf values evaluated at the values in x , returned as a scalar value or an array of scalar values. p is the same size as x and nu after any necessary scalar expansion. Each element in p is the cdf value of the distribution specified by the corresponding element in nu , evaluated at the corresponding element in x .

More About

Chi-Square cdf

The chi-square distribution is a one-parameter family of curves. The parameter ν is the degrees of freedom.

The cdf of the chi-square distribution is

$$p = F(x | \nu) = \int_0^x \frac{t^{(\nu-2)/2} e^{-t/2}}{2^{\nu/2} \Gamma(\nu/2)} dt,$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result p is the probability that a single observation from the chi-square distribution with ν degrees of freedom falls in the interval $[0, x]$.

For more information, see “Chi-Square Distribution” on page B-28.

Alternative Functionality

- `chi2cdf` is a function specific to the chi-square distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `chi2cdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2gof

Chi-square goodness-of-fit test

Syntax

```
h = chi2gof(x)
h = chi2gof(x,Name,Value)
[h,p] = chi2gof(____)
[h,p,stats] = chi2gof(____)
```

Description

`h = chi2gof(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with a mean and variance estimated from `x`, using the chi-square goodness-of-fit test on page 32-299. The alternative hypothesis is that the data does not come from such a distribution. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = chi2gof(x,Name,Value)` returns a test decision for the chi-square goodness-of-fit test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than normal, or change the significance level of the test.

`[h,p] = chi2gof(____)` also returns the p -value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,stats] = chi2gof(____)` also returns the structure `stats`, containing information about the test statistic.

Examples

Test for Normal Distribution

Create a standard normal probability distribution object. Generate a data vector `x` using random numbers from the distribution.

```
pd = makedist('Normal');
rng default; % for reproducibility
x = random(pd,100,1);
```

Test the null hypothesis that the data in `x` comes from a population with a normal distribution.

```
h = chi2gof(x)
h = 0
```

The returned value `h = 0` indicates that `chi2gof` does not reject the null hypothesis at the default 5% significance level.

Test Hypothesis at Different Significance Level

Create a standard normal probability distribution object. Generate a data vector x using random numbers from the distribution.

```
pd = makedist('Normal');
rng default; % for reproducibility
x = random(pd,100,1);
```

Test the null hypothesis that the data in x comes from a population with a normal distribution at the 1% significance level.

```
[h,p] = chi2gof(x,'Alpha',0.01)
```

```
h = 0
```

```
p = 0.3775
```

The returned value $h = 0$ indicates that `chi2gof` does not reject the null hypothesis at the 1% significance level.

Test for Weibull Distribution Using Probability Distribution Object

Load the light bulb lifetime sample data.

```
load lightbulb
```

Create a vector from the first column of the data matrix, which contains the lifetime in hours of the light bulbs.

```
x = lightbulb(:,1);
```

Test the null hypothesis that the data in x comes from a population with a Weibull distribution. Use `fitdist` to create a probability distribution object with A and B parameters estimated from the data.

```
pd = fitdist(x,'Weibull');
h = chi2gof(x,'CDF',pd)
```

```
h = 1
```

The returned value $h = 1$ indicates that `chi2gof` rejects the null hypothesis at the default 5% significance level.

Test for Poisson Distribution

Create six bins, numbered 0 through 5, to use for data pooling.

```
bins = 0:5;
```

Create a vector containing the observed counts for each bin and compute the total number of observations.

```
obsCounts = [6 16 10 12 4 2];
n = sum(obsCounts);
```

Fit a Poisson probability distribution object to the data and compute the expected count for each bin. Use the transpose operator `.'` to transform `bins` and `obsCounts` from row vectors to column vectors.

```
pd = fitdist(bins', 'Poisson', 'Frequency', obsCounts');
expCounts = n * pdf(pd, bins);
```

Test the null hypothesis that the data in `obsCounts` comes from a Poisson distribution with a lambda parameter equal to `lambdaHat`.

```
[h,p,st] = chi2gof(bins, 'Ctrs', bins, ...
                  'Frequency', obsCounts, ...
                  'Expected', expCounts, ...
                  'NParams', 1)

h = 0
p = 0.4654

st = struct with fields:
    chi2stat: 2.5550
    df: 3
    edges: [-0.5000 0.5000 1.5000 2.5000 3.5000 5.5000]
    O: [6 16 10 12 6]
    E: [7.0429 13.8041 13.5280 8.8383 6.0284]
```

The returned value `h = 0` indicates that `chi2gof` does not reject the null hypothesis at the default 5% significance level. The vector `E` contains the expected counts for each bin under the null hypothesis, and `O` contains the observed counts for each bin.

Test for Normal Distribution Using Function Handle

Use the probability distribution function `normcdf` as a function handle in the chi-square goodness-of-fit test (`chi2gof`).

Test the null hypothesis that the sample data in the input vector `x` comes from a normal distribution with parameters μ and σ equal to the mean (`mean`) and standard deviation (`std`) of the sample data, respectively.

```
rng('default') % For reproducibility
x = normrnd(50, 5, 100, 1);
h = chi2gof(x, 'cdf', {@normcdf, mean(x), std(x)})

h = 0
```

The returned result `h = 0` indicates that `chi2gof` does not reject the null hypothesis at the default 5% significance level.

Input Arguments

x — Sample data

vector

Sample data for the hypothesis test, specified as a vector.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'NBins', 8, 'Alpha', 0.01` pools the data into eight bins and conducts the hypothesis test at the 1% significance level.

NBins — Number of bins

10 (default) | positive integer value

Number of bins to use for the data pooling, specified as the comma-separated pair consisting of `'NBins'` and a positive integer value. If you specify a value for `NBins`, do not specify a value for `Ctrs` or `Edges`.

Example: `'NBins', 8`

Data Types: `single` | `double`

Ctrs — Bin centers

vector

Bin centers, specified as the comma-separated pair consisting of `'Ctrs'` and a vector of center values for each bin. If you specify a value for `Ctrs`, do not specify a value for `NBins` or `Edges`.

Example: `'Ctrs', [1 2 3 4 5]`

Data Types: `single` | `double`

Edges — Bin edges

vector

Bin edges, specified as the comma-separated pair consisting of `'Edges'` and a vector of edge values for each bin. If you specify a value for `Edges`, do not specify a value for `NBins` or `Ctrs`.

Example: `'Edges', [-2.5 -1.5 -0.5 0.5 1.5 2.5]`

Data Types: `single` | `double`

CDF — cdf of hypothesized distribution

probability distribution object | function handle | cell array

The cdf of the hypothesized distribution, specified as the comma-separated pair consisting of `'CDF'` and a probability distribution object, function handle, or cell array.

- If `CDF` is a probability distribution object, the degrees of freedom account for whether you estimate the parameters using `fitdist` or specify them using `makedist`.
- If `CDF` is a function handle, the distribution function must take `x` as its only argument.
- If `CDF` is a cell array, the first element must be a function handle, and the remaining elements must be parameter values, one per cell. The function must take `x` as its first argument, and the other parameters in the array as later arguments.

If you specify a value for `CDF`, do not specify a value for `Expected`.

Example: `'CDF', pd_object`

Data Types: `single` | `double`

Expected — Expected counts

vector of nonnegative values

Expected counts for each bin, specified as the comma-separated pair of 'Expected' and a vector of nonnegative values. If Expected depends on estimated parameters, use `NParams` to ensure that `chi2gof` correctly calculates the degrees of freedom. If you specify a value for Expected, do not specify a value for CDF.

Example: 'Expected', [19.1446 18.3789 12.3224 8.2432 4.1378]

Data Types: `single` | `double`

NParams — Number of estimated parameters

positive integer value

Number of estimated parameters used to describe the null distribution, specified as the comma-separated pair consisting of 'NParams' and a positive integer value. This value adjusts the degrees of freedom of the test based on the number of estimated parameters used to compute the cdf or expected counts.

The default value for `NParams` depends on how you specify the null distribution:

- If you specify CDF as a probability distribution object, `NParams` is equal to the number of estimated parameters used to create the object.
- If you specify CDF as a function name or handle, the default value of `NParams` is 0.
- If you specify CDF as a cell array, the default value of `NParams` is the number of parameters in the array.
- If you specify Expected, the default value of `NParams` is 0.

Example: 'NParams', 1

Data Types: `single` | `double`

EMin — Minimum expected count per bin

5 (default) | nonnegative integer value

Minimum expected count per bin, specified as the comma-separated pair consisting of 'EMin' and a nonnegative integer value. If the bin at the extreme end of either tail has an expected value less than `EMin`, it is combined with a neighboring bin until the count in each extreme bin is at least 5. If any interior bins have a count less than 5, `chi2gof` displays a warning, but does not combine the interior bins. In that case, you should use fewer bins, or provide bin centers or edges, to increase the expected counts in all bins. Specify `EMin` as 0 to prevent the combining of bins.

Example: 'EMin', 0

Data Types: `single` | `double`

Frequency — Frequency

vector of nonnegative integer values

Frequency of data values, specified as the comma-separated pair consisting of 'Frequency' and a vector of nonnegative integer values that is the same length as the vector `x`.

Example: 'Frequency', [20 16 13 10 8]

Data Types: `single` | `double`

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha', 0.01

Data Types: `single` | `double`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — p-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

stats — Test statistics

structure

Test statistics, returned as a structure containing the following:

- `chi2stat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.
- `edges` — Vector of bin edges after pooling.
- `O` — Vector of observed counts for each bin.
- `E` — Vector of expected counts for each bin.

More About

Chi-Square Goodness-of-Fit Test

The chi-square goodness-of-fit test determines if a data sample comes from a specified probability distribution, with parameters estimated from the data.

The test groups the data into bins, calculating the observed and expected counts for those bins, and computing the chi-square test statistic

$$\chi^2 = \sum_{i=1}^N (O_i - E_i)^2 / E_i,$$

where O_i are the observed counts and E_i are the expected counts based on the hypothesized distribution. The test statistic has an approximate chi-square distribution when the counts are sufficiently large.

Algorithms

`chi2gof` compares the value of the test statistic to a chi-square distribution with degrees of freedom equal to $n_{bins} - 1 - n_{params}$, where n_{bins} is the number of bins used for the data pooling and n_{params} is the number of estimated parameters used to determine the expected counts. If there are not enough degrees of freedom to conduct the test, `chi2gof` returns the p -value as NaN.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2inv

Chi-square inverse cumulative distribution function

Syntax

```
x = chi2inv(p,nu)
```

Description

`x = chi2inv(p,nu)` returns the inverse cumulative distribution function (icdf) of the chi-square distribution with degrees of freedom `nu`, evaluated at the probability values in `p`.

Examples

Compute Chi-Square icdf

Find the 95th percentile for the chi-square distribution with 10 degrees of freedom.

```
x = chi2inv(0.95,10)
```

```
x = 18.3070
```

If you generate random numbers from this chi-square distribution, you would observe numbers greater than 18.3 only 5% of the time.

Median of Chi-Square Distributions

Compute the medians of the chi-square distributions with degrees of freedom one through six.

```
x = chi2inv(0.50,1:6)
```

```
x = 1×6
```

```
    0.4549    1.3863    2.3660    3.3567    4.3515    5.3481
```

Input Arguments

p — Probability values at which to evaluate icdf

scalar value in $[0, 1]$ | array of scalar values

Probability values at which to evaluate the icdf, specified as a scalar value or an array of scalar values, where each element is in the range $[0, 1]$.

- To evaluate the icdf at multiple values, specify `p` using an array.

- To evaluate the icdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `p` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2inv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding probabilities in `p`.

Example: `[0.1,0.5,0.9]`

Data Types: `single` | `double`

nu — Degrees of freedom

positive scalar value | array of positive scalar values

Degrees of freedom for the chi-square distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the icdf at multiple values, specify `p` using an array.
- To evaluate the icdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `p` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2inv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding probabilities in `p`.

Example: `[9 19 49 99]`

Data Types: `single` | `double`

Output Arguments

x — icdf values

scalar value | array of scalar values

icdf values evaluated at the probabilities in `p`, returned as a scalar value or an array of scalar values. `x` is the same size as `p` and `nu` after any necessary scalar expansion. Each element in `x` is the icdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding probabilities in `p`.

More About

Chi-Square icdf

The chi-square distribution is a one-parameter family of curves. The parameter ν is the degrees of freedom.

The icdf of the chi-square distribution is

$$x = F^{-1}(p|\nu) = \{x: F(x|\nu) = p\},$$

where

$$p = F(x|\nu) = \int_0^x \frac{t^{(\nu-2)/2} e^{-t/2}}{2^{\nu/2} \Gamma(\nu/2)} dt,$$

ν is the degrees of freedom, and $\Gamma(\cdot)$ is the Gamma function. The result p is the probability that a single observation from the chi-square distribution with ν degrees of freedom falls in the interval $[0, x]$.

For more information, see “Chi-Square Distribution” on page B-28.

Alternative Functionality

- `chi2inv` is a function specific to the chi-square distribution. Statistics and Machine Learning Toolbox also offers the generic function `icdf`, which supports various probability distributions. To use `icdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `chi2inv` is faster than the generic function `icdf`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2pdf

Chi-square probability density function

Syntax

```
y = chi2pdf(x,nu)
```

Description

`y = chi2pdf(x,nu)` returns the probability density function (pdf) of the chi-square distribution with `nu` degrees of freedom, evaluated at the values in `x`.

Examples

Compute Chi-Square pdf

Compute the density of the observed value 2 in the chi-square distribution with 3 degrees of freedom.

```
y1 = chi2pdf(2,3)
```

```
y1 = 0.2076
```

Compute the density of the observed value 4 in the chi-square distributions with degrees of freedom 1 through 6.

```
y2 = chi2pdf(4,1:6)
```

```
y2 = 1×6
```

```
0.0270 0.0677 0.1080 0.1353 0.1440 0.1353
```

The mean of the chi-square distribution is equal to the degrees of freedom. Compute the density of the mean for the chi-square distributions with degrees of freedom 1 through 6.

```
nu = 1:6;
```

```
x = nu;
```

```
y3 = chi2pdf(x,nu)
```

```
y3 = 1×6
```

```
0.2420 0.1839 0.1542 0.1353 0.1220 0.1120
```

As the degrees of freedom increase, the density of the mean decreases.

Input Arguments

x — Values at which to evaluate pdf

nonnegative scalar value | array of nonnegative scalar values

Values at which to evaluate the pdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2pdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: [3 4 7 9]

Data Types: `single` | `double`

nu — Degrees of freedom

positive scalar value | array of positive scalar values

Degrees of freedom for the chi-square distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2pdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: [9 19 49 99]

Data Types: `single` | `double`

Output Arguments

y — pdf values

scalar value | array of scalar values

pdf values evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `p` is the same size as `x` and `nu` after any necessary scalar expansion. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

More About

Chi-Square pdf

The chi-square distribution is a one-parameter family of curves. The parameter ν is the degrees of freedom.

The pdf of the chi-square distribution is

$$y = f(x|\nu) = \frac{x^{(\nu-2)/2} e^{-x/2}}{2^{\nu/2} \Gamma(\nu/2)}$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function.

For more information, see “Chi-Square Distribution” on page B-28.

Alternative Functionality

- `chi2pdf` is a function specific to the chi-square distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `chi2pdf` is faster than the generic function `pdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2rnd

Chi-square random numbers

Syntax

```
r = chi2rnd(nu)
r = chi2rnd(nu,sz1,...,szN)
r = chi2rnd(nu,sz)
```

Description

`r = chi2rnd(nu)` generates a random number from the chi-square distribution with `nu` degrees of freedom.

`r = chi2rnd(nu,sz1,...,szN)` generates an array of random numbers from the chi-square distribution, where `sz1,...,szN` indicates the size of each dimension.

`r = chi2rnd(nu,sz)` generates an array of random numbers from the chi-square distribution, where vector `sz` specifies `size(r)`.

Examples

Generate Chi-Square Random Number

Generate a single random number from the chi-square distribution with 10 degrees of freedom.

```
nu = 10;
r = chi2rnd(nu)

r = 19.7102
```

Generate Chi-Square Random Numbers

Generate a 1-by-6 array of chi-square random numbers with 1 degree of freedom.

```
nu1 = ones(1,6); % 1-by-6 array of ones
r1 = chi2rnd(nu1)

r1 = 1×6
    2.5368    0.2447    0.4314    2.0153    0.0418    4.3486
```

By default, `chi2rnd` generates an array that is the same size as `nu`.

If you specify `nu` as a scalar, `chi2rnd` expands `nu` into a constant array with dimensions specified by `sz1,...,szN`.

Generate a 2-by-6 array of chi-square random numbers, all with 3 degrees of freedom.

```
nu2 = 3;
sz1 = 2;
sz2 = 6;
r2 = chi2rnd(nu2,sz1,sz2)
```

```
r2 = 2×6
```

```
    0.5761    5.3582    1.0124    0.9851    1.0529    3.0765
    7.9240    1.7373    0.6291    7.0240    1.8496    2.2690
```

If you specify both `nu` and `sz` as arrays, then the dimensions specified by `sz` must match the dimension of `nu`.

Generate a 1-by-6 array of chi-square random numbers with 3 to 8 degrees of freedom.

```
nu3 = 3:8;
sz = [1 6];
r3 = chi2rnd(nu3,sz)
```

```
r3 = 1×6
```

```
    3.9690    7.0961    4.5651    2.4606    13.5038    8.8495
```

Input Arguments

nu — Degrees of freedom

positive scalar value | array of positive scalar values

Degrees of freedom for the chi-square distribution, specified as a positive scalar value or an array of positive scalar values.

To generate random numbers from multiple distributions, specify `nu` using an array. Each element in `r` is the random number generated from the distribution specified by the corresponding element in `nu`.

Example: [9 19 49 99]

Data Types: `single` | `double`

sz1, ..., szN — Size of each dimension (as separate arguments)

integers

Size of each dimension, specified as separate arguments of integers.

If `nu` is an array, then the specified dimensions `sz1, ..., szN` must match the dimensions of `nu`. The default values of `sz1, ..., szN` are the dimensions of `nu`.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is 0 or negative, then `r` is an empty array.
- Beyond the second dimension, `chi2rnd` ignores trailing dimensions with a size of 1. For example, `chi2rnd(5,3,1,1,1)` produces a 3-by-1 vector of random numbers from the distribution with five degrees of freedom.

Example: 2, 3

Data Types: `single` | `double`

sz — Size of each dimension (as a row vector)

row vector of integers

Size of each dimension, specified as a row vector of integers.

If `nu` is an array, then the specified dimensions `sz` must match the dimensions of `nu`. The default values of `sz` are the dimensions of `nu`.

- If you specify a single value [`sz1`], then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is 0 or negative, then `r` is an empty array.
- Beyond the second dimension, `chi2rnd` ignores trailing dimensions with a size of 1. For example, `chi2rnd(5, [3 1 1 1])` produces a 3-by-1 vector of random numbers from the distribution with five degrees of freedom.

Example: [2 3]

Data Types: `single` | `double`

Output Arguments

r — Chi-square random numbers

scalar value | array of scalar values

Chi-square random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1`, . . . , `szN` or `sz`. Each element in `r` is the random number generated from the distribution specified by the corresponding element in `nu`.

Alternative Functionality

- `chi2rnd` is a function specific to the chi-square distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, specify the probability distribution name and its parameters. Note that the distribution-specific function `chi2rnd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers from the sequence returned by MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2stat

Chi-square mean and variance

Syntax

```
[M,V] = chi2stat(NU)
```

Description

`[M,V] = chi2stat(NU)` returns the mean of and variance for the chi-square distribution with degrees of freedom parameters specified by `NU`. `NU` can be a vector, a matrix, or a multidimensional array. The degrees of freedom parameters in `NU` must be positive.

The mean of the chi-square distribution is ν , the degrees of freedom parameter, and the variance is 2ν .

Examples

```
nu = 1:10;
nu = nu'*nu;
[m,v] = chi2stat(nu)
m =
 1  2  3  4  5  6  7  8  9 10
 2  4  6  8 10 12 14 16 18 20
 3  6  9 12 15 18 21 24 27 30
 4  8 12 16 20 24 28 32 36 40
 5 10 15 20 25 30 35 40 45 50
 6 12 18 24 30 36 42 48 54 60
 7 14 21 28 35 42 49 56 63 70
 8 16 24 32 40 48 56 64 72 80
 9 18 27 36 45 54 63 72 81 90
10 20 30 40 50 60 70 80 90 100

v =
 2  4  6  8 10 12 14 16 18 20
 4  8 12 16 20 24 28 32 36 40
 6 12 18 24 30 36 42 48 54 60
 8 16 24 32 40 48 56 64 72 80
10 20 30 40 50 60 70 80 90 100
12 24 36 48 60 72 84 96 108 120
14 28 42 56 70 84 98 112 126 140
16 32 48 64 80 96 112 128 144 160
18 36 54 72 90 108 126 144 162 180
20 40 60 80 100 120 140 160 180 200
```

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

cholcov

Cholesky-like covariance decomposition

Syntax

```
T = cholcov(SIGMA)
[T,num] = cholcov(SIGMA)
[T,num] = cholcov(SIGMA,0)
```

Description

`T = cholcov(SIGMA)` computes T such that $SIGMA = T'*T$. $SIGMA$ must be square, symmetric, and positive semi-definite. If $SIGMA$ is positive definite, then T is the square, upper triangular Cholesky factor. If $SIGMA$ is not positive definite, T is computed from an eigenvalue decomposition of $SIGMA$. T is not necessarily triangular or square in this case. Any eigenvectors whose corresponding eigenvalue is close to zero (within a small tolerance) are omitted. If any remaining eigenvalues are negative, T is empty.

`[T,num] = cholcov(SIGMA)` returns the number `num` of negative eigenvalues of $SIGMA$, and T is empty if `num` is positive. If `num` is zero, $SIGMA$ is positive semi-definite. If $SIGMA$ is not square and symmetric, `num` is NaN and T is empty.

`[T,num] = cholcov(SIGMA,0)` returns `num` equal to zero if $SIGMA$ is positive definite, and T is the Cholesky factor. If $SIGMA$ is not positive definite, `num` is a positive integer and T is empty. `[...] = cholcov(SIGMA,1)` is equivalent to `[...] = cholcov(SIGMA)`.

Examples

The following 4-by-4 covariance matrix is rank-deficient:

```
C1 = [2 1 1 2;1 2 1 2;1 1 2 2;2 2 2 3]
C1 =
```

```
     2     1     1     2
     1     2     1     2
     1     1     2     2
     2     2     2     3
```

```
rank(C1)
ans =
     3
```

Use `cholcov` to factor $C1$:

```
T = cholcov(C1)
T =
   -0.2113    0.7887   -0.5774         0
    0.7887   -0.2113   -0.5774         0
    1.1547    1.1547    1.1547    1.7321
```

```
C2 = T'*T
C2 =
    2.0000    1.0000    1.0000    2.0000
```

```
1.0000    2.0000    1.0000    2.0000
1.0000    1.0000    2.0000    2.0000
2.0000    2.0000    2.0000    3.0000
```

Use T to generate random data with the specified covariance:

```
C3 = cov(randn(1e6,3)*T)
C3 =
    1.9973    0.9982    0.9995    1.9975
    0.9982    1.9962    0.9969    1.9956
    0.9995    0.9969    1.9980    1.9972
    1.9975    1.9956    1.9972    2.9951
```

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

See Also

`chol` | `cov`

Introduced in R2007a

ClassificationBaggedEnsemble

Package: classreg.learning.classif
Superclasses: ClassificationEnsemble

Classification ensemble grown by resampling

Description

`ClassificationBaggedEnsemble` combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

Construction

Create a bagged classification ensemble object using `fitcensemble`. Set the name-value pair argument 'Method' of `fitcensemble` to 'Bag' to use bootstrap aggregation (bagging, for example, random forest).

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the 'NumBins' name-value pair argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the 'NumBins' value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
```

```
    Xbinned(:,j) = xbinned;  
end
```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

ClassNames

List of the elements in Y with duplicates removed. ClassNames can be a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. ClassNames has the same data type as the data in the argument Y. (The software treats string arrays as cell arrays of character vectors.)

CombineWeights

Character vector describing how ens combines weak learner weights, either 'WeightedSum' or 'WeightedAverage'.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then ExpandedPredictorNames includes the names that describe the expanded variables. Otherwise, ExpandedPredictorNames is the same as PredictorNames.

FitInfo

Numeric array of fit information. The FitInfoDescription property describes the content of this array.

FitInfoDescription

Character vector describing the meaning of the FitInfo array.

FResample

Numeric scalar between 0 and 1. FResample is the fraction of training data fitcensemble resampled at random for every weak learner when constructing the ensemble.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a BayesianOptimization object or a table of hyperparameters and associated values. Nonempty when the OptimizeHyperparameters name-value pair is nonempty at creation. Value depends on the setting of the HyperparameterOptimizationOptions name-value pair at creation:

- 'bayesopt' (default) — Object of class BayesianOptimization

- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Method

Character vector describing the method that creates ens.

ModelParameters

Parameters used in training ens.

NumTrained

Number of trained weak learners in ens, a scalar.

PredictorNames

Cell array of names for the predictor variables, in the order in which they appear in X.

ReasonForTermination

Character vector describing the reason `fitcensemble` stopped adding weak learners to the ensemble.

Replace

Logical value indicating if the ensemble was trained with replacement (`true`) or without replacement (`false`).

ResponseName

Character vector with the name of the response variable Y.

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```
ens.ScoreTransform = 'function'
```

or

```
ens.ScoreTransform = @function
```

Trained

Trained learners, a cell array of compact classification models.

TrainedWeights

Numeric vector of trained weights for the weak learners in ens. `TrainedWeights` has T elements, where T is the number of weak learners in `learners`.

UseObsForLearner

Logical matrix of size N-by-NumTrained, where N is the number of observations in the training data and NumTrained is the number of trained weak learners. UseObsForLearner(I, J) is true if observation I was used for training learner J, and is false otherwise.

W

Scaled weights, a vector with length n, the number of rows in X. The sum of the elements of W is 1.

X

Matrix or table of predictor values that trained the ensemble. Each column of X represents one variable, and each row represents one observation.

Y

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector with the same number of rows as X. Each row of Y represents the classification of the corresponding row of X.

Methods

oobEdge	Out-of-bag classification edge
oobLoss	Out-of-bag classification error
oobMargin	Out-of-bag classification margins
oobPermutedPredictorImportance	Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of classification trees
oobPredict	Predict out-of-bag response of ensemble

Inherited Methods

compact	Compact classification ensemble
crossval	Cross validate ensemble
resubEdge	Classification edge by resubstitution
resubLoss	Classification error by resubstitution
resubMargin	Classification margins by resubstitution
resubPredict	Classify observations in ensemble of classification models
resume	Resume training ensemble
edge	Classification edge
loss	Classification error
margin	Classification margins
predict	Classify observations using ensemble of classification models
predictorImportance	Estimates of predictor importance for classification ensemble of decision trees
removeLearners	Remove members of compact classification ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Bagged Ensemble of Classification Trees

Load the ionosphere data set.

```
load ionosphere
```

You can train a bagged ensemble of 100 classification trees using all measurements.

```
Mdl = fitcensemble(X,Y,'Method','Bag')
```

`fitcensemble` uses a default template tree object `templateTree()` as a weak learner when 'Method' is 'Bag'. In this example, for reproducibility, specify 'Reproducible', true when you create a tree template object, and then use the object as a weak learner.

```
rng('default') % For reproducibility
t = templateTree('Reproducible',true); % For reproducibility of random predictor selections
Mdl = fitcensemble(X,Y,'Method','Bag','Learners',t)
```

```
Mdl =
  classreg.learning.classif.ClassificationBaggedEnsemble
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
  NumObservations: 351
        NumTrained: 100
            Method: 'Bag'
      LearnerNames: {'Tree'}
ReasonForTermination: 'Terminated normally after completing the requested number of training
          FitInfo: []
  FitInfoDescription: 'None'
            FResample: 1
              Replace: 1
  UseObsForLearner: [351x100 logical]
```

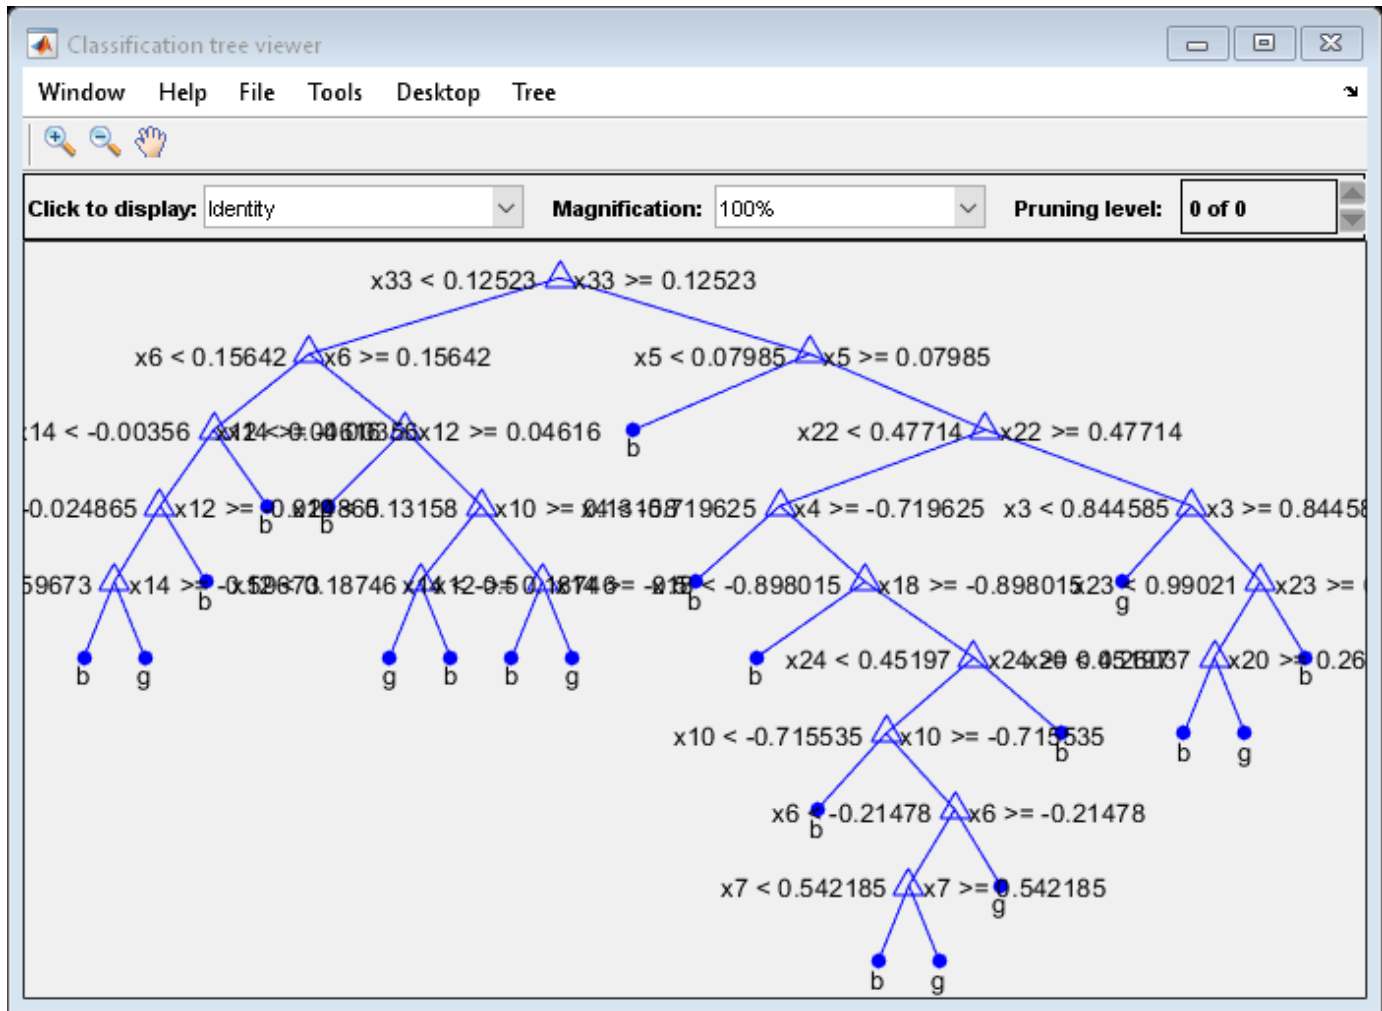

Properties, Methods

`Mdl` is a `ClassificationBaggedEnsemble` model object.

`Mdl.Trained` is the property that stores a 100-by-1 cell vector of the trained classification trees (`CompactClassificationTree` model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trained{1},'Mode','graph')
```

By default, `fitensemble` grows deep decision trees for bagged ensembles.

Estimate the in-sample misclassification rate.

```
L = resubLoss(Mdl)
```

```
L = 0
```

L is 0, which indicates that Mdl is perfect at classifying the training data.

Tip

For a bagged ensemble of classification trees, the `Trained` property of `ens` stores a cell vector of `ens.NumTrained CompactClassificationTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(ens.Trained{t})
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train an ensemble by using `fitcensemble`, code generation limitations for the weak learners used in the ensemble also apply to the ensemble. For more details, see the Code Generation sections of `CompactClassificationDiscriminant` and `CompactClassificationTree`.
- For fixed-point code generation, you must train an ensemble using tree learners.

For more information, see “Introduction to Code Generation” on page 31-2.

ClassificationECOC

Multiclass model for support vector machines (SVMs) and other classifiers

Description

`ClassificationECOC` is an error-correcting output codes (ECOC) classifier on page 32-334 for multiclass learning, where the classifier consists of multiple binary learners such as support vector machines (SVMs). Trained `ClassificationECOC` classifiers store training data, parameter values, prior probabilities, and coding matrices. Use these classifiers to perform tasks such as predicting labels or posterior probabilities for new data (see `predict`).

Creation

Create a `ClassificationECOC` object by using `fitcecoc`.

If you specify linear or kernel binary learners without specifying cross-validation options, then `fitcecoc` returns a `CompactClassificationECOC` object instead.

Properties

After you create a `ClassificationECOC` model object, you can use dot notation to access its properties. For an example, see “Train Multiclass Model Using SVM Learners” on page 32-328.

ECOC Properties

BinaryLearners — Trained binary learners

cell vector of model objects

Trained binary learners, specified as a cell vector of model objects. The number of binary learners depends on the number of classes in Y and the coding design.

The software trains `BinaryLearner{j}` according to the binary problem specified by `CodingMatrix(:,j)`. For example, for multiclass learning using SVM learners, each element of `BinaryLearners` is a `CompactClassificationSVM` classifier.

Data Types: cell

BinaryLoss — Binary learner loss function

'binodeviance' | 'exponential' | 'hamming' | 'hinge' | 'linear' | 'logit' | 'quadratic'

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets `BinaryLoss` to 'hamming'. To potentially increase accuracy, specify a binary loss function other than the default during a prediction or loss computation by using the 'BinaryLoss' name-value pair argument of `predict` or `loss`.

Data Types: char

BinaryY — Binary learner class labels

numeric matrix

Binary learner class labels, specified as a numeric matrix. `BinaryY` is a `NumObservations`-by-`L` matrix, where `L` is the number of binary learners (`length(Mdl.BinaryLearners)`).

Elements of `BinaryY` are `-1`, `0`, or `1`, and the value corresponds to a dichotomous class assignment. This table describes how learner `j` assigns observation `k` to a dichotomous class corresponding to the value of `BinaryY(k,j)`.

Value	Dichotomous Class Assignment
-1	Learner <code>j</code> assigns observation <code>k</code> to a negative class.
0	Before training, learner <code>j</code> removes observation <code>k</code> from the data set.
1	Learner <code>j</code> assigns observation <code>k</code> to a positive class.

Data Types: double

BinEdges — Bin edges for numeric predictors

cell array of numeric vectors | []

Bin edges for numeric predictors, specified as a cell array of `p` numeric vectors, where `p` is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value pair argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains NaNs, then the corresponding `Xbinned` values are NaNs.

Data Types: `cell`

CodingMatrix — Class assignment codes

numeric matrix

Class assignment codes for the binary learners, specified as a numeric matrix. `CodingMatrix` is a K -by- L matrix, where K is the number of classes and L is the number of binary learners.

The elements of `CodingMatrix` are -1 , 0 , or 1 , and the values correspond to dichotomous class assignments. This table describes how learner j assigns observations in class i to a dichotomous class corresponding to the value of `CodingMatrix(i, j)`.

Value	Dichotomous Class Assignment
-1	Learner j assigns observations in class i to a negative class.
0	Before training, learner j removes observations in class i from the data set.
1	Learner j assigns observations in class i to a positive class.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64`

CodingName — Coding design name

character vector

Coding design name, specified as a character vector. For more details, see “Coding Design” on page 32-334.

Data Types: `char`

LearnerWeights — Binary learner weights

numeric row vector

Binary learner weights, specified as a numeric row vector. The length of `LearnerWeights` is equal to the number of binary learners (`length(Mdl.BinaryLearners)`).

`LearnerWeights(j)` is the sum of the observation weights that binary learner j uses to train its classifier.

The software uses `LearnerWeights` to fit posterior probabilities by minimizing the Kullback-Leibler divergence. The software ignores `LearnerWeights` when it uses the quadratic programming method of estimating posterior probabilities.

Data Types: `double` | `single`

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

vector of positive integers | []

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels `Y`. (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

ModelParameters — Parameter values

object

Parameter values, such as the name-value pair argument values, used to train the ECOC classifier, specified as an object. `ModelParameters` does not contain estimated parameters.

Access properties of `ModelParameters` using dot notation. For example, list the templates containing parameters of the binary learners by using `Mdl.ModelParameters.BinaryLearner`.

NumObservations — Number of observations

positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data X , specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in X .

Data Types: cell

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as the number of classes in `ClassNames`, and the order of the elements corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: double

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: char

RowsUsed — Rows used in fitting

[] (default) | logical vector

Rows of the original data X used in fitting the `ClassificationECOC` model, specified as a logical vector. This property is empty if all rows are used.

Data Types: logical

ScoreTransform — Score transformation function to apply to predicted scores

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter this code and replace *function* with a value in the table.

```
Mdl.ScoreTransform = 'function';
```

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$

Value	Description
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

W — Observation weights

numeric vector

Observation weights used to train the ECOC classifier, specified as a numeric vector. *W* has `NumObservations` elements.

The software normalizes the weights used for training so that `nansum(W)` is 1.

Data Types: single | double

X — Unstandardized predictor data

numeric matrix | table

Unstandardized predictor data used to train the ECOC classifier, specified as a numeric matrix or table.

Each row of *X* corresponds to one observation, and each column corresponds to one variable.

Data Types: single | double | table

Y — Observed class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Observed class labels used to train the ECOC classifier, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. *Y* has `NumObservations` elements and has the same data type as the input argument *Y* of `fitcecoc`. (The software treats string arrays as cell arrays of character vectors.)

Each row of *Y* represents the observed classification of the corresponding row of *X*.

Data Types: categorical | char | logical | single | double | cell

Hyperparameter Optimization Properties

HyperparameterOptimizationResults — Description of cross-validation optimization of hyperparameters

BayesianOptimization object | table

Description of the cross-validation optimization of hyperparameters, specified as a BayesianOptimization object or a table of hyperparameters and associated values. This property is nonempty if the 'OptimizeHyperparameters' name-value pair argument is nonempty when you create the model. The value of HyperparameterOptimizationResults depends on the setting of the Optimizer field in the HyperparameterOptimizationOptions structure when you create the model, as described in this table.

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'bayesopt' (default)	Object of class BayesianOptimization
'gridsearch' or 'randomsearch'	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Object Functions

compareHoldout	Compare accuracies of two classification models using new data
compact	Reduce size of multiclass error-correcting output codes (ECOC) model
crossval	Cross-validate multiclass error-correcting output codes (ECOC) model
discardSupportVectors	Discard support vectors of linear SVM binary learners in ECOC model
edge	Classification edge for multiclass error-correcting output codes (ECOC) model
loss	Classification loss for multiclass error-correcting output codes (ECOC) model
margin	Classification margins for multiclass error-correcting output codes (ECOC) model
predict	Classify observations using multiclass error-correcting output codes (ECOC) model
resubEdge	Resubstitution classification edge for multiclass error-correcting output codes (ECOC) model
resubLoss	Resubstitution classification loss for multiclass error-correcting output codes (ECOC) model
resubMargin	Resubstitution classification margins for multiclass error-correcting output codes (ECOC) model
resubPredict	Classify observations in multiclass error-correcting output codes (ECOC) model

Examples

Train Multiclass Model Using SVM Learners

Train a multiclass error-correcting output codes (ECOC) model using support vector machine (SVM) binary learners.

Load Fisher's iris data set. Specify the predictor data X and the response data Y .

```
load fisheriris
X = meas;
Y = species;
```

Train a multiclass ECOC model using the default options.

```
Mdl = fitcecoc(X,Y)

Mdl =
  ClassificationECOC
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
  BinaryLearners: {3x1 cell}
      CodingName: 'onevsone'
```

Properties, Methods

`Mdl` is a `ClassificationECOC` model. By default, `fitcecoc` uses SVM binary learners and a one-versus-one coding design. You can access `Mdl` properties using dot notation.

Display the class names and the coding design matrix.

```
Mdl.ClassNames

ans = 3x1 cell
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
CodingMat = Mdl.CodingMatrix
```

```
CodingMat = 3x3

     1     1     0
    -1     0     1
     0    -1    -1
```

A one-versus-one coding design for three classes yields three binary learners. The columns of `CodingMat` correspond to the learners, and the rows correspond to the classes. The class order is the same as the order in `Mdl.ClassNames`. For example, `CodingMat(:,1)` is `[1; -1; 0]` and indicates that the software trains the first SVM binary learner using all observations classified as 'setosa' and 'versicolor'. Because 'setosa' corresponds to 1, it is the positive class; 'versicolor' corresponds to -1, so it is the negative class.

You can access each binary learner using cell indexing and dot notation.

```
Mdl.BinaryLearners{1} % The first binary learner

ans =
  classreg.learning.classif.CompactClassificationSVM
      ResponseName: 'Y'
```

```

CategoricalPredictors: []
    ClassNames: [-1 1]
    ScoreTransform: 'none'
        Beta: [4x1 double]
        Bias: 1.4505
    KernelParameters: [1x1 struct]

```

Properties, Methods

Compute the resubstitution classification error.

```
error = resubLoss(Mdl)
```

```
error = 0.0067
```

The classification error on the training data is small, but the classifier might be an overfitted model. You can cross-validate the classifier using `crossval` and compute the cross-validation classification error instead.

Inspect Binary Learner Properties of ECOC Classifier

Train an ECOC classifier using SVM binary learners. Then, access properties of the binary learners, such as estimated parameters, by using dot notation.

Load Fisher's iris data set. Specify the petal dimensions as the predictors and the species names as the response.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Train an ECOC classifier using SVM binary learners and the default coding design (one-versus-one). Standardize the predictors and save the support vectors.

```

t = templateSVM('Standardize',true,'SaveSupportVectors',true);
predictorNames = {'petalLength','petalWidth'};
responseName = 'irisSpecies';
classNames = {'setosa','versicolor','virginica'}; % Specify class order
Mdl = fitcecoc(X,Y,'Learners',t,'ResponseName',responseName,...
    'PredictorNames',predictorNames,'ClassNames',classNames)

```

```

Mdl =
    ClassificationECOC
        PredictorNames: {'petalLength' 'petalWidth'}
        ResponseName: 'irisSpecies'
    CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
        ScoreTransform: 'none'
        BinaryLearners: {3x1 cell}
        CodingName: 'onevsone'

```

Properties, Methods

`t` is a template object that contains options for SVM classification. The function `fitcecoc` uses default values for the empty (`[]`) properties. `Mdl` is a `ClassificationECOC` classifier. You can access properties of `Mdl` using dot notation.

Display the class names and the coding design matrix.

`Mdl.ClassNames`

```
ans = 3x1 cell
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

`Mdl.CodingMatrix`

```
ans = 3x3
     1     1     0
    -1     0     1
     0    -1    -1
```

The columns correspond to SVM binary learners, and the rows correspond to the distinct classes. The row order is the same as the order in the `ClassNames` property of `Mdl`. For each column:

- 1 indicates that `fitcecoc` trains the SVM using observations in the corresponding class as members of the positive group.
- -1 indicates that `fitcecoc` trains the SVM using observations in the corresponding class as members of the negative group.
- 0 indicates that the SVM does not use observations in the corresponding class.

In the first SVM, for example, `fitcecoc` assigns all observations to 'setosa' or 'versicolor', but not 'virginica'.

Access properties of the SVMs using cell subscripting and dot notation. Store the standardized support vectors of each SVM. Unstandardize the support vectors.

```
L = size(Mdl.CodingMatrix,2); % Number of SVMs
sv = cell(L,1); % Preallocate for support vector indices
for j = 1:L
    SVM = Mdl.BinaryLearners{j};
    sv{j} = SVM.SupportVectors;
    sv{j} = sv{j}.*SVM.Sigma + SVM.Mu;
end
```

`sv` is a cell array of matrices containing the unstandardized support vectors for the SVMs.

Plot the data, and identify the support vectors.

```
figure
gscatter(X(:,1),X(:,2),Y);
hold on
markers = {'ko','ro','bo'}; % Should be of length L
for j = 1:L
    svj = sv{j};
    plot(svj(:,1),svj(:,2),markers{j},...)
```

```

        'MarkerSize',10 + (j - 1)*3);
end
title('Fisher's Iris -- ECOC Support Vectors')
xlabel(predictorNames{1})
ylabel(predictorNames{2})
legend([classNames,{'Support vectors - SVM 1',...
    'Support vectors - SVM 2','Support vectors - SVM 3'}],...
    'Location','Best')
hold off

```

You can pass `Mdl` to these functions:

- `predict`, to classify new observations
- `resubLoss`, to estimate the classification error on the training data
- `crossval`, to perform 10-fold cross-validation

Cross-Validate ECOC Classifier

Cross-validate an ECOC classifier with SVM binary learners, and estimate the generalized classification error.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```

load fisheriris
X = meas;

```

```
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and standardize the predictors.

```
t = templateSVM('Standardize',true)

t =
Fit template for classification SVM.

          Type: 'classification'
```

`t` is an SVM template. Most of the template object properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train the ECOC classifier, and specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross-validate `Mdl` using 10-fold cross-validation.

```
CVMdl = crossval(Mdl);
```

`CVMdl` is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalized classification error.

```
genError = kfoldLoss(CVMdl)
genError = 0.0400
```

The generalized classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

More About

Error-Correcting Output Codes Model

An error-correcting output codes (ECOC) model reduces the problem of classification with three or more classes to a set of binary classification problems.

ECOC classification requires a coding design, which determines the classes that the binary learners train on, and a decoding scheme, which determines how the results (predictions) of the binary classifiers are aggregated.

Assume the following:

- The classification problem has three classes.
- The coding design is one-versus-one. For three classes, this coding design is

	Learner 1	Learner 2	Learner 3
Class 1	1	1	0
Class 2	-1	0	1
Class 3	0	-1	-1

- The decoding scheme uses loss g .
- The learners are SVMs.

To build this classification model, the ECOC algorithm follows these steps.

- 1 Learner 1 trains on observations in Class 1 or Class 2, and treats Class 1 as the positive class and Class 2 as the negative class. The other learners are trained similarly.
- 2 Let M be the coding design matrix with elements m_{kl} , and s_l be the predicted classification score for the positive class of learner l . The algorithm assigns a new observation to the class (\hat{k}) that minimizes the aggregation of the losses for the L binary learners.

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{l=1}^L |m_{kl}| g(m_{kl}, s_l)}{\sum_{l=1}^L |m_{kl}|}.$$

ECOC models can improve classification accuracy, compared to other multiclass models [2].

Coding Design

A coding design is a matrix where elements direct which classes are trained by each binary learner, that is, how the multiclass problem is reduced to a series of binary problems.

Each row of the coding design corresponds to a distinct class, and each column corresponds to a binary learner. In a ternary coding design, for a particular column (or binary learner):

- A row containing 1 directs the binary learner to group all observations in the corresponding class into a positive class.
- A row containing -1 directs the binary learner to group all observations in the corresponding class into a negative class.
- A row containing 0 directs the binary learner to ignore all observations in the corresponding class.

Coding design matrices with large, minimal, pairwise row distances based on the Hamming measure are optimal. For details on the pairwise row distance, see “Random Coding Design Matrices” on page 32-1532 and [4].

This table describes popular coding designs.

Coding Design	Description	Number of Learners	Minimal Pairwise Row Distance
one-versus-all (OVA)	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.	K	2
one-versus-one (OVO)	For each binary learner, one class is positive, another is negative, and the rest are ignored. This design exhausts all combinations of class pair assignments.	$K(K - 1)/2$	1
binary complete	This design partitions the classes into all binary combinations, and does not ignore any classes. That is, all class assignments are -1 and 1 with at least one positive class and one negative class in the assignment for each binary learner.	$2^{K-1} - 1$	2^{K-2}
ternary complete	This design partitions the classes into all ternary combinations. That is, all class assignments are 0, -1, and 1 with at least one positive class and one negative class in the assignment for each binary learner.	$(3^K - 2^{K+1} + 1)/2$	3^{K-2}

Coding Design	Description	Number of Learners	Minimal Pairwise Row Distance
ordinal	For the first binary learner, the first class is negative and the rest are positive. For the second binary learner, the first two classes are negative and the rest are positive, and so on.	$K - 1$	1
dense random	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see "Random Coding Design Matrices" on page 32-1532.	Random, but approximately $10 \log_2 K$	Variable
sparse random	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see "Random Coding Design Matrices" on page 32-1532.	Random, but approximately $15 \log_2 K$	Variable

This plot compares the number of binary learners for the coding designs with increasing K .

Algorithms

Random Coding Design Matrices

For a given number of classes K , the software generates random coding design matrices as follows.

- 1 The software generates one of these matrices:
 - a Dense random — The software assigns 1 or -1 with equal probability to each element of the K -by- L_d coding design matrix, where $L_d \approx \lceil 10 \log_2 K \rceil$.
 - b Sparse random — The software assigns 1 to each element of the K -by- L_s coding design matrix with probability 0.25, -1 with probability 0.25, and 0 with probability 0.5, where $L_s \approx \lceil 15 \log_2 K \rceil$.
- 2 If a column does not contain at least one 1 and at least one -1, then the software removes that column.
- 3 For distinct columns u and v , if $u = v$ or $u = -v$, then the software removes v from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal, pairwise row distance based on the Hamming measure ([4]) given by

$$\Delta(k_1, k_2) = 0.5 \sum_{l=1}^L |m_{k_1 l}| |m_{k_2 l}| |m_{k_1 l} - m_{k_2 l}|,$$

where $m_{k,j}$ is an element of coding design matrix j .

Support Vector Storage

By default and for efficiency, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties for all linear SVM binary learners. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors',true)
Mdl = fitcecoc(X,Y,'Learners',t);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

Alternative Functionality

You can use these alternative algorithms to train a multiclass model:

- Classification ensembles—see `fitcensemble` and `ClassificationEnsemble`
- Classification trees—see `fitctree` and `ClassificationTree`
- Discriminant analysis classifiers—see `fitcdiscr` and `ClassificationDiscriminant`
- k -nearest neighbor classifiers—see `fitcknn` and `ClassificationKNN`
- Naive Bayes classifiers—see `fitcnb` and `ClassificationNaiveBayes`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train an ECOC model by using `fitcecoc`, the following restrictions apply.
 - You cannot fit posterior probabilities by using the `'FitPosterior'` name-value pair argument.
 - All binary learners must be either SVM classifiers or linear classification models. For the `'Learners'` name-value pair argument, you can specify:
 - `'svm'` or `'linear'`

- An SVM template object or a cell array of such objects (see `templateSVM`)
- A linear classification model template object or a cell array of such objects (see `templateLinear`)
- When you generate code using a coder configurer for `predict` and `update`, the following additional restrictions apply for binary learners.
 - If you use a cell array of SVM template objects, the value of `'Standardize'` for SVM learners must be consistent. For example, if you specify `'Standardize', true` for one SVM learner, you must specify the same value for all SVM learners.
 - If you use a cell array of SVM template objects, and you use one SVM learner with a linear kernel (`'KernelFunction', 'linear'`) and another with a different type of kernel function, then you must specify `'SaveSupportVectors', true` for the learner with a linear kernel.

For details, see `ClassificationECOCoderConfigurer`. For information on name-value pair arguments that you cannot modify when you retrain a model, see “Tips” on page 32-5748.

- Code generation limitations for SVM classifiers and linear classification models also apply to ECOC classifiers, depending on the choice of binary learners. For more details, see “Code Generation” on page 32-700 of the `CompactClassificationSVM` class and “Code Generation” on page 32-390 of the `ClassificationLinear` class.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2014b

ClassificationECOCoderConfigurer

Coder configurer for multiclass model using binary learners

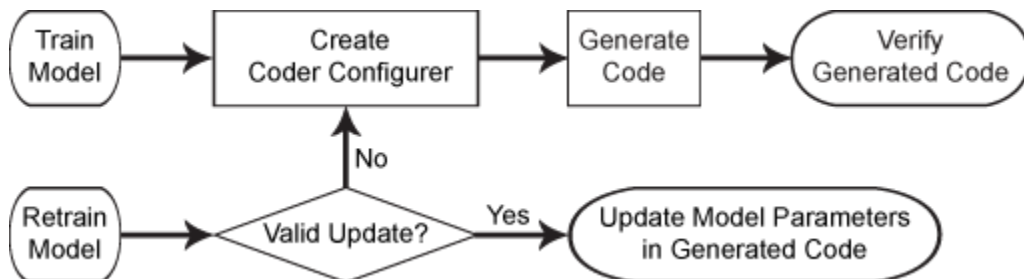

Description

A `ClassificationECOCoderConfigurer` object is a coder configurer of a multiclass error-correcting output codes (ECOC) classification model (`ClassificationECOC` or `CompactClassificationECOC`) that uses support vector machine (SVM) or linear binary learners.

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes of model parameters by using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the ECOC model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.

For the code generation usage notes and limitations of a multiclass ECOC classification model, see the Code Generation sections of `CompactClassificationECOC`, `predict`, and `update`.

Creation

After training a multiclass ECOC classification model with SVM or linear binary learners by using `fitcecoc`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

predict Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

X — Coder attributes of predictor data

LearnerCoderInput object

Coder attributes of predictor data to pass to the generated C/C++ code for the `predict` function of the ECOC classification model, specified as a `LearnerCoderInput` on page 32-355 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- `SizeVector` — The default value is the array size of the input `X`.
 - If the `Value` attribute of the `ObservationsIn` property for the `ClassificationECOCoderConfigurer` is `'rows'`, then this `SizeVector` value is `[n p]`, where `n` corresponds to the number of observations and `p` corresponds to the number of predictors.
 - If the `Value` attribute of the `ObservationsIn` property for the `ClassificationECOCoderConfigurer` is `'columns'`, then this `SizeVector` value is `[p n]`.

To switch the elements of `SizeVector` (for example, to change `[n p]` to `[p n]`), modify the `Value` attribute of the `ObservationsIn` property for the `ClassificationECOCoderConfigurer` accordingly. You cannot modify the `SizeVector` value directly.

- `VariableDimensions` — The default value is `[0 0]`, which indicates that the array size is fixed as specified in `SizeVector`.

You can set this value to `[1 0]` if the `SizeVector` value is `[n p]` or to `[0 1]` if it is `[p n]`, which indicates that the array has variable-size rows and fixed-size columns. For example, `[1 0]` specifies that the first value of `SizeVector` (`n`) is the upper bound for the number of rows, and the second value of `SizeVector` (`p`) is the number of columns.

- `DataType` — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- `Tunability` — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, to generate C/C++ code that accepts predictor data with 100 observations (in rows) of three predictor variables (in columns), specify these coder attributes of `X` for the coder configurer `configurer`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

`[0 0]` indicates that the first and second dimensions of `X` (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify these coder attributes of X:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

[1 0] indicates that the first dimension of X (number of observations) has a variable size and the second dimension of X (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as Inf.

BinaryLoss — Coder attributes of binary learner loss function

EnumeratedInput object

Coder attributes of the binary learner loss function ('BinaryLoss' name-value pair argument of predict), specified as an EnumeratedInput on page 32-356 object.

The default attribute values of the EnumeratedInput object are based on the default values of the predict function:

- **Value** — Binary learner loss function, specified as one of the character vectors in BuiltInOptions or a character vector designating a custom function name. If the binary learners are SVMs or linear classification models of SVM learners, the default value is 'hinge'. If the binary learners are linear classification models of logistic regression learners, the default value is 'quadratic'.

To use a custom option, define a custom function on the MATLAB search path, and specify Value as the name of the custom function.

- **SelectedOption** — This value is 'Built-in' (default) or 'Custom'. The software sets SelectedOption according to Value. This attribute is read-only.
- **BuiltInOptions** — Cell array of 'hamming', 'linear', 'quadratic', 'exponential', 'binodeviance', 'hinge', and 'logit'. This attribute is read-only.
- **IsConstant** — This value must be true.
- **Tunability** — The default value is false. If you specify other attribute values when Tunability is false, the software sets Tunability to true.

Decoding — Coder attributes of decoding scheme

EnumeratedInput object

Coder attributes of the decoding scheme ('Decoding' name-value pair argument of predict), specified as an EnumeratedInput on page 32-356 object.

The default attribute values of the EnumeratedInput object are based on the default values of the predict function:

- **Value** — Decoding scheme value, specified as 'lossweighted' (default), 'lossbased', or a LearnerCoderInput on page 32-355 object.

If you set IsConstant to false, then the software changes Value to a LearnerCoderInput on page 32-355 object with these read-only coder attribute values:

- **SizeVector** — [1 12]

- `VariableDimensions` — [0 1]
- `DataType` — 'char'
- `Tunability` — 1

The input in the generated code is a variable-size, tunable character vector that is either 'lossweighted' or 'lossbased'.

- `SelectedOption` — This value is 'Built-in' (default) or 'NonConstant'. The software sets `SelectedOption` according to `Value`. This attribute is read-only.
- `BuiltInOptions` — Cell array of 'lossweighted' and 'lossbased'. This attribute is read-only.
- `IsConstant` — The default value is true. If you set this value to false, the software changes `Value` to a `LearnerCoderInput` object.
- `Tunability` — The default value is false. If you specify other attribute values when `Tunability` is false, the software sets `Tunability` to true.

ObservationsIn — Coder attributes of predictor data observation dimension

EnumeratedInput object

Coder attributes of the predictor data observation dimension ('ObservationsIn' name-value pair argument of `predict`), specified as an `EnumeratedInput` on page 32-356 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the 'ObservationsIn' name-value pair argument determines the default values of the `EnumeratedInput` coder attributes:

- `Value` — The default value is the predictor data observation dimension you use when creating the coder configurer, specified as 'rows' or 'columns'. If you do not specify 'ObservationsIn' when creating the coder configurer, the default value is 'rows'.

This value must be 'rows' for a model that uses SVM binary learners.

- `SelectedOption` — This value is always 'Built-in'. This attribute is read-only.
- `BuiltInOptions` — Cell array of 'rows' and 'columns'. This attribute is read-only.
- `IsConstant` — This value must be true.
- `Tunability` — The default value is false if you specify 'ObservationsIn', 'rows' when creating the coder configurer, and true if you specify 'ObservationsIn', 'columns'. If you set `Tunability` to false, the software sets `Value` to 'rows'. If you specify other attribute values when `Tunability` is false, the software sets `Tunability` to true.

NumOutputs — Number of outputs in predict

1 (default) | 2 | 3

Number of output arguments to return from the generated C/C++ code for the `predict` function of the ECOC classification model, specified as 1, 2, or 3.

The output arguments of `predict` are, in order: `label` (predicted class labels), `NegLoss` (negated average binary losses), and `PBScore` (positive-class scores). `predict` in the generated C/C++ code returns the first `n` outputs of the `predict` function, where `n` is the `NumOutputs` value.

After creating the coder configurer `configurer`, you can specify the number of outputs by using dot notation.

```
configurer.NumOutputs = 2;
```

The `NumOutputs` property is equivalent to the `'-nargout'` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of an ECOC classification model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `double`

update Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` on page 32-355 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

BinaryLearners — Coder attributes of trained binary learners

`ClassificationSVMCoderConfigurer` object | `ClassificationLinearCoderConfigurer` object

Coder attributes of the trained binary learners (`BinaryLearners` of an ECOC classification model), specified as a `ClassificationSVMCoderConfigurer` object (for SVM binary learners) or a `ClassificationLinearCoderConfigurer` object (for linear binary learners).

Use the `update` arguments of the SVM or linear coder configurer object to specify the coder attributes of all binary learners.

- For `ClassificationSVMCoderConfigurer`, the update arguments are `Alpha`, `Beta`, `Bias`, `Cost`, `Mu`, `Prior`, `Scale`, `Sigma`, `SupportVectorLabels`, and `SupportVectors`.
- For `ClassificationLinearCoderConfigurer`, the update arguments are `Beta`, `Bias`, `Cost`, and `Prior`.

For the configuration of `BinaryLearners`, the software uses only the `update` argument properties and ignores the other properties of the object.

When you train an ECOC model with SVM binary learners, each learner can have a different number of support vectors. Therefore, the software configures the default attribute values of the `LearnerCoderInput` on page 32-355 objects for `Alpha`, `SupportVectorLabels`, and `SupportVectors` to accommodate all binary learners, based on the input argument `Mdl` of `learnerCoderConfigurer`.

- `SizeVector`
 - This value is `[s 1]` for `Alpha` and `SupportVectorLabels`, where `s` is the largest number of support vectors in the binary learners.
 - This value is `[s p]` for `SupportVectors`, where `p` is the number of predictors.
- `VariableDimensions` — This value is `[0 0]` or `[1 0]`. If each learner has the same number of support vectors, the default value is `[0 0]`. Otherwise, this value must be `[1 0]`.

- `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
- `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — If you train a model with a linear kernel function, and the model stores the linear predictor coefficients (Beta) without the support vectors and related values, then this value must be false. Otherwise, this value must be true.

For details about the other update arguments, see update arguments on page 32-495 of `ClassificationSVMCoderConfigurer` and update arguments on page 32-393 of `ClassificationLinearCoderConfigurer`.

Cost — Coder attributes of misclassification cost

`LearnerCoderInput` object

Coder attributes of the misclassification cost (Cost of an ECOC classification model), specified as a `LearnerCoderInput` on page 32-355 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[c c]`, where `c` is the number of classes.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — The default value is true.

Prior — Coder attributes of prior probabilities

`LearnerCoderInput` object

Coder attributes of the prior probabilities (Prior of an ECOC classification model), specified as a `LearnerCoderInput` on page 32-355 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[1 c]`, where `c` is the number of classes.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — The default value is true.

Other Configurer Options

OutputFileName — File name of generated C/C++ code

'ClassificationECOCModel' (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function `generateCode` of `ClassificationECOCoderConfigurer` generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer `configurer`, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: `char`

Verbose — Verbosity level

`true` (logical 1) (default) | `false` (logical 0)

Verbosity level, specified as `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
<code>true</code> (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
<code>false</code> (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: `logical`

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

CodeGenerationArguments — codegen arguments

cell array

This property is read-only.

`codegen` arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: `cell`

PredictInputs — List of tunable input arguments of predict

cell array

This property is read-only.

List of tunable input arguments of the entry-point function `predict.m` for code generation, specified as a cell array. The cell array contains another cell array that includes `coder.PrimitiveType` objects and `coder.Constant` objects.

If you modify the coder attributes of `predict` arguments on page 32-341, then the software updates the corresponding objects accordingly. If you specify the `Tunability` attribute as `false`, then the software removes the corresponding objects from the `PredictInputs` list.

The cell array in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: `cell`

UpdateInputs — List of tunable input arguments of update

cell array

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure. The structure includes a `coder.CellType` object for `BinaryLearners` and `coder.PrimitiveType` objects for `Cost` and `Prior`.

If you modify the coder attributes of `update` arguments on page 32-344, then the software updates the corresponding objects accordingly. If you specify the `Tunability` attribute as `false`, then the software removes the corresponding object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

Data Types: `cell`

Object Functions

<code>generateCode</code>	Generate C/C++ code using coder configurer
<code>generateFiles</code>	Generate MATLAB files for code generation using coder configurer
<code>validatedUpdateInputs</code>	Validate and extract machine learning model parameters to update

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load Fisher's iris data set and train a multiclass ECOC model using SVM binary learners.

```
load fisheriris
X = meas;
Y = species;
Mdl = fitcecoc(X,Y);
```

`Mdl` is a `ClassificationECOC` object.

Create a coder configurer for the `ClassificationECOC` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X)

configurer =
  ClassificationECOCoderConfigurer with properties:

  Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
    Prior: [1x1 LearnerCoderInput]
    Cost: [1x1 LearnerCoderInput]

  Predict Inputs:
    X: [1x1 LearnerCoderInput]

  Code Generation Parameters:
    NumOutputs: 1
    OutputFileName: 'ClassificationECOCModel'
```

Properties, Methods

`configurer` is a `ClassificationECOCoderConfigurer` object, which is a coder configurer of a `ClassificationECOC` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the ECOC classification model (`Mdl`) with default settings.

generateCode(configurer)

generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationECOCModel.mat'

The generateCode function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationECOCModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationECOCModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

type predict.m

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:36:34
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

type update.m

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:36:34
initialize('update',varargin{:});
end
```

type initialize.m

```

Update Parameters of ECOC Classification Model in Generated Code

Train an error-correcting output codes (ECOC) model using SVM binary learners and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the ECOC model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using different settings, and update parameters in the generated code without regenerating the code.

Train Model

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create an SVM binary learner template to use a Gaussian kernel function and to standardize predictor data.

```
t = templateSVM('KernelFunction','gaussian','Standardize',true);
```

Train a multiclass ECOC model using the template `t`.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

`Mdl` is a `ClassificationECOC` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationECOC` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns the first two outputs of the `predict` function, which are the predicted labels and negated average binary losses.

```
configurer = learnerCoderConfigurer(Mdl,X,'NumOutputs',2)
```

```
configurer =
  ClassificationECOCoderConfigurer with properties:

  Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
    Prior: [1x1 LearnerCoderInput]
    Cost: [1x1 LearnerCoderInput]

  Predict Inputs:
    X: [1x1 LearnerCoderInput]

  Code Generation Parameters:
    NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'
```

Properties, Methods

`configurer` is a `ClassificationECOCoderConfigurer` object, which is a coder configurer of a `ClassificationECOC` object. The display shows the tunable input arguments of `predict` and `update`: `X`, `BinaryLearners`, `Prior`, and `Cost`.

Specify Coder Attributes of Parameters

Specify the coder attributes of `predict` arguments (predictor data and the name-value pair arguments `'Decoding'` and `'BinaryLoss'`) and `update` arguments (support vectors of the SVM learners) so that you can use these arguments as the input arguments of `predict` and `update` in the generated code.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 4];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 4 predictors, so the second value of the `SizeVector` attribute must be 4 and the second value of the `VariableDimensions` attribute must be `false`.

Next, modify the coder attributes of `BinaryLoss` and `Decoding` to use the `'BinaryLoss'` and `'Decoding'` name-value pair arguments in the generated code. Display the coder attributes of `BinaryLoss`.

```
configurer.BinaryLoss
ans =
    EnumeratedInput with properties:
        Value: 'hinge'
        SelectedOption: 'Built-in'
        BuiltInOptions: {1x7 cell}
        IsConstant: 1
        Tunability: 0
```

To use a nondefault value in the generated code, you must specify the value before generating the code. Specify the `Value` attribute of `BinaryLoss` as `'exponential'`.

```
configurer.BinaryLoss.Value = 'exponential';
configurer.BinaryLoss
ans =
    EnumeratedInput with properties:
```

```
        Value: 'exponential'  
SelectedOption: 'Built-in'  
BuiltInOptions: {1x7 cell}  
    IsConstant: 1  
    Tunability: 1
```

If you modify attribute values when `Tunability` is false (logical 0), the software sets the `Tunability` to true (logical 1).

Display the coder attributes of `Decoding`.

```
configurer.Decoding
```

```
ans =  
    EnumeratedInput with properties:  
  
        Value: 'lossweighted'  
SelectedOption: 'Built-in'  
BuiltInOptions: {'lossweighted' 'lossbased'}  
    IsConstant: 1  
    Tunability: 0
```

Specify the `IsConstant` attribute of `Decoding` as false so that you can use all available values in `BuiltInOptions` in the generated code.

```
configurer.Decoding.IsConstant = false;  
configurer.Decoding
```

```
ans =  
    EnumeratedInput with properties:  
  
        Value: [1x1 LearnerCoderInput]  
SelectedOption: 'NonConstant'  
BuiltInOptions: {'lossweighted' 'lossbased'}  
    IsConstant: 0  
    Tunability: 1
```

The software changes the `Value` attribute of `Decoding` to a `LearnerCoderInput` object so that you can use both 'lossweighted' and 'lossbased' as the value of 'Decoding'. Also, the software sets the `SelectedOption` to 'NonConstant' and the `Tunability` to true.

Finally, modify the coder attributes of `SupportVectors` in `BinaryLearners`. Display the coder attributes of `SupportVectors`.

```
configurer.BinaryLearners.SupportVectors
```

```
ans =  
    LearnerCoderInput with properties:  
  
        SizeVector: [54 4]  
VariableDimensions: [1 0]  
        DataType: 'double'  
    Tunability: 1
```

The default value of `VariableDimensions` is `[true false]` because each learner has a different number of support vectors. If you retrain the ECOC model using new data or different settings, the number of support vectors in the SVM learners can vary. Therefore, increase the upper bound of the number of support vectors.

```
configurer.BinaryLearners.SupportVectors.SizeVector = [150 4];
```

`SizeVector` attribute for `Alpha` has been modified to satisfy configuration constraints.
`SizeVector` attribute for `SupportVectorLabels` has been modified to satisfy configuration constraints.

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Display the coder configurer.

```
configurer
```

```
configurer =
  ClassificationECOCoderConfigurer with properties:

  Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
      Prior: [1x1 LearnerCoderInput]
      Cost: [1x1 LearnerCoderInput]

  Predict Inputs:
    X: [1x1 LearnerCoderInput]
    BinaryLoss: [1x1 EnumeratedInput]
    Decoding: [1x1 EnumeratedInput]

  Code Generation Parameters:
    NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'
```

Properties, Methods

The display now includes `BinaryLoss` and `Decoding` as well.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the ECOC classification model (Mdl).

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
 'initialize.m', 'predict.m', 'update.m', 'ClassificationECOCModel.mat'

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationECOCModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationECOCModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument. Because you specified `'Decoding'` as a tunable input argument by changing the `IsConstant` attribute before generating the code, you also need to specify it in the call to the MEX function, even though `'lossweighted'` is the default value of `'Decoding'`.

```
[label,NegLoss] = predict(Mdl,X,'BinaryLoss','exponential');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential','Decoding');
```

Compare `label` to `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical
     1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`NegLoss_mex` might include round-off differences compared to `NegLoss`. In this case, compare `NegLoss_mex` to `NegLoss`, allowing a small tolerance.

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
     0x1 empty double column vector
```

The comparison confirms that `NegLoss` and `NegLoss_mex` are equal within the tolerance $1e-8$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using a different setting. Specify `'KernelScale'` as `'auto'` so that the software selects an appropriate scale factor using a heuristic procedure.

```
t_new = templateSVM('KernelFunction','gaussian','Standardize',true,'KernelScale','auto');
retrainedMdl = fitcecoc(X,Y,'Learners',t_new);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationECOCModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` to the outputs from the `predict` function in the updated MEX function.

```
[label,NegLoss] = predict(retrainedMdl,X,'BinaryLoss','exponential','Decoding','lossbased');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential','Decoding');
isequal(label,label_mex)
```

```
ans = logical
     1
```

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
```

```
     0x1 empty double column vector
```

The comparison confirms that `label` and `label_mex` are equal, and `NegLoss` and `NegLoss_mex` are equal within the tolerance.

More About

LearnerCoderInput Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
SizeVector	<p>Array size if the corresponding <code>VariableDimensions</code> value is <code>false</code>.</p> <p>Upper bound of the array size if the corresponding <code>VariableDimensions</code> value is <code>true</code>. To allow an unbounded array, specify the bound as <code>Inf</code>.</p>
VariableDimensions	<p>Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0):</p> <ul style="list-style-type: none"> A value of <code>true</code> (logical 1) means that the corresponding dimension has a variable size. A value of <code>false</code> (logical 0) means that the corresponding dimension has a fixed size.
DataType	Data type of the array

Attribute Name	Description
Tunability	Indicator specifying whether or not <code>predict</code> or <code>update</code> includes the argument as an input in the generated code, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0). If you specify other attribute values when <code>Tunability</code> is <code>false</code> , the software sets <code>Tunability</code> to <code>true</code> .

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of the coefficients `Alpha` in `BinaryLearners` of the coder configurer `configurer`:

```
configurer.BinaryLearners.Alpha.SizeVector = [100 1];  
configurer.BinaryLearners.Alpha.VariableDimensions = [1 0];  
configurer.BinaryLearners.Alpha.DataType = 'double';
```

If you specify the verbosity level (`Verbose`) as `true` (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

EnumeratedInput Object

A coder configurer uses an `EnumeratedInput` object to specify the coder attributes of `predict` input arguments that have a finite set of available values.

An `EnumeratedInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
Value	<p>Value of the <code>predict</code> argument in the generated code, specified as a character vector or a <code>LearnerCoderInput</code> on page 32-355 object.</p> <ul style="list-style-type: none"> • Character vector in <code>BuiltInOptions</code> — You can specify one of the <code>BuiltInOptions</code> using either the option name or its index value. For example, to choose the first option, specify <code>Value</code> as either the first character vector in <code>BuiltInOptions</code> or <code>1</code>. • Character vector designating a custom function name — To use a custom option, define a custom function on the MATLAB search path, and specify <code>Value</code> as the name of the custom function. • <code>LearnerCoderInput</code> on page 32-355 object — If you set <code>IsConstant</code> to <code>false</code> (logical <code>0</code>), then the software changes <code>Value</code> to a <code>LearnerCoderInput</code> on page 32-355 object with the following read-only coder attribute values. These values indicate that the input in the generated code is a variable-size, tunable character vector that is one of the available values in <code>BuiltInOptions</code>. <ul style="list-style-type: none"> • <code>SizeVector</code> — <code>[1 c]</code>, indicating the upper bound of the array size, where <code>c</code> is the length of the longest available character vector in <code>Option</code> • <code>VariableDimensions</code> — <code>[0 1]</code>, indicating that the array is a variable-size vector • <code>DataType</code> — <code>'char'</code> • <code>Tunability</code> — <code>1</code> <p>The default value of <code>Value</code> is consistent with the default value of the corresponding <code>predict</code> argument, which is one of the character vectors in <code>BuiltInOptions</code>.</p>
SelectedOption	<p>Status of the selected option, specified as <code>'Built-in'</code>, <code>'Custom'</code>, or <code>'NonConstant'</code>. The software sets <code>SelectedOption</code> according to <code>Value</code>:</p> <ul style="list-style-type: none"> • <code>'Built-in'</code> (default) — When <code>Value</code> is one of the character vectors in <code>BuiltInOptions</code> • <code>'Custom'</code> — When <code>Value</code> is a character vector that is not in <code>BuiltInOptions</code> • <code>'NonConstant'</code> — When <code>Value</code> is a <code>LearnerCoderInput</code> on page 32-355 object <p>This attribute is read-only.</p>
BuiltInOptions	<p>List of available character vectors for the corresponding <code>predict</code> argument, specified as a cell array.</p> <p>This attribute is read-only.</p>

Attribute Name	Description
IsConstant	<p>Indicator specifying whether or not the array value is a compile-time constant (<code>coder.Constant</code>) in the generated code, specified as <code>true</code> (logical 1, default) or <code>false</code> (logical 0).</p> <p>If you set this value to <code>false</code>, then the software changes <code>Value</code> to a <code>LearnerCoderInput</code> on page 32-355 object.</p>
Tunability	<p>Indicator specifying whether or not <code>predict</code> includes the argument as an input in the generated code, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0, default).</p> <p>If you specify other attribute values when <code>Tunability</code> is <code>false</code>, the software sets <code>Tunability</code> to <code>true</code>.</p>

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of `BinaryLoss` of the coder configurer configurer:

```
configurer.BinaryLoss.Value = 'linear';
```

Topics

“Introduction to Code Generation” on page 31-2

“Code Generation for Prediction and Update Using Coder Configurer” on page 31-68

Introduced in R2019a

ClassificationDiscriminant class

Superclasses: CompactClassificationDiscriminant

Discriminant analysis classification

Description

A `ClassificationDiscriminant` object encapsulates a discriminant analysis classifier, which is a Gaussian mixture model for data generation. A `ClassificationDiscriminant` object can predict responses for new data using the `predict` method. The object contains the data used for training, so can compute resubstitution predictions.

Construction

Create a `ClassificationDiscriminant` object by using `fitcdiscr`.

Properties

BetweenSigma

p-by-p matrix, the between-class covariance, where p is the number of predictors.

CategoricalPredictors

Categorical predictor indices, which is always empty (`[]`).

ClassNames

List of the elements in the training data Y with duplicates removed. `ClassNames` can be a categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. `ClassNames` has the same data type as the data in the argument Y. (The software treats string arrays as cell arrays of character vectors.)

Coeffs

k-by-k structure of coefficient matrices, where k is the number of classes. `Coeffs(i, j)` contains coefficients of the linear or quadratic boundaries between classes i and j. Fields in `Coeffs(i, j)`:

- `DiscrimType`
- `Class1` — `ClassNames(i)`
- `Class2` — `ClassNames(j)`
- `Const` — A scalar
- `Linear` — A vector with p components, where p is the number of columns in X
- `Quadratic` — p-by-p matrix, exists for quadratic `DiscrimType`

The equation of the boundary between class i and class j is

$$\text{Const} + \text{Linear} * x + x' * \text{Quadratic} * x = 0,$$

where x is a column vector of length p .

If `fitcdiscr` had the `FillCoeffs` name-value pair set to `'off'` when constructing the classifier, `Coeffs` is empty (`[]`).

Cost

Square matrix, where `Cost(i,j)` is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response.

Change a `Cost` matrix using dot notation: `obj.Cost = costMatrix`.

Delta

Value of the Delta threshold for a linear discriminant model, a nonnegative scalar. If a coefficient of `obj` has magnitude smaller than `Delta`, `obj` sets this coefficient to 0 , and so you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

Change `Delta` using dot notation: `obj.Delta = newDelta`.

DeltaPredictor

Row vector of length equal to the number of predictors in `obj`. If `DeltaPredictor(i) < Delta` then coefficient i of the model is 0 .

If `obj` is a quadratic discriminant model, all elements of `DeltaPredictor` are 0 .

DiscrimType

Character vector specifying the discriminant type. One of:

- `'linear'`
- `'quadratic'`
- `'diagLinear'`
- `'diagQuadratic'`
- `'pseudoLinear'`
- `'pseudoQuadratic'`

Change `DiscrimType` using dot notation: `obj.DiscrimType = newDiscrimType`.

You can change between linear types, or between quadratic types, but cannot change between linear and quadratic types.

Gamma

Value of the Gamma regularization parameter, a scalar from 0 to 1 . Change `Gamma` using dot notation: `obj.Gamma = newGamma`.

- If you set `1` for linear discriminant, the discriminant sets its type to `'diagLinear'`.

- If you set a value between `MinGamma` and 1 for linear discriminant, the discriminant sets its type to `'linear'`.
- You cannot set values below the value of the `MinGamma` property.
- For quadratic discriminant, you can set either 0 (for `DiscrimType 'quadratic'`) or 1 (for `DiscrimType 'diagQuadratic'`).

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

LogDetSigma

Logarithm of the determinant of the within-class covariance matrix. The type of `LogDetSigma` depends on the discriminant type:

- Scalar for linear discriminant analysis
- Vector of length `K` for quadratic discriminant analysis, where `K` is the number of classes

MinGamma

Nonnegative scalar, the minimal value of the `Gamma` parameter so that the correlation matrix is invertible. If the correlation matrix is not singular, `MinGamma` is 0.

ModelParameters

Parameters used in training obj.

Mu

Class means, specified as a `K`-by-`p` matrix of scalar values class means of size. `K` is the number of classes, and `p` is the number of predictors. Each row of `Mu` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the `ClassNames` attribute.

NumObservations

Number of observations in the training data, a numeric scalar. `NumObservations` can be less than the number of rows of input data `X` when there are missing values in `X` or response `Y`.

PredictorNames

Cell array of names for the predictor variables, in the order in which they appear in the training data `X`.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`.

Add or change a Prior vector using dot notation: `obj.Prior = priorVector`.

ResponseName

Character vector describing the response variable Y.

ScoreTransform

Character vector representing a built-in transformation function, or a function handle for transforming scores. 'none' means no transformation; equivalently, 'none' means `@(x)x`. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitcdiscr`.

Implement dot notation to add or change a `ScoreTransform` function using one of the following:

- `cobj.ScoreTransform = 'function'`
- `cobj.ScoreTransform = @function`

Sigma

Within-class covariance matrix or matrices. The dimensions depend on `DiscrimType`:

- 'linear' (default) — Matrix of size p-by-p, where p is the number of predictors
- 'quadratic' — Array of size p-by-p-by-K, where K is the number of classes
- 'diagLinear' — Row vector of length p
- 'diagQuadratic' — Array of size 1-by-p-by-K
- 'pseudoLinear' — Matrix of size p-by-p
- 'pseudoQuadratic' — Array of size p-by-p-by-K

W

Scaled weights, a vector with length n, the number of rows in X.

X

Matrix of predictor values. Each column of X represents one predictor (variable), and each row represents one observation.

Xcentered

X data with class means subtracted. If $Y(i)$ is of class j ,

$$X_{centered}(i,:) = X(i,:) - \mu(j,:),$$

where μ is the class mean property.

Y

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector with the same number of rows as X. Each row of Y represents the classification of the corresponding row of X.

Methods

compact	Compact discriminant analysis classifier
crossval	Cross-validated discriminant analysis classifier
cvshrink	Cross-validate regularization of linear discriminant
resubEdge	Classification edge by resubstitution
resubLoss	Classification error by resubstitution
resubMargin	Classification margins by resubstitution
resubPredict	Predict resubstitution labels of discriminant analysis classification model

Inherited Methods

edge	Classification edge
logP	Log unconditional probability density for discriminant analysis classifier
loss	Classification error
mahal	Mahalanobis distance to class means
margin	Classification margins
nLinearCoeffs	Number of nonzero linear coefficients
predict	Predict labels using discriminant analysis classification model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Discriminant Analysis Model

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis model using the entire data set.

```
Mdl = fitcdiscr(meas,species)
```

```
Mdl =
  ClassificationDiscriminant
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
  NumObservations: 150
      DiscrimType: 'linear'
              Mu: [3x4 double]
              Coeffs: [3x3 struct]
```

Properties, Methods

`Mdl` is a `ClassificationDiscriminant` model. To access its properties, use dot notation. For example, display the group means for each predictor.

```
Mdl.Mu
```

```
ans = 3x4
```

```
    5.0060    3.4280    1.4620    0.2460
    5.9360    2.7700    4.2600    1.3260
    6.5880    2.9740    5.5520    2.0260
```

To predict labels for new observations, pass `Mdl` and predictor data to `predict`.

More About

Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).
- For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
- For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \operatorname{argmin}_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k|x)C(y|k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k|x)$ is the posterior probability on page 20-6 of class k for observation x .
- $C(y|k)$ is the cost on page 20-7 of classifying an observation as y when its true class is k .

For details, see “Prediction Using Discriminant Analysis Models” on page 20-6.

Regularization

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, γ and δ , that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let Σ represent the covariance matrix of the data X , and let \hat{X} be the centered data (the data X minus the mean by class). Define

$$D = \text{diag}(\widehat{X}^T * \widehat{X}).$$

The regularized covariance matrix $\widetilde{\Sigma}$ is

$$\widetilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq \text{MinGamma}$, $\widetilde{\Sigma}$ is nonsingular.

Let μ_k be the mean vector for those elements of X in class k , and let μ_0 be the global mean vector (the mean of the rows of X). Let C be the correlation matrix of the data X , and let \widetilde{C} be the regularized correlation matrix:

$$\widetilde{C} = (1 - \gamma)C + \gamma I,$$

where I is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point x is

$$(x - \mu_0)^T \widetilde{\Sigma}^{-1} (\mu_k - \mu_0) = [(x - \mu_0)^T D^{-1/2}] [\widetilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)].$$

The parameter δ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $[\widetilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)]$ is set to zero if it is smaller in magnitude than the threshold δ . Therefore, for class k , if component j is thresholded to zero, component j of x does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(i)$, all classes k have

$$|\widetilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)| \leq \delta.$$

Therefore, when $\delta \geq \text{DeltaPredictor}(i)$, the regularized classifier does not use predictor i .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train a discriminant analysis model by using `fitcdiscr` or create a compact discriminant analysis model by using `makecdiscr`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.

- The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
- The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011b

ClassificationEnsemble

Package: classreg.learning.classif

Superclasses: CompactClassificationEnsemble

Ensemble classifier

Description

`ClassificationEnsemble` combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners. It stores data used for training, can compute resubstitution predictions, and can resume training if desired.

Construction

Create a classification ensemble object using `fitcensemble`.

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value pair argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains NaNs, then the corresponding `Xbinned` values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

ClassNames

List of the elements in `Y` with duplicates removed. `ClassNames` can be a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. `ClassNames` has the same data type as the data in the argument `Y`. (The software treats string arrays as cell arrays of character vectors.)

CombineWeights

Character vector describing how `ens` combines weak learner weights, either `'WeightedSum'` or `'WeightedAverage'`.

Cost

Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response. This property is read-only.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

FitInfo

Numeric array of fit information. The `FitInfoDescription` property describes the content of this array.

FitInfoDescription

Character vector describing the meaning of the `FitInfo` array.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`

- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

LearnerNames

Cell array of character vectors with names of weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, `LearnerNames` is {'Tree'}.

Method

Character vector describing the method that creates `ens`.

ModelParameters

Parameters used in training `ens`.

NumObservations

Numeric scalar containing the number of observations in the training data.

NumTrained

Number of trained weak learners in `ens`, a scalar.

PredictorNames

Cell array of names for the predictor variables, in the order in which they appear in `X`.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

ReasonForTermination

Character vector describing the reason `fitcensemble` stopped adding weak learners to the ensemble.

ResponseName

Character vector with the name of the response variable `Y`.

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```
ens.ScoreTransform = 'function'
```

or

```
ens.ScoreTransform = @function
```

Trained

A cell vector of trained classification models.

- If Method is 'LogitBoost' or 'GentleBoost', then ClassificationEnsemble stores trained learner j in the CompactRegressionLearner property of the object stored in Trained{ j }. That is, to access trained learner j , use `ens.Trained{j}.CompactRegressionLearner`.
- Otherwise, cells of the cell vector contain the corresponding, compact classification models.

TrainedWeights

Numeric vector of trained weights for the weak learners in `ens`. TrainedWeights has T elements, where T is the number of weak learners in `learners`.

UsePredForLearner

Logical matrix of size P -by-`NumTrained`, where P is the number of predictors (columns) in the training data X . UsePredForLearner(i, j) is `true` when learner j uses predictor i , and is `false` otherwise. For each learner, the predictors have the same order as the columns in the training data X .

If the ensemble is not of type `Subspace`, all entries in UsePredForLearner are `true`.

W

Scaled weights, a vector with length n , the number of rows in X . The sum of the elements of W is 1.

X

Matrix or table of predictor values that trained the ensemble. Each column of X represents one variable, and each row represents one observation.

Y

Numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. Each row of Y represents the classification of the corresponding row of X .

Methods

<code>compact</code>	Compact classification ensemble
<code>crossval</code>	Cross validate ensemble
<code>resubEdge</code>	Classification edge by resubstitution
<code>resubLoss</code>	Classification error by resubstitution
<code>resubMargin</code>	Classification margins by resubstitution
<code>resubPredict</code>	Classify observations in ensemble of classification models
<code>resume</code>	Resume training ensemble

Inherited Methods

edge	Classification edge
loss	Classification error
margin	Classification margins
predict	Classify observations using ensemble of classification models
predictorImportance	Estimates of predictor importance for classification ensemble of decision trees
removeLearners	Remove members of compact classification ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Boosted Classification Ensemble

Load the ionosphere data set.

```
load ionosphere
```

Train a boosted ensemble of 100 classification trees using all measurements and the AdaBoostM1 method.

```
Mdl = fitensemble(X,Y,'Method','AdaBoostM1')
```

```
Mdl =
  classreg.learning.classif.ClassificationEnsemble
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
    NumObservations: 351
         NumTrained: 100
           Method: 'AdaBoostM1'
    LearnerNames: {'Tree'}
ReasonForTermination: 'Terminated normally after completing the requested number of training iterations'
          FitInfo: [100x1 double]
  FitInfoDescription: {2x1 cell}
```

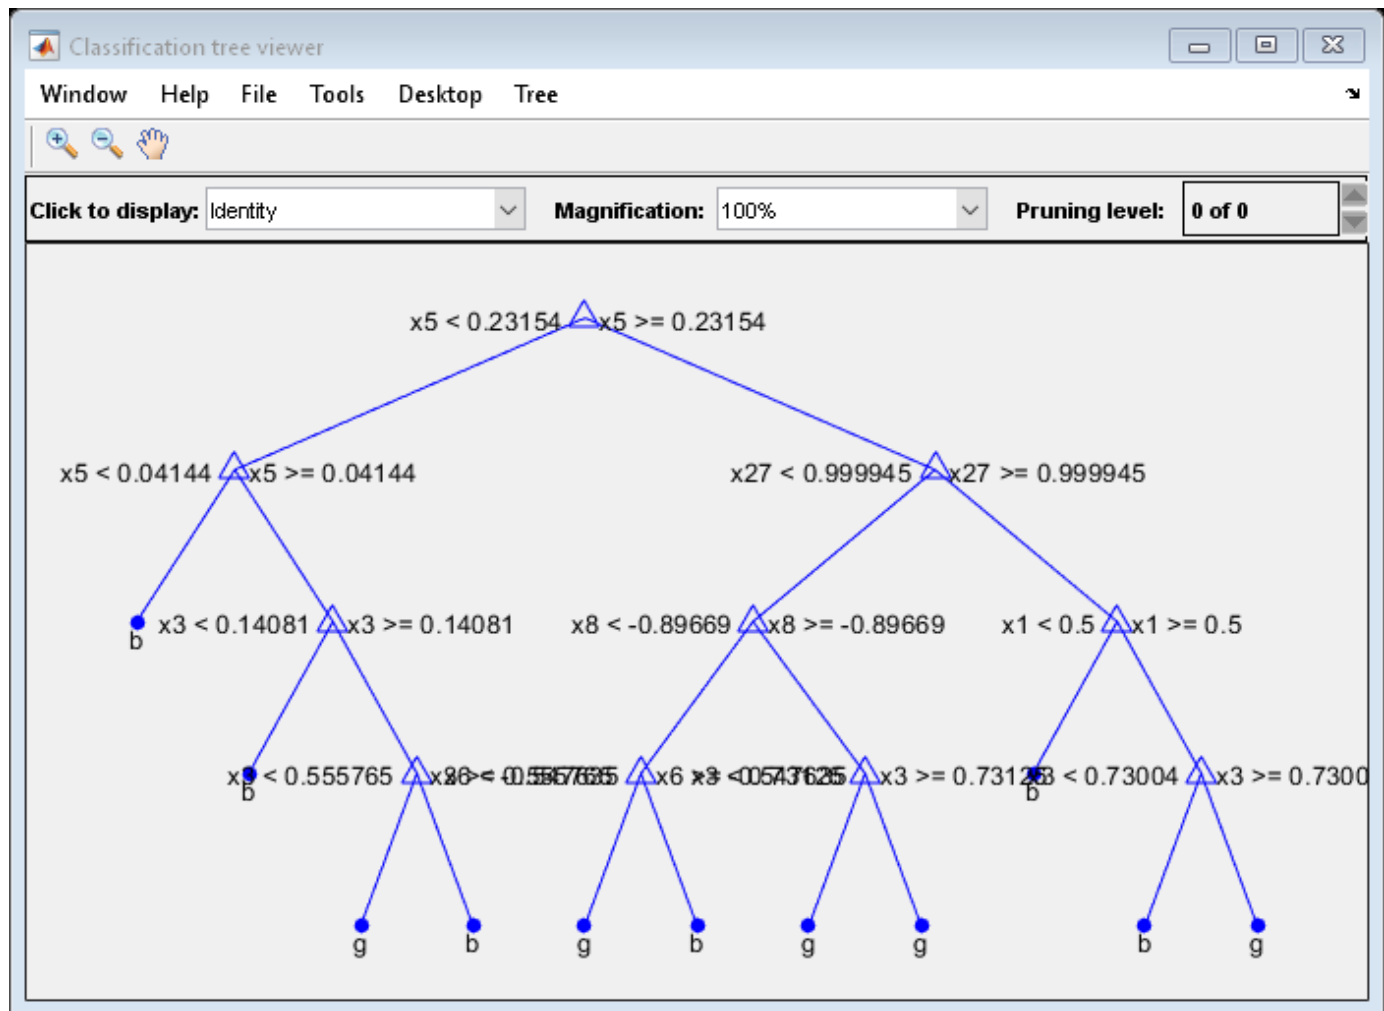

Properties, Methods

Mdl is a ClassificationEnsemble model object.

Mdl.Trained is the property that stores a 100-by-1 cell vector of the trained classification trees (CompactClassificationTree model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trained{1},'Mode','graph')
```

By default, `fitensemble` grows shallow trees for boosted ensembles of trees.

Predict the label of the mean of X .

```
predMeanX = predict(Mdl,mean(X))
```

```
predMeanX = 1x1 cell array
    {'g'}
```

Tip

For an ensemble of classification trees, the `Trained` property of `ens` stores an `ens.NumTrained-by-1` cell vector of compact classification models. For a textual or graphical display of tree t in the cell vector, enter:

- `view(ens.Trained{t}.CompactRegressionLearner)` for ensembles aggregated using LogitBoost or GentleBoost.
- `view(ens.Trained{t})` for all other aggregation methods.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train an ensemble by using `fitcensemble`, code generation limitations for the weak learners used in the ensemble also apply to the ensemble. For more details, see the Code Generation sections of `ClassificationKNN`, `CompactClassificationDiscriminant`, and `CompactClassificationTree`.
- For fixed-point code generation, you must train an ensemble using tree learners.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a

ClassificationKNN

k-nearest neighbor classification

Description

`ClassificationKNN` is a nearest-neighbor classification model in which you can alter both the distance metric and the number of nearest neighbors. Because a `ClassificationKNN` classifier stores training data, you can use the model to compute resubstitution predictions. Alternatively, use the model to classify new observations using the `predict` method.

Creation

Create a `ClassificationKNN` model using `fitcknn`.

Properties

KNN Properties

BreakTies — Tie-breaking algorithm

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by `predict` when multiple classes have the same smallest cost, specified as one of the following:

- 'smallest' — Use the smallest index among tied groups.
- 'nearest' — Use the class with the nearest neighbor among tied groups.
- 'random' — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the *k* nearest neighbors. `BreakTies` applies when `IncludeTies` is `false`.

Change `BreakTies` using dot notation: `mdl.BreakTies = newBreakTies`.

Distance — Distance metric

'cityblock' | 'chebychev' | 'correlation' | 'cosine' | 'euclidean' | function handle | ...

Distance metric, specified as a character vector or a function handle. The values allowed depend on the `NSMethod` property.

NSMethod	Distance Metric Allowed
'exhaustive'	Any distance metric of <code>ExhaustiveSearcher</code>
'kdtree'	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

The following table lists the `ExhaustiveSearcher` distance metrics.

Value	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C . The default value of C is the sample covariance matrix of X , as computed by <code>nancov(X)</code> . To specify a different value for C , set the <code>DistParameter</code> property of <code>mdl</code> using dot notation.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, set the <code>DistParameter</code> property of <code>mdl</code> using dot notation.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S . The default value of S is the standard deviation computed from X , $S = \text{nanstd}(X)$. To specify another value for S , set the <code>DistParameter</code> property of <code>mdl</code> using dot notation.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> where <ul style="list-style-type: none"> • ZI is a 1-by-N vector containing one row of X or Y. • ZJ is an $M2$-by-N matrix containing multiple rows of X or Y. • $D2$ is an $M2$-by-1 vector of distances, and $D2(k)$ is the distance between observations ZI and $ZJ(k, :)$.

For more information, see “Distance Metrics” on page 18-11.

Change Distance using dot notation: `mdl.Distance = newDistance`.

If `NSMethod` is 'kdtree', you can use dot notation to change `Distance` only for the metrics 'cityblock', 'chebychev', 'euclidean', and 'minkowski'.

Data Types: char | function_handle

DistanceWeight – Distance weighting function

'equal' | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as one of the values in this table.

Value	Description
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance ²
@fcn	<i>fcn</i> is a function that accepts a matrix of nonnegative distances and returns a matrix of the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

Change DistanceWeight using dot notation: `mdl.DistanceWeight = newDistanceWeight`.

Data Types: char | function_handle

DistParameter — Parameter for distance metric

positive definite covariance matrix | positive scalar | vector of positive scale values

Parameter for the distance metric, specified as one of the values described in this table.

Distance Metric	Parameter
'mahalanobis'	Positive definite covariance matrix C
'minkowski'	Minkowski distance exponent, a positive scalar
'seuclidean'	Vector of positive scale values with length equal to the number of columns of X

For any other distance metric, the value of DistParameter must be [].

You can alter DistParameter using dot notation: `mdl.DistParameter = newDistParameter`. However, if Distance is 'mahalanobis' or 'seuclidean', then you cannot alter DistParameter.

Data Types: single | double

IncludeTies — Tie inclusion flag

false (default) | true

Tie inclusion flag indicating whether predict includes all the neighbors whose distance values are equal to the *k*th smallest distance, specified as false or true. If IncludeTies is true, predict includes all of these neighbors. Otherwise, predict uses exactly *k* neighbors (see the BreakTies property).

Change IncludeTies using dot notation: `mdl.IncludeTies = newIncludeTies`.

Data Types: logical

NSMethod — Nearest neighbor search method

'kdtree' | 'exhaustive'

This property is read-only.

Nearest neighbor search method, specified as either 'kdtree' or 'exhaustive'.

- 'kdtree' — Creates and uses a Kd-tree to find nearest neighbors.
- 'exhaustive' — Uses the exhaustive search algorithm. When predicting the class of a new point x_{new} , the software computes the distance values from all points in X to x_{new} to find nearest neighbors.

The default value is 'kdtree' when X has 10 or fewer columns, X is not sparse, and the distance metric is a 'kdtree' type. Otherwise, the default value is 'exhaustive'.

NumNeighbors — Number of nearest neighbors

positive integer value

Number of nearest neighbors in X used to classify each point during prediction, specified as a positive integer value.

Change NumNeighbors using dot notation: `mdl.NumNeighbors = newNumNeighbors`.

Data Types: `single` | `double`

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

[] | vector of positive integers

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: `double`

ClassNames — Names of classes in training data Y

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Names of the classes in the training data Y with duplicates removed, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as Y . (The software treats string arrays as cell arrays of character vectors.)

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Cost of misclassification

square matrix

Cost of the misclassification of a point, specified as a square matrix. $Cost(i, j)$ is the cost of classifying a point into class j if its true class is i (that is, the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns in `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response.

By default, $Cost(i, j) = 1$ if $i \neq j$, and $Cost(i, j) = 0$ if $i = j$. In other words, the cost is 0 for correct classification and 1 for incorrect classification.

Change a `Cost` matrix using dot notation: `mdl.Cost = costMatrix`.

Data Types: `single` | `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

This property is read-only.

Expanded predictor names, specified as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

ModelParameters — Parameters used in training ClassificationKNN

structure

This property is read-only.

Parameters used in training the `ClassificationKNN` model, specified as a structure.

Data Types: `struct`

Mu — Predictor means

numeric vector

This property is read-only.

Predictor means, specified as a numeric vector of length `numel(PredictorNames)`.

If you do not standardize `mdl` when training the model using `fitcknn`, then `Mu` is empty (`[]`).

Data Types: `single` | `double`

NumObservations — Number of observations

positive integer scalar

This property is read-only.

Number of observations used in training the `ClassificationKNN` model, specified as a positive integer scalar. This number can be less than the number of rows in the training data because rows containing NaN values are not part of the fit.

Data Types: `double`

PredictorNames — Predictor variable names

cell array of character vectors

This property is read-only.

Predictor variable names, specified as a cell array of character vectors. The variable names are in the same order in which they appear in the training data `X`.

Data Types: `cell`

Prior — Prior probabilities for each class

numeric vector

Prior probabilities for each class, specified as a numeric vector. The order of the elements in `Prior` corresponds to the order of the classes in `ClassNames`.

Add or change a `Prior` vector using dot notation: `mdl.Prior = priorVector`.

Data Types: `single` | `double`

ResponseName — Response variable name

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

RowsUsed — Rows used in fitting

`[]` | logical vector

This property is read-only.

Rows of the original data `X` used in fitting the `ClassificationKNN` model, specified as a logical vector. This property is empty if all rows are used.

Data Types: `logical`

ScoreTransform — Score transformation

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as either a character vector or a function handle.

This table summarizes the available character vectors.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Change `ScoreTransform` using dot notation: `mdl.ScoreTransform = newScoreTransform`.

Data Types: `char` | `function_handle`

Sigma — Predictor standard deviations

numeric vector

This property is read-only.

Predictor standard deviations, specified as a numeric vector of length `numel(PredictorNames)`.

If you do not standardize the predictor variables during training, then `Sigma` is empty (`[]`).

Data Types: `single` | `double`

W — Observation weights

vector of nonnegative values

This property is read-only.

Observation weights, specified as a vector of nonnegative values with the same number of rows as `Y`. Each entry in `W` specifies the relative importance of the corresponding observation in `Y`.

Data Types: `single` | `double`

X — Unstandardized predictor data

numeric matrix

This property is read-only.

Unstandardized predictor data, specified as a numeric matrix. Each column of `X` represents one predictor (variable), and each row represents one observation.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Each value in `Y` is the observed class label for the corresponding row in `X`.

`Y` has the same data type as the data in `Y` used for training the model. (The software treats string arrays as cell arrays of character vectors.)

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

Hyperparameter Optimization Properties

HyperparameterOptimizationResults — Cross-validation optimization of hyperparameters

`BayesianOptimization` object | table

This property is read-only.

Cross-validation optimization of hyperparameters, specified as a `BayesianOptimization` object or a table of hyperparameters and associated values. This property is nonempty when the `'OptimizeHyperparameters'` name-value pair argument is nonempty when you create the model using `fitcknn`. The value depends on the setting of the `'HyperparameterOptimizationOptions'` name-value pair argument when you create the model:

- 'bayesopt' (default) — Object of class BayesianOptimization
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Object Functions

compareHoldout	Compare accuracies of two classification models using new data
crossval	Cross-validated k-nearest neighbor classifier
edge	Edge of k-nearest neighbor classifier
loss	Loss of k-nearest neighbor classifier
margin	Margin of k-nearest neighbor classifier
predict	Predict labels using k-nearest neighbor classification model
resubEdge	Edge of k-nearest neighbor classifier by resubstitution
resubLoss	Loss of k-nearest neighbor classifier by resubstitution
resubMargin	Margin of k-nearest neighbor classifier by resubstitution
resubPredict	Predict resubstitution labels of k-nearest neighbor classifier

Examples

Train k-Nearest Neighbor Classifier

Train a k -nearest neighbor classifier for Fisher's iris data, where k , the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbor classifier. Standardize the noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

```
Mdl =
  ClassificationKNN
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
    NumObservations: 150
           Distance: 'euclidean'
      NumNeighbors: 5
```

Properties, Methods

Mdl is a trained ClassificationKNN classifier, and some of its properties appear in the Command Window.

To access the properties of Mdl, use dot notation.

```
Mdl.ClassNames
```

```
ans = 3x1 cell
      {'setosa'   }
      {'versicolor'}
      {'virginica' }
```

```
Mdl.Prior
```

```
ans = 1x3
      0.3333    0.3333    0.3333
```

`Mdl.Prior` contains the class prior probabilities, which you can specify using the 'Prior' name-value pair argument in `fitcknn`. The order of the class prior probabilities corresponds to the order of the classes in `Mdl.ClassNames`. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3, respectively.

```
Mdl.Prior = [0.5 0.2 0.3];
```

You can pass `Mdl` to `predict` to label new measurements or `crossval` to cross-validate the classifier.

Tips

- The compact function reduces the size of most classification models by removing the training data properties and any other properties that are not required to predict the labels of new observations. Because k -nearest neighbor classification models require all of the training data to predict labels, you cannot reduce the size of a `ClassificationKNN` model.

Alternative Functionality

`knnsearch` finds the k -nearest neighbors of points. `rangesearch` finds all the points within a fixed distance. You can use these functions for classification, as shown in “Classify Query Data” on page 18-17. If you want to perform classification, then using `ClassificationKNN` models can be more convenient because you can train a classifier in one step (using `fitcknn`) and classify in other steps (using `predict`). Alternatively, you can train a k -nearest neighbor classification model using one of the cross-validation options in the call to `fitcknn`. In this case, `fitcknn` returns a `ClassificationPartitionedModel` cross-validated model object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.

- When you train a *k*-nearest neighbor classification model by using `fitcknn`, the following restrictions apply.
 - The class labels input argument value (*Y*) cannot be a categorical array.
 - Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the `'CategoricalPredictors'` name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
 - The value of the `'ClassNames'` name-value pair argument cannot be a categorical array.
 - The value of the `'Distance'` name-value pair argument cannot be a custom distance function.
 - The value of the `'DistanceWeight'` name-value pair argument can be a custom distance weight function, but it cannot be an anonymous function.
 - The value of the `'ScoreTransform'` name-value pair argument cannot be an anonymous function.

ClassificationLinear class

Linear model for binary classification of high-dimensional data

Description

`ClassificationLinear` is a trained linear model object for binary classification; the linear model is a support vector machine (SVM) or logistic regression model. `fitclinear` fits a `ClassificationLinear` model by minimizing the objective function using techniques that reduce computation time for high-dimensional data sets (e.g., stochastic gradient descent). The classification loss plus the regularization term compose the objective function.

Unlike other classification models, and for economical memory usage, `ClassificationLinear` model objects do not store the training data. However, they do store, for example, the estimated linear model coefficients, prior-class probabilities, and the regularization strength.

You can use trained `ClassificationLinear` models to predict labels or classification scores for new data. For details, see `predict`.

Construction

Create a `ClassificationLinear` object by using `fitclinear`.

Properties

Linear Classification Properties

Lambda — Regularization term strength

nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as a nonnegative scalar or vector of nonnegative values.

Data Types: `double` | `single`

Learner — Linear classification model type

'logistic' | 'svm'

Linear classification model type, specified as 'logistic' or 'svm'.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Loss Function	FittedLoss Value
'logistic'	Logistic regression	Deviance (logistic): $\ell[y, f(x)] = \log$ $\{1 + \exp[-yf(x)]\}$	'logit'

Value	Algorithm	Loss Function	FittedLoss Value
'svm'	Support vector machine	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$	'hinge'

Beta – Linear coefficient estimates

numeric vector

Linear coefficient estimates, specified as a numeric vector with length equal to the number of predictors.

Data Types: double

Bias – Estimated bias term

numeric scalar

Estimated bias term or model intercept, specified as a numeric scalar.

Data Types: double

FittedLoss – Loss function used to fit linear model

'hinge' | 'logit'

Loss function used to fit the linear model, specified as 'hinge' or 'logit'.

Value	Algorithm	Loss Function	Learner Value
'hinge'	Support vector machine	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$	'svm'
'logit'	Logistic regression	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$	'logistic'

Regularization – Complexity penalty type

'lasso (L1)' | 'ridge (L2)'

Complexity penalty type, specified as 'lasso (L1)' or 'ridge (L2)'.

The software composes the objective function for minimization from the sum of the average loss function (see FittedLoss) and a regularization value from this table.

Value	Description
'lasso (L1)'	Lasso (L_1) penalty: $\lambda \sum_{j=1}^p \beta_j $
'ridge (L2)'	Ridge (L_2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

λ specifies the regularization term strength (see Lambda).

The software excludes the bias term (β_0) from the regularization penalty.

Other Classification Properties**CategoricalPredictors – Indices of categorical predictors**

[]

Indices of categorical predictors, whose value is always empty ([]) because a `ClassificationLinear` model does not support categorical predictors.

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels `Y`. (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

Data Types: `double`

ModelParameters — Parameters used for training model

structure

Parameters used for training the `ClassificationLinear` model, specified as a structure.

Access fields of `ModelParameters` using dot notation. For example, access the relative tolerance on the linear coefficients and the bias term by using `Mdl.ModelParameters.BetaTolerance`.

Data Types: `struct`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data X , specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in X .

Data Types: `cell`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

Because a `ClassificationLinear` model does not support categorical predictors, `ExpandedPredictorNames` and `PredictorNames` are equal.

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

Data Types: `double`

ScoreTransform — Score transformation function

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For linear classification models and before transformation, the predicted classification score for the observation x (row vector) is $f(x) = x\beta + b$, where β and b correspond to `Mdl.Beta` and `Mdl.Bias`, respectively.

To change the score transformation function to, for example, *function*, use dot notation.

- For a built-in function, enter this code and replace *function* with a value in the table.

```
Mdl.ScoreTransform = 'function';
```

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: `char` | `function_handle`

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

Methods

edge	Classification edge for linear classification models
loss	Classification loss for linear classification models
margin	Classification margins for linear classification models
predict	Predict labels for linear classification models
selectModels	Choose subset of regularized, binary linear classification models

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Linear Classification Model

Train a binary, linear classification model using support vector machines, dual SGD, and ridge regularization.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Train the model using the entire data set. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
rng(1); % For reproducibility
[Mdl,FitInfo] = fitlinear(X,Ystats)
```

```
Mdl =
  ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'none'
             Beta: [34023x1 double]
             Bias: -1.0059
             Lambda: 3.1674e-05
             Learner: 'svm'
```

Properties, Methods

```

FitInfo = struct with fields:
    Lambda: 3.1674e-05
    Objective: 5.3783e-04
    PassLimit: 10
    NumPasses: 10
    BatchLimit: []
    NumIterations: 238561
    GradientNorm: NaN
    GradientTolerance: 0
    RelativeChangeInBeta: 0.0562
    BetaTolerance: 1.0000e-04
    DeltaGradient: 1.4582
    DeltaGradientTolerance: 1
    TerminationCode: 0
    TerminationStatus: {'Iteration limit exceeded.'}
    Alpha: [31572x1 double]
    History: []
    FitTime: 0.2391
    Solver: {'dual'}

```

`Mdl` is a `ClassificationLinear` model. You can pass `Mdl` and the training or new data to `loss` to inspect the in-sample classification error. Or, you can pass `Mdl` and new predictor data to `predict` to predict class labels for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. Because training time is small, you can try to retrain the model, but increase the number of passes through the data. This can improve measures like `DeltaGradient`.

Predict Class Labels Using Linear Classification Model

Load the NLP data set.

```

load nlpdata
n = size(X,1); % Number of observations

```

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```

Ystats = Y == 'stats';

```

Hold out 5% of the data.

```

rng(1); % For reproducibility
cvp = cvpartition(n,'Holdout',0.05)

```

```

cvp =
Hold-out cross validation partition
    NumObservations: 31572
    NumTestSets: 1
    TrainSize: 29994
    TestSize: 1578

```

`cvp` is a `CVPartition` object that defines the random partition of n data into training and test sets.

Train a binary, linear classification model using the training set that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. For faster training time, orient the predictor data matrix so that the observations are in columns.

```
idxTrain = training(cvp); % Extract training set indices
X = X';
Mdl = fitclinear(X(:,idxTrain),Ystats(idxTrain),'ObservationsIn','columns');
```

Predict observations and classification error for the hold out sample.

```
idxTest = test(cvp); % Extract test set indices
labels = predict(Mdl,X(:,idxTest),'ObservationsIn','columns');
L = loss(Mdl,X(:,idxTest),Ystats(idxTest),'ObservationsIn','columns')
```

```
L = 7.1753e-04
```

`Mdl` misclassifies fewer than 1% of the out-of-sample observations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train a linear classification model by using `fitclinear`, the following restrictions apply.
 - The predictor data input argument value (X) must be a full, numeric matrix.
 - The class labels input argument value (Y) cannot be a categorical array.
 - The value of the `'ClassNames'` name-value pair argument or property cannot be a categorical array.
 - You can specify only one regularization strength, either `'auto'` or a nonnegative scalar for the `'Lambda'` name-value pair argument.
 - The value of the `'ScoreTransform'` name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2016a

ClassificationLinearCoderConfigurer

Coder configurer for linear binary classification of high-dimensional data

Description

A `ClassificationLinearCoderConfigurer` object is a coder configurer of a linear classification model (`ClassificationLinear`) used for binary classification of high-dimensional data.

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes of linear model parameters by using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the linear classification model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the linear model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.

For the code generation usage notes and limitations of a linear classification model, see the Code Generation sections of `ClassificationLinear`, `predict`, and `update`.

Creation

After training a linear classification model by using `fitLinear`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of the `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

`predict` Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

X — Coder attributes of predictor data

LearnerCoderInput object

Coder attributes of the predictor data to pass to the generated C/C++ code for the `predict` function of the linear classification model, specified as a `LearnerCoderInput` on page 32-402 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- **SizeVector** — The default value is the array size of the input `X`.
 - If the `Value` attribute of the `ObservationsIn` property for the `ClassificationLinearCoderConfigurer` is `'rows'`, then this `SizeVector` value is `[n p]`, where `n` corresponds to the number of observations and `p` corresponds to the number of predictors.
 - If the `Value` attribute of the `ObservationsIn` property for the `ClassificationLinearCoderConfigurer` is `'columns'`, then this `SizeVector` value is `[p n]`.

To switch the elements of `SizeVector` (for example, to change `[n p]` to `[p n]`), modify the `Value` attribute of the `ObservationsIn` property for the `ClassificationLinearCoderConfigurer` accordingly. You cannot modify the `SizeVector` value directly.

- **VariableDimensions** — The default value is `[0 0]`, which indicates that the array size is fixed as specified in `SizeVector`.

You can set this value to `[1 0]` if the `SizeVector` value is `[n p]` or to `[0 1]` if it is `[p n]`, which indicates that the array has variable-size rows and fixed-size columns. For example, `[1 0]` specifies that the first value of `SizeVector` (`n`) is the upper bound for the number of rows, and the second value of `SizeVector` (`p`) is the number of columns.

- **DataType** — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- **Tunability** — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, to generate C/C++ code that accepts predictor data with 100 observations (in rows) of three predictor variables (in columns), specify these coder attributes of `X` for the coder configurer `configurer`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

`[0 0]` indicates that the first and second dimensions of `X` (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify these coder attributes of `X`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

`[1 0]` indicates that the first dimension of `X` (number of observations) has a variable size and the second dimension of `X` (number of predictor variables) has a fixed size. The specified number of

observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

ObservationsIn — Coder attributes of predictor data observation dimension

EnumeratedInput object

Coder attributes of the predictor data observation dimension ('ObservationsIn' name-value pair argument of `predict`), specified as an EnumeratedInput on page 32-403 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the 'ObservationsIn' name-value pair argument determines the default values of the EnumeratedInput coder attributes:

- **Value** — The default value is the predictor data observation dimension you use when creating the coder configurer, specified as 'rows' or 'columns'. If you do not specify 'ObservationsIn' when creating the coder configurer, the default value is 'rows'.
- **SelectedOption** — This value is always 'Built-in'. This attribute is read-only.
- **BuiltInOptions** — Cell array of 'rows' and 'columns'. This attribute is read-only.
- **IsConstant** — This value must be true.
- **Tunability** — The default value is false if you specify 'ObservationsIn', 'rows' when creating the coder configurer, and true if you specify 'ObservationsIn', 'columns'. If you set Tunability to false, the software sets Value to 'rows'. If you specify other attribute values when Tunability is false, the software sets Tunability to true.

NumOutputs — Number of outputs in predict

1 (default) | 2

Number of output arguments to return from the generated C/C++ code for the `predict` function of the linear classification model, specified as 1 or 2.

The output arguments of `predict` are `Label` (predicted class labels) and `Score` (classification scores), in that order. `predict` in the generated C/C++ code returns the first `n` outputs of the `predict` function, where `n` is the `NumOutputs` value.

After creating the coder configurer `configurer`, you can specify the number of outputs by using dot notation.

```
configurer.NumOutputs = 2;
```

The `NumOutputs` property is equivalent to the '-nargout' compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of a linear classification model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `double`

update Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the

parameters before generating code. Use a `LearnerCoderInput` on page 32-402 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

Beta — Coder attributes of linear predictor coefficients

`LearnerCoderInput` object

Coder attributes of the linear predictor coefficients (**Beta** of a linear classification model), specified as a `LearnerCoderInput` on page 32-402 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[p 1]`, where `p` is the number of predictors in `Mdl`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

Bias — Coder attributes of bias term

`LearnerCoderInput` object

Coder attributes of the bias term (**Bias** of a linear classification model), specified as a `LearnerCoderInput` on page 32-402 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[1 1]`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

Cost — Coder attributes of misclassification cost

`LearnerCoderInput` object

Coder attributes of the misclassification cost (**Cost** of a linear classification model), specified as a `LearnerCoderInput` on page 32-402 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[2 2]`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — The default value is `true`.

Prior — Coder attributes of prior probabilities

LearnerCoderInput object

Coder attributes of the prior probabilities (Prior of a linear classification model), specified as a `LearnerCoderInput` on page 32-402 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be [1 2].
- `VariableDimensions` — This value must be [0 0], indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — The default value is true.

Other Configurer Options**OutputFileName — File name of generated C/C++ code**

'ClassificationLinearModel' (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function `generateCode` of `ClassificationLinearCoderConfigurer` generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer `configurer`, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: char

Verbose — Verbosity level

true (logical 1) (default) | false (logical 0)

Verbosity level, specified as `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
true (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
false (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints,

then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: `logical`

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

CodeGenerationArguments — codegen arguments

cell array

This property is read-only.

`codegen` arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: `cell`

PredictInputs — List of tunable input arguments of predict

cell array

This property is read-only.

List of tunable input arguments of the entry-point function `predict.m` for code generation, specified as a cell array. The cell array contains another cell array that includes `coder.PrimitiveType` objects and `coder.Constant` objects.

If you modify the coder attributes of `predict` arguments on page 32-391, then the software updates the corresponding objects accordingly. If you specify the `Tunability` attribute as `false`, then the software removes the corresponding objects from the `PredictInputs` list.

The cell array in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: `cell`

UpdateInputs — List of tunable input arguments of update

cell array of a structure including `coder.PrimitiveType` objects

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure including `coder.PrimitiveType` objects. Each `coder.PrimitiveType` object includes the coder attributes of a tunable machine learning model parameter.

If you modify the coder attributes of a model parameter by using the coder configurer properties (`update Arguments` on page 32-393 properties), then the software updates the corresponding `coder.PrimitiveType` object accordingly. If you specify the `Tunability` attribute of a machine learning model parameter as `false`, then the software removes the corresponding `coder.PrimitiveType` object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

Data Types: `cell`

Object Functions

<code>generateCode</code>	Generate C/C++ code using coder configurer
<code>generateFiles</code>	Generate MATLAB files for code generation using coder configurer
<code>validatedUpdateInputs</code>	Validate and extract machine learning model parameters to update

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `ionosphere` data set, and train a binary linear classification model. Pass the transposed predictor matrix `Xnew` to `fitclinear`, and use the `'ObservationsIn'` name-value pair argument to specify that the columns of `Xnew` correspond to observations.

```
load ionosphere
Xnew = X';
Mdl = fitclinear(Xnew,Y,'ObservationsIn','columns');
```

`Mdl` is a `ClassificationLinear` object.

Create a coder configurer for the `ClassificationLinear` model by using `learnerCoderConfigurer`. Specify the predictor data `Xnew`, and use the `'ObservationsIn'`

name-value pair argument to specify the observation dimension of `Xnew`. The `learnerCoderConfigurer` function uses these input arguments to configure the coder attributes of the corresponding input arguments of `predict`.

```
configurer = learnerCoderConfigurer(Mdl,Xnew,'ObservationsIn','columns')
```

```
configurer =  
  ClassificationLinearCoderConfigurer with properties:
```

```
  Update Inputs:  
      Beta: [1x1 LearnerCoderInput]  
      Bias: [1x1 LearnerCoderInput]  
      Prior: [1x1 LearnerCoderInput]  
      Cost: [1x1 LearnerCoderInput]  
  
  Predict Inputs:  
      X: [1x1 LearnerCoderInput]

```

Properties, Methods

`configurer` is a `ClassificationLinearCoderConfigurer` object, which is a coder configurer of a `ClassificationLinear` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the linear classification model (`Mdl`).

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:  
'initialize.m', 'predict.m', 'update.m', 'ClassificationLinearModel.mat'
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationLinearModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationLinearModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

```
type predict.m
```

```
function varargout = predict(X,varargin) %#codegen  
% Autogenerated by MATLAB, 29-Feb-2020 10:23:22
```

```

[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end

type update.m

function update(varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:23:22
initialize('update',varargin{:});
end

type initialize.m

function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:23:22
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('ClassificationLinearModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Beta
        %                               Bias
        %                               Prior
        %                               Cost
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X, ObservationsIn
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
    end
end
end
end

```

Update Parameters of Linear Classification Model in Generated Code

Train a linear classification model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the linear model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the entire data set, and update parameters in the generated code without regenerating the code.

Train Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g'). Train a binary linear classification model using half of the observations. Transpose the predictor data, and use the 'ObservationsIn' name-value pair argument to specify that the columns of `XTrain` correspond to observations.

```
load ionosphere

rng('default') % For reproducibility
n = length(Y);
c = cvpartition(Y,'HoldOut',0.5);
idxTrain = training(c,1);
XTrain = X(idxTrain,:);
YTrain = Y(idxTrain);

Mdl = fitclinear(XTrain,YTrain,'ObservationsIn','columns');
```

Mdl is a ClassificationLinear object.

Create Coder Configurer

Create a coder configurer for the ClassificationLinear model by using learnerCoderConfigurer. Specify the predictor data XTrain, and use the 'ObservationsIn' name-value pair argument to specify the observation dimension of XTrain. The learnerCoderConfigurer function uses these input arguments to configure the coder attributes of the corresponding input arguments of predict. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

```
configurer = learnerCoderConfigurer(Mdl,XTrain,'ObservationsIn','columns','NumOutputs',2);
```

configurer is a ClassificationLinearCoderConfigurer object, which is a coder configurer of a ClassificationLinear object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the linear classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of the predictor data that you want to pass to the generated code.

Specify the coder attributes of the X property of configurer so that the generated code accepts any number of observations. Modify the SizeVector and VariableDimensions attributes. The SizeVector attribute specifies the upper bound of the predictor data size, and the VariableDimensions attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [34 Inf];
configurer.X.VariableDimensions
```

```
ans = 1x2 logical array
```

```
    0    1
```

The size of the first dimension is the number of predictor variables. This value must be fixed for a machine learning model. Because the predictor data contains 34 predictors, the value of the SizeVector attribute must be 34 and the value of the VariableDimensions attribute must be 0.

The size of the second dimension is the number of observations. Setting the value of the SizeVector attribute to Inf causes the software to change the value of the VariableDimensions attribute to 1. In other words, the upper bound of the size is Inf and the size is variable, meaning that the predictor data can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The order of the dimensions in `SizeVector` and `VariableDimensions` depends on the coder attributes of `ObservationsIn`.

```
configurer.ObservationsIn
```

```
ans =
  EnumeratedInput with properties:
      Value: 'columns'
 SelectedOption: 'Built-in'
 BuiltInOptions: {'rows' 'columns'}
   IsConstant: 1
  Tunability: 1
```

When the `Value` attribute of the `ObservationsIn` property is `'columns'`, the first dimension of the `SizeVector` and `VariableDimensions` attributes of `X` corresponds to the number of predictors, and the second dimension corresponds to the number of observations. When the `Value` attribute of `ObservationsIn` is `'rows'`, the order of the dimensions is switched.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the linear classification model (`Mdl`).

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationLinearModel.mat'
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationLinearModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationLinearModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[label,score] = predict(Mdl,XTrain,'ObservationsIn','columns');
[label_mex,score_mex] = ClassificationLinearModel('predict',XTrain,'ObservationsIn','columns');
```

Compare `label` and `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical
      1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

Compare `score` and `score_mex`.

```
max(abs(score-score_mex),[],'all')
```

```
ans = 0
```

In general, `score_mex` might include round-off differences compared to `score`. In this case, the comparison confirms that `score` and `score_mex` are equal.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitlinear(X',Y,'ObservationsIn','columns');
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationLinearModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[label,score] = predict(retrainedMdl,X','ObservationsIn','columns');
[label_mex,score_mex] = ClassificationLinearModel('predict',X','ObservationsIn','columns');
isequal(label,label_mex)
```

```
ans = logical
      1
```

```
max(abs(score-score_mex),[],'all')
```

```
ans = 0
```

The comparison confirms that `label` and `label_mex` are equal, and that the score values are equal.

More About

LearnerCoderInput Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
<code>SizeVector</code>	<p>Array size if the corresponding <code>VariableDimensions</code> value is <code>false</code>.</p> <p>Upper bound of the array size if the corresponding <code>VariableDimensions</code> value is <code>true</code>. To allow an unbounded array, specify the bound as <code>Inf</code>.</p>
<code>VariableDimensions</code>	<p>Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0):</p> <ul style="list-style-type: none"> A value of <code>true</code> (logical 1) means that the corresponding dimension has a variable size. A value of <code>false</code> (logical 0) means that the corresponding dimension has a fixed size.
<code>DataType</code>	Data type of the array
<code>Tunability</code>	<p>Indicator specifying whether or not <code>predict</code> or <code>update</code> includes the argument as an input in the generated code, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0).</p> <p>If you specify other attribute values when <code>Tunability</code> is <code>false</code>, the software sets <code>Tunability</code> to <code>true</code>.</p>

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the data type of the bias term `Bias` of the coder configurer `configurer`:

```
configurer.Bias.DataType = 'single';
```

If you specify the verbosity level (`Verbose`) as `true` (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

EnumeratedInput Object

A coder configurer uses an `EnumeratedInput` object to specify the coder attributes of `predict` input arguments that have a finite set of available values.

An `EnumeratedInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
Value	<p>Value of the <code>predict</code> argument in the generated code, specified as a character vector or a <code>LearnerCoderInput</code> on page 32-402 object.</p> <ul style="list-style-type: none"> • Character vector in <code>BuiltInOptions</code> — You can specify one of the <code>BuiltInOptions</code> using either the option name or its index value. For example, to choose the first option, specify <code>Value</code> as either the first character vector in <code>BuiltInOptions</code> or <code>1</code>. • Character vector designating a custom function name — To use a custom option, define a custom function on the MATLAB search path, and specify <code>Value</code> as the name of the custom function. • <code>LearnerCoderInput</code> on page 32-402 object — If you set <code>IsConstant</code> to <code>false</code> (logical <code>0</code>), then the software changes <code>Value</code> to a <code>LearnerCoderInput</code> on page 32-402 object with the following read-only coder attribute values. These values indicate that the input in the generated code is a variable-size, tunable character vector that is one of the available values in <code>BuiltInOptions</code>. <ul style="list-style-type: none"> • <code>SizeVector</code> — <code>[1 c]</code>, indicating the upper bound of the array size, where <code>c</code> is the length of the longest available character vector in <code>Option</code> • <code>VariableDimensions</code> — <code>[0 1]</code>, indicating that the array is a variable-size vector • <code>DataType</code> — <code>'char'</code> • <code>Tunability</code> — <code>1</code> <p>The default value of <code>Value</code> is consistent with the default value of the corresponding <code>predict</code> argument, which is one of the character vectors in <code>BuiltInOptions</code>.</p>
SelectedOption	<p>Status of the selected option, specified as <code>'Built-in'</code>, <code>'Custom'</code>, or <code>'NonConstant'</code>. The software sets <code>SelectedOption</code> according to <code>Value</code>:</p> <ul style="list-style-type: none"> • <code>'Built-in'</code> (default) — When <code>Value</code> is one of the character vectors in <code>BuiltInOptions</code> • <code>'Custom'</code> — When <code>Value</code> is a character vector that is not in <code>BuiltInOptions</code> • <code>'NonConstant'</code> — When <code>Value</code> is a <code>LearnerCoderInput</code> on page 32-402 object <p>This attribute is read-only.</p>
BuiltInOptions	<p>List of available character vectors for the corresponding <code>predict</code> argument, specified as a cell array.</p> <p>This attribute is read-only.</p>

Attribute Name	Description
IsConstant	<p>Indicator specifying whether or not the array value is a compile-time constant (<code>coder.Constant</code>) in the generated code, specified as <code>true</code> (logical 1, default) or <code>false</code> (logical 0).</p> <p>If you set this value to <code>false</code>, then the software changes <code>Value</code> to a <code>LearnerCoderInput</code> on page 32-402 object.</p>
Tunability	<p>Indicator specifying whether or not <code>predict</code> includes the argument as an input in the generated code, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0, default).</p> <p>If you specify other attribute values when <code>Tunability</code> is <code>false</code>, the software sets <code>Tunability</code> to <code>true</code>.</p>

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of `ObservationsIn` of the coder configurer configurer:

```
configurer.ObservationsIn.Value = 'columns';
```

Introduced in R2019b

ClassificationNaiveBayes class

Superclasses: CompactClassificationNaiveBayes

Naive Bayes classification

Description

`ClassificationNaiveBayes` is a naive Bayes on page 32-414 classifier for multiclass learning. Use `fitcnb` and the training data to train a `ClassificationNaiveBayes` classifier.

Trained `ClassificationNaiveBayes` classifiers store the training data, parameter values, data distribution, and prior probabilities. You can use these classifiers to:

- Estimate resubstitution predictions. For details, see `resubPredict`.
- Predict labels or posterior probabilities for new data. For details, see `predict`.

Construction

Create a `ClassificationNaiveBayes` object by using `fitcnb`.

Properties

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

CategoricalLevels — Multivariate multinomial levels

cell vector of numeric vectors

Multivariate multinomial levels, specified as a cell vector of numeric vectors. `CategoricalLevels` has length equal to the number of predictors (`size(X,2)`).

The cells of `CategoricalLevels` correspond to predictors that you specified as 'mvmn' (i.e., having a multivariate multinomial distribution) during training. Cells that do not correspond to a multivariate multinomial distribution are empty (`[]`).

If predictor j is multivariate multinomial, then `CategoricalLevels{j}` is a list of all distinct values of predictor j in the sample (NaNs removed from `unique(X(:,j))`).

Data Types: `cell`

ClassNames — Distinct class names

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Distinct class names, specified as a categorical or character array, logical or numeric vector, or cell vector of character vectors.

`ClassNames` is the same data type as `Y`, and has K elements or rows for character arrays. (The software treats string arrays as cell arrays of character vectors.)

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification cost

square matrix

Misclassification cost, specified as a K -by- K square matrix.

The value of `Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` correspond to the order of the classes in `ClassNames`.

The value of `Cost` does not influence training. You can reset `Cost` after training `Mdl` using dot notation, e.g., `Mdl.Cost = [0 0.5; 1 0];`.

Data Types: `double` | `single`

DistributionNames — Predictor distributions

'normal' (default) | 'kernel' | 'mn' | 'mvnm' | cell array of character vectors

Predictor distributions `fitcnb` uses to model the predictors, specified as a character vector or cell array of character vectors.

This table summarizes the available distributions.

Value	Description
'kernel'	Kernel smoothing density estimate.
'mn'	Multinomial bag-of-tokens model on page 32-414. Indicates that all predictors have this distribution.
'mvnm'	Multivariate multinomial distribution.
'normal'	Normal (Gaussian) distribution.

If `Distribution` is a 1-by- P cell array of character vectors, then the software models feature j using the distribution in element j of the cell array.

Data Types: `char` | `cell`

DistributionParameters — Distribution parameter estimates

cell array

Distribution parameter estimates, specified as a cell array. `DistributionParameters` is a K -by- D cell array, where cell (k, d) contains the distribution parameter estimates for instances of predictor d in class k . The order of the rows corresponds to the order of the classes in the property `ClassNames`, and the order of the predictors corresponds to the order of the columns of `X`.

If class k has no observations for predictor j , then `DistributionParameters{k, j}` is empty (`[]`).

The elements of `DistributionParameters` depends on the distributions of the predictors. This table describes the values in `DistributionParameters{k, j}`.

Distribution of Predictor <i>j</i>	Value
kernel	A <code>KernelDistribution</code> model. Display properties using cell indexing and dot notation. For example, to display the estimated bandwidth of the kernel density for predictor 2 in the third class, use <code>Mdl.DistributionParameters{3,2}.Bandwidth</code> .
mn	A scalar representing the probability that token <i>j</i> appears in class <i>k</i> . For details, see “Algorithms” on page 32-415.
mvmn	A numeric vector containing the probabilities for each possible level of predictor <i>j</i> in class <i>k</i> . The software orders the probabilities by the sorted order of all unique levels of predictor <i>j</i> (stored in the property <code>CategoricalLevels</code>). For more details, see “Algorithms” on page 32-415.
normal	A 2-by-1 numeric vector. The first element is the sample mean and the second element is the sample standard deviation.

Data Types: cell

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: cell

HyperparameterOptimizationResults — Description of cross-validation optimization of hyperparameters

BayesianOptimization object | table

Description of the cross-validation optimization of hyperparameters, specified as a `BayesianOptimization` object or a table of hyperparameters and associated values. This property is nonempty if the 'OptimizeHyperparameters' name-value pair argument is nonempty when you create the model. The value of `HyperparameterOptimizationResults` depends on the setting of the `Optimizer` field in the `HyperparameterOptimizationOptions` structure when you create the model, as described in this table.

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'bayesopt' (default)	Object of class <code>BayesianOptimization</code>

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'gridsearch' or 'randomsearch'	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Kernel – Kernel smoother types

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | cell array of character vectors

Kernel smoother types, specified as a character vector or cell array of character vectors. `Kernel` has length equal to the number of predictors (`size(X,2)`). `Kernel{j}` corresponds to predictor j , and contains a character vector describing the type of kernel smoother. This table describes the supported kernel smoother types. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
'box'	Box (uniform)	$f(x) = 0.5I\{ x \leq 1\}$
'epanechnikov'	Epanechnikov	$f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$
'normal'	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}}\exp(-0.5x^2)$
'triangle'	Triangular	$f(x) = (1 - x)I\{ x \leq 1\}$

If a cell is empty (`[]`), then the software did not fit a kernel distribution to the corresponding predictor.

Data Types: char | cell

ModelParameters – Parameter values used to train

object

Parameter values used to train the classifier (such as the name-value pair argument values), specified as an object. This table summarizes the properties of `ModelParameters`. The properties correspond to the name-value pair argument values set for training the classifier.

Property	Purpose
<code>DistributionNames</code>	Data distribution or distributions. This is the same value as the property <code>DistributionNames</code> .
<code>Kernel</code>	Kernel smoother type. This is the same as the property <code>Kernel</code> .
<code>Method</code>	Training method. For naive Bayes, the value is 'NaiveBayes'.
<code>Support</code>	Kernel-smoothing density support. This is the same as the property <code>Support</code> .
<code>Type</code>	Learning type. For classification, the value is 'classification'.

Property	Purpose
Width	Kernel smoothing window width. This is the same as the property Width.

Access fields of `ModelParameters` using dot notation. For example, access the kernel support using `Mdl.ModelParameters.Support`.

NumObservations — Number of training observations

numeric scalar

Number of training observations, specified as a numeric scalar.

If `X` or `Y` contain missing values, then `NumObservations` might be less than the length of `Y`.

Data Types: `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names, specified as a cell array of character vectors. The order of the elements in `PredictorNames` corresponds to the order in `X`.

Data Types: `cell`

Prior — Class prior probabilities

numeric vector

Class prior probabilities, specified as a numeric row vector. `Prior` is a 1-by- K vector, and the order of its elements correspond to the elements of `ClassNames`.

`fitcnb` normalizes the prior probabilities you set using the name-value pair parameter '`Prior`' so that `sum(Prior) = 1`.

The value of `Prior` does not change the best-fitting model. Therefore, you can reset `Prior` after training `Mdl` using dot notation, e.g., `Mdl.Prior = [0.2 0.8];`

Data Types: `double` | `single`

ResponseName — Response name

character vector

Response name, specified as a character vector.

Data Types: `char`

ScoreTransform — Classification score transformation function

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Classification score transformation function, specified as a character vector or function handle.

To change the score transformation function to e.g., *function*, use dot notation.

- For a built-in function, enter this code and replace *function* with a value in the table.

```
Mdl.ScoreTransform = 'function';
```

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

Support — Kernel smoother density support

cell vector

Kernel smoother density support, specified as a cell vector. **Support** has length equal to the number of predictors (`size(X,2)`). The cells represent the regions to apply the kernel density.

This table describes the supported options.

Value	Description
1-by-2 numeric row vector	For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support.
'positive'	The density support is all positive real values.
'unbounded'	The density support is all real values.

If a cell is empty ([]), then the software did not fit a kernel distribution to the corresponding predictor.

W — Observation weights

numeric vector

Observation weights, specified as a numeric vector.

The length of **W** is `NumObservations`.

`fitcnb` normalizes the value you set for the name-value pair parameter '**Weights**' so that the weights within a particular class sum to the prior probability for that class.

Data Types: double

Width — Kernel smoother window width

numeric matrix

Kernel smoother window width, specified as a numeric matrix. `Width` is a K -by- P matrix, where K is the number of classes in the data, and P is the number of predictors (`size(X,2)`).

`Width(k,j)` is the kernel smoother window width for the kernel smoothing density of predictor j within class k . NaNs in column j indicate that the software did not fit predictor j using a kernel density.

X — Unstandardized predictor data

numeric matrix

Unstandardized predictor data, specified as a numeric matrix. X has `NumObservations` rows and P columns.

Each row of X corresponds to one observation, and each column corresponds to one variable.

The software excludes rows removed due to missing values from X .

Data Types: double

Y — Observed class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Observed class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y is the same data type as the input argument Y of `fitcnb`. (The software treats string arrays as cell arrays of character vectors.)

Each row of Y represents the observed classification of the corresponding row of X .

The software excludes elements removed due to missing values from Y .

Data Types: categorical | char | logical | single | double | cell

Methods

<code>compact</code>	Compact naive Bayes classifier
<code>crossval</code>	Cross-validated naive Bayes classifier
<code>resubEdge</code>	Classification edge for naive Bayes classifiers by resubstitution
<code>resubLoss</code>	Classification loss for naive Bayes classifiers by resubstitution
<code>resubMargin</code>	Classification margins for naive Bayes classifiers by resubstitution
<code>resubPredict</code>	Predict resubstitution labels of naive Bayes classifier

Inherited Methods

edge Classification edge for naive Bayes classifiers
 logP Log unconditional probability density for naive Bayes classifier
 loss Classification error for naive Bayes classifier
 margin Classification margins for naive Bayes classifiers
 predict Predict labels using naive Bayes classification model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train a Naive Bayes Classifier

Construct a naive Bayes classifier for Fisher's iris data. Also, specify prior probabilities after training.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a naive Bayes classifier.

```
Mdl = fitcnb(X,Y)
```

```
Mdl =
  ClassificationNaiveBayes
      ResponseName: 'Y'
  CategoricalPredictors: []
           ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
      NumObservations: 150
  DistributionNames: {'normal' 'normal' 'normal' 'normal'}
  DistributionParameters: {3x4 cell}
```

Properties, Methods

Mdl is a trained `ClassificationNaiveBayes` classifier, and some of its properties display in the Command Window. By default, the software treats each predictor as independent, and fits them using normal distributions.

To access the properties of Mdl, use dot notation.

```
Mdl.ClassNames
```

```
ans = 3x1 cell
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
Mdl.Prior
```

```
ans = 1x3
    0.3333    0.3333    0.3333
```

`Mdl.Prior` contains the class prior probabilities, which are settable using the name-value pair argument `'Prior'` in `fitcnb`. The order of the class prior probabilities corresponds to the order of the classes in `Mdl.ClassNames`. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3 respectively.

```
Mdl.Prior = [0.5 0.2 0.3];
```

You can pass `Mdl` to e.g., `predict` to label new measurements, or `crossval` to cross validate the classifier.

More About

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor j is the nonnegative number of occurrences of token j in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm:

- 1 Estimates the densities of the predictors within each class.
- 2 Models posterior probabilities according to Bayes rule. That is, for all $k = 1, \dots, K$,

$$\hat{P}(Y = k | X_1, \dots, X_P) = \frac{\pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)}{\sum_{k=1}^K \pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)},$$

where:

- Y is the random variable corresponding to the class index of an observation.
 - X_1, \dots, X_P are the random predictors of an observation.
 - $\pi(Y = k)$ is the prior probability that a class index is k .
- 3** Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability $\hat{P}(Y = k | X_1, \dots, X_P) \propto \pi(Y = k)P_{mn}(X_1, \dots, X_P | Y = k)$, where $P_{mn}(X_1, \dots, X_P | Y = k)$ is the probability mass function of a multinomial distribution.

Algorithms

- If you specify 'DistributionNames', 'mn' when training MdI using fitcnb, then the software fits a multinomial distribution using the bag-of-tokens model on page 32-1656. The software stores the probability that token j appears in class k in the property DistributionParameters{ k, j }. Using additive smoothing [2], the estimated probability is

$$P(\text{token } j \mid \text{class } k) = \frac{1 + c_{j|k}}{P + c_k},$$

where:

- $c_{j|k} = n_k \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i: y_i \in \text{class } k} w_i}$; which is the weighted number of occurrences of token j in class k .
 - n_k is the number of observations in class k .
 - w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
 - $c_k = \sum_{j=1}^P c_{j|k}$; which is the total weighted number of occurrences of all tokens in class k .
- If you specify 'DistributionNames', 'mvmn' when training MdI using fitcnb, then:
 - 1** For each predictor, the software collects a list of the unique levels, stores the sorted list in CategoricalLevels, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
 - 2** For predictor j in class k , the software counts instances of each categorical level using the list stored in CategoricalLevels{ j }.
 - 3** The software stores the probability that predictor j , in class k , has level L in the property DistributionParameters{ k, j }, for all levels in CategoricalLevels{ j }. Using additive smoothing [2], the estimated probability is

$$P(\text{predictor } j = L \mid \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

where:

- $$m_{j|k}(L) = n_k \frac{\sum_{i: y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i: y_i \in \text{class } k} w_i};$$
 which is the weighted number of observations for which predictor j equals L in class k .
- n_k is the number of observations in class k .
- $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
- w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
- m_j is the number of distinct levels in predictor j .
- m_k is the weighted number of observations in class k .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train a naive Bayes model by using `fitcnb`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the 'CategoricalPredictors' name-value pair argument.
 - The value of the 'DistributionNames' name-value pair argument cannot contain 'mn' or 'mvmn'.
 - The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
 - The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

ClassificationPartitionedECOC

Cross-validated multiclass ECOC model for support vector machines (SVMs) and other classifiers

Description

`ClassificationPartitionedECOC` is a set of error-correcting output codes (ECOC) models trained on cross-validated folds. Estimate the quality of the cross-validated classification by using one or more “kfold” functions: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, `kfoldEdge`, and `kfoldfun`.

Every “kfold” method uses models trained on training-fold (in-fold) observations to predict the response for validation-fold (out-of-fold) observations. For example, suppose you cross-validate using five folds. In this case, the software randomly assigns each observation into five groups of equal size (roughly). The training fold contains four of the groups (roughly 4/5 of the data), and the validation fold contains the other group (roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

- 1 The software trains the first model (stored in `CVMdl.Trained{1}`) by using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model (stored in `CVMdl.Trained{2}`) by using the observations in the first group and the last three groups. The software reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third, fourth, and fifth models.

If you validate by using `kfoldPredict`, the software computes predictions for the observations in group i by using the i th model. In short, the software estimates a response for every observation by using the model trained without that observation.

Creation

You can create a `ClassificationPartitionedECOC` model in two ways:

- Create a cross-validated ECOC model from an ECOC model by using the `crossval` object function.
- Create a cross-validated ECOC model by using the `fitcecoc` function and specifying one of the name-value pair arguments `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Properties

Cross-Validation Properties

`CrossValidatedModel` — Cross-validated model name

character vector

Cross-validated model name, specified as a character vector.

For example, `'ECOC'` specifies a cross-validated ECOC model.

Data Types: char

KFold — Number of cross-validated folds

positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: double

ModelParameters — Cross-validation parameter values

object

Cross-validation parameter values, specified as an object. The parameter values correspond to the name-value pair argument values used to cross-validate the ECOC classifier. `ModelParameters` does not contain estimated parameters.

You can access the properties of `ModelParameters` using dot notation.

NumObservations — Number of observations

positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

Partition — Data partition

`cvpartition` model

Data partition indicating how the software splits the data into cross-validation folds, specified as a `cvpartition` model.

Trained — Compact classifiers trained on cross-validation folds

cell array of `CompactClassificationECOC` models

Compact classifiers trained on cross-validation folds, specified as a cell array of `CompactClassificationECOC` models. `Trained` has k cells, where k is the number of folds.

Data Types: cell

W — Observation weights

numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. `W` has `NumObservations` elements.

The software normalizes the weights used for training so that `nansum(W)` is 1.

Data Types: single | double

X — Unstandardized predictor data

numeric matrix | table

Unstandardized predictor data used to cross-validate the classifier, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

Data Types: single | double | table

Y – Observed class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y has `NumObservations` elements and has the same data type as the input argument Y that you pass to `fitcecoc` to cross-validate the model. (The software treats string arrays as cell arrays of character vectors.)

Each row of Y represents the observed classification of the corresponding row of X.

Data Types: categorical | char | logical | single | double | cell

ECOC Properties**BinaryLoss – Binary learner loss function**

'binodeviance' | 'exponential' | 'hamming' | 'hinge' | 'linear' | 'logit' | 'quadratic'

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets `BinaryLoss` to 'hamming'. To potentially increase accuracy, specify a binary loss function other than the default during a prediction or loss computation by using the 'BinaryLoss' name-value pair argument of `kfoldPredict` or `kfoldLoss`.

Data Types: char

BinaryY – Binary learner class labels

numeric matrix | []

Binary learner class labels, specified as a numeric matrix or [].

- If the coding matrix is the same across all folds, then `BinaryY` is a `NumObservations`-by-`L` matrix, where `L` is the number of binary learners (`size(CodingMatrix,2)`).

The elements of `BinaryY` are `-1`, `0`, or `1`, and the values correspond to dichotomous class assignments. This table describes how learner `j` assigns observation `k` to a dichotomous class corresponding to the value of `BinaryY(k,j)`.

Value	Dichotomous Class Assignment
-1	Learner <code>j</code> assigns observation <code>k</code> to a negative class.
0	Before training, learner <code>j</code> removes observation <code>k</code> from the data set.
1	Learner <code>j</code> assigns observation <code>k</code> to a positive class.

- If the coding matrix varies across folds, then `BinaryY` is empty ([]).

Data Types: double

CodingMatrix – Codes specifying class assignments

numeric matrix | []

Codes specifying class assignments for the binary learners, specified as a numeric matrix or [].

- If the coding matrix is the same across all folds, then `CodingMatrix` is a K -by- L matrix, where K is the number of classes and L is the number of binary learners.

The elements of `CodingMatrix` are -1 , 0 , or 1 , and the values correspond to dichotomous class assignments. This table describes how learner j assigns observations in class i to a dichotomous class corresponding to the value of `CodingMatrix(i, j)`.

Value	Dichotomous Class Assignment
-1	Learner j assigns observations in class i to a negative class.
0	Before training, learner j removes observations in class i from the data set.
1	Learner j assigns observations in class i to a positive class.

- If the coding matrix varies across folds, then `CodingMatrix` is empty (`[]`). You can obtain the coding matrix for each fold by using the `Trained` property. For example, `CVMdl.Trained{1}.CodingMatrix` is the coding matrix in the first fold of the cross-validated ECOC model `CVMdl`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64`

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

vector of positive integers | `[]`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels Y . (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: double

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data X , specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in X .

Data Types: cell

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as the number of classes in `ClassNames`, and the order of the elements corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: double

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: char

ScoreTransform — Score transformation function to apply to predicted scores

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter this code and replace *function* with a value in the table.

```
Mdl.ScoreTransform = 'function';
```

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$

Value	Description
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

Object Functions

kfoldEdge Classification edge for cross-validated ECOC model
 kfoldLoss Classification loss for cross-validated ECOC model
 kfoldMargin Classification margins for cross-validated ECOC model
 kfoldPredict Classify observations in cross-validated ECOC model
 kfoldfun Cross-validate function using cross-validated ECOC model

Examples

Cross-Validate ECOC Classifier

Cross-validate an ECOC classifier with SVM binary learners, and estimate the generalized classification error.

Load Fisher's iris data set. Specify the predictor data X and the response data Y.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and standardize the predictors.

```
t = templateSVM('Standardize',true)
```

```
t =
Fit template for classification SVM.
```

```

          Alpha: [0x1 double]
    BoxConstraint: []
          CacheSize: []
    CachingMethod: ''
          ClipAlphas: []
DeltaGradientTolerance: []
          Epsilon: []
          GapTolerance: []
          KKTolerance: []
    IterationLimit: []
    KernelFunction: ''
          KernelScale: []
```

```

        KernelOffset: []
    KernelPolynomialOrder: []
        NumPrint: []
            Nu: []
        OutlierFraction: []
    RemoveDuplicates: []
        ShrinkagePeriod: []
            Solver: ''
    StandardizeData: 1
    SaveSupportVectors: []
        VerbosityLevel: []
            Version: 2
                Method: 'SVM'
                    Type: 'classification'

```

`t` is an SVM template. Most of the template object properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train the ECOC classifier, and specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross-validate `Mdl` using 10-fold cross-validation.

```
CVMDL = crossval(Mdl);
```

`CVMDL` is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalized classification error.

```
genError = kfoldLoss(CVMDL)
```

```
genError = 0.0400
```

The generalized classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

Speed Up Training ECOC Classifiers Using Binning and Parallel Computing

Train a one-versus-all ECOC classifier using a `GentleBoost` ensemble of decision trees with surrogate splits. To speed up training, bin numeric predictors and use parallel computing. Binning is valid only when `fitcecoc` uses a tree learner. After training, estimate the classification error using 10-fold cross-validation. Note that parallel computing requires `Parallel Computing Toolbox™`.

Load Sample Data

Load and inspect the `arrhythmia` data set.

```
load arrhythmia
[n,p] = size(X)
```

```
n = 452
```

```

p = 279

isLabels = unique(Y);
nLabels = numel(isLabels)

nLabels = 13

tabulate(categorical(Y))

```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

The data set contains 279 predictors, and the sample size of 452 is relatively small. Of the 16 distinct labels, only 13 are represented in the response (Y). Each label describes various degrees of arrhythmia, and 54.20% of the observations are in class 1.

Train One-Versus-All ECOC Classifier

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify 'GentleBoost' for the method, 100 for the number of learners, and a decision tree template that uses surrogate splits because there are missing observations.

```

tTree = templateTree('surrogate','on');
tEnsemble = templateEnsemble('GentleBoost',100,tTree);

```

tEnsemble is a template object. Most of its properties are empty, but the software fills them with their default values during training.

Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. To speed up training, use binning and parallel computing.

- Binning ('NumBins',50) — When you have a large training data set, you can speed up training (a potential decrease in accuracy) by using the 'NumBins' name-value pair argument. This argument is valid only when fitcecoc uses a tree learner. If you specify the 'NumBins' value, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data. You can try 'NumBins',50 first, and then change the 'NumBins' value depending on the accuracy and training speed.
- Parallel computing ('Options',statset('UseParallel',true)) — With a Parallel Computing Toolbox license, you can speed up the computation by using parallel computing, which sends each binary learner to a worker in the pool. The number of workers depends on your system configuration. When you use decision trees for binary learners, fitcecoc parallelizes training using Intel® Threading Building Blocks (TBB) for dual-core systems and above. Therefore, specifying the 'UseParallel' option is not helpful on a single computer. Use this option on a cluster.

Additionally, specify that the prior probabilities are $1/K$, where $K = 13$ is the number of distinct classes.

```
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Coding','onevsall','Learners',tEnsemble,...
    'Prior','uniform','NumBins',50,'Options',options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

Mdl is a ClassificationECOC model.

Cross-Validation

Cross-validate the ECOC classifier using 10-fold cross-validation.

```
CVMdl = crossval(Mdl,'Options',options);
```

```
Warning: One or more folds do not contain points from all the groups.
```

CVMdl is a ClassificationPartitionedECOC model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation. For example, access the results of the first fold by entering `CVMdl.Trained{1}`.

Use the cross-validated ECOC classifier to predict validation-fold labels. You can compute the confusion matrix by using `confusionchart`. Move and resize the chart by changing the inner position property to ensure that the percentages appear in the row summary.

```
oofLabel = kfoldPredict(CVMdl,'Options',options);
ConfMat = confusionchart(Y,oofLabel,'RowSummary','total-normalized');
ConfMat.InnerPosition = [0.10 0.12 0.85 0.85];
```

1	212	13			1	2				8			9	46.9%	7.3%	
2	19	20		1		1				1		1	1	4.4%	5.3%	
3		1	14											3.1%	0.2%	
4	3	1		10	1									2.2%	1.1%	
5	7				3					2			1	0.7%	2.2%	
6	1	1				22							1	4.9%	0.7%

15	1	1	1	1	1										1.1%	
16	14	2	1			2	1					1	1		4.9%	
	1	2	3	4	5	6	7	8	9	10	14	15	16			
	Predicted Class															

Reproduce Binned Data

Reproduce binned predictor data by using the BinEdges property of the trained model and the discretize function.

```

X = Mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end

```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

Introduced in R2014b

ClassificationPartitionedEnsemble

Package: `classreg.learning.partition`

Superclasses: `ClassificationPartitionedModel`

Cross-validated classification ensemble

Description

`ClassificationPartitionedEnsemble` is a set of classification ensembles trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more “kfold” methods: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, `kfoldEdge`, and `kfoldfun`.

Every “kfold” method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in `Trained{1}` was trained on X and Y with the first 1/5 excluded, the second model stored in `Trained{2}` was trained on X and Y with the second 1/5 excluded, and so on. When you call `kfoldPredict`, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model, and so on. In short, response for every observation is computed by `kfoldPredict` using the model trained without this observation.

Construction

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a classification ensemble. For syntax details, see the `crossval` method reference page.

`cvens = fitcensemble(X,Y,Name,Value)` creates a cross-validated ensemble when `Name` is one of `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. For syntax details, see the `fitcensemble` function reference page.

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value pair argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
```

```

idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end

```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. **CategoricalPredictors** contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

ClassNames

List of the elements in Y with duplicates removed. **ClassNames** can be a numeric vector, vector of categorical variables, logical vector, character array, or cell array of character vectors. **ClassNames** has the same data type as the data in the argument Y. (The software treats string arrays as cell arrays of character vectors.)

Combiner

Cell array of combiners across all folds.

Cost

Square matrix, where $Cost(i, j)$ is the cost of classifying a point into class j if its true class is i (the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of **Cost** corresponds to the order of the classes in **ClassNames**. The number of rows and columns in **Cost** is the number of unique classes in the response. This property is read-only.

CrossValidatedModel

Name of the cross-validated model, a character vector.

Kfold

Number of folds used in a cross-validated ensemble, a positive integer.

ModelParameters

Object holding parameters of cvens.

NumObservations

Number of data points used in training the ensemble, a positive integer.

NTrainedPerFold

Number of data points used in training each fold of the ensemble, a positive integer.

Partition

Partition of class `cvpartition` used in creating the cross-validated ensemble.

PredictorNames

Cell array of names for the predictor variables, in the order in which they appear in X .

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

ResponseName

Name of the response variable Y , a character vector.

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```
ens.ScoreTransform = 'function'
```

or

```
ens.ScoreTransform = @function
```

Trainable

Cell array of ensembles trained on cross-validation folds. Every ensemble is full, meaning it contains its training data and weights.

Trained

Cell array of compact ensembles trained on cross-validation folds.

W

Scaled weights, a vector with length n , the number of rows in X .

X

A matrix or table of predictor values. Each column of X represents one variable, and each row represents one observation.

Y

Numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. Each row of Y is the response to the data in the corresponding row of X.

Methods

kfoldEdge	Classification edge for observations not used for training
kfoldLoss	Classification loss for observations not used for training
resume	Resume training learners on cross-validation folds

Inherited Methods

kfoldEdge	Classification edge for observations not used for training
kfoldfun	Cross validate function
kfoldLoss	Classification loss for observations not used for training
kfoldMargin	Classification margins for observations not used for training
kfoldPredict	Predict response for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Evaluate K-Fold Cross-Validation Error for Classification Ensemble

Evaluate the k-fold cross-validation error for a classification ensemble that models the Fisher iris data.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Create a cross-validated ensemble from ens and find the k-fold cross-validation error.

```
rng(10,'twister') % For reproducibility
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L = 0.0467
```

ClassificationPartitionedKernel

Cross-validated, binary kernel classification model

Description

`ClassificationPartitionedKernel` is a binary kernel classification model, trained on cross-validated folds. You can estimate the quality of classification, or how well the kernel classification model generalizes, using one or more “kfold” functions: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, and `kfoldEdge`.

Every “kfold” method uses models trained on training-fold (in-fold) observations to predict the response for validation-fold (out-of-fold) observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five groups of equal size (roughly). The training fold contains four of the groups (that is, roughly 4/5 of the data) and the validation fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

- 1 The software trains the first model (stored in `CVMdl.Trained{1}`) by using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model (stored in `CVMdl.Trained{2}`) using the observations in the first group and the last three groups. The software reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third, fourth, and fifth models.

If you validate by using `kfoldPredict`, the software computes predictions for the observations in group i by using the i th model. In short, the software estimates a response for every observation by using the model trained without that observation.

Note `ClassificationPartitionedKernel` model objects do not store the predictor data set.

Creation

You can create a `ClassificationPartitionedKernel` model by training a classification kernel model using `fitckernel` and specifying one of these name-value pair arguments: `'Crossval'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name

character vector

This property is read-only.

Cross-validated model name, specified as a character vector.

For example, 'Kernel' specifies a cross-validated kernel model.

Data Types: char

KFold — Number of cross-validated folds

positive integer scalar

This property is read-only.

Number of cross-validated folds, specified as a positive integer scalar.

Data Types: double

ModelParameters — Cross-validation parameter values

object

This property is read-only.

Cross-validation parameter values, specified as an object. The parameter values correspond to the name-value pair argument values used to cross-validate the kernel classifier. `ModelParameters` does not contain estimated parameters.

You can access the properties of `ModelParameters` using dot notation.

NumObservations — Number of observations

positive numeric scalar

This property is read-only.

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

Partition — Data partition

cvpartition model

This property is read-only.

Data partition indicating how the software splits the data into cross-validation folds, specified as a `cvpartition` model.

Trained — Kernel classifiers trained on cross-validation folds

cell array of `ClassificationKernel` models

This property is read-only.

Kernel classifiers trained on cross-validation folds, specified as a cell array of `ClassificationKernel` models. `Trained` has k cells, where k is the number of folds.

Data Types: cell

W — Observation weights

numeric vector

This property is read-only.

Observation weights used to cross-validate the model, specified as a numeric vector. `W` has `NumObservations` elements.

The software normalizes the weights used for training so that `nansum(W)` is 1.

Data Types: `single` | `double`

Y — Observed class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `Y` has `NumObservations` elements and has the same data type as the input argument `Y` that you pass to `fitckernel` to cross-validate the model. (The software treats string arrays as cell arrays of character vectors.)

Each row of `Y` represents the observed classification of the corresponding row of `X`.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

`[]`

This property is read-only.

Categorical predictor indices, specified as an empty numeric value. In general, `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. Because `ClassificationKernel` models can be trained on numeric predictor data only, this property is empty (`[]`).

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the observed class labels property `Y` and determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

Data Types: `double`

PredictorNames — Predictor names

`{'x1', 'x2', ...}`

This property is read-only.

Predictor names in order of their appearance in the predictor data X , specified as a cell array of character vectors of the form `{'x1', 'x2', ...}`. The length of `PredictorNames` is equal to the number of columns in X .

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as there are classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

Data Types: `double`

ResponseName — Response variable name

`'Y'`

This property is read-only.

Response variable name, specified as `'Y'`. Because `ClassificationKernel` models cannot be trained on tabular data, this property is always `'Y'`.

Data Types: `char`

ScoreTransform — Score transformation function

`'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | `'none'` | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For a kernel classification model Mdl , and before the score transformation, the predicted classification score for the observation x (row vector) is $f(x) = T(x)\beta + b$.

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

To change the `CVMDL` score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter this code and replace *function* with a value from the table.

```
CVMDL.ScoreTransform = 'function';
```

Value	Description
<code>'doublelogit'</code>	$1/(1 + e^{-2x})$
<code>'invlogit'</code>	$\log(x / (1 - x))$
<code>'ismax'</code>	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
<code>'logit'</code>	$1/(1 + e^{-x})$

Value	Description
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function or a function that you define, enter its function handle.

```
CVMDL.ScoreTransform = @function;
```

function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle

Object Functions

kfoldEdge Classification edge for cross-validated kernel classification model
kfoldLoss Classification loss for cross-validated kernel classification model
kfoldMargin Classification margins for cross-validated kernel classification model
kfoldPredict Classify observations in cross-validated kernel classification model

Examples

Cross-Validate Kernel Classification Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
rng('default') % For reproducibility
```

Cross-validate a binary kernel classification model. By default, the software uses 10-fold cross-validation.

```
CVMDL = fitckernel(X,Y,'CrossVal','on')

CVMDL =
  classreg.learning.partition.ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
      ResponseName: 'Y'
    NumObservations: 351
      KFold: 10
      Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
```

Properties, Methods

```
numel(CVMdl.Trained)
```

```
ans = 10
```

CVMdl is a ClassificationPartitionedKernel model. Because fitckernel implements 10-fold cross-validation, CVMdl contains 10 ClassificationKernel models that the software trains on training-fold (in-fold) observations.

Estimate the cross-validated classification error.

```
kfoldLoss(CVMdl)
```

```
ans = 0.0940
```

The classification error rate is approximately 9%.

ClassificationPartitionedKernelECOC

Cross-validated kernel error-correcting output codes (ECOC) model for multiclass classification

Description

`ClassificationPartitionedKernelECOC` is an error-correcting output codes (ECOC) model composed of kernel classification models, trained on cross-validated folds. Estimate the quality of the classification by cross-validation using one or more “kfold” functions: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, and `kfoldEdge`.

Every “kfold” method uses models trained on training-fold (in-fold) observations to predict the response for validation-fold (out-of-fold) observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five groups of equal size (roughly). The training fold contains four of the groups (that is, roughly 4/5 of the data) and the validation fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

- 1 The software trains the first model (stored in `CVMdl.Trained{1}`) by using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model (stored in `CVMdl.Trained{2}`) using the observations in the first group and the last three groups. The software reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third, fourth, and fifth models.

If you validate by using `kfoldPredict`, the software computes predictions for the observations in group i by using the i th model. In short, the software estimates a response for every observation by using the model trained without that observation.

Note `ClassificationPartitionedKernelECOC` model objects do not store the predictor data set.

Creation

You can create a `ClassificationPartitionedKernelECOC` model by training an ECOC model using `fitcecoc` and specifying these name-value pair arguments:

- `'Learners'` - Set the value to `'kernel'`, a template object returned by `templateKernel`, or a cell array of such template objects.
- One of the arguments `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

For more details, see `fitcecoc`.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name

character vector

This property is read-only.

Cross-validated model name, specified as a character vector.

For example, 'KernelECOC' specifies a cross-validated kernel ECOC model.

Data Types: char

KFold — Number of cross-validated folds

positive integer scalar

This property is read-only.

Number of cross-validated folds, specified as a positive integer scalar.

Data Types: double

ModelParameters — Cross-validation parameter values

object

This property is read-only.

Cross-validation parameter values, specified as an object. The parameter values correspond to the name-value pair argument values used to cross-validate the ECOC classifier. `ModelParameters` does not contain estimated parameters.

You can access the properties of `ModelParameters` using dot notation.

NumObservations — Number of observations

positive numeric scalar

This property is read-only.

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

Partition — Data partition

cvpartition model

This property is read-only.

Data partition indicating how the software splits the data into cross-validation folds, specified as a `cvpartition` model.

Trained — Compact classifiers trained on cross-validation folds

cell array of `CompactClassificationECOC` models

This property is read-only.

Compact classifiers trained on cross-validation folds, specified as a cell array of `CompactClassificationECOC` models. Trained has k cells, where k is the number of folds.

Data Types: `cell`

W — Observation weights

numeric vector

This property is read-only.

Observation weights used to cross-validate the model, specified as a numeric vector. `W` has `NumObservations` elements.

The software normalizes the weights used for training so that `nansum(W)` is 1.

Data Types: `single` | `double`

Y — Observed class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `Y` has `NumObservations` elements and has the same data type as the input argument `Y` that you pass to `fitcecoc` to cross-validate the model. (The software treats string arrays as cell arrays of character vectors.)

Each row of `Y` represents the observed classification of the corresponding row of `X`.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

ECOC Properties

BinaryLoss — Binary learner loss function

'binodeviance' | 'exponential' | 'hamming' | 'hinge' | 'linear' | 'logit' | 'quadratic'

This property is read-only.

Binary learner loss function, specified as a character vector representing the loss function name.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is 'hinge'. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is 'quadratic'. To potentially increase accuracy, specify a binary loss function other than the default during a prediction or loss computation by using the 'BinaryLoss' name-value pair argument of `kfoldPredict` or `kfoldLoss`.

Data Types: `char`

BinaryY — Binary learner class labels

numeric matrix | []

This property is read-only.

Binary learner class labels, specified as a numeric matrix or [].

- If the coding matrix is the same across all folds, then `BinaryY` is a `NumObservations-by-L` matrix, where L is the number of binary learners (`size(CodingMatrix,2)`).

The elements of `BinaryY` are `-1`, `0`, or `1`, and the values correspond to dichotomous class assignments. This table describes how learner `j` assigns observation `k` to a dichotomous class corresponding to the value of `BinaryY(k, j)`.

Value	Dichotomous Class Assignment
-1	Learner <code>j</code> assigns observation <code>k</code> to a negative class.
0	Before training, learner <code>j</code> removes observation <code>k</code> from the data set.
1	Learner <code>j</code> assigns observation <code>k</code> to a positive class.

- If the coding matrix varies across folds, then `BinaryY` is empty (`[]`).

Data Types: `double`

CodingMatrix — Codes specifying class assignments

numeric matrix | `[]`

This property is read-only.

Codes specifying class assignments for the binary learners, specified as a numeric matrix or `[]`.

- If the coding matrix is the same across all folds, then `CodingMatrix` is a K -by- L matrix, where K is the number of classes and L is the number of binary learners.

The elements of `CodingMatrix` are `-1`, `0`, or `1`, and the values correspond to dichotomous class assignments. This table describes how learner `j` assigns observations in class `i` to a dichotomous class corresponding to the value of `CodingMatrix(i, j)`.

Value	Dichotomous Class Assignment
-1	Learner <code>j</code> assigns observations in class <code>i</code> to a negative class.
0	Before training, learner <code>j</code> removes observations in class <code>i</code> from the data set.
1	Learner <code>j</code> assigns observations in class <code>i</code> to a positive class.

- If the coding matrix varies across folds, then `CodingMatrix` is empty (`[]`). You can obtain the coding matrix for each fold by using the `Trained` property. For example, `CVMDL.Trained{1}.CodingMatrix` is the coding matrix in the first fold of the cross-validated ECOC model `CVMDL`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64`

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

`[]`

This property is read-only.

Categorical predictor indices, specified as an empty numeric value. In general, `CategoricalPredictors` contains index values corresponding to the columns of the predictor data

that contain categorical predictors. Because `ClassificationKernel` models can be trained on numeric predictor data only, this property is empty (`[]`).

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the observed class labels property `Y` and determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

Data Types: `double`

PredictorNames — Predictor names

`{'x1', 'x2', ...}`

This property is read-only.

Predictor names in order of their appearance in the predictor data `X`, specified as a cell array of character vectors of the form `{'x1', 'x2', ...}`. The length of `PredictorNames` is equal to the number of columns in `X`.

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as there are classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

Data Types: `double`

ResponseName — Response variable name

`'Y'`

This property is read-only.

Response variable name, specified as `'Y'`. Because `ClassificationKernel` models cannot be trained on tabular data, this property is always `'Y'`.

Data Types: `char`

ScoreTransform — Score transformation function

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For a kernel classification model Mdl , and before the score transformation, the predicted classification score for the observation x (row vector) is $f(x) = T(x)\beta + b$.

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

To change the $CVMdl$ score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter this code and replace *function* with a value from the table.

```
CVMdl.ScoreTransform = 'function';
```

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function or a function that you define, enter its function handle.

```
CVMdl.ScoreTransform = @function;
```

function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle

Object Functions

kfoldEdge Classification edge for cross-validated kernel ECOC model
kfoldLoss Classification loss for cross-validated kernel ECOC model
kfoldMargin Classification margins for cross-validated kernel ECOC model
kfoldPredict Classify observations in cross-validated kernel ECOC model

Examples

Cross-Validate Multiclass Kernel Classification Model

Create a cross-validated, multiclass kernel ECOC classification model using `fitcecoc`.

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate a multiclass kernel ECOC classification model that can identify the species of a flower based on the flower's measurements.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')

CVMdl =
  classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
      ResponseName: 'Y'
    NumObservations: 150
      KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
```

Properties, Methods

`CVMdl` is a `ClassificationPartitionedKernelECOC` cross-validated model. `fitcecoc` implements 10-fold cross-validation by default. Therefore, `CVMdl.Trained` contains a 10-by-1 cell array of ten `CompactClassificationECOC` models, one for each fold. Each compact ECOC model is composed of binary kernel classification models.

Estimate the classification error by passing `CVMdl` to `kfoldLoss`.

```
error = kfoldLoss(CVMdl)

error = 0.0333
```

The estimated classification error is about 3% misclassified observations.

To change default options when training ECOC models composed of kernel classification models, create a kernel classification model template using `templateKernel`, and then pass the template to `fitcecoc`.

ClassificationPartitionedLinear

Package: `classreg.learning.partition`

Superclasses: `ClassificationPartitionedModel`

Cross-validated linear model for binary classification of high-dimensional data

Description

`ClassificationPartitionedLinear` is a set of linear classification models trained on cross-validated folds. To obtain a cross-validated, linear classification model, use `fitclinear` and specify one of the cross-validation options. You can estimate the quality of classification, or how well the linear classification model generalizes, using one or more of these “kfold” methods: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, and `kfoldEdge`.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five roughly equally sized groups. The training fold contains four of the groups (that is, roughly 4/5 of the data) and the test fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

- 1 The software trains the first model (stored in `CVMdl.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model, which is stored in `CVMdl.Trained{2}`, using the observations in the first group and last three groups. The software reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third through fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Note `ClassificationPartitionedLinear` model objects do not store the predictor data set.

Construction

`CVMdl = fitclinear(X,Y,Name,Value)` creates a cross-validated, linear classification model when `Name` is either `'CrossVal'`, `'CVPartition'`, `'Holdout'`, or `'KFold'`. For more details, see `fitclinear`.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name

character vector

Cross-validated model name, specified as a character vector.

For example, 'Linear' specifies a cross-validated linear model for binary classification or regression.

Data Types: char

KFold — Number of cross-validated folds

positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: double

ModelParameters — Cross-validation parameter values

object

Cross-validation parameter values, e.g., the name-value pair argument values used to cross-validate the linear model, specified as an object. ModelParameters does not contain estimated parameters.

Access properties of ModelParameters using dot notation.

NumObservations — Number of observations

positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

Partition — Data partition

cvpartition model

Data partition indicating how the software splits the data into cross-validation folds, specified as a cvpartition model.

Trained — Linear classification models trained on cross-validation folds

cell array of ClassificationLinear model objects

Linear classification models trained on cross-validation folds, specified as a cell array of ClassificationLinear models. Trained has k cells, where k is the number of folds.

Data Types: cell

W — Observation weights

numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. W has NumObservations elements.

The software normalizes W so that the weights for observations within a particular class sum up to the prior probability of that class.

Data Types: single | double

Y — Observed class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y has NumObservations elements, and

is the same data type as the input argument `Y` that you passed to `fitclinear` to cross-validate the model. (The software treats string arrays as cell arrays of character vectors.)

Each row of `Y` represents the observed classification of the corresponding observation in the predictor data.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

vector of positive integers | `[]`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels `Y`. (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

$\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

Data Types: `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in their order of appearance in predictor data used to train `CVMDL`, specified as a cell array of character vectors. `PredictorNames` has length equal to the number of predictor variables in the predictor data.

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as the number of classes in `ClassNames`, and the order of the elements corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: double

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: char

ScoreTransform — Score transformation function

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For linear classification models and before transformation, the predicted classification score for the observation x (row vector) is $f(x) = x\beta + b$, where β and b correspond to `Mdl.Beta` and `Mdl.Bias`, respectively.

To change the score transformation function to, for example, *function*, use dot notation.

- For a built-in function, enter this code and replace *function* with a value in the table.

```
Mdl.ScoreTransform = 'function';
```

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle

Methods

kfoldEdge	Classification edge for observations not used for training
kfoldLoss	Classification loss for observations not used in training
kfoldMargin	Classification margins for observations not used in training
kfoldPredict	Predict labels for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Create Cross-Validated Binary Linear Classification Model

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitlinear(X,Ystats,'CrossVal','on')
```

```
CVMdl =
  classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
      ResponseName: 'Y'
    NumObservations: 31572
          KFold: 10
      Partition: [1x1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'
```

Properties, Methods

CVMdl is a `ClassificationPartitionedLinear` cross-validated model. Because `fitlinear` implements 10-fold cross-validation by default, `CVMdl.Trained` contains ten `ClassificationLinear` models that contain the results of training linear classification models for each of the folds.

Estimate labels for out-of-fold observations and estimate the generalization error by passing `CVMDL` to `kfoldPredict` and `kfoldLoss`, respectively.

```
oofLabels = kfoldPredict(CVMDL);
ge = kfoldLoss(CVMDL)

ge = 7.6017e-04
```

The estimated generalization error is less than 0.1% misclassified observations.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, implement 5-fold cross-validation.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Estimate the coefficients using `SpaRSA`. Lower the tolerance on the gradient of the objective function to `1e-8`.

```
X = X';
rng(10); % For reproducibility
CVMDL = fitlinear(X, Ystats, 'ObservationsIn', 'columns', 'KFold', 5, ...
    'Learner', 'logistic', 'Solver', 'sparsa', 'Regularization', 'lasso', ...
    'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMDL =
  classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
      ResponseName: 'Y'
    NumObservations: 31572
      KFold: 5
    Partition: [1x1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'
```

Properties, Methods

```
numCLModels = numel(CVMdl.Trained)
```

```
numCLModels = 5
```

CVMdl is a `ClassificationPartitionedLinear` model. Because `fitlinear` implements 5-fold cross-validation, CVMdl contains 5 `ClassificationLinear` models that the software trains on each fold.

Display the first trained linear classification model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
  ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'logit'
        Beta: [34023×11 double]
        Bias: [-13.2904 -13.2904 -13.2904 -13.2904 -9.9357 -7.0782 -5.4335 -4.5473 -3.4223
        Lambda: [1.0000e-06 3.5481e-06 1.2589e-05 4.4668e-05 1.5849e-04 5.6234e-04 0.0020 0.
        Learner: 'logistic'
```

Properties, Methods

Mdl1 is a `ClassificationLinear` model object. `fitlinear` constructed Mdl1 by training on the first four folds. Because Lambda is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in Lambda.

Estimate the cross-validated classification error.

```
ce = kfoldLoss(CVMdl);
```

Because there are 11 regularization strengths, ce is a 1-by-11 vector of classification error rates.

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitlinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} classification error')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
```

```
title('Test-Sample Statistics')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

ClassificationPartitionedLinearECOC

Package: `classreg.learning.partition`

Superclasses: `ClassificationPartitionedModel`

Cross-validated linear error-correcting output codes model for multiclass classification of high-dimensional data

Description

`ClassificationPartitionedLinearECOC` is a set of error-correcting output codes (ECOC) models composed of linear classification models, trained on cross-validated folds. Estimate the quality of classification by cross-validation using one or more “kfold” functions: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, and `kfoldEdge`.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five roughly equal-sized groups. The training fold contains four of the groups (that is, roughly 4/5 of the data) and the test fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows.

- 1 The software trains the first model (stored in `CVMDL.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model (stored in `CVMDL.Trained{2}`) using the observations in the first group and last three groups. The software reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third, fourth, and fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Note `ClassificationPartitionedLinearECOC` model objects do not store the predictor data set.

Construction

`CVMDL = fitcecoc(X,Y,'Learners',t,Name,Value)` returns a cross-validated, linear ECOC model when:

- `t` is 'Linear' or a template object returned by `templateLinear`.
- `Name` is one of 'CrossVal', 'CVPartition', 'Holdout', or 'KFold'.

For more details, see `fitcecoc`.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name

character vector

Cross-validated model name, specified as a character vector.

For example, 'ECOC' specifies a cross-validated ECOC model.

Data Types: char

KFold — Number of cross-validated folds

positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: double

ModelParameters — Cross-validation parameter values

object

Cross-validation parameter values, e.g., the name-value pair argument values used to cross-validate the ECOC classifier, specified as an object. `ModelParameters` does not contain estimated parameters.

Access properties of `ModelParameters` using dot notation.

NumObservations — Number of observations

positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

Partition — Data partition

cvpartition model

Data partition indicating how the software splits the data into cross-validation folds, specified as a `cvpartition` model.

Trained — Compact classifiers trained on cross-validation folds

cell array of `CompactClassificationECOC` models

Compact classifiers trained on cross-validation folds, specified as a cell array of `CompactClassificationECOC` models. `Trained` has k cells, where k is the number of folds.

Data Types: cell

W — Observation weights

numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. `W` has `NumObservations` elements.

The software normalizes the weights used for training so that `nansum(W)` is 1.

Data Types: `single` | `double`

Y — Observed class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y has `NumObservations` elements, and is the same data type as the input argument Y that you passed to `fitcecoc` to cross-validate the model. (The software treats string arrays as cell arrays of character vectors.)

Each row of Y represents the observed classification of the observation in the predictor data.

Data Types: `char` | `cell` | `categorical` | `logical` | `single` | `double`

ECOC Properties

BinaryLoss — Binary learner loss function

'binodeviance' | 'exponential' | 'hamming' | 'hinge' | 'linear' | 'logit' | 'quadratic'

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets `BinaryLoss` to 'hamming'. To potentially increase accuracy, specify a binary loss function other than the default during a prediction or loss computation by using the 'BinaryLoss' name-value pair argument of `predict` or `loss`.

Data Types: `char`

BinaryY — Binary learner class labels

numeric matrix | []

Binary learner class labels, specified as a numeric matrix or [].

- If the coding matrix is the same across folds, then `BinaryY` is a `NumObservations`-by-`L` matrix, where `L` is the number of binary learners (`size(CodingMatrix,2)`).

Elements of `BinaryY` are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes how learner `j` assigns observation `k` to a dichotomous class corresponding to the value of `BinaryY(k,j)`.

Value	Dichotomous Class Assignment
-1	Learner <code>j</code> assigns observation <code>k</code> to a negative class.
0	Before training, learner <code>j</code> removes observation <code>k</code> from the data set.
1	Learner <code>j</code> assigns observation <code>k</code> to a positive class.

- If the coding matrix varies across folds, then `BinaryY` is empty ([]).

Data Types: `double`

CodingMatrix — Codes specifying class assignments

numeric matrix | []

Codes specifying class assignments for the binary learners, specified as a numeric matrix or [].

- If the coding matrix is the same across folds, then `CodingMatrix` is a K -by- L matrix. K is the number of classes and L is the number of binary learners.

Elements of `CodingMatrix` are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes how learner j assigns observations in class i to a dichotomous class corresponding to the value of `CodingMatrix(i, j)`.

Value	Dichotomous Class Assignment
-1	Learner j assigns observations in class i to a negative class.
0	Before training, learner j removes observations in class i from the data set.
1	Learner j assigns observations in class i to a positive class.

- If the coding matrix varies across folds, then `CodingMatrix` is empty ([]). Obtain the coding matrix for each fold using the `Trained` property. For example, `CVMdl.Trained{1}.CodingMatrix` is the coding matrix in the first fold of the cross-validated ECOC model `CVMdl`.

Data Types: double | single | int8 | int16 | int32 | int64

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

vector of positive integers | []

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: single | double

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels Y . (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: categorical | char | logical | single | double | cell

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in their order of appearance in predictor data used to train `CVMDL`, specified as a cell array of character vectors. `PredictorNames` has length equal to the number of predictor variables in the predictor data.

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as the number of classes in `ClassNames`, and the order of the elements corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

ScoreTransform — Score transformation function

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For linear classification models and before transformation, the predicted classification score for the observation x (row vector) is $f(x) = x\beta + b$, where β and b correspond to `Mdl.Beta` and `Mdl.Bias`, respectively.

To change the score transformation function to, for example, *function*, use dot notation.

- For a built-in function, enter this code and replace *function* with a value in the table.

```
Mdl.ScoreTransform = 'function';
```

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$

Value	Description
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle

Methods

kfoldEdge	Classification edge for observations not used for training
kfoldLoss	Classification loss for observations not used in training
kfoldMargin	Classification margins for observations not used in training
kfoldPredict	Predict labels for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Create Cross-Validated Multiclass Linear Classification Model

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

Cross-validate a multiclass, linear classification model that can identify which MATLAB® toolbox a documentation web page is from based on counts of words on the page.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','linear','CrossVal','on')

CVMdl =
    classreg.learning.partition.ClassificationPartitionedLinearECOC
    CrossValidatedModel: 'LinearECOC'
    ResponseName: 'Y'
```

```

NumObservations: 31572
      KFold: 10
      Partition: [1x1 cvpartition]
      ClassNames: [1x13 categorical]
      ScoreTransform: 'none'

```

Properties, Methods

`CVMDL` is a `ClassificationPartitionedLinearECOC` cross-validated model. Because `fitcecoc` implements 10-fold cross-validation by default, `CVMDL.Trained` contains a 10-by-1 cell vector of ten `CompactClassificationECOC` models that contain the results of training ECOC models composed of binary, linear classification models for each of the folds.

Estimate labels for out-of-fold observations and estimate the generalization error by passing `CVMDL` to `kfoldPredict` and `kfoldLoss`, respectively.

```

oofLabels = kfoldPredict(CVMDL);
ge = kfoldLoss(CVMDL)

ge = 0.0958

```

The estimated generalization error is about 10% misclassified observations.

To improve generalization error, try specifying another solver, such as `LBFSGS`. To change default options when training ECOC models composed of linear classification models, create a linear classification model template using `templateLinear`, and then pass the template to `fitcecoc`.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for an ECOC model composed of linear classification models that use logistic regression learners, implement 5-fold cross-validation.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in `Y` that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-7} through 10^{-2} .

```
Lambda = logspace(-7,-2,11);
```

Create a linear classification model template that specifies to use logistic regression learners, use lasso penalties with strengths in `Lambda`, train using `SparSA`, and lower the tolerance on the gradient of the objective function to $1e-8$.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';
rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5);
```

CVMdl is a ClassificationPartitionedLinearECOC model.

Dissect CVMdl, and each model within it.

```
numECOCModels = numel(CVMdl.Trained)
```

```
numECOCModels = 5
```

```
ECOCmdl1 = CVMdl.Trained{1}
```

```
ECOCmdl1 =
  classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [comm    dsp    simulink  others]
    ScoreTransform: 'none'
    BinaryLearners: {6x1 cell}
    CodingMatrix: [4x6 double]
```

Properties, Methods

```
numCLModels = numel(ECOCmdl1.BinaryLearners)
```

```
numCLModels = 6
```

```
CLMdl1 = ECOCmdl1.BinaryLearners{1}
```

```
CLMdl1 =
  ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [-1 1]
    ScoreTransform: 'logit'
        Beta: [34023x11 double]
        Bias: [-0.3125 -0.3596 -0.3596 -0.3596 -0.3596 -0.3596 -0.1593 -0.0737 -0.1759 -0.3125]
        Lambda: [1.0000e-07 3.1623e-07 1.0000e-06 3.1623e-06 1.0000e-05 3.1623e-05 1.0000e-04 3.1623e-04 1.0000e-03 3.1623e-03]
    Learner: 'logistic'
```

Properties, Methods

Because `fitcecoc` implements 5-fold cross-validation, CVMdl contains a 5-by-1 cell array of `CompactClassificationECOC` models that the software trains on each fold. The `BinaryLearners` property of each `CompactClassificationECOC` model contains the `ClassificationLinear` models. The number of `ClassificationLinear` models within each compact ECOC model depends on the number of distinct labels and coding design. Because `Lambda` is a sequence of regularization strengths, you can think of CLMdl1 as 11 models, one for each regularization strength in `Lambda`.

Determine how well the models generalize by plotting the averages of the 5-fold classification error for each regularization strength. Identify the regularization strength that minimizes the generalization error over the grid.

```

ce = kfoldLoss(CVMdl);
figure;
plot(log10(Lambda),log10(ce))
[~,minCEIdx] = min(ce);
minLambda = Lambda(minCEIdx);
hold on
plot(log10(minLambda),log10(ce(minCEIdx)),'ro');
ylabel('log_{10} 5-fold classification error')
xlabel('log_{10} Lambda')
legend('MSE','Min classification error')
hold off

```

Train an ECOC model composed of linear classification model using the entire data set, and specify the minimal regularization strength.

```

t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',minLambda,'GradientTolerance',1e-8);
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');

```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Introduced in R2016a

ClassificationPartitionedModel

Package: `classreg.learning.partition`

Cross-validated classification model

Description

`ClassificationPartitionedModel` is a set of classification models trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more “kfold” methods: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, `kfoldEdge`, and `kfoldfun`.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, the software randomly assigns each observation into five roughly equally sized groups. The training fold contains four of the groups (i.e., roughly 4/5 of the data) and the test fold contains the other group (i.e., roughly 1/5 of the data). In this case, cross validation proceeds as follows:

- The software trains the first model (stored in `CVMDL.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
- The software trains the second model (stored in `CVMDL.Trained{2}`) using the observations in the first group and last three groups, and reserves the observations in the second group for validation.
- The software proceeds in a similar fashion for the third to fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Construction

`CVMDL = crossval(Mdl)` creates a cross-validated classification model from a classification model (`Mdl`).

Alternatively:

- `CVDiscrMdl = fitcdiscr(X,Y,Name,Value)`
- `CVKNNMdl = fitcknn(X,Y,Name,Value)`
- `CVNBMDL = fitcnb(X,Y,Name,Value)`
- `CVSVMMDL = fitcsvm(X,Y,Name,Value)`
- `CVTreeMdl = fitctree(X,Y,Name,Value)`

create a cross-validated model when `name` is either `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. For syntax details, see `fitcdiscr`, `fitcknn`, `fitcnb`, `fitcsvm`, and `fitctree`.

Input Arguments

Mdl

A classification model. `Mdl` can be any of the following:

- A classification tree trained using `fitctree`
- A discriminant analysis classifier trained using `fitcdiscr`
- A naive Bayes classifier trained using `fitcnb`
- A nearest-neighbor classifier trained using `fitcknn`
- A support vector machine classifier trained using `fitcsvm`

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value pair argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains NaNs, then the corresponding `Xbinned` values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

If `Mdl` is a trained discriminant analysis classifier, then `CategoricalPredictors` is always empty (`[]`).

ClassNames

Unique class labels used in training the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

Cost

Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response.

If `CVModel` is a cross-validated `ClassificationDiscriminant`, `ClassificationKNN`, or `ClassificationNaiveBayes` model, then you can change its cost matrix to e.g., `CostMatrix`, using dot notation.

```
CVModel.Cost = CostMatrix;
```

CrossValidatedModel

Name of the cross-validated model, which is a character vector.

KFold

Number of folds used in cross-validated model, which is a positive integer.

ModelParameters

Object holding parameters of `CVModel`.

Partition

The partition of class `CVPartition` used in creating the cross-validated model.

PredictorNames

Predictor variable names, specified as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the training data.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`.

If `CVModel` is a cross-validated `ClassificationDiscriminant` or `ClassificationNaiveBayes` model, then you can change its vector of priors to e.g., `priorVector`, using dot notation.

```
CVModel.Prior = priorVector;
```

ResponseName

Response variable name, specified as a character vector.

ScoreTransform

Score transformation, specified as a character vector or function handle. `ScoreTransform` represents a built-in transformation function or a function handle for transforming predicted classification scores.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter a character vector.

```
Mdl.ScoreTransform = 'function';
```

This table describes the available built-in functions.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Trained

The trained learners, which is a cell array of compact classification models.

W

The scaled weights, which is a vector with length n , the number of rows in X .

X

A matrix or table of predictor values. Each column of X represents one variable, and each row represents one observation.

Y

Categorical or character array, logical or numeric vector, or cell array of character vectors specifying the class labels for each observation. Y has the same number of rows as X, and each entry of Y is the response to the data in the corresponding row of X.

Methods

kfoldEdge	Classification edge for observations not used for training
kfoldfun	Cross validate function
kfoldLoss	Classification loss for observations not used for training
kfoldMargin	Classification margins for observations not used for training
kfoldPredict	Predict response for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Evaluate the Classification Error of a Classification Tree Classifier

Evaluate the k -fold cross-validation error for a classification tree model.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree using default options.

```
Mdl = fitctree(meas,species);
```

Cross validate the classification tree model.

```
CVMdl = crossval(Mdl);
```

Estimate the 10-fold cross-validation loss.

```
L = kfoldLoss(CVMdl)
```

```
L = 0.0533
```

Estimate Posterior Probabilities for Test Samples

Estimate positive class posterior probabilities for the test set of an SVM algorithm.

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Specify a 20% holdout sample. It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Holdout',0.2,'Standardize',true,...
    'ClassNames',{'b','g'});
```

CVSVMModel is a trained ClassificationPartitionedModel cross-validated classifier.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```
ScoreCVSVMModel = fitSVMPosterior(CVSVMModel);
```

ScoreSVMModel is a trained ClassificationPartitionedModel cross-validated classifier containing the optimal score transformation function estimated from the training data.

Estimate the out-of-sample positive class posterior probabilities. Display the results for the first 10 out-of-sample observations.

```
[~,OOSPostProbs] = kfoldPredict(ScoreCVSVMModel);
indx = ~isnan(OOSPostProbs(:,2));
hoObs = find(indx); % Holdout observation numbers
OOSPostProbs = [hoObs, OOSPostProbs(indx,2)];
table(OOSPostProbs(1:10,1),OOSPostProbs(1:10,2),...
    'VariableNames',{'ObservationIndex','PosteriorProbability'})
```

```
ans=10x2 table
    ObservationIndex    PosteriorProbability
    _____    _____
         6              0.17378
         7              0.89637
         8              0.0076609
         9              0.91602
        16              0.026718
        22              4.6081e-06
        23              0.9024
        24              2.4129e-06
        38              0.00042697
        41              0.86427
```

Tips

To estimate posterior probabilities of trained, cross-validated SVM classifiers, use `fitSVMPosterior`.

Topics

“Cross Validating a Discriminant Analysis Classifier” on page 20-17

ClassificationSVM

Support vector machine (SVM) for one-class and binary classification

Description

`ClassificationSVM` is a support vector machine (SVM) classifier on page 32-488 for one-class and two-class learning. Trained `ClassificationSVM` classifiers store training data, parameter values, prior probabilities, support vectors, and algorithmic implementation information. Use these classifiers to perform tasks such as fitting a score-to-posterior-probability transformation function (see `fitPosterior`) and predicting labels for new data (see `predict`).

Creation

Create a `ClassificationSVM` object by using `fitcsvm`.

Properties

SVM Properties

Alpha — Trained classifier coefficients

numeric vector

This property is read-only.

Trained classifier coefficients, specified as an s -by-1 numeric vector. s is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`.

`Alpha` contains the trained classifier coefficients from the dual problem, that is, the estimated Lagrange multipliers. If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations that are support vectors, `Alpha` contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one observation from the set of duplicates and a coefficient of 0 to all other duplicate observations in the set.

Data Types: `single` | `double`

Beta — Linear predictor coefficients

numeric vector

This property is read-only.

Linear predictor coefficients, specified as a numeric vector. The length of `Beta` is equal to the number of predictors used to train the model.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. `Beta` stores one value for each predictor variable, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then `Beta` is a numeric vector containing five values.

If `KernelParameters.Function` is 'linear', then the classification score for the observation x is

$$f(x) = (x/s)\beta + b.$$

`Mdl` stores β , b , and s in the properties `Beta`, `Bias`, and `KernelParameters.Scale`, respectively.

To estimate classification scores manually, you must first apply any transformations to the predictor data that were applied during training. Specifically, if you specify 'Standardize', `true` when using `fitsvm`, then you must standardize the predictor data manually by using the mean `Mdl.Mu` and standard deviation `Mdl.Sigma`, and then divide the result by the kernel scale in `Mdl.KernelParameters.Scale`.

All SVM functions, such as `resubPredict` and `predict`, apply any required transformation before estimation.

If `KernelParameters.Function` is not 'linear', then `Beta` is empty (`[]`).

Data Types: `single` | `double`

Bias — Bias term

scalar

This property is read-only.

Bias term, specified as a scalar.

Data Types: `single` | `double`

BoxConstraints — Box constraints

numeric vector

This property is read-only.

Box constraints, specified as a numeric vector of n -by-1 box constraints on page 32-486. n is the number of observations in the training data (see the `NumObservations` property).

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitsvm`, then for a given set of duplicate observations, MATLAB sums the box constraints and then attributes the sum to one observation. MATLAB attributes the box constraints of 0 to all other observations in the set.

Data Types: `single` | `double`

CacheInfo — Caching information

structure array

This property is read-only.

Caching information, specified as a structure array. The caching information contains the fields described in this table.

Field	Description
Size	The cache size (in MB) that the software reserves to train the SVM classifier. For details, see 'CacheSize'.

Field	Description
Algorithm	The caching algorithm that the software uses during optimization. Currently, the only available caching algorithm is Queue. You cannot set the caching algorithm.

Display the fields of `CacheInfo` by using dot notation. For example, `Mdl.CacheInfo.Size` displays the value of the cache size.

Data Types: `struct`

IsSupportVector — Support vector indicator

logical vector

This property is read-only.

Support vector indicator, specified as an n -by-1 logical vector that flags whether a corresponding observation in the predictor data matrix is a “Support Vector” on page 32-488. n is the number of observations in the training data (see `NumObservations`).

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations that are support vectors, `IsSupportVector` flags only one observation as a support vector.

Data Types: `logical`

KernelParameters — Kernel parameters

structure array

This property is read-only.

Kernel parameters, specified as a structure array. The kernel parameters property contains the fields listed in this table.

Field	Description
Function	Kernel function used to compute the elements of the Gram matrix on page 32-1689. For details, see 'KernelFunction'.
Scale	Kernel scale parameter used to scale all elements of the predictor data on which the model is trained. For details, see 'KernelScale'.

To display the values of `KernelParameters`, use dot notation. For example, `Mdl.KernelParameters.Scale` displays the kernel scale parameter value.

The software accepts `KernelParameters` as inputs and does not modify them.

Data Types: `struct`

Nu — One-class learning parameter

positive scalar

This property is read-only.

One-class learning on page 32-487 parameter ν , specified as a positive scalar.

Data Types: `single` | `double`

OutlierFraction — Proportion of outliers

numeric scalar

This property is read-only.

Proportion of outliers in the training data, specified as a numeric scalar.

Data Types: `double`

Solver — Optimization routine`'ISDA' | 'L1QP' | 'SMO'`

This property is read-only.

Optimization routine used to train the SVM classifier, specified as `'ISDA'`, `'L1QP'`, or `'SMO'`. For more details, see `'Solver'`.

SupportVectorLabels — Support vector class labels*s*-by-1 numeric vector

This property is read-only.

Support vector class labels, specified as an *s*-by-1 numeric vector. *s* is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`.

A value of `+1` in `SupportVectorLabels` indicates that the corresponding support vector is in the positive class (`ClassNames{2}`). A value of `-1` indicates that the corresponding support vector is in the negative class (`ClassNames{1}`).

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations that are support vectors, `SupportVectorLabels` contains one unique support vector label.

Data Types: `single` | `double`

SupportVectors — Support vectors*s*-by-*p* numeric matrix

This property is read-only.

Support vectors in the trained classifier, specified as an *s*-by-*p* numeric matrix. *s* is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`, and *p* is the number of predictor variables in the predictor data.

`SupportVectors` contains rows of the predictor data *X* that MATLAB considers to be support vectors. If you specify `'Standardize'`, `true` when training the SVM classifier using `fitcsvm`, then `SupportVectors` contains the standardized rows of *X*.

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations that are support vectors, `SupportVectors` contains one unique support vector.

Data Types: `single` | `double`

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

vector of positive integers | []

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: `single` | `double`

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used in training the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

Cost — Misclassification cost

numeric square matrix

This property is read-only.

Misclassification cost, specified as a numeric square matrix, where $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i .

During training, the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

- For two-class learning, `Cost` always has this form: $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$. The rows correspond to the true class and the columns correspond to the predicted class. The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.
- For one-class learning, $\text{Cost} = 0$.

For more details, see Algorithms on page 32-489.

Data Types: `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

This property is read-only.

Expanded predictor names, specified as a cell array of character vectors.

If the model uses dummy variable encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

Gradient — Training data gradient values

numeric vector

This property is read-only.

Training data gradient values, specified as a numeric vector. The length of `Gradient` is equal to the number of observations (see `NumObservations`).

Data Types: `single` | `double`

ModelParameters — Parameters used to train model

structure array

This property is read-only.

Parameters used to train the `ClassificationSVM` model, specified as a structure array. `ModelParameters` contains parameter values such as the name-value pair argument values used to train the SVM classifier. `ModelParameters` does not contain estimated parameters.

Access the fields of `ModelParameters` by using dot notation. For example, access the initial values for estimating `Alpha` by using `Mdl.ModelParameters.Alpha`.

Data Types: `struct`

Mu — Predictor means

numeric vector | []

This property is read-only.

Predictor means, specified as a numeric vector. If you specify `'Standardize',1` or `'Standardize',true` when you train an SVM classifier using `fitcsvm`, then the length of `Mu` is equal to the number of predictors.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. `Mu` stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set `'Standardize',false` when you train the SVM classifier using `fitcsvm`, then `Mu` is an empty vector (`[]`).

Data Types: `single` | `double`

NumObservations — Number of observations

numeric scalar

This property is read-only.

Number of observations in the training data stored in `X` and `Y`, specified as a numeric scalar.

Data Types: `single` | `double`

PredictorNames — Predictor variable names

cell array of character vectors

This property is read-only.

Predictor variable names, specified as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the training data.

Data Types: `cell`

Prior — Prior probabilities

numeric vector

This property is read-only.

Prior probabilities for each class, specified as a numeric vector. The order of the elements of `Prior` corresponds to the elements of `Mdl.ClassNames`.

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

For more details, see Algorithms on page 32-489.

Data Types: `single` | `double`

ResponseName — Response variable name

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

RowsUsed — Rows used in fitting

`[]` | logical vector

This property is read-only.

Rows of the original data X used in fitting the `ClassificationSVM` model, specified as a logical vector. This property is empty if all rows are used.

Data Types: `logical`

ScoreTransform — Score transformation

character vector | function handle

Score transformation, specified as a character vector or function handle. `ScoreTransform` represents a built-in transformation function or a function handle for transforming predicted classification scores.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter a character vector.

```
Mdl.ScoreTransform = 'function';
```

This table describes the available built-in functions.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$

Value	Description
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

Sigma — Predictor standard deviations

[] (default) | numeric vector

This property is read-only.

Predictor standard deviations, specified as a numeric vector.

If you specify 'Standardize', true when you train the SVM classifier using `fitcsvm`, then the length of Sigma is equal to the number of predictor variables.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. Sigma stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set 'Standardize', false when you train the SVM classifier using `fitcsvm`, then Sigma is an empty vector ([]).

Data Types: single | double

W — Observation weights

ones(n, 1) (default) | numeric vector

This property is read-only.

Observation weights used to train the SVM classifier, specified as an n -by-1 numeric vector. n is the number of observations (see `NumObservations`).

`fitcsvm` normalizes the observation weights specified in the 'Weights' name-value pair argument so that the elements of W within a particular class sum up to the prior probability of that class.

Data Types: `single` | `double`

X — Unstandardized predictors

numeric matrix | table

This property is read-only.

Unstandardized predictors used to train the SVM classifier, specified as a numeric matrix or table.

Each row of X corresponds to one observation, and each column corresponds to one variable.

MATLAB excludes observations containing at least one missing value, and removes corresponding elements from Y.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Class labels used to train the SVM classifier, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y is the same data type as the input argument Y of `fitcsvm`. (The software treats string arrays as cell arrays of character vectors.)

Each row of Y represents the observed classification of the corresponding row of X.

MATLAB excludes elements containing missing values, and removes corresponding observations from X.

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

Convergence Control Properties

ConvergenceInfo — Convergence information

structure array

This property is read-only.

Convergence information, specified as a structure array.

Field	Description
<code>Converged</code>	Logical flag indicating whether the algorithm converged (1 indicates convergence).
<code>ReasonForConvergence</code>	Character vector indicating the criterion the software uses to detect convergence.
<code>Gap</code>	Scalar feasibility gap between the dual and primal objective functions.
<code>GapTolerance</code>	Scalar feasibility gap tolerance. Set this tolerance, for example to <code>1e-2</code> , by using the name-value pair argument <code>'GapTolerance', 1e-2</code> of <code>fitcsvm</code> .

Field	Description
DeltaGradient	Scalar-attained gradient difference between upper and lower violators
DeltaGradientTolerance	Scalar tolerance for the gradient difference between upper and lower violators. Set this tolerance, for example to $1e-2$, by using the name-value pair argument 'DeltaGradientTolerance', $1e-2$ of <code>fitcsvm</code> .
LargestKKTViolation	Maximal scalar Karush-Kuhn-Tucker (KKT) violation value.
KKTTolerance	Scalar tolerance for the largest KKT violation. Set this tolerance, for example, to $1e-3$, by using the name-value pair argument 'KKTTolerance', $1e-3$ of <code>fitcsvm</code> .
History	Structure array containing convergence information at set optimization iterations. The fields are: <ul style="list-style-type: none"> • NumIterations: numeric vector of iteration indices for which the software records convergence information • Gap: numeric vector of Gap values at the iterations • DeltaGradient: numeric vector of DeltaGradient values at the iterations • LargestKKTViolation: numeric vector of LargestKKTViolation values at the iterations • NumSupportVectors: numeric vector indicating the number of support vectors at the iterations • Objective: numeric vector of Objective values at the iterations
Objective	Scalar value of the dual objective function.

Data Types: `struct`

NumIterations – Number of iterations

positive integer

This property is read-only.

Number of iterations required by the optimization routine to attain convergence, specified as a positive integer.

To set the limit on the number of iterations to 1000, for example, specify 'IterationLimit', 1000 when you train the SVM classifier using `fitcsvm`.

Data Types: `double`

ShrinkagePeriod — Number of iterations between reductions of active set

nonnegative integer

This property is read-only.

Number of iterations between reductions of the active set, specified as a nonnegative integer.

To set the shrinkage period to 1000, for example, specify 'ShrinkagePeriod', 1000 when you train the SVM classifier using `fitcsvm`.

Data Types: `single` | `double`**Hyperparameter Optimization Properties****HyperparameterOptimizationResults — Description of cross-validation optimization of hyperparameters**

BayesianOptimization object | table

This property is read-only.

Description of the cross-validation optimization of hyperparameters, specified as a BayesianOptimization object or a table of hyperparameters and associated values. This property is nonempty when the 'OptimizeHyperparameters' name-value pair argument of `fitcsvm` is nonempty at creation. The value of `HyperparameterOptimizationResults` depends on the setting of the `Optimizer` field in the `HyperparameterOptimizationOptions` structure of `fitcsvm` at creation, as described in this table.

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'bayesopt' (default)	Object of class BayesianOptimization
'gridsearch' or 'randomsearch'	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Object Functions

<code>compact</code>	Reduce size of support vector machine (SVM) classifier
<code>compareHoldout</code>	Compare accuracies of two classification models using new data
<code>crossval</code>	Cross-validate support vector machine (SVM) classifier
<code>discardSupportVectors</code>	Discard support vectors for linear support vector machine (SVM) classifier
<code>edge</code>	Find classification edge for support vector machine (SVM) classifier
<code>fitPosterior</code>	Fit posterior probabilities for support vector machine (SVM) classifier
<code>loss</code>	Find classification error for support vector machine (SVM) classifier
<code>margin</code>	Find classification margins for support vector machine (SVM) classifier
<code>predict</code>	Classify observations using support vector machine (SVM) classifier
<code>resubEdge</code>	Find classification edge for support vector machine (SVM) classifier by resubstitution
<code>resubLoss</code>	Find classification loss for support vector machine (SVM) classifier by resubstitution

resume Resume training support vector machine (SVM) classifier

Examples

Train SVM Classifier

Load Fisher's iris data set. Remove the sepal lengths and widths and all observed setosa irises.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
y = species(inds);
```

Train an SVM classifier using the processed data set.

```
SVMMModel = fitcsvm(X,y)

SVMMModel =
  ClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'versicolor' 'virginica'}
      ScoreTransform: 'none'
  NumObservations: 100
      Alpha: [24x1 double]
      Bias: -14.4149
  KernelParameters: [1x1 struct]
  BoxConstraints: [100x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [100x1 logical]
      Solver: 'SMO'
```

Properties, Methods

`SVMMModel` is a trained `ClassificationSVM` classifier. Display the properties of `SVMMModel`. For example, to determine the class order, use dot notation.

```
classOrder = SVMMModel.ClassNames
```

```
classOrder = 2x1 cell
    {'versicolor'}
    {'virginica' }
```

The first class ('versicolor') is the negative class, and the second ('virginica') is the positive class. You can change the class order during training by using the 'ClassNames' name-value pair argument.

Plot a scatter diagram of the data and circle the support vectors.

```
sv = SVMMModel.SupportVectors;
figure
gscatter(X(:,1),X(:,2),y)
hold on
```

```

plot(sv(:,1),sv(:,2),'ko','MarkerSize',10)
legend('versicolor','virginica','Support Vector')
hold off

```

The support vectors are observations that occur on or beyond their estimated class boundaries.

You can adjust the boundaries (and, therefore, the number of support vectors) by setting a box constraint during training using the 'BoxConstraint' name-value pair argument.

Train and Cross-Validate SVM Classifier

Load the `ionosphere` data set.

```
load ionosphere
```

Train and cross-validate an SVM classifier. Standardize the predictor data and specify the order of the classes.

```

rng(1); % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Standardize',true,...
    'ClassNames',{'b','g'},'CrossVal','on')

CVSVMModel =
    classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'SVM'

```

```

    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'

```

Properties, Methods

`CVSVMModel` is a `ClassificationPartitionedModel` cross-validated SVM classifier. By default, the software implements 10-fold cross-validation.

Alternatively, you can cross-validate a trained `ClassificationSVM` classifier by passing it to `crossval`.

Inspect one of the trained folds using dot notation.

```
CVSVMModel.Trained{1}
```

```

ans =
    classreg.learning.classif.CompactClassificationSVM
        ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'b' 'g'}
        ScoreTransform: 'none'
            Alpha: [78x1 double]
            Bias: -0.2209
    KernelParameters: [1x1 struct]
        Mu: [1x34 double]
        Sigma: [1x34 double]
    SupportVectors: [78x34 double]
    SupportVectorLabels: [78x1 double]

```

Properties, Methods

Each fold is a `CompactClassificationSVM` classifier trained on 90% of the data.

Estimate the generalization error.

```
genError = kfoldLoss(CVSVMModel)
```

```
genError = 0.1168
```

On average, the generalization error is approximately 12%.

More About

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, which helps to prevent overfitting (regularization).

If you increase the box constraint, then the SVM classifier assigns fewer support vectors. However, increasing the box constraint can lead to longer training times.

Gram Matrix

The Gram matrix of a set of n vectors $\{x_1, \dots, x_n; x_j \in R^p\}$ is an n -by- n matrix with element (j, k) defined as $G(x_j, x_k) = \langle \phi(x_j), \phi(x_k) \rangle$, an inner product of the transformed predictors using the kernel function ϕ .

For nonlinear SVM, the algorithm forms a Gram matrix using the rows of the predictor data X . The dual formalization replaces the inner product of the observations in X with corresponding elements of the resulting Gram matrix (called the "kernel trick"). Consequently, nonlinear SVM operates in the transformed predictor space to find a separating hyperplane.

Karush-Kuhn-Tucker Complementarity Conditions

KKT complementarity conditions are optimization constraints required for optimal nonlinear programming solutions.

In SVM, the KKT complementarity conditions are

$$\begin{cases} \alpha_j [y_j f(x_j) - 1 + \xi_j] = 0 \\ \xi_j (C - \alpha_j) = 0 \end{cases}$$

for all $j = 1, \dots, n$, where $f(x_j) = \phi(x_j)' \beta + b$, ϕ is a kernel function (see Gram matrix on page 32-1689), and ξ_j is a slack variable. If the classes are perfectly separable, then $\xi_j = 0$ for all $j = 1, \dots, n$.

One-Class Learning

One-class learning, or unsupervised SVM, aims to separate data from the origin in the high-dimensional predictor space (not the original predictor space), and is an algorithm used for outlier detection.

The algorithm resembles that of SVM for binary classification on page 32-1690. The objective is to minimize the dual expression

$$0.5 \sum_{j,k} \alpha_j \alpha_k G(x_j, x_k)$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to

$$\sum \alpha_j = n\nu$$

and $0 \leq \alpha_j \leq 1$ for all $j = 1, \dots, n$. The value of $G(x_j, x_k)$ is in element (j, k) of the Gram matrix on page 32-1689.

A small value of ν leads to fewer support vectors and, therefore, a smooth, crude decision boundary. A large value of ν leads to more support vectors and, therefore, a curvy, flexible decision boundary. The optimal value of ν should be large enough to capture the data complexity and small enough to avoid overtraining. Also, $0 < \nu \leq 1$.

For more details, see [5].

Support Vector

Support vectors are observations corresponding to strictly positive estimates of $\alpha_1, \dots, \alpha_n$.

SVM classifiers that yield fewer support vectors for a given training set are preferred.

Support Vector Machines for Binary Classification

The SVM binary classification algorithm searches for an optimal hyperplane that separates the data into two classes. For separable classes, the optimal hyperplane maximizes a margin (space that does not contain any observations) surrounding itself, which creates boundaries for the positive and negative classes. For inseparable classes, the objective is the same, but the algorithm imposes a penalty on the length of the margin for every observation that is on the wrong side of its class boundary.

The linear SVM score function is

$$f(x) = x'\beta + b,$$

where:

- x is an observation (corresponding to a row of X).
- The vector β contains the coefficients that define an orthogonal vector to the hyperplane (corresponding to `Mdl.Beta`). For separable data, the optimal margin length is $2/\|\beta\|$.
- b is the bias term (corresponding to `Mdl.Bias`).

The root of $f(x)$ for particular coefficients defines a hyperplane. For a particular hyperplane, $f(z)$ is the distance from point z to the hyperplane.

The algorithm searches for the maximum margin length, while keeping observations in the positive ($y = 1$) and negative ($y = -1$) classes separate.

- For separable classes, the objective is to minimize $\|\beta\|$ with respect to the β and b subject to $y_j f(x_j) \geq 1$, for all $j = 1, \dots, n$. This is the primal formalization for separable classes.
- For inseparable classes, the algorithm uses slack variables (ξ_j) to penalize the objective function for observations that cross the margin boundary for their class. $\xi_j = 0$ for observations that do not cross the margin boundary for their class, otherwise $\xi_j \geq 0$.

The objective is to minimize $0.5\|\beta\|^2 + C\sum \xi_j$ with respect to the β , b , and ξ_j subject to $y_j f(x_j) \geq 1 - \xi_j$ and $\xi_j \geq 0$ for all $j = 1, \dots, n$, and for a positive scalar box constraint on page 32-1689 C . This is the primal formalization for inseparable classes.

The algorithm uses the Lagrange multipliers method to optimize the objective, which introduces n coefficients $\alpha_1, \dots, \alpha_n$ (corresponding to `Mdl.Alpha`). The dual formalizations for linear SVM are as follows:

- For separable classes, minimize

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k x_j' x_k - \sum_{j=1}^n \alpha_j$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to $\sum \alpha_j y_j = 0$, $\alpha_j \geq 0$ for all $j = 1, \dots, n$, and Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-1690.

- For inseparable classes, the objective is the same as for separable classes, except for the additional condition $0 \leq \alpha_j \leq C$ for all $j = 1, \dots, n$.

The resulting score function is

$$\widehat{f}(x) = \sum_{j=1}^n \widehat{\alpha}_j y_j x' x_j + \widehat{b}.$$

\widehat{b} is the estimate of the bias and $\widehat{\alpha}_j$ is the j th estimate of the vector $\widehat{\alpha}$, $j = 1, \dots, n$. Written this way, the score function is free of the estimate of β as a result of the primal formalization.

The SVM algorithm classifies a new observation z using $\text{sign}(\widehat{f}(z))$.

In some cases, a nonlinear boundary separates the classes. Nonlinear SVM works in a transformed predictor space to find an optimal, separating hyperplane.

The dual formalization for nonlinear SVM is

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k G(x_j, x_k) - \sum_{j=1}^n \alpha_j$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to $\sum \alpha_j y_j = 0$, $0 \leq \alpha_j \leq C$ for all $j = 1, \dots, n$, and the KKT complementarity conditions. $G(x_k, x_j)$ are elements of the Gram matrix on page 32-1689. The resulting score function is

$$\widehat{f}(x) = \sum_{j=1}^n \widehat{\alpha}_j y_j G(x, x_j) + \widehat{b}.$$

For more details, see Understanding Support Vector Machines on page 18-145, [1], and [3].

Algorithms

- For the mathematical formulation of the SVM binary classification algorithm, see “Support Vector Machines for Binary Classification” on page 32-1690 and “Understanding Support Vector Machines” on page 18-145.
- NaN, <undefined>, empty character vector (' '), empty string (" "), and <missing> values indicate missing values. `fitsvm` removes entire rows of data corresponding to a missing response. When computing total weights (see the next bullets), `fitsvm` ignores any weight corresponding to an observation with at least one missing predictor. This action can lead to unbalanced prior probabilities in balanced-class problems. Consequently, observation box constraints might not equal `BoxConstraint`.
- `fitsvm` removes observations that have zero weight or prior probability.
- For two-class learning, if you specify the cost matrix `C` (see `Cost`), then the software updates the class prior probabilities p (see `Prior`) to p_c by incorporating the penalties described in `C`.

Specifically, `fitsvm` completes these steps:

- 1 Compute $p_c^* = p'C$.
- 2 Normalize p_c^* so that the updated prior probabilities sum to 1.

$$p_c = \frac{1}{\sum_{j=1}^K p_{c,j}^*} p_c^*.$$

K is the number of classes.

- 3 Reset the cost matrix to the default

$$C = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

- 4 Remove observations from the training data corresponding to classes with zero prior probability.
- For two-class learning, `fitcsvm` normalizes all observation weights (see `Weights`) to sum to 1. The function then renormalizes the normalized weights to sum up to the updated prior probability of the class to which the observation belongs. That is, the total weight for observation j in class k is

$$w_j^* = \frac{w_j}{\sum_{\forall j \in \text{Class } k} w_j} p_{c,k}.$$

w_j is the normalized weight for observation j ; $p_{c,k}$ is the updated prior probability of class k (see previous bullet).

- For two-class learning, `fitcsvm` assigns a box constraint to each observation in the training data. The formula for the box constraint of observation j is

$$C_j = nC_0w_j^*.$$

n is the training sample size, C_0 is the initial box constraint (see the 'BoxConstraint' name-value pair argument), and w_j^* is the total weight of observation j (see previous bullet).

- If you set 'Standardize', `true` and the 'Cost', 'Prior', or 'Weights' name-value pair argument, then `fitcsvm` standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, `fitcsvm` standardizes predictor j (x_j) using

$$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

$$\mu_j^* = \frac{1}{\sum_k w_k^*} \sum_k w_k^* x_{jk}.$$

x_{jk} is observation k (row) of predictor j (column).

$$(\sigma_j^*)^2 = \frac{v_1}{v_1^2 - v_2} \sum_k w_k^* (x_{jk} - \mu_j^*)^2.$$

$$v_1 = \sum_j w_j^*.$$

$$v_2 = \sum_j (w_j^*)^2.$$

- Assume that p is the proportion of outliers that you expect in the training data, and that you set 'OutlierFraction', p .
 - For one-class learning, the software trains the bias term such that $100p\%$ of the observations in the training data have negative scores.
 - The software implements robust learning for two-class learning. In other words, the software attempts to remove $100p\%$ of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.
 - The PredictorNames property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then PredictorNames is a 1-by-3 cell array of character vectors containing the original names of the predictor variables.
 - The ExpandedPredictorNames property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then ExpandedPredictorNames is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.
 - Similarly, the Beta property stores one beta coefficient for each predictor, including the dummy variables.
 - The SupportVectors property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are m support vectors and three predictors, one of which is a categorical variable with three levels. Then SupportVectors is an n -by-5 matrix.
 - The X property stores the training data as originally input and does not include the dummy variables. When the input is a table, X contains only the columns used as predictors.
- For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.
 - For a variable with k ordered levels, the software creates $k - 1$ dummy variables. The j th dummy variable is -1 for levels up to j , and $+1$ for levels $j + 1$ through k .
 - The names of the dummy variables stored in the ExpandedPredictorNames property indicate the first level with the value $+1$. The software stores $k - 1$ additional predictor names for the dummy variables, including the names of levels 2, 3, ..., k .
- All solvers implement $L1$ soft-margin minimization.
- For one-class learning, the software estimates the Lagrange multipliers, $\alpha_1, \dots, \alpha_n$, such that

$$\sum_{j=1}^n \alpha_j = n\nu.$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train an SVM model by using `fitcsvm`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the 'CategoricalPredictors' name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
 - The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
 - The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function. For generating code that predicts posterior probabilities given new observations, pass a trained SVM model to `fitPosterior` or `fitSVMPosterior`. The `ScoreTransform` property of the returned model contains an anonymous function that represents the score-to-posterior-probability function and is configured for code generation.
 - For fixed-point code generation, the value of the 'ScoreTransform' name-value pair argument cannot be 'invlogit'.

For more information, see "Introduction to Code Generation" on page 31-2.

ClassificationSVMCoderConfigurer

Coder configurer for support vector machine (SVM) for one-class and binary classification

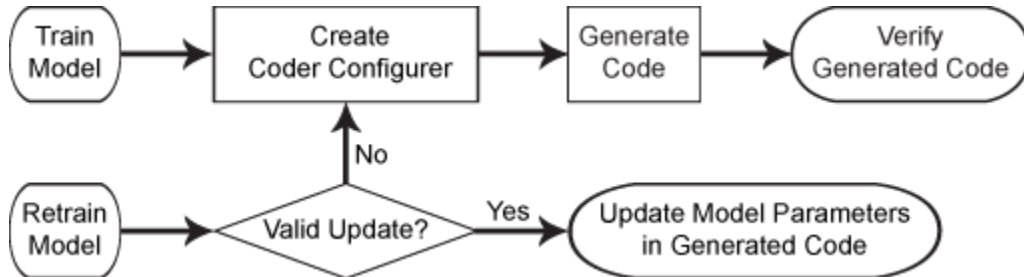

Description

A `ClassificationSVMCoderConfigurer` object is a coder configurer of an SVM classification model (`ClassificationSVM` or `CompactClassificationSVM`).

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes of SVM model parameters by using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the SVM classification model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the SVM model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.

For the code generation usage notes and limitations of an SVM classification model, see the Code Generation sections of `CompactClassificationSVM`, `predict`, and `update`.

Creation

After training an SVM classification model by using `fitsvm`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

`predict` Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

X — Coder attributes of predictor data

LearnerCoderInput object

Coder attributes of predictor data to pass to the generated C/C++ code for the `predict` function of the SVM classification model, specified as a `LearnerCoderInput` on page 32-506 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- `SizeVector` — The default value is the array size of the input `X`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- `Tunability` — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, to generate C/C++ code that accepts predictor data with 100 observations of three predictor variables, specify these coder attributes of `X` for the coder configurer `configurer`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

`[0 0]` indicates that the first and second dimensions of `X` (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify these coder attributes of `X`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

`[1 0]` indicates that the first dimension of `X` (number of observations) has a variable size and the second dimension of `X` (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

NumOutputs — Number of outputs in predict

1 (default) | 2

Number of output arguments to return from the generated C/C++ code for the `predict` function of the SVM classification model, specified as 1 or 2.

The output arguments of `predict` are `label` (predicted class labels) and `score` (scores or posterior probabilities) in the order of listed. `predict` in the generated C/C++ code returns the first `n` outputs of the `predict` function, where `n` is the `NumOutputs` value.

After creating the coder configurer `configurer`, you can specify the number of outputs by using dot notation.

```
configurer.NumOutputs = 2;
```

The `NumOutputs` property is equivalent to the `'-nargout'` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of an SVM classification model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `double`

update Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` on page 32-506 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

Alpha — Coder attributes of trained classifier coefficients

`LearnerCoderInput` object

Coder attributes of the trained classifier coefficients (`Alpha` of an SVM classification model), specified as a `LearnerCoderInput` on page 32-506 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[s, 1]`, where `s` is the number of support vectors in `Mdl`.
- `VariableDimensions` — This value is `[0 0]` (default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — If you train a model with a linear kernel function, and the model stores the linear predictor coefficients (`Beta`) without the support vectors and related values, then this value must be `false`. Otherwise, this value must be `true`.

Beta — Coder attributes of linear predictor coefficients

`LearnerCoderInput` object

Coder attributes of the linear predictor coefficients (`Beta` of an SVM classification model), specified as a `LearnerCoderInput` on page 32-506 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- **SizeVector** — This value must be $[p \ 1]$, where p is the number of predictors in `Mdl`.
- **VariableDimensions** — This value must be $[0 \ 0]$, indicating that the array size is fixed as specified in `SizeVector`.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- **Tunability** — If you train a model with a linear kernel function, and the model stores the linear predictor coefficients (Beta) without the support vectors and related values, then this value must be `true`. Otherwise, this value must be `false`.

Bias — Coder attributes of bias term

`LearnerCoderInput` object

Coder attributes of the bias term (Bias of an SVM classification model), specified as a `LearnerCoderInput` on page 32-506 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- **SizeVector** — This value must be $[1 \ 1]$.
- **VariableDimensions** — This value must be $[0 \ 0]$, indicating that the array size is fixed as specified in `SizeVector`.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- **Tunability** — This value must be `true`.

Cost — Coder attributes of misclassification cost

`LearnerCoderInput` object

Coder attributes of the misclassification cost (Cost of an SVM classification model), specified as a `LearnerCoderInput` on page 32-506 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- **SizeVector** — For binary classification, this value must be $[2 \ 2]$. For one-class classification, this value must be $[1 \ 1]$.
- **VariableDimensions** — This value must be $[0 \ 0]$, indicating that the array size is fixed as specified in `SizeVector`.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- **Tunability** — For binary classification, the default value is `true`. For one-class classification, this value must be `false`.

Mu — Coder attributes of predictor means

`LearnerCoderInput` object

Coder attributes of the predictor means (Mu of an SVM classification model), specified as a `LearnerCoderInput` on page 32-506 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- **SizeVector** — If you train MdL using standardized predictor data by specifying 'Standardize', true, this value must be [1, p], where p is the number of predictors in MdL. Otherwise, this value must be [0, 0].
- **VariableDimensions** — This value must be [0 0], indicating that the array size is fixed as specified in SizeVector.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train MdL.
- **Tunability** — If you train MdL using standardized predictor data by specifying 'Standardize', true, the default value is true. Otherwise, this value must be false.

Prior — Coder attributes of prior probabilities

LearnerCoderInput object

Coder attributes of the prior probabilities (Prior of an SVM classification model), specified as a LearnerCoderInput on page 32-506 object.

The default attribute values of the LearnerCoderInput object are based on the input argument MdL of learnerCoderConfigurer:

- **SizeVector** — For binary classification, this value must be [1 2]. For one-class classification, this value must be [1 1].
- **VariableDimensions** — This value must be [0 0], indicating that the array size is fixed as specified in SizeVector.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train MdL.
- **Tunability** — For binary classification, the default value is true. For one-class classification, this value must be false.

Scale — Coder attributes of kernel scale parameter

LearnerCoderInput object

Coder attributes of the kernel scale parameter (KernelParameters.Scale of an SVM classification model), specified as a LearnerCoderInput on page 32-506 object.

The default attribute values of the LearnerCoderInput object are based on the input argument MdL of learnerCoderConfigurer:

- **SizeVector** — This value must be [1 1].
- **VariableDimensions** — This value must be [0 0], indicating that the array size is fixed as specified in SizeVector.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train MdL.
- **Tunability** — The default value is true.

Sigma — Coder attributes of predictor standard deviations

LearnerCoderInput object

Coder attributes of the predictor standard deviations (Sigma of an SVM classification model), specified as a LearnerCoderInput on page 32-506 object.

The default attribute values of the LearnerCoderInput object are based on the input argument MdL of learnerCoderConfigurer:

- **SizeVector** — If you train `Mdl` using standardized predictor data by specifying `'Standardize', true`, this value must be `[1, p]`, where `p` is the number of predictors in `Mdl`. Otherwise, this value must be `[0, 0]`.
- **VariableDimensions** — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- **DataType** — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- **Tunability** — If you train `Mdl` using standardized predictor data by specifying `'Standardize', true`, the default value is `true`. Otherwise, this value must be `false`.

SupportVectorLabels — Coder attributes of support vector class labels

`LearnerCoderInput` object

Coder attributes of the support vector class labels (`SupportVectorLabels` of an SVM classification model), specified as a `LearnerCoderInput` on page 32-506 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- **SizeVector** — The default value is `[s, 1]`, where `s` is the number of support vectors in `Mdl`.
- **VariableDimensions** — This value is `[0 0]`(default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- **DataType** — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- **Tunability** — If you train a model with a linear kernel function, and the model stores the linear predictor coefficients (`Beta`) without the support vectors and related values, then this value must be `false`. Otherwise, this value must be `true`.

SupportVectors — Coder attributes of support vectors

`LearnerCoderInput` object

Coder attributes of the support vectors (`SupportVectors` of an SVM classification model), specified as a `LearnerCoderInput` on page 32-506 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- **SizeVector** — The default value is `[s, p]`, where `s` is the number of support vectors, and `p` is the number of predictors in `Mdl`.
- **VariableDimensions** — This value is `[0 0]`(default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- **DataType** — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.

- **Tunability** — If you train a model with a linear kernel function, and the model stores the linear predictor coefficients (Beta) without the support vectors and related values, then this value must be false. Otherwise, this value must be true.

Other Configurer Options

OutputFileName — File name of generated C/C++ code

'ClassificationSVMModel' (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function `generateCode` of `ClassificationSVMCoderConfigurer` generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer `configurer`, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: `char`

Verbose — Verbosity level

`true` (logical 1) (default) | `false` (logical 0)

Verbosity level, specified as `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
<code>true</code> (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
<code>false</code> (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: `logical`

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

CodeGenerationArguments — codegen arguments

cell array

This property is read-only.

`codegen` arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: cell

PredictInputs — Input argument of predict

cell array of a `coder.PrimitiveType` object

This property is read-only.

Input argument of the entry-point function `predict.m` for code generation, specified as a cell array of a `coder.PrimitiveType` object. The `coder.PrimitiveType` object includes the coder attributes of the predictor data stored in the `X` property.

If you modify the coder attributes of the predictor data, then the software updates the `coder.PrimitiveType` object accordingly.

The `coder.PrimitiveType` object in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: cell

UpdateInputs — List of tunable input arguments of update

cell array of a structure including `coder.PrimitiveType` objects

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure including `coder.PrimitiveType` objects. Each

`coder.PrimitiveType` object includes the coder attributes of a tunable machine learning model parameter.

If you modify the coder attributes of a model parameter by using the coder configurer properties (update Arguments on page 32-495 properties), then the software updates the corresponding `coder.PrimitiveType` object accordingly. If you specify the `Tunability` attribute of a machine learning model parameter as `false`, then the software removes the corresponding `coder.PrimitiveType` object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer configurer.

Data Types: `cell`

Object Functions

<code>generateCode</code>	Generate C/C++ code using coder configurer
<code>generateFiles</code>	Generate MATLAB files for code generation using coder configurer
<code>validatedUpdateInputs</code>	Validate and extract machine learning model parameters to update

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `ionosphere` data set and train a binary SVM classification model.

```
load ionosphere
Mdl = fitcsvm(X,Y);
```

`Mdl` is a `ClassificationSVM` object.

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X)
```

```
configurer =
  ClassificationSVMCoderConfigurer with properties:
```

```
  Update Inputs:
      Alpha: [1x1 LearnerCoderInput]
  SupportVectors: [1x1 LearnerCoderInput]
  SupportVectorLabels: [1x1 LearnerCoderInput]
      Scale: [1x1 LearnerCoderInput]
      Bias: [1x1 LearnerCoderInput]
      Prior: [1x1 LearnerCoderInput]
      Cost: [1x1 LearnerCoderInput]
```

```
  Predict Inputs:
      X: [1x1 LearnerCoderInput]
```

```
Code Generation Parameters:
    NumOutputs: 1
    OutputFileName: 'ClassificationSVMModel'
```

Properties, Methods

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the SVM classification model (`Mdl`) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationSVMModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationSVMModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

```
type predict.m
```

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:17:24
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

```
type update.m
```

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:17:24
initialize('update',varargin{:});
end
```

```
type initialize.m
```

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:17:24
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('ClassificationSVMModel.mat');
end
```

```

switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                               SupportVectors
        %                               SupportVectorLabels
        %                               Scale
        %                               Bias
        %                               Prior
        %                               Cost
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
    end
end
end

```

Update Parameters of SVM Classification Model in Generated Code

Train a SVM model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g'). Train a binary SVM classification model using the first 50 observations.

```
load ionosphere
Mdl = fitcsvm(X(1:50,:),Y(1:50));
```

Mdl is a ClassificationSVM object.

Create Coder Configurer

Create a coder configurer for the ClassificationSVM model by using `learnerCoderConfigurer`. Specify the predictor data X. The `learnerCoderConfigurer` function uses the input X to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50:),'NumOutputs',2);
```

configurer is a ClassificationSVMCoderConfigurer object, which is a coder configurer of a ClassificationSVM object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 34];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 34 predictors, so the value of the `SizeVector` attribute must be 34 and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 34];
```

```
SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constraints.
```

```
configurer.SupportVectors.VariableDimensions = [true false];
```

```
VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints.
VariableDimensions attribute for SupportVectorLabels has been modified to satisfy configuration constraints.
```

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM classification model (Mdl) with default settings.

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'
```

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `ClassificationSVMModel` for the two entry-point functions in the `codegen\mex\ClassificationSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[label,score] = predict(Mdl,X);
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
```

Compare `label` and `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical
      1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`score_mex` might include round-off differences compared with `score`. In this case, compare `score_mex` and `score`, allowing a small tolerance.

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `score` and `score_mex` are equal within the tolerance `1e-8`.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitcsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[label,score] = predict(retrainedMdl,X);
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
isequal(label,label_mex)

ans = logical
     1

find(abs(score-score_mex) > 1e-8)

ans =

     0x1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and the score values are equal within the tolerance.

More About

LearnerCoderInput Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
SizeVector	Array size if the corresponding <code>VariableDimensions</code> value is <code>false</code> . Upper bound of the array size if the corresponding <code>VariableDimensions</code> value is <code>true</code> . To allow an unbounded array, specify the bound as <code>Inf</code> .
VariableDimensions	Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0): <ul style="list-style-type: none"> A value of <code>true</code> (logical 1) means that the corresponding dimension has a variable size. A value of <code>false</code> (logical 0) means that the corresponding dimension has a fixed size.
DataType	Data type of the array
Tunability	Indicator specifying whether or not <code>predict</code> or <code>update</code> includes the argument as an input in the generated code, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0). If you specify other attribute values when <code>Tunability</code> is <code>false</code> , the software sets <code>Tunability</code> to <code>true</code> .

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of the coefficients `Alpha` of the coder configurer `configurer` as follows:

```
configurer.Alpha.SizeVector = [100 1];  
configurer.Alpha.VariableDimensions = [1 0];  
configurer.Alpha.DataType = 'double';
```

If you specify the verbosity level (Verbose) as true (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

Topics

“Introduction to Code Generation” on page 31-2

“Code Generation for Prediction and Update Using Coder Configurer” on page 31-68

Introduced in R2018b

ClassificationTree class

Superclasses: CompactClassificationTree

Binary decision tree for multiclass classification

Description

A `ClassificationTree` object represents a decision tree with binary splits for classification. An object of this class can predict responses for new data using the `predict` method. The object contains the data used for training, so it can also compute resubstitution predictions.

Construction

Create a `ClassificationTree` object by using `fitctree`.

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value pair argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains NaNs, then the corresponding `Xbinned` values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

CategoricalSplit

An n -by-2 cell array, where n is the number of categorical splits in `tree`. Each row in `CategoricalSplits` gives left and right values for a categorical split. For each branch node with categorical split j based on a categorical predictor variable z , the left child is chosen if z is in `CategoricalSplits(j,1)` and the right child is chosen if z is in `CategoricalSplits(j,2)`. The splits are in the same order as nodes of the tree. Find the nodes for these splits by selecting 'categorical' cuts from top to bottom in the `CutType` property.

Children

An n -by-2 array containing the numbers of the child nodes for each node in `tree`, where n is the number of nodes. Leaf nodes have child node 0.

ClassCount

An n -by- k array of class counts for the nodes in `tree`, where n is the number of nodes and k is the number of classes. For any node number i , the class counts `ClassCount(i,:)` are counts of observations (from the data used in fitting the tree) from each class satisfying the conditions for node i .

ClassNames

List of the elements in `Y` with duplicates removed. `ClassNames` can be a categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. `ClassNames` has the same data type as the data in the argument `Y`. (The software treats string arrays as cell arrays of character vectors.)

ClassProbability

An n -by- k array of class probabilities for the nodes in `tree`, where n is the number of nodes and k is the number of classes. For any node number i , the class probabilities `ClassProbability(i,:)` are the estimated probabilities for each class for a point satisfying the conditions for node i .

Cost

Square matrix, where `Cost(i,j)` is the cost of classifying a point into class j if its true class is i (the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response. This property is read-only.

CutCategories

An n -by-2 cell array of the categories used at branches in `tree`, where n is the number of nodes. For each branch node i based on a categorical predictor variable X , the left child is chosen if X is among

the categories listed in `CutCategories{i,1}`, and the right child is chosen if X is among those listed in `CutCategories{i,2}`. Both columns of `CutCategories` are empty for branch nodes based on continuous predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPoint

An n -element vector of the values used as cut points in `tree`, where n is the number of nodes. For each branch node i based on a continuous predictor variable X , the left child is chosen if $X < \text{CutPoint}(i)$ and the right child is chosen if $X \geq \text{CutPoint}(i)$. `CutPoint` is NaN for branch nodes based on categorical predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutType

An n -element cell array indicating the type of cut at each node in `tree`, where n is the number of nodes. For each node i , `CutType{i}` is:

- 'continuous' — If the cut is defined in the form $X < v$ for a variable X and cut point v .
- 'categorical' — If the cut is defined by whether a variable X takes a value in a set of categories.
- '' — If i is a leaf node.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictor

An n -element cell array of the names of the variables used for branching in each node in `tree`, where n is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty character vector.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictorIndex

An n -element array of numeric indices for the variables used for branching in each node in `tree`, where n is the number of nodes. For more information, see `CutPredictor`.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty

when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- 'bayesopt' (default) — Object of class `BayesianOptimization`
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

IsBranchNode

An n -element logical vector that is `true` for each branch node and `false` for each leaf node of `tree`.

ModelParameters

Parameters used in training `tree`. To display all parameter values, enter `tree.ModelParameters`. To access a particular parameter, use dot notation.

NumObservations

Number of observations in the training data, a numeric scalar. `NumObservations` can be less than the number of rows of input data X when there are missing values in X or response Y .

NodeClass

An n -element cell array with the names of the most probable classes in each node of `tree`, where n is the number of nodes in the tree. Every element of this array is a character vector equal to one of the class names in `ClassNames`.

NodeError

An n -element vector of the errors of the nodes in `tree`, where n is the number of nodes. `NodeError(i)` is the misclassification probability for node i .

NodeProbability

An n -element vector of the probabilities of the nodes in `tree`, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

NodeRisk

An n -element vector of the risk of the nodes in the tree, where n is the number of nodes. The risk for each node is the measure of impurity (Gini index or deviance) for this node weighted by the node probability. If the tree is grown by `twoing`, the risk for each node is zero.

NodeSize

An n -element vector of the sizes of the nodes in `tree`, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

NumNodes

The number of nodes in `tree`.

Parent

An n -element vector containing the number of the parent node for each node in `tree`, where n is the number of nodes. The parent of the root node is 0.

PredictorNames

Cell array of character vectors containing the predictor names, in the order which they appear in `X`.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

PruneAlpha

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to M , then `PruneAlpha` has $M + 1$ elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

PruneList

An n -element numeric vector with the pruning levels in each node of `tree`, where n is the number of nodes. The pruning levels range from 0 (no pruning) to M , where M is the distance between the deepest leaf and the root node.

ResponseName

A character vector that specifies the name of the response variable (`Y`).

RowsUsed

An n -element logical vector indicating which rows of the original predictor data (`X`) were used in fitting. If the software uses all rows of `X`, then `RowsUsed` is an empty array (`[]`).

ScoreTransform

Function handle for transforming predicted classification scores, or character vector representing a built-in transformation function.

`none` means no transformation, or `@(x)x`.

To change the score transformation function to, for example, *function*, use dot notation.

- For available functions (see `fitctree`), enter

```
Mdl.ScoreTransform = 'function';
```
- You can set a function handle for an available function, or a function you define yourself by entering

```
tree.ScoreTransform = @function;
```

SurrogateCutCategories

An n -element cell array of the categories used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutCategories{k}` is a cell array. The length of

`SurrogateCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutCategories{k}` is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutCategories` contains an empty cell.

SurrogateCutFlip

An n -element cell array of the numeric cut assignments used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutFlip{k}` is a numeric vector. The length of `SurrogateCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or $+1$. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and the cut assignment for this surrogate split is $+1$, or if $Z \geq C$ and the cut assignment for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and the cut assignment for this surrogate split is $+1$, or if $Z < C$ and the cut assignment for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutFlip` contains an empty array.

SurrogateCutPoint

An n -element cell array of the numeric values used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutPoint{k}` is a numeric vector. The length of `SurrogateCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutPoint{k}` is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z < C$ and `SurrogateCutFlip` for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables returned by `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPoint` contains an empty cell.

SurrogateCutType

An n -element cell array indicating types of surrogate splits at each node in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutType{k}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutType` contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form $Z < V$ for a variable Z and cut point V or 'categorical' if the cut is defined by whether Z takes a value in a set of categories.

SurrogateCutPredictor

An n -element cell array of the names of the variables used for surrogate splits in each node in `tree`, where n is the number of nodes in `tree`. Every element of `SurrogateCutPredictor` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPredictor` contains an empty cell.

SurrogatePredictorAssociation

An n -element cell array of the predictive measures of association for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogatePredictorAssociation{k}` is a numeric vector. The length of `SurrogatePredictorAssociation{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogatePredictorAssociation{k}` gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogatePredictorAssociation` contains an empty cell.

W

The scaled weights, a vector with length n , the number of rows in `X`.

X

A matrix or table of predictor values. Each column of `X` represents one variable, and each row represents one observation.

Y

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. Each row of `Y` represents the classification of the corresponding row of `X`.

Methods

<code>compact</code>	Compact tree
<code>crossval</code>	Cross-validated decision tree
<code>cvloss</code>	Classification error by cross validation
<code>prune</code>	Produce sequence of classification subtrees by pruning
<code>resubEdge</code>	Classification edge by resubstitution
<code>resubLoss</code>	Classification error by resubstitution
<code>resubMargin</code>	Classification margins by resubstitution
<code>resubPredict</code>	Predict resubstitution labels of classification tree

Inherited Methods

edge	Classification edge
loss	Classification error
margin	Classification margins
surrogateAssociation	Mean predictive measure of association for surrogate splits in classification tree
predict	Predict labels using classification tree
predictorImportance	Estimates of predictor importance for classification tree
view	View classification tree

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Grow a Classification Tree

Grow a classification tree using the `ionosphere` data set.

```
load ionosphere
tc = fitctree(X,Y)

tc =
  ClassificationTree
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      NumObservations: 351
```

Properties, Methods

Control Tree Depth

You can control the depth of the trees using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters. `fitctree` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

Load the `ionosphere` data set.

```
load ionosphere
```

The default values of the tree depth controllers for growing classification trees are:

- $n - 1$ for `MaxNumSplits`. n is the training sample size.
- 1 for `MinLeafSize`.
- 10 for `MinParentSize`.

These default values tend to grow deep trees for large training sample sizes.

Train a classification tree using the default values for tree depth control. Cross-validate the model by using 10-fold cross-validation.

```
rng(1); % For reproducibility
MdlDefault = fitctree(X,Y,'CrossVal','on');
```

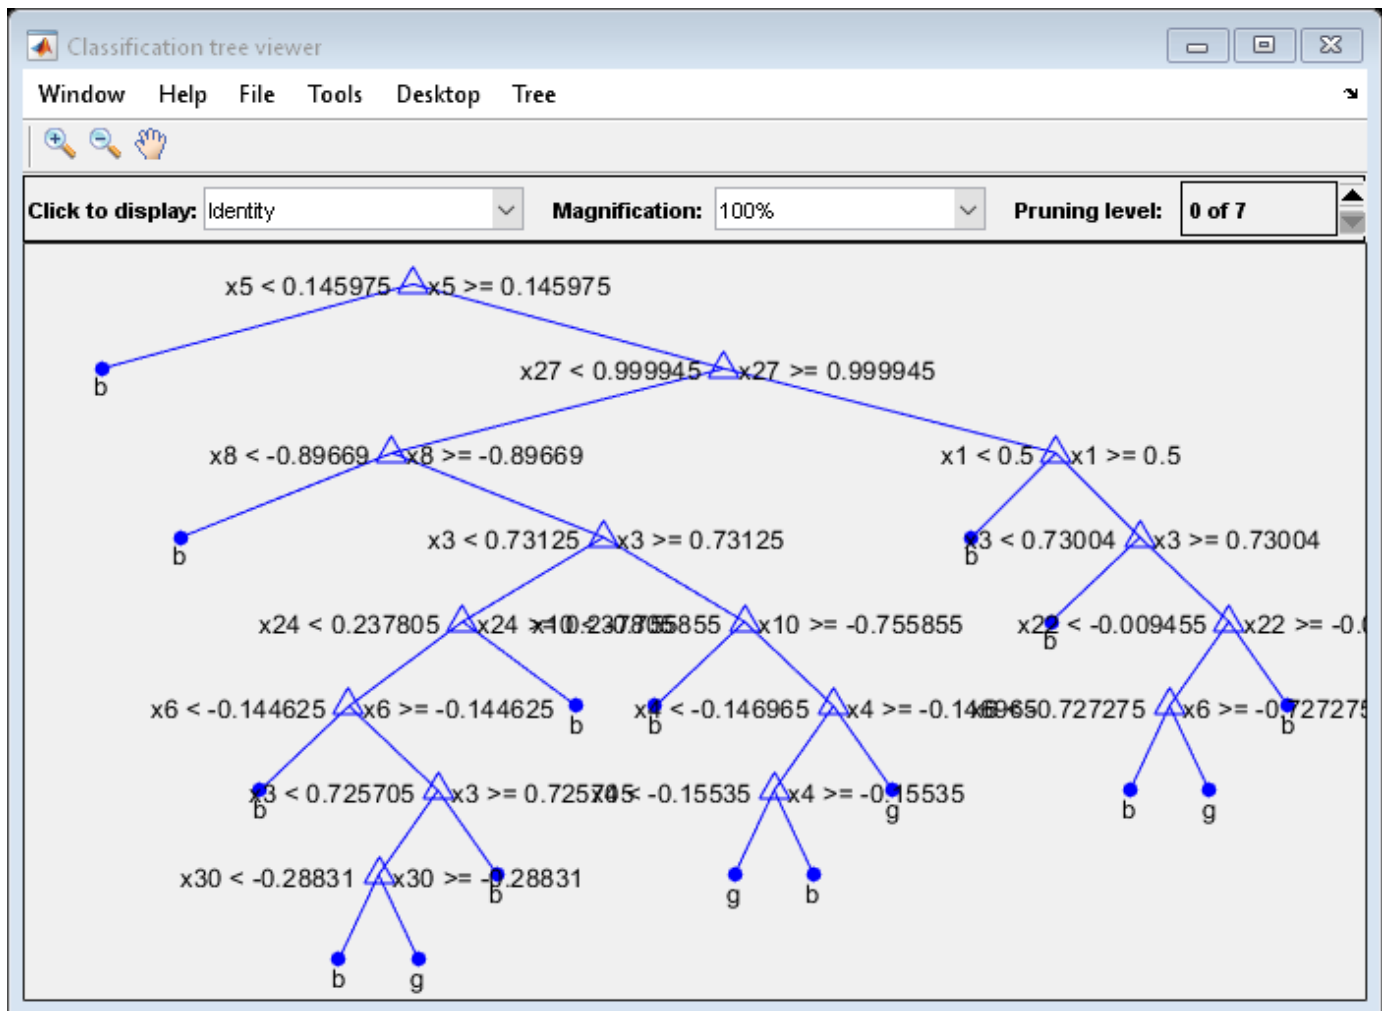

Draw a histogram of the number of imposed splits on the trees. Also, view one of the trees.

```
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);
```

```
figure;
histogram(mdlDefaultNumSplits)
```

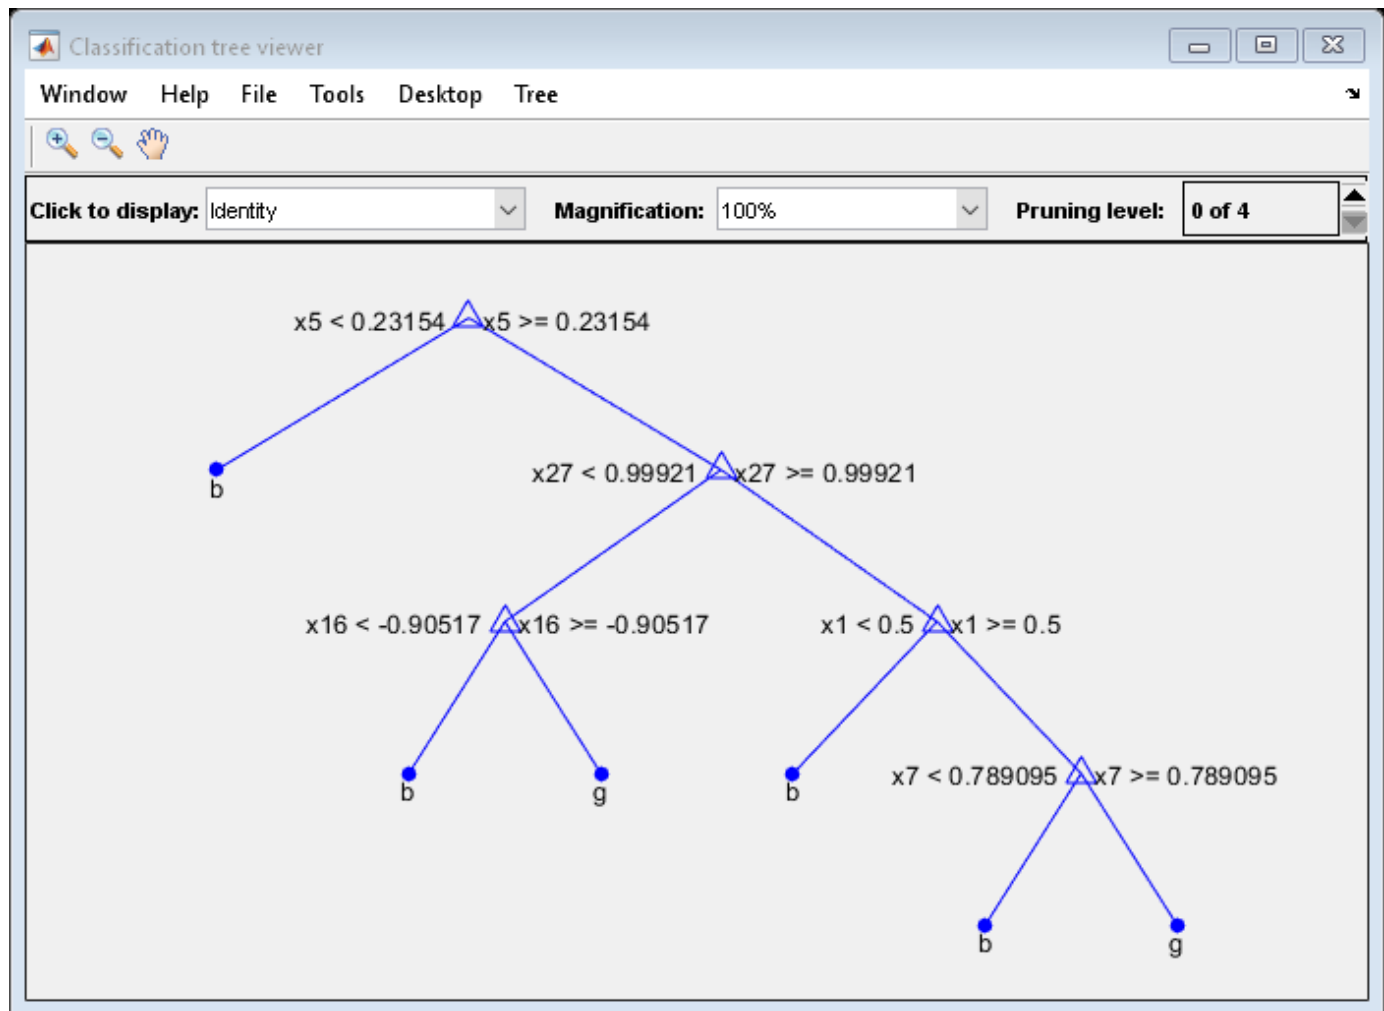

```
view(MdlDefault.Trained{1}, 'Mode', 'graph')
```

The average number of splits is around 15.

Suppose that you want a classification tree that is not as complex (deep) as the ones trained using the default number of splits. Train another classification tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default classification tree. Cross-validate the model by using 10-fold cross-validation.

```
Mdl7 = fitctree(X,Y,'MaxNumSplits',7,'CrossVal','on');
view(Mdl7.Trained{1},'Mode','graph')
```

Compare the cross-validation classification errors of the models.

```
classErrorDefault = kfoldLoss(MdlDefault)
```

```
classErrorDefault = 0.1140
```

```
classError7 = kfoldLoss(Mdl7)
```

```
classError7 = 0.1254
```

Mdl7 is much less complex and performs only slightly worse than MdlDefault.

More About

Impurity and Node Error

ClassificationTree splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the SplitCriterion name-value pair argument:

- Gini's Diversity Index (gdi) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance (' deviance ') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$- \sum_i p(i) \log_2 p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule (' twoing ') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left(\sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and therefore similar to the parent node. The split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is

$$1 - \max_j p(j).$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train a classification tree using `fitctree`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the 'CategoricalPredictors' name-value pair

argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.

- The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
- The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function. For fixed-point code generation, the 'ScoreTransform' value cannot be 'invlogit'.
- You cannot use surrogate splits, that is, the value of the 'Surrogate' name-value pair argument must be 'off'.

For more information, see “Introduction to Code Generation” on page 31-2.

ClassificationTreeCoderConfigurer

Coder configurer of binary decision tree model for multiclass classification

Description

A `ClassificationTreeCoderConfigurer` object is a coder configurer of a binary decision tree model for multiclass classification (`ClassificationTree` or `CompactClassificationTree`).

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes of the tree model parameters by using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the classification tree model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the tree model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.

For the code generation usage notes and limitations of a classification tree model, see the Code Generation sections of `CompactClassificationTree`, `predict`, and `update`.

Creation

After training a classification tree model by using `fitctree`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of the `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

`predict` Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

X — Coder attributes of predictor data

LearnerCoderInput object

Coder attributes of the predictor data to pass to the generated C/C++ code for the `predict` function of the classification tree model, specified as a `LearnerCoderInput` on page 32-534 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- `SizeVector` — The default value is the array size of the input `X`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- `Tunability` — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, to generate C/C++ code that accepts predictor data with 100 observations of three predictor variables, specify these coder attributes of `X` for the coder configurer `configurer`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

`[0 0]` indicates that the first and second dimensions of `X` (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify these coder attributes of `X`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

`[1 0]` indicates that the first dimension of `X` (number of observations) has a variable size and the second dimension of `X` (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

NumOutputs — Number of outputs in predict

1 (default) | 2 | 3 | 4

Number of output arguments to return from the generated C/C++ code for the `predict` function of the classification tree model, specified as 1, 2, 3, or 4.

The output arguments of `predict` are `label` (predicted class labels), `score` (posterior probabilities), `node` (node numbers for predicted classes), and `cnum` (class numbers of predicted labels), in that order. `predict` in the generated C/C++ code returns the first `n` outputs of the `predict` function, where `n` is the `NumOutputs` value.

After creating the coder configurer `configurer`, you can specify the number of outputs by using dot notation.

```
configurer.NumOutputs = 2;
```

The `NumOutputs` property is equivalent to the `'-nargout'` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of a classification tree model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `double`

update Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` on page 32-534 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

Children — Coder attributes of child nodes for each node

`LearnerCoderInput` object

Coder attributes of the child nodes for each node in the tree (`Children` of a classification tree model), specified as a `LearnerCoderInput` on page 32-534 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[nd 2]`, where `nd` is the number of nodes in `Mdl`.
- `VariableDimensions` — This value is `[0 0]` (default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

If you modify the first dimension of `SizeVector` to be `newnd`, then the software modifies the first dimension of the `SizeVector` attribute to be `newnd` for the properties `ClassProbability`, `CutPoint`, and `CutPredictorIndex`. Similarly, if you modify the first dimension of `VariableDimensions` to be `1`, then the software modifies the first dimension of the `VariableDimensions` attribute to be `1` for these properties.

ClassProbability — Coder attributes of class probabilities for each node

`LearnerCoderInput` object

Coder attributes of the class probabilities for each node in the tree (`ClassProbability` of a classification tree model), specified as a `LearnerCoderInput` on page 32-534 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is $[nd \ c]$, where `nd` is the number of nodes in `Mdl` and `c` is the number of classes.
- `VariableDimensions` — This value is $[0 \ 0]$ (default) or $[1 \ 0]$.
 - $[0 \ 0]$ indicates that the array size is fixed as specified in `SizeVector`.
 - $[1 \ 0]$ indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

If you modify the first dimension of `SizeVector` to be `newnd`, then the software modifies the first dimension of the `SizeVector` attribute to be `newnd` for the properties `Children`, `CutPoint`, and `CutPredictorIndex`. Similarly, if you modify the first dimension of `VariableDimensions` to be `1`, then the software modifies the first dimension of the `VariableDimensions` attribute to be `1` for these properties.

Cost — Coder attributes of misclassification cost

`LearnerCoderInput` object

Coder attributes of the misclassification cost (`Cost` of a classification tree model), specified as a `LearnerCoderInput` on page 32-534 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be $[c \ c]$, where `c` is the number of classes.
- `VariableDimensions` — This value must be $[0 \ 0]$, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — The default value is `true`.

CutPoint — Coder attributes of cut point for each node

`LearnerCoderInput` object

Coder attributes of the cut point for each node in the tree (`CutPoint` of a classification tree model), specified as a `LearnerCoderInput` on page 32-534 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is $[nd \ 1]$, where `nd` is the number of nodes in `Mdl`.
- `VariableDimensions` — This value is $[0 \ 0]$ (default) or $[1 \ 0]$.

- `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
- `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

If you modify the first dimension of `SizeVector` to be `newnd`, then the software modifies the first dimension of the `SizeVector` attribute to be `newnd` for the properties `Children`, `ClassProbability`, and `CutPredictorIndex`. Similarly, if you modify the first dimension of `VariableDimensions` to be 1, then the software modifies the first dimension of the `VariableDimensions` attribute to be 1 for these properties.

CutPredictorIndex — Coder attributes of cut predictor index for each node

`LearnerCoderInput` object

Coder attributes of the cut predictor index for each node in the tree (`CutPredictorIndex` of a classification tree model), specified as a `LearnerCoderInput` on page 32-534 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[nd 1]`, where `nd` is the number of nodes in `Mdl`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

If you modify the first dimension of `SizeVector` to be `newnd`, then the software modifies the first dimension of the `SizeVector` attribute to be `newnd` for the properties `Children`, `ClassProbability`, and `CutPoint`. Similarly, if you modify the first dimension of `VariableDimensions` to be 1, then the software modifies the first dimension of the `VariableDimensions` attribute to be 1 for these properties.

Prior — Coder attributes of prior probabilities

`LearnerCoderInput` object

Coder attributes of the prior probabilities (`Prior` of a classification tree model), specified as a `LearnerCoderInput` on page 32-534 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[1 c]`, where `c` is the number of classes.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.

- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train MdL.
- **Tunability** — The default value is true.

Other Configurer Options

OutputFileName — File name of generated C/C++ code

'ClassificationTreeModel' (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function `generateCode` of `ClassificationTreeCoderConfigurer` generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer `configurer`, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: char

Verbose — Verbosity level

true (logical 1) (default) | false (logical 0)

Verbosity level, specified as true (logical 1) or false (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
true (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
false (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: logical

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

CodeGenerationArguments — codegen arguments

cell array

This property is read-only.

`codegen` arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: cell

PredictInputs — Input argument of predict

cell array of a `coder.PrimitiveType` object

This property is read-only.

Input argument of the entry-point function `predict.m` for code generation, specified as a cell array of a `coder.PrimitiveType` object. The `coder.PrimitiveType` object includes the coder attributes of the predictor data stored in the `X` property.

If you modify the coder attributes of the predictor data, then the software updates the `coder.PrimitiveType` object accordingly.

The `coder.PrimitiveType` object in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: cell

UpdateInputs — List of tunable input arguments of update

cell array of a structure including `coder.PrimitiveType` objects

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure including `coder.PrimitiveType` objects. Each

`coder.PrimitiveType` object includes the coder attributes of a tunable machine learning model parameter.

If you modify the coder attributes of a model parameter by using the coder configurer properties (update Arguments on page 32-523 properties), then the software updates the corresponding `coder.PrimitiveType` object accordingly. If you specify the `Tunability` attribute of a machine learning model parameter as `false`, then the software removes the corresponding `coder.PrimitiveType` object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

Data Types: `cell`

Object Functions

<code>generateCode</code>	Generate C/C++ code using coder configurer
<code>generateFiles</code>	Generate MATLAB files for code generation using coder configurer
<code>validatedUpdateInputs</code>	Validate and extract machine learning model parameters to update

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `fisheriris` data set, which contains flower data, and train a decision tree model.

```
load fisheriris
X = meas;
Y = species;
Mdl = fitctree(X,Y);
```

`Mdl` is a `ClassificationTree` object.

Create a coder configurer for the `ClassificationTree` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X)

configurer =
  ClassificationTreeCoderConfigurer with properties:

  Update Inputs:
    Children: [1x1 LearnerCoderInput]
    ClassProbability: [1x1 LearnerCoderInput]
    CutPoint: [1x1 LearnerCoderInput]
    CutPredictorIndex: [1x1 LearnerCoderInput]
    Prior: [1x1 LearnerCoderInput]
    Cost: [1x1 LearnerCoderInput]

  Predict Inputs:
    X: [1x1 LearnerCoderInput]
```

```
Code Generation Parameters:
    NumOutputs: 1
    OutputFileName: 'ClassificationTreeModel'
```

Properties, Methods

`configurer` is a `ClassificationTreeCoderConfigurer` object, which is a coder configurer of a `ClassificationTree` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the classification tree model (`Mdl`) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationTreeModel.mat'

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationTreeModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationTreeModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

```
type predict.m
```

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:31:30
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

```
type update.m
```

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:31:30
initialize('update',varargin{:});
end
```

```
type initialize.m
```

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:31:30
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('ClassificationTreeModel.mat');
```

```

end
switch(command)
case 'update'
    % Update struct fields: Children
    %                               ClassProbability
    %                               CutPoint
    %                               CutPredictorIndex
    %                               Prior
    %                               Cost
    model = update(model,varargin{:});
case 'predict'
    % Predict Inputs: X
    X = varargin{1};
    if nargin == 2
        [varargout{1:nargout}] = predict(model,X);
    else
        PVPairs = cell(1,nargin-2);
        for i = 1:nargin-2
            PVPairs{1,i} = varargin{i+1};
        end
        [varargout{1:nargout}] = predict(model,X,PVPairs{:});
    end
end
end
end

```

Update Parameters of Classification Tree Model in Generated Code

Train a decision tree for multiclass classification using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the entire data set, and update parameters in the generated code without regenerating the code.

Train Model

Load the `fisheriris` data set, which contains flower data. This data set has four predictors: the sepal length, sepal width, petal length, and petal width of the flowers. The response variable contains the flower species names: `setosa`, `versicolor`, and `virginica`. Train a classification tree model using half of the observations.

```

load fisheriris
X = meas;
Y = species;

rng('default') % For reproducibility
n = length(Y);
c = cvpartition(Y,'HoldOut',0.5);
idxTrain = training(c,1);
XTrain = X(idxTrain,:);
YTrain = Y(idxTrain);

Mdl = fitctree(XTrain,YTrain);

```

`Mdl` is a `ClassificationTree` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationTree` model by using `learnerCoderConfigurer`. Specify the predictor data. The `learnerCoderConfigurer` function uses the input `XTrain` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 4 so that the generated code returns predicted labels, scores, node numbers, and class numbers.

```
configurer = learnerCoderConfigurer(Mdl,XTrain,'NumOutputs',4);
```

`configurer` is a `ClassificationTreeCoderConfigurer` object, which is a coder configurer of a `ClassificationTree` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the classification tree model parameters so that you can update the parameters in the generated code after retraining the model.

First, specify the coder attributes of the `X` property of `configurer` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 4];
configurer.X.VariableDimensions
```

```
ans = 1x2 logical array
```

```
    1    0
```

The size of the first dimension is the number of observations. Setting the value of the `SizeVector` attribute to `Inf` causes the software to change the value of the `VariableDimensions` attribute to `1`. In other words, the upper bound of the size is `Inf` and the size is variable, meaning that the predictor data can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. Because the predictor data contains 4 predictors, the value of the `SizeVector` attribute must be 4 and the value of the `VariableDimensions` attribute must be `0`.

If you retrain the tree model using new data or different settings, the number of nodes in the tree can vary. Therefore, specify the first dimension of the `SizeVector` attribute of one of these properties so that you can update the number of nodes in the generated code: `Children`, `ClassProbability`, `CutPoint`, or `CutPredictorIndex`. The software then modifies the other properties automatically.

For example, set the first value of the `SizeVector` attribute of the `CutPoint` property to `Inf`. The software modifies the `SizeVector` and `VariableDimensions` attributes of `Children`, `ClassProbability`, and `CutPredictorIndex` to match the new upper bound on the number of nodes in the tree. Additionally, the first value of the `VariableDimensions` attribute of `CutPoint` changes to `1`.

```
configurer.CutPoint.SizeVector = [Inf 1];
```

```
SizeVector attribute for Children has been modified to satisfy configuration constraints.
SizeVector attribute for CutPredictorIndex has been modified to satisfy configuration constraints.
```

```
VariableDimensions attribute for Children has been modified to satisfy configuration constraints
VariableDimensions attribute for CutPredictorIndex has been modified to satisfy configuration constraints
SizeVector attribute for ClassProbability has been modified to satisfy configuration constraints
VariableDimensions attribute for ClassProbability has been modified to satisfy configuration constraints
```

```
configurer.CutPoint.VariableDimensions
```

```
ans = 1x2 logical array
```

```
    1    0
```

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the classification tree model (`Mdl`).

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationTreeModel.mat'
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationTreeModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationTreeModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same output arguments. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[label,score,node,cnum] = predict(Mdl,XTrain);
[label_mex,score_mex,node_mex,cnum_mex] = ClassificationTreeModel('predict',XTrain);
```

Compare `label` and `label_mex` by using `isequal`. Similarly, compare `node` to `node_mex` and `cnum` to `cnum_mex`.

```
isequal(label,label_mex)
```

```
ans = logical
     1
```

```
isequal(node,node_mex)
```

```
ans = logical
     1
```

```
isequal(cnum,cnum_mex)
```

```
ans = logical
      1
```

`isequal` returns logical 1 (true) if all the input arguments are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels, node numbers, and class numbers.

Compare `score` and `score_mex`.

```
max(abs(score-score_mex),[],'all')
```

```
ans = 0
```

In general, `score_mex` might include round-off differences compared to `score`. In this case, the comparison confirms that `score` and `score_mex` are equal.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitctree(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationTreeModel('update',params)
```

Verify Generated Code

Compare the output arguments from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[label,score,node,cnum] = predict(retrainedMdl,X);
[label_mex,score_mex,node_mex,cnum_mex] = ClassificationTreeModel('predict',X);
```

```
isequal(label,label_mex)
```

```
ans = logical
      1
```

```
isequal(node,node_mex)
```

```
ans = logical
      1
```

```
isequal(cnum,cnum_mex)
```

```
ans = logical
      1
```

```
max(abs(score-score_mex),[],'all')
```

```
ans = 0
```

The comparison confirms that the labels, node numbers, class numbers, and scores are equal.

More About

LearnerCoderInput Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
<code>SizeVector</code>	<p>Array size if the corresponding <code>VariableDimensions</code> value is <code>false</code>.</p> <p>Upper bound of the array size if the corresponding <code>VariableDimensions</code> value is <code>true</code>. To allow an unbounded array, specify the bound as <code>Inf</code>.</p>
<code>VariableDimensions</code>	<p>Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0):</p> <ul style="list-style-type: none"> A value of <code>true</code> (logical 1) means that the corresponding dimension has a variable size. A value of <code>false</code> (logical 0) means that the corresponding dimension has a fixed size.
<code>DataType</code>	Data type of the array
<code>Tunability</code>	<p>Indicator specifying whether or not <code>predict</code> or <code>update</code> includes the argument as an input in the generated code, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0).</p> <p>If you specify other attribute values when <code>Tunability</code> is <code>false</code>, the software sets <code>Tunability</code> to <code>true</code>.</p>

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of the `CutPoint` property of the coder configurer configurer:

```
configurer.CutPoint.SizeVector = [20 1];
configurer.CutPoint.VariableDimensions = [1 0];
```

If you specify the verbosity level (`Verbose`) as `true` (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

Introduced in R2019b

classify

Discriminant analysis

Syntax

```
class = classify(sample,training,group)
class = classify(sample,training,group,'type')
class = classify(sample,training,group,'type',prior)
[class,err] = classify(...)
[class,err,POSTERIOR] = classify(...)
[class,err,POSTERIOR,logp] = classify(...)
[class,err,POSTERIOR,logp,coeff] = classify(...)
```

Description

`class = classify(sample,training,group)` classifies each row of the data in `sample` into one of the groups in `training`. `sample` and `training` must be matrices with the same number of columns. `group` is a grouping variable for `training`. Its unique values define groups; each element defines the group to which the corresponding row of `training` belongs. `group` can be a categorical variable, a numeric vector, a character array, a string array, or a cell array of character vectors. `training` and `group` must have the same number of rows. `classify` treats <undefined> values, NaNs, empty character vectors, empty strings, and <missing> string values in `group` as missing data values, and ignores the corresponding rows of `training`. The output `class` indicates the group to which each row of `sample` has been assigned, and is of the same type as `group`.

`class = classify(sample,training,group,'type')` allows you to specify the type of discriminant function. Specify `type` inside single quotes. `type` is one of:

- `linear` — Fits a multivariate normal density to each group, with a pooled estimate of covariance. This is the default.
- `diaglinear` — Similar to `linear`, but with a diagonal covariance matrix estimate (naive Bayes classifiers).
- `quadratic` — Fits multivariate normal densities with covariance estimates stratified by group.
- `diagquadratic` — Similar to `quadratic`, but with a diagonal covariance matrix estimate (naive Bayes classifiers).
- `mahalanobis` — Uses Mahalanobis distances with stratified covariance estimates.

`class = classify(sample,training,group,'type',prior)` allows you to specify prior probabilities for the groups. `prior` is one of:

- A numeric vector the same length as the number of unique values in `group` (or the number of levels defined for `group`, if `group` is categorical). If `group` is numeric or categorical, the order of `prior` must correspond to the ordered values in `group`. Otherwise, the order of `prior` must correspond to the order of the first occurrence of the values in `group`.
- A 1-by-1 structure with fields:
 - `prob` — A numeric vector.

- `group` — Of the same type as `group`, containing unique values indicating the groups to which the elements of `prob` correspond.

As a structure, `prior` can contain groups that do not appear in `group`. This can be useful if `training` is a subset a larger training set. `classify` ignores any groups that appear in the structure but not in the `group` array.

- The character vector or string scalar `'empirical'`, indicating that group prior probabilities should be estimated from the group relative frequencies in `training`.

`prior` defaults to a numeric vector of equal probabilities, i.e., a uniform distribution. `prior` is not used for discrimination by Mahalanobis distance, except for error rate calculation.

`[class,err] = classify(...)` also returns an estimate `err` of the misclassification error rate based on the `training` data. `classify` returns the apparent error rate, i.e., the percentage of observations in `training` that are misclassified, weighted by the prior probabilities for the groups.

`[class,err,POSTERIOR] = classify(...)` also returns a matrix `POSTERIOR` of estimates of the posterior probabilities that the *j*th training group was the source of the *i*th sample observation, i.e., $Pr(\text{group } j | \text{obs } i)$. `POSTERIOR` is not computed for Mahalanobis discrimination.

`[class,err,POSTERIOR,logp] = classify(...)` also returns a vector `logp` containing estimates of the logarithms of the unconditional predictive probability density of the sample observations, $p(\text{obs } i) = \sum p(\text{obs } i | \text{group } j) Pr(\text{group } j)$ over all groups. `logp` is not computed for Mahalanobis discrimination.

`[class,err,POSTERIOR,logp,coeff] = classify(...)` also returns a structure array `coeff` containing coefficients of the boundary curves between pairs of groups. Each element `coeff(I,J)` contains information for comparing group I to group J in the following fields:

- `type` — Type of discriminant function, from the `type` input.
- `name1` — Name of the first group.
- `name2` — Name of the second group.
- `const` — Constant term of the boundary equation (K)
- `linear` — Linear coefficients of the boundary equation (L)
- `quadratic` — Quadratic coefficient matrix of the boundary equation (Q)

For the `linear` and `diaglinear` types, the `quadratic` field is absent, and a row `x` from the sample array is classified into group I rather than group J if $\theta < K+x*L$. For the other types, `x` is classified into group I if $\theta < K+x*L+x*Q*x'$.

Examples

Classify Using Discriminant Analysis

For training data, use Fisher's sepal measurements for iris versicolor and virginica:

```
load fisheriris
SL = meas(51:end,1);
SW = meas(51:end,2);
group = species(51:end);
h1 = gscatter(SL,SW,group, 'rb', 'v^', [], 'off');
```

```
set(h1,'LineWidth',2)
legend('Fisher versicolor','Fisher virginica',...
      'Location','NW')
```

Classify a grid of measurements on the same scale:

```
[X,Y] = meshgrid(linspace(4.5,8),linspace(2,4));
X = X(:); Y = Y(:);
[C,err,P,logp,coeff] = classify([X Y],[SL SW],...
                               group,'Quadratic');
```

Visualize the classification:

```
hold on;
gscatter(X,Y,C,'rb','.',1,'off');
K = coeff(1,2).const;
L = coeff(1,2).linear;
Q = coeff(1,2).quadratic;
% Function to compute K + L*v + v'*Q*v for multiple vectors
% v=[x;y]. Accepts x and y as scalars or column vectors.
f = @(x,y) K + L(1)*x + L(2)*y + Q(1,1)*x.*x + (Q(1,2)+Q(2,1))*x.*y + Q(2,2)*y.*y;
h2 = fimplicit(f,[4.5 8 2 4]);
set(h2,'Color','m','LineWidth',2,'DisplayName','Decision Boundary')
axis([4.5 8 2 4])
xlabel('Sepal Length')
ylabel('Sepal Width')
title('\bf Classification with Fisher Training Data')
```

Alternative Functionality

The `fitcdiscr` function also performs discriminant analysis. You can train a classifier by using the `fitcdiscr` function and predict labels of new data by using the `predict` function. The `fitcdiscr` supports cross-validation and hyperparameter optimization and does not require you to fit the classifier every time you make a new prediction or you change prior probabilities.

Introduced before R2006a

cluster

Construct agglomerative clusters from linkages

Syntax

```
T = cluster(Z,'Cutoff',C)
T = cluster(Z,'Cutoff',C,'Depth',D)
T = cluster(Z,'Cutoff',C,'Criterion',criterion)

T = cluster(Z,'MaxClust',N)
```

Description

`T = cluster(Z,'Cutoff',C)` defines clusters from an agglomerative hierarchical cluster tree `Z`. The input `Z` is the output of the `linkage` function for an input data matrix `X`. `cluster` cuts `Z` into clusters, using `C` as a threshold for the inconsistency coefficients (or inconsistent values) of nodes in the tree. The output `T` contains cluster assignments of each observation (row of `X`).

`T = cluster(Z,'Cutoff',C,'Depth',D)` evaluates inconsistent values by looking to a depth `D` below each node.

`T = cluster(Z,'Cutoff',C,'Criterion',criterion)` uses either `'inconsistent'` (default) or `'distance'` as the criterion for defining clusters. `criterion` must be less than `C` for `cluster` to define clusters.

`T = cluster(Z,'MaxClust',N)` defines a maximum of `N` clusters using `'distance'` as the criterion for defining clusters.

Examples

Define Clusters by Specifying Depth

Perform agglomerative clustering on randomly generated data by evaluating inconsistent values to a depth of four below each node.

Randomly generate the sample data.

```
rng('default'); % For reproducibility
X = [(randn(20,2)*0.75)+1;
      (randn(20,2)*0.25)-1];
```

Create a scatter plot of the data.

```
scatter(X(:,1),X(:,2));
title('Randomly Generated Data');
```

Create a hierarchical cluster tree using the `ward` linkage method.

```
Z = linkage(X, 'ward');
```

Create a dendrogram plot of the data.

```
dendrogram(Z)
```

The scatter plot and the dendrogram plot seem to show two clusters in the data.

Cluster the data using a threshold of 3 for the inconsistency coefficient and looking to a depth of 4 below each node. Plot the resulting clusters.

```
T = cluster(Z, 'cutoff', 3, 'Depth', 4);
gscatter(X(:,1), X(:,2), T)
```

`cluster` identifies two clusters in the data.

Cluster Data Using Distance Criterion

Perform agglomerative clustering on the `fisheriris` data set using 'distance' as the criterion for defining clusters. Visualize the cluster assignments of the data.

Load the `fisheriris` data set.

```
load fisheriris
```

Visualize a 2-D scatter plot of the data using `species` as the grouping variable. Specify marker colors and marker symbols for the three different species.

```
gscatter(meas(:,1),meas(:,2),species,'rgb','do*')
title("Actual Clusters of Fisher's Iris Data")
```

`cluster` identifies three classes for the specified values of `cutoff` and `Criterion`.

Visualize a 2-D scatter plot of the clustering results using `T` as the grouping variable. Specify marker colors and marker symbols for the three different classes.

```
gscatter(meas(:,1),meas(:,2),T,'rgb','do*')
title("Cluster Assignments of Fisher's Iris Data")
```

Clustering correctly identifies the setosa class (class 2) as belonging to a distinct cluster, but poorly distinguishes between the versicolor and virginica classes (classes 1 and 3, respectively). Note that the scatter plot labels the classes using the numbers contained in `T`.

Compare Cluster Assignments to Classes

Find a maximum of three clusters in the `fisheriris` data set and compare cluster assignments of the flowers to their known classification.

Load the sample data.

```
load fisheriris
```

Create a hierarchical cluster tree using the 'average' method and the 'chebychev' metric.

```
Z = linkage(meas,'average','chebychev');
```

Find a maximum of three clusters in the data.

```
T = cluster(Z, 'maxclust', 3);
```

Create a dendrogram plot of Z. To see the three clusters, use 'ColorThreshold' with a cutoff halfway between the third-from-last and second-from-last linkages.

```
cutoff = median([Z(end-2,3) Z(end-1,3)]);
dendrogram(Z, 'ColorThreshold', cutoff)
```

Display the last two rows of Z to see how the three clusters are combined into one. `linkage` combines the 293rd (blue) cluster with the 297th (red) cluster to form the 298th cluster with a linkage of 1.7583. `linkage` then combines the 296th (green) cluster with the 298th cluster.

```
lastTwo = Z(end-1:end,:)
```

```
lastTwo = 2×3
```

```
293.0000 297.0000 1.7583
296.0000 298.0000 3.4445
```

See how the cluster assignments correspond to the three species. For example, one of the clusters contains 50 flowers of the second species and 40 flowers of the third species.

```
crosstab(T, species)
```

```
ans = 3×3  
  
    0    0   10  
    0   50   40  
   50    0    0
```

Cluster Data and Plot Result

Randomly generate sample data with 20,000 observations.

```
rng('default') % For reproducibility  
X = rand(20000,3);
```

Create a hierarchical cluster tree using the ward linkage method. In this case, the 'SaveMemory' option of the `clusterdata` function is set to 'on' by default. In general, specify the best value for 'SaveMemory' based on the dimensions of X and the available memory.

```
Z = linkage(X, 'ward');
```

Cluster the data into a maximum of four groups and plot the result.

```
c = cluster(Z, 'Maxclust',4);  
scatter3(X(:,1),X(:,2),X(:,3),10,c)
```

`cluster` identifies four groups in the data.

Input Arguments

Z — Agglomerative hierarchical cluster tree

numeric matrix

Agglomerative hierarchical cluster tree that is the output of the `linkage` function, specified as a numeric matrix. For an input data matrix X with m rows (or observations), `linkage` returns an $(m - 1)$ -by-3 matrix Z . For an explanation of how `linkage` creates the cluster tree, see `Z`.

Example: `Z = linkage(X)`, where X is an input data matrix

Data Types: `single` | `double`

C — Threshold for defining clusters

positive scalar | vector of positive scalars

Threshold for defining clusters, specified as a positive scalar or a vector of positive scalars. `cluster` uses C as a threshold for either the heights or the inconsistency coefficients of nodes, depending on the `criterion` for defining clusters in a hierarchical cluster tree.

- If the criterion for defining clusters is `'distance'`, then `cluster` groups all leaves at or below a node into a cluster, provided that the height of the node is less than C .
- If the criterion for defining clusters is `'inconsistent'`, then the `inconsistent` values of a node and all its subnodes must be less than C for `cluster` to group them into a cluster. `cluster` begins from the root of the cluster tree Z and steps down through the tree until it encounters a node whose `inconsistent` value is less than the threshold C , and whose subnodes (or descendants) have `inconsistent` values less than C . Then `cluster` groups all leaves at or below the node into a cluster (or a singleton if the node itself is a leaf). `cluster` follows every branch in the tree until all leaf nodes are in clusters.

Example: `cluster(Z, 'Cutoff', 0.5)`

Data Types: `single` | `double`

D — Depth for computing inconsistent values

2 (default) | numeric scalar

Depth for computing inconsistent values, specified as a numeric scalar. `cluster` evaluates inconsistent values by looking to a depth D below each node.

Example: `cluster(Z, 'Cutoff', 0.5, 'Depth', 3)`

Data Types: `single` | `double`

criterion — Criterion for defining clusters

`'inconsistent'` (default) | `'distance'`

Criterion for defining clusters, specified as `'inconsistent'` or `'distance'`.

If the criterion for defining clusters is `'distance'`, then `cluster` groups all leaves at or below a node into a cluster (or a singleton if the node itself is a leaf), provided that the height of the node is less than C . The height of a node in a tree represents the distance between the two subnodes that are merged at that node. Specifying `'distance'` results in clusters that correspond to a horizontal slice of the dendrogram plot of Z .

If the criterion for defining clusters is 'inconsistent', then `cluster` groups a node and all its subnodes into a cluster, provided that the inconsistency coefficients (or inconsistent values) of the node and subnodes are less than `C`. Specifying 'inconsistent' is equivalent to `cluster(Z, 'Cutoff', C)`.

Example: `cluster(Z, 'Cutoff', 0.5, 'Criterion', 'distance')`

Data Types: `char` | `string`

N — Maximum number of clusters

positive integer | vector of positive integers

Maximum number of clusters to form, specified as a positive integer or a vector of positive integers. `cluster` constructs a maximum of `N` clusters, using 'distance' as the criterion for defining clusters. The height of each node in the tree represents the distance between the two subnodes merged at that node. `cluster` finds the smallest height at which a horizontal cut through the tree will leave `N` or fewer clusters. See Specify Arbitrary Clusters on page 16-16 for more details.

Example: `cluster(Z, 'MaxClust', 5)`

Data Types: `single` | `double`

Output Arguments

T — Cluster assignment

numeric vector | numeric matrix

Cluster assignment, returned as a numeric vector or matrix. For the $(m - 1)$ -by-3 hierarchical cluster tree `Z` (the output of `linkage` given input `X`), `T` contains the cluster assignments of the m rows (observations) of `X`.

The size of `T` depends on the corresponding size of `C` or `N`.

- If `C` is a positive scalar, then `T` is a vector of length m .
- If `N` is a positive integer, then `T` is a vector of length m .
- If `C` is a length l vector of positive scalars, then `T` is an m -by- l matrix with one column per value in `C`.
- If `N` is a length l vector of positive integers, then `T` is an m -by- l matrix with one column per value in `N`.

Alternative Functionality

If you have an input data matrix `X`, you can use `clusterdata` to perform agglomerative clustering and return cluster indices for each observation (row) in `X`. The `clusterdata` function performs all the necessary steps for you, so you do not need to execute the `pdist`, `linkage`, and `cluster` functions separately.

"Hierarchical Clustering" on page 16-6

Introduced before R2006a

cluster

Construct clusters from Gaussian mixture distribution

Syntax

```
idx = cluster(gm,X)
[idx,nlogL] = cluster(gm,X)
[idx,nlogL,P] = cluster(gm,X)
[idx,nlogL,P,logpdf] = cluster(gm,X)
[idx,nlogL,P,logpdf,d2] = cluster(gm,X)
```

Description

`idx = cluster(gm,X)` partitions the data in X into k clusters determined by the k Gaussian mixture components in gm . The value in `idx(i)` is the cluster index of observation i and indicates the component with the largest posterior probability given the observation i .

`[idx,nlogL] = cluster(gm,X)` also returns the negative loglikelihood of the Gaussian mixture model gm given the data X .

`[idx,nlogL,P] = cluster(gm,X)` also returns the posterior probabilities of each Gaussian mixture component in gm given each observation in X .

`[idx,nlogL,P,logpdf] = cluster(gm,X)` also returns a logarithm of the estimated probability density function (pdf) evaluated at each observation in X .

`[idx,nlogL,P,logpdf,d2] = cluster(gm,X)` also returns the squared Mahalanobis distance of each observation in X to each Gaussian mixture component in gm .

Examples

Cluster Data

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the `mvnrnd` function. Fit a Gaussian mixture model (GMM) to the generated data by using the `fitgmdist` function. Then, use the `cluster` function to partition the data into two clusters determined by the fitted GMM components.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

```
mu1 = [2 2];           % Mean of the 1st component
sigma1 = [2 0; 0 1];  % Covariance of the 1st component
mu2 = [-2 -1];        % Mean of the 2nd component
sigma2 = [1 0; 0 1];  % Covariance of the 2nd component
```

Generate an equal number of random variates from each component, and combine the two sets of random variates.

```

rng('default') % For reproducibility
r1 = mvnrnd(mu1,sigma1,1000);
r2 = mvnrnd(mu2,sigma2,1000);
X = [r1; r2];

```

The combined data set X contains random variates following a mixture of two bivariate Gaussian distribution.

Fit a two-component GMM to X .

```
gm = fitgmdist(X,2);
```

Plot X by using `scatter`. Visualize the fitted model `gm` by using `pdf` and `fcontour`.

```

figure
scatter(X(:,1),X(:,2),10,'.') % Scatter plot with points of size 10
hold on
gmPDF = @(x,y)reshape(pdf(gm,[x(:) y(:)]),size(x));
fcontour(gmPDF,[-6 8 -4 6])

```

Partition the data into clusters by passing the fitted GMM and the data to `cluster`.

```
idx = cluster(gm,X);
```

Use `gscatter` to create a scatter plot grouped by `idx`.

```
figure;  
gscatter(X(:,1),X(:,2),idx);  
legend('Cluster 1','Cluster 2','Location','best');
```

Input Arguments

gm — Gaussian mixture distribution

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

X — Data

n-by-*m* numeric matrix

Data, specified as an *n*-by-*m* numeric matrix, where *n* is the number of observations and *m* is the number of variables in each observation.

To provide meaningful clustering results, *X* must come from the same population as the data used to create `gm`.

If a row of `X` contains NaNs, then `cluster` excludes the row from the computation. The corresponding value in `idx`, `P`, `logpdf`, and `d2` is NaN.

Data Types: `single` | `double`

Output Arguments

idx — Cluster index

n-by-1 positive integer vector

Cluster index, returned as an *n*-by-1 positive integer vector, where *n* is the number of observations in `X`.

`idx(i)` is the cluster index of observation `i` and indicates the Gaussian mixture component with the largest posterior probability given the observation `i`.

nlogL — Negative loglikelihood

numeric value

Negative loglikelihood value of the Gaussian mixture model `gm` given the data `X`, returned as a numeric value.

P — Posterior probability

n-by-*k* numeric vector

Posterior probability of each Gaussian mixture component in `gm` given each observation in `X`, returned as an *n*-by-*k* numeric vector, where *n* is the number of observations in `X` and *k* is the number of mixture components in `gm`.

`P(i, j)` is the posterior probability of the *j*th Gaussian mixture component given observation `i`, `Probability(component j | observation i)`.

logpdf — Logarithm of estimated pdf

n-by-1 numeric vector

Logarithm of the estimated pdf, evaluated at each observation in `X`, returned as an *n*-by-1 numeric vector, where *n* is the number of observations in `X`.

`logpdf(i)` is the logarithm of the estimated pdf at observation `i`. The `cluster` function computes the estimated pdf by using the likelihood of each component given each observation and the component probabilities.

$$\text{logpdf}(i) = \log \sum_{j=1}^k L(C_j | O_i) P(C_j),$$

where $L(C_j | O_i)$ is the likelihood of component *j* given observation `i`, and $P(C_j)$ is the probability of component *j*. The `cluster` function computes the likelihood term by using the multivariate normal pdf of the *j*th Gaussian mixture component evaluated at observation `i`. The component probabilities are the mixing proportions of mixture components, the `ComponentProportion` property of `gm`.

d2 — Squared Mahalanobis distance

n-by-*k* numeric matrix

Squared Mahalanobis distance of each observation in X to each Gaussian mixture component in `gm`, returned as an n -by- k numeric matrix, where n is the number of observations in X and k is the number of mixture components in `gm`.

`d2(i, j)` is the squared distance of observation i to the j th Gaussian mixture component.

ClusterCriterion

Package: clustering.evaluation

Clustering evaluation object

Description

Create a clustering evaluation object using `evalclusters`.

Properties

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

CriterionValues

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

NumObservations

Number of observations in the data matrix `X`, minus the number of missing (NaN) values in `X`, stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

X

Data used for clustering, stored as a matrix of numerical values.

Methods

addK	Evaluate additional numbers of clusters
plot	Plot clustering evaluation object criterion values
compact	Compact clustering evaluation object

clusterdata

Construct agglomerative clusters from data

Syntax

```
T = clusterdata(X,cutoff)
```

```
T = clusterdata(X,Name,Value)
```

Description

`T = clusterdata(X,cutoff)` returns cluster indices for each observation (row) of an input data matrix `X`, given a threshold `cutoff` for cutting an agglomerative hierarchical tree that the `linkage` function generates from `X`.

`clusterdata` supports agglomerative clustering and incorporates the `pdist`, `linkage`, and `cluster` functions, which you can use separately for more detailed analysis. See Algorithm Description on page 16-6 for more details.

`T = clusterdata(X,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify `'MaxClust',5` to find a maximum of five clusters.

Examples

Find Limited Number of Clusters from Sample Data

Find and visualize a maximum of three clusters in a randomly generated data set using two different approaches:

- 1 Specify a value for the `cutoff` input argument.
- 2 Specify a value for the `'MaxClust'` name-value pair argument.

Create a sample data set consisting of randomly generated data from three standard uniform distributions.

```
rng('default'); % For reproducibility
X = [gallery('uniformdata',[10 3],12); ...
     gallery('uniformdata',[10 3],13)+1.2; ...
     gallery('uniformdata',[10 3],14)+2.5];
y = [ones(10,1);2*(ones(10,1));3*(ones(10,1))]; % Actual classes
```

Create a scatter plot of the data.

```
scatter3(X(:,1),X(:,2),X(:,3),100,y,'filled')
title('Randomly Generated Data in Three Clusters');
```

Find a maximum of three clusters in the data by specifying the value 3 for the `cutoff` input argument.

```
T1 = clusterdata(X,3);
```

Because the value of `cutoff` is greater than 2, `clusterdata` interprets `cutoff` as the maximum number of clusters.

Plot the data with the resulting cluster assignments.

```
scatter3(X(:,1),X(:,2),X(:,3),100,T1,'filled')  
title('Result of Clustering');
```

Find a maximum of three clusters by specifying the value 3 for the 'MaxClust' name-value pair argument.

```
T2 = clusterdata(X, 'Maxclust', 3);
```

Plot the data with the resulting cluster assignments.

```
scatter3(X(:,1),X(:,2),X(:,3),100,T2, 'filled')  
title('Result of Clustering');
```

Using both approaches, `clusterdata` identifies the three distinct clusters in the data.

Create and Cluster Hierarchical Tree

Create a hierarchical cluster tree and find clusters in one step. Visualize the clusters using a 3-D scatter plot.

Create a 20,000-by-3 matrix of sample data generated from the standard uniform distribution.

```
rng('default'); % For reproducibility
X = rand(20000,3);
```

Find a maximum of four clusters in a hierarchical cluster tree created using the `ward` linkage method. Specify `'SaveMemory'` as `'on'` to construct clusters without computing the distance matrix. Otherwise, you can receive an out-of-memory error if your machine does not have enough memory to hold the distance matrix.

```
T = clusterdata(X,'Linkage','ward','SaveMemory','on','Maxclust',4);
```

Plot the data with each cluster shown in a different color.

```
scatter3(X(:,1),X(:,2),X(:,3),10,T)
```

`clusterdata` identifies four clusters in the data.

Input Arguments

X — Input data

numeric matrix

Input data, specified as a numeric matrix with two or more rows. The rows represent observations, and the columns represent categories or dimensions.

Data Types: `single` | `double`

cutoff — Threshold for cutting the hierarchical tree

positive scalar between 0 and 2 | positive integer ≥ 2

Threshold for cutting the hierarchical tree defined by `linkage`, specified as a positive scalar between 0 and 2 or a positive integer ≥ 2 . `clusterdata` behaves differently depending on the value specified for `cutoff`.

- If $0 < \text{cutoff} < 2$, then `clusterdata` forms clusters when inconsistent values are greater than `cutoff`.
- If `cutoff` is an integer ≥ 2 , then `clusterdata` forms a maximum of `cutoff` clusters.

Example: `clusterdata(X,3)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `clusterdata(X, 'Linkage', 'ward', 'MaxClust', 3)` specifies creating a maximum of three clusters of `X` using Ward linkage.

Criterion — Criterion for defining clusters

`'inconsistent'` | `'distance'`

Criterion for defining clusters in a hierarchical cluster tree, specified as the comma-separated pair consisting of `'Criterion'` and either `'inconsistent'` or `'distance'`. When you specify `'Criterion'`, you must also specify a value for `MaxClust` or `Cutoff`.

Example: `clusterdata(X, 'Criterion', 'distance', 'Cutoff', .5)`

Data Types: `char` | `string`

Cutoff — Cutoff for inconsistent or distance criterion

positive scalar

Cutoff for inconsistent or distance criterion, specified as the comma-separated pair consisting of `'Cutoff'` and a positive scalar. `clusterdata` uses `Cutoff` as a threshold for either the heights or the inconsistency coefficients of nodes, depending on the value of `Criterion`. If you specify a value for `'Cutoff'` without specifying the criterion for defining clusters, then `clusterdata` uses the `'inconsistent'` criterion by default.

- If `'Criterion'` is `'distance'`, then `clusterdata` groups all leaves at or below a node into a cluster, provided that the height of the node is less than `Cutoff`.
- If `'Criterion'` is `'inconsistent'`, then the `inconsistent` values of a node and all its subnodes must be less than `Cutoff` for `clusterdata` to group them into a cluster.

Example: `clusterdata(X, 'Cutoff', 0.2)`

Data Types: `single` | `double`

Depth — Depth for computing inconsistent values

numeric scalar

Depth for computing inconsistent values, specified as the comma-separated pair consisting of `'Depth'` and a numeric scalar. `clusterdata` evaluates inconsistent values by looking to the specified depth below each node in the hierarchical cluster tree. When you specify `'Depth'`, you must also specify a value for `MaxClust` or `Cutoff`.

Example: `clusterdata(X, 'Depth', 3, 'Cutoff', 0.5)`

Data Types: `single` | `double`

Distance — Distance metric

`'euclidean'` (default) | `'squareeuclidean'` | `'seuclidean'` | `'mahalanobis'` | function handle | ...

Distance metric, specified as the comma-separated pair consisting of 'Distance' and any distance metric accepted by the `pdist` function, as described in the following table. When you specify 'Distance', you must also specify a value for `MaxClust` or `Cutoff`.

Metric	Description
'euclidean'	Euclidean distance (default)
'squaredeuclidean'	Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, $S = \text{nanstd}(X)$.
'mahalanobis'	Mahalanobis distance using the sample covariance of X , $C = \text{nancov}(X)$
'cityblock'	City block distance
'minkowski'	Minkowski distance. The default exponent is 2. To use a different exponent P , specify P after 'minkowski', where P is a positive scalar value: 'minkowski', P .
'chebychev'	Chebychev distance (maximum coordinate difference)
'cosine'	One minus the cosine of the included angle between points (treated as vectors)
'correlation'	One minus the sample correlation between points (treated as sequences of values)
'hamming'	Hamming distance, which is the percentage of coordinates that differ
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values)
@ <i>distfun</i>	<p>Custom distance function handle. A distance function has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-n vector containing a single observation. • ZJ is an $m2$-by-n matrix containing multiple observations. <code>distfun</code> must accept a matrix ZJ with an arbitrary number of observations. • $D2$ is an $m2$-by-1 vector of distances, and $D2(k)$ is the distance between observations ZI and $ZJ(k, :)$. <p>If your data is not sparse, using a built-in distance is generally faster than using a function handle.</p>

For more information, see “Distance Metrics” on page 32-3925.

Example: `clusterdata(X,'Distance','minkowski','MaxClust',4)`

Data Types: char | string | function_handle

Linkage — Algorithm for computing the distance between clusters

'average' | 'centroid' | 'complete' | 'median' | 'single' | 'ward' | 'weighted' | ...

Algorithm for computing distance between clusters, specified as the comma-separated pair consisting of 'Linkage' and any algorithm accepted by the `linkage` function, as described in the following table. When you specify 'Linkage', you must also specify a value for `MaxClust` or `Cutoff`.

Algorithm	Description
'average'	Unweighted average distance (UPGMA)
'centroid'	Centroid distance (UPGMC), appropriate for Euclidean distances only
'complete'	Farthest distance
'median'	Weighted center of mass distance (WPGMC), appropriate for Euclidean distances only
'single'	Shortest distance
'ward'	Inner squared distance (minimum variance algorithm), appropriate for Euclidean distances only
'weighted'	Weighted average distance (WPGMA)

For more information, see “Linkages” on page 32-3087.

Example: `clusterdata(X,'Linkage','median','MaxClust',4)`

Data Types: char | string

MaxClust — Maximum number of clusters

positive integer

Maximum number of clusters to form, specified as the comma-separated pair consisting of 'MaxClust' and a positive integer.

Example: `clusterdata(X,'MaxClust',4)`

Data Types: single | double

SaveMemory — Option for saving memory

'on' | 'off'

Option for saving memory, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. The 'on' setting causes `clusterdata` to construct clusters without computing the distance matrix. The 'on' setting applies when both of these conditions are satisfied:

- Linkage is 'centroid', 'median', or 'ward'.
- Distance is 'euclidean' (default).

When these two conditions apply, the default value for 'SaveMemory' is 'on' if X has 20 columns or fewer, or if the computer does not have enough memory to store the distance matrix. Otherwise, the default value for 'SaveMemory' is 'off'.

When 'SaveMemory' is 'on', the linkage run time is proportional to the number of dimensions (number of columns of X). When 'SaveMemory' is 'off', the linkage memory requirement is proportional to N^2 , where N is the number of observations. Choosing the best (least-time) setting for 'SaveMemory' depends on the problem dimensions, number of observations, and available memory. The default 'SaveMemory' setting is a rough approximation of an optimal setting.

Example: 'SaveMemory', 'on'

Data Types: char | string

Output Arguments

T — Cluster indices

numeric column vector

Cluster indices, returned as a numeric column vector. T has as many rows as X, and each row of T indicates the cluster assignment of the corresponding observation in X.

Tips

- If 'Linkage' is 'centroid' or 'median', then linkage can produce a cluster tree that is not monotonic. This result occurs when the distance from the union of two clusters, r and s , to a third cluster is less than the distance between r and s . In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this result, specify another value for 'Linkage'. The following image shows a nonmonotonic cluster tree.

In this case, cluster 1 and cluster 3 are joined into a new cluster, while the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3.

Algorithms

If you specify a value c for the `cutoff` input argument, then `T = clusterdata(X,c)` performs the following steps:

- 1 Create a vector of the Euclidean distance between pairs of observations in X by using `pdist`.

$$Y = \text{pdist}(X, 'euclidean')$$
- 2 Create an agglomerative hierarchical cluster tree from Y by using `linkage` with the 'single' method for computing the shortest distance between clusters.

$$Z = \text{linkage}(Y, 'single')$$
- 3 If $0 < c < 2$, use `cluster` to define clusters from Z when inconsistent values are less than c .

```
T = cluster(Z, 'Cutoff', c)
```

- 4** If `c` is an integer value ≥ 2 , use `cluster` to find a maximum of `c` clusters from `Z`.

```
T = cluster(Z, 'MaxClust', c)
```

Alternative Functionality

If you have a hierarchical cluster tree `Z` (the output of the `linkage` function for the input data matrix `X`), you can use `cluster` to perform agglomerative clustering on `Z` and return the cluster assignment for each observation (row) in `X`.

Topics

“Hierarchical Clustering” on page 16-6

Introduced before R2006a

cmdscale

Classical multidimensional scaling

Syntax

```
Y = cmdscale(D)
[Y,e] = cmdscale(D)
[Y,e] = cmdscale(D,p)
```

Description

`Y = cmdscale(D)` takes an n -by- n distance matrix D , and returns an n -by- p configuration matrix Y . Rows of Y are the coordinates of n points in p -dimensional space for some $p < n$. When D is a Euclidean distance matrix, the distances between those points are given by D . p is the dimension of the smallest space in which the n points whose inter-point distances are given by D can be embedded.

`[Y,e] = cmdscale(D)` also returns the eigenvalues of $Y*Y'$. When D is Euclidean, the first p elements of e are positive, the rest zero. If the first k elements of e are much larger than the remaining $(n-k)$, then you can use the first k columns of Y as k -dimensional points whose inter-point distances approximate D . This can provide a useful dimension reduction for visualization, e.g., for $k = 2$.

D need not be a Euclidean distance matrix. If it is non-Euclidean or a more general dissimilarity matrix, then some elements of e are negative, and `cmdscale` chooses p as the number of positive eigenvalues. In this case, the reduction to p or fewer dimensions provides a reasonable approximation to D only if the negative elements of e are small in magnitude.

`[Y,e] = cmdscale(D,p)` also accepts a positive integer p between 1 and n . p specifies the dimensionality of the desired embedding Y . If a p dimensional embedding is possible, then Y will be of size n -by- p and e will be of size p -by-1. If only a q dimensional embedding with $q < p$ is possible, then Y will be of size n -by- q and e will be of size p -by-1. Specifying p may reduce the computational burden when n is very large.

You can specify D as either a full dissimilarity matrix, or in upper triangle vector form such as is output by `pdist`. A full dissimilarity matrix must be real and symmetric, and have zeros along the diagonal and positive elements everywhere else. A dissimilarity matrix in upper triangle form must have real, positive entries. You can also specify D as a full similarity matrix, with ones along the diagonal and all other elements less than one. `cmdscale` transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in Y equal or approximate $\sqrt{1-D}$. To use a different transformation, you must transform the similarities prior to calling `cmdscale`.

Examples

Construct a Map Using Multidimensional Scaling

This example shows how to construct a map of 10 US cities based on the distances between those cities, using `cmdscale`.

First, create the distance matrix and pass it to `cmdscale`. In this example, `D` is a full distance matrix: it is square and symmetric, has positive entries off the diagonal, and has zeros on the diagonal.

```
cities = ...
{'Atl','Chi','Den','Hou','LA','Mia','NYC','SF','Sea','WDC'};
D = [
    0 587 1212 701 1936 604 748 2139 2182 543;
    587 0 920 940 1745 1188 713 1858 1737 597;
    1212 920 0 879 831 1726 1631 949 1021 1494;
    701 940 879 0 1374 968 1420 1645 1891 1220;
    1936 1745 831 1374 0 2339 2451 347 959 2300;
    604 1188 1726 968 2339 0 1092 2594 2734 923;
    748 713 1631 1420 2451 1092 0 2571 2408 205;
    2139 1858 949 1645 347 2594 2571 0 678 2442;
    2182 1737 1021 1891 959 2734 2408 678 0 2329;
    543 597 1494 1220 2300 923 205 2442 2329 0];
[Y,eigvals] = cmdscale(D);
```

Next, look at the eigenvalues returned by `cmdscale`. Some of these are negative, indicating that the original distances are not Euclidean. This is because of the curvature of the earth.

```
format short g
[eigvals eigvals/max(abs(eigvals))]
```

```
ans = 10×2
```

```

9.5821e+06      1
1.6868e+06      0.17604
 8157.3         0.0008513
 1432.9         0.00014954
  508.67        5.3085e-05
   25.143        2.624e-06
4.6705e-10      4.8741e-17
  -897.7        -9.3685e-05
 -5467.6        -0.0005706
 -35479         -0.0037026
```

However, in this case, the two largest positive eigenvalues are much larger in magnitude than the remaining eigenvalues. So, despite the negative eigenvalues, the first two coordinates of `Y` are sufficient for a reasonable reproduction of `D`.

```
Dtriu = D(find(tril(ones(10),-1)))';
maxrelerr = max(abs(Dtriu-pdist(Y(:,1:2))))./max(Dtriu)
```

```
maxrelerr =
 0.0075371
```

Here is a plot of the reconstructed city locations as a map. The orientation of the reconstruction is arbitrary.

```
plot(Y(:,1),Y(:,2),'.')
text(Y(:,1)+25,Y(:,2),cities)
xlabel('Miles')
ylabel('Miles')
```

Evaluate Reconstructions Using Different Distance Metrics

Determine how the quality of reconstruction varies when you reduce points to distances using different metrics.

Generate ten points in 4-D space that are close to 3-D space. Take a linear transformation of the points so that their transformed values are close to a 3-D subspace that does not align with the coordinate axes.

```
rng default % Set the seed for reproducibility
A = [normrnd(0,1,10,3) normrnd(0,0.1,10,1)];
B = randn(4,4);
X = A*B;
```

Reduce the points in X to distances by using the Euclidean metric. Find a configuration Y with the inter-point distances.

```
D = pdist(X, 'euclidean');
Y = cmdscale(D);
```

Compare the quality of the reconstructions when using 2, 3, or 4 dimensions. The small maxerr3 value indicates that the first 3 dimensions provide a good reconstruction.

```
maxerr2 = max(abs(pdist(X)-pdist(Y(:,1:2))))
```

```
maxerr2 = 0.1631
maxerr3 = max(abs(pdist(X)-pdist(Y(:,1:3))))
maxerr3 = 0.0187
maxerr4 = max(abs(pdist(X)-pdist(Y)))
maxerr4 = 7.9936e-15
```

Reduce the points in X to distances by using the 'cityblock' metric. Find a configuration Y with the inter-point distances.

```
D = pdist(X, 'cityblock');
[Y,e] = cmdscale(D);
```

Evaluate the quality of the reconstruction. e contains at least one negative element of large magnitude, which might account for the poor quality of the reconstruction.

```
maxerr = max(abs(pdist(X)-pdist(Y)))
maxerr = 9.0488
min(e)
ans = -5.6586
```

Introduced before R2006a

coefCI

Package:

Confidence intervals of coefficient estimates of generalized linear regression model

Syntax

```
ci = coefCI mdl
ci = coefCI(mdl,alpha)
```

Description

`ci = coefCI(mdl)` returns 95% confidence intervals for the coefficients in `mdl`.

`ci = coefCI(mdl,alpha)` returns confidence intervals using the confidence level $1 - \alpha$.

Examples

Find Confidence Intervals for Model Coefficients

Find the confidence intervals for the coefficients of a fitted generalized linear regression model.

Generate sample data using Poisson random numbers with two underlying predictors $X(:,1)$ and $X(:,2)$.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson')
```

```
mdl =
Generalized linear regression model:
  log(y) ~ 1 + x1 + x2
  Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0405	0.022122	47.034	0
x1	0.9968	0.003362	296.49	0
x2	1.987	0.0063433	313.24	0

100 observations, 97 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0

Find 95% (default) confidence intervals for the coefficients of the model.

```
ci = coefCI mdl

ci = 3×2

    0.9966    1.0844
    0.9901    1.0035
    1.9744    1.9996
```

Find 99% confidence intervals for the coefficients.

```
alpha = 0.01;
ci = coefCI mdl, alpha

ci = 3×2

    0.9824    1.0986
    0.9880    1.0056
    1.9703    2.0036
```

Input Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object | CompactGeneralizedLinearModel object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`, or a `CompactGeneralizedLinearModel` object created using `compact`.

alpha — Significance level

0.05 (default) | numeric value in the range [0,1]

Significance level for the confidence interval, specified as a numeric value in the range [0,1]. The confidence level of `ci` is equal to $100(1 - \alpha)\%$. `alpha` is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: single | double

Output Arguments

ci — Confidence intervals

numeric matrix

Confidence intervals, returned as a k -by-2 numeric matrix, where k is the number of coefficients. The j th row of `ci` is the confidence interval of the j th coefficient of `mdl`. The name of coefficient j is stored in the `CoefficientNames` property of `mdl`.

Data Types: single | double

More About

Confidence Interval

The coefficient confidence intervals provide a measure of precision for regression coefficient estimates.

A $100(1 - \alpha)\%$ confidence interval gives the range that the corresponding regression coefficient will be in with $100(1 - \alpha)\%$ confidence, meaning that $100(1 - \alpha)\%$ of the intervals resulting from repeated experimentation will contain the true value of the coefficient.

The software finds confidence intervals using the Wald method. The $100*(1 - \alpha)\%$ confidence intervals for regression coefficients are

$$b_i \pm t_{(1 - \alpha/2, n - p)}SE(b_i),$$

where b_i is the coefficient estimate, $SE(b_i)$ is the standard error of the coefficient estimate, and $t_{(1-\alpha/2, n-p)}$ is the $100(1 - \alpha/2)$ percentile of t -distribution with $n - p$ degrees of freedom. n is the number of observations and p is the number of regression coefficients.

“Generalized Linear Model Workflow” on page 12-28

Introduced in R2012a

coefCI

Class: GeneralizedLinearMixedModel

Confidence intervals for coefficients of generalized linear mixed-effects model

Syntax

```
feCI = coefCI(glme)
feCI = coefCI(glme,Name,Value)
[feCI,reCI] = coefCI( ___ )
```

Description

`feCI = coefCI(glme)` returns the 95% confidence intervals for the fixed-effects coefficients in the generalized linear mixed-effects model `glme`.

`feCI = coefCI(glme,Name,Value)` returns the confidence intervals using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify a different confidence level or the method used to compute the approximate degrees of freedom.

`[feCI,reCI] = coefCI(___)` also returns the confidence intervals for the random-effects coefficients using any of the previous syntaxes.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range [0,1]

Significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

DFMethod — Method for computing approximate degrees of freedom

'residual' (default) | 'none'

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

Value	Description
'residual'	The degrees of freedom value is assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'none'	The degrees of freedom is set to infinity.

Example: 'DFMethod', 'none'

Output Arguments

feCI — Fixed-effects confidence intervals

p-by-2 matrix

Fixed-effects confidence intervals, returned as a *p*-by-2 matrix. feCI contains the confidence limits that correspond to the *p*-by-1 fixed-effects vector returned by the fixedEffects method. The first column of feCI contains the lower confidence limits and the second column contains the upper confidence limits.

When fitting a GLME model using fitglme and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'):

- If you specify the 'CovarianceMethod' name-value pair argument as 'conditional', then the confidence intervals are conditional on the estimated covariance parameters.
- If you specify the 'CovarianceMethod' name-value pair argument as 'JointHessian', then the confidence intervals account for the uncertainty in the estimated covariance parameters.

When fitting a GLME model using fitglme and one of the pseudo likelihood fit methods ('MPL' or 'REML'), coefci uses the fitted linear mixed effects model from the final pseudo likelihood iteration to compute confidence intervals on the fixed effects.

reCI — Random-effects confidence intervals

q-by-2 matrix

Random-effects confidence intervals, returned as a *q*-by-2 matrix. reCI contains the confidence limits corresponding to the *q*-by-1 random-effects vector B returned by the randomEffects method. The first column of reCI contains the lower confidence limits, and the second column contains the upper confidence limits.

When fitting a GLME model using fitglme and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), coefCI computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. Alternatively, you can interpret the confidence intervals from coefCI as approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using fitglme and one of the pseudo likelihood fit methods ('MPL' or 'REML'), coefci uses the fitted linear mixed effects model from the final pseudo likelihood iteration to compute confidence intervals on the random effects.

Examples

95% Confidence Intervals for Fixed Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.

- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', 'Di
```

Use `fixedEffects` to display the estimates and names of the fixed-effects coefficients in `glme`.

```
[beta, betanames] = fixedEffects(glme)
```

```
beta = 6×1
```

```
    1.4689
   -0.3677
   -0.0945
   -0.2832
   -0.0719
    0.0711
```

```
betanames=6×1 table
      Name
```

```
-----
{'(Intercept)'}
{'newprocess' }
{'time_dev'   }
{'temp_dev'   }
{'supplier_C' }
{'supplier_B' }
```

Each row of `beta` contains the estimated value for the coefficient named in the corresponding row of `betanames`. For example, the value `-0.0945` in row 3 of `beta` is the estimated coefficient for the predictor variable `time_dev`.

Compute the 95% confidence intervals for the fixed-effects coefficients.

```
feCI = coefCI(glme)
```

```
feCI = 6×2
```

```
    1.1515    1.7864
   -0.7202   -0.0151
   -1.7395    1.5505
   -2.1926    1.6263
   -0.2268    0.0831
   -0.0826    0.2247
```

Column 1 of `feCI` contains the lower bound of the 95% confidence interval. Column 2 contains the upper bound. Row 1 corresponds to the intercept term. Rows 2, 3, and 4 correspond to `newprocess`, `time_dev`, and `temp_dev`, respectively. Rows 5 and 6 correspond to the indicator variables `supplier_C` and `supplier_B`, respectively. For example, the 95% confidence interval for the coefficient for `time_dev` is `[-1.7395, 1.5505]`. Some of the confidence intervals include 0, which

indicates that those predictors are not significant at the 5% significance level. To obtain specific p -values for each fixed-effects term, use `fixedEffects`. To test significance for entire terms, use `anova`.

99% Confidence Intervals for Random Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).

- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', 'Di
```

Use `randomEffects` to compute and display the estimates of the empirical Bayes predictors (EBPs) for the random effects associated with `factory`.

```
[B,Bnames] = randomEffects(glme)
```

```
B = 20×1
```

```
0.2913
0.1542
-0.2633
-0.4257
0.5453
-0.1069
0.3040
-0.1653
-0.1458
-0.0816
⋮
```

```
Bnames=20×3 table
```

Group	Level	Name
{'factory'}	{'1' }	{'(Intercept)'} }
{'factory'}	{'2' }	{'(Intercept)'} }
{'factory'}	{'3' }	{'(Intercept)'} }
{'factory'}	{'4' }	{'(Intercept)'} }
{'factory'}	{'5' }	{'(Intercept)'} }
{'factory'}	{'6' }	{'(Intercept)'} }
{'factory'}	{'7' }	{'(Intercept)'} }
{'factory'}	{'8' }	{'(Intercept)'} }
{'factory'}	{'9' }	{'(Intercept)'} }
{'factory'}	{'10' }	{'(Intercept)'} }
{'factory'}	{'11' }	{'(Intercept)'} }
{'factory'}	{'12' }	{'(Intercept)'} }
{'factory'}	{'13' }	{'(Intercept)'} }
{'factory'}	{'14' }	{'(Intercept)'} }
{'factory'}	{'15' }	{'(Intercept)'} }
{'factory'}	{'16' }	{'(Intercept)'} }
	⋮	

Each row of `B` contains the estimated EBPs for the random-effects coefficient named in the corresponding row of `Bnames`. For example, the value `-0.2633` in row 3 of `B` is the estimated coefficient of `'(Intercept)'` for level `'3'` of `factory`.

Compute the 99% confidence intervals of the EBPs for the random effects.

```
[feCI, reCI] = coefCI(glme, 'Alpha', 0.01);
reCI
```

```
reCI = 20x2
```

```
-0.2125    0.7951
-0.3510    0.6595
-0.8219    0.2954
-0.9953    0.1440
 0.0730    1.0176
-0.6362    0.4224
-0.1796    0.7877
-0.7044    0.3738
-0.6795    0.3880
-0.6142    0.4509
  :
```

Column 1 of `reCI` contains the lower bound of the 99% confidence interval. Column 2 contains the upper bound. Each row corresponds to a level of `factory`, in the order shown in `Bnames`. For example, row 3 corresponds to the coefficient of `'(Intercept)'` for level `'3'` of `factory`, which has a 99% confidence interval of `[-0.8219, 0.2954]`. For additional statistics related to each random-effects term, use `randomEffects`.

coefCI

Package:

Confidence intervals of coefficient estimates of linear regression model

Syntax

```
ci = coefCI mdl
ci = coefCI(mdl,alpha)
```

Description

`ci = coefCI(mdl)` returns 95% confidence intervals for the coefficients in `mdl`.

`ci = coefCI(mdl,alpha)` returns confidence intervals using the confidence level $1 - \alpha$.

Examples

Find Confidence Intervals for Model Coefficients

Fit a linear regression model and obtain the default 95% confidence intervals for the resulting model coefficients.

Load the `carbig` data set and create a table in which the `Origin` predictor is categorical.

```
load carbig
Origin = categorical(cellstr(Origin));
tbl = table(Horsepower,Weight,MPG,Origin);
```

Fit a linear regression model. Specify `Horsepower`, `Weight`, and `Origin` as predictor variables, and specify `MPG` as the response variable.

```
modelspec = 'MPG ~ 1 + Horsepower + Weight + Origin';
mdl = fitlm(tbl,modelspec);
```

View the names of the coefficients.

```
mdl.CoefficientNames
```

```
ans = 1x9 cell
  Columns 1 through 4
    {'(Intercept)'}    {'Horsepower'}    {'Weight'}    {'Origin_France'}

  Columns 5 through 7
    {'Origin_Germany'}    {'Origin_Italy'}    {'Origin_Japan'}

  Columns 8 through 9
    {'Origin_Sweden'}    {'Origin_USA'}
```

Find confidence intervals for the coefficients of the model.

```
ci = coefCI mdl
```

```
ci = 9×2

Specify Confidence Level

Fit a linear regression model and obtain the confidence intervals for the resulting model coefficients using a specified confidence level.

Load the `carbig` data set and create a table in which the `Origin` predictor is categorical.

```
load carbig
Origin = categorical(cellstr(Origin));
tbl = table(Horsepower,Weight,MPG,Origin);
```

Fit a linear regression model. Specify `Horsepower`, `Weight`, and `Origin` as predictor variables, and specify `MPG` as the response variable.

```
modelspec = 'MPG ~ 1 + Horsepower + Weight + Origin';
mdl = fitlm(tbl,modelspec);
```

Find 99% confidence intervals for the coefficients.

```
ci = coefCI(mdl,.01)
```

```
ci = 9×2
```

```
 40.7365  62.5635
 -0.0816 -0.0246
 -0.0062 -0.0034
 -20.0560  2.3459
 -18.3615  3.3546
 -19.9433  2.7955
 -17.1045  4.4676
 -21.2858  1.2002
 -19.8995  1.6238
```

The confidence intervals are wider than the default 95% confidence intervals in “Find Confidence Intervals for Model Coefficients” on page 32-583.

Input Arguments

mdl — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a LinearModel object created by using `fitlm` or `stepwiselm`, or a CompactLinearModel object created by using `compact`.

alpha — Significance level

0.05 (default) | numeric value in the range [0,1]

Significance level for the confidence interval, specified as a numeric value in the range [0,1]. The confidence level of `ci` is equal to $100(1 - \alpha)\%$. `alpha` is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: single | double

Output Arguments

ci — Confidence intervals

numeric matrix

Confidence intervals, returned as a k -by-2 numeric matrix, where k is the number of coefficients. The j th row of `ci` is the confidence interval of the j th coefficient of `mdl`. The name of coefficient j is stored in the `CoefficientNames` property of `mdl`.

Data Types: single | double

More About

Confidence Interval

The coefficient confidence intervals provide a measure of precision for regression coefficient estimates.

A $100(1 - \alpha)\%$ confidence interval gives the range that the corresponding regression coefficient will be in with $100(1 - \alpha)\%$ confidence, meaning that $100(1 - \alpha)\%$ of the intervals resulting from repeated experimentation will contain the true value of the coefficient.

The software finds confidence intervals using the Wald method. The $100*(1 - \alpha)\%$ confidence intervals for regression coefficients are

$$b_i \pm t_{(1 - \alpha/2, n - p)}SE(b_i),$$

where b_i is the coefficient estimate, $SE(b_i)$ is the standard error of the coefficient estimate, and $t_{(1 - \alpha/2, n - p)}$ is the $100(1 - \alpha/2)$ percentile of t -distribution with $n - p$ degrees of freedom. n is the number of observations and p is the number of regression coefficients.

coefCI

Class: LinearMixedModel

Confidence intervals for coefficients of linear mixed-effects model

Syntax

```
feCI = coefCI(lme)
feCI = coefCI(lme,Name,Value)
[feCI,reCI] = coefCI(____)
```

Description

`feCI = coefCI(lme)` returns the 95% confidence intervals for the fixed-effects coefficients in the linear mixed-effects model `lme`.

`feCI = coefCI(lme,Name,Value)` returns the 95% confidence intervals for the fixed-effects coefficients in the linear mixed-effects model `lme` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the confidence level or method to compute the degrees of freedom.

`[feCI,reCI] = coefCI(____)` also returns the 95% confidence intervals for the random-effects coefficients in the linear mixed-effects model `lme`.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

DFMethod — Method for computing approximate degrees of freedom

'residual' (default) | 'satterthwaite' | 'none'

Method for computing approximate degrees of freedom for confidence interval computation, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'residual'	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'satterthwaite'	Satterthwaite approximation.
'none'	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod', 'satterthwaite'

Output Arguments**feCI — Fixed-effects confidence intervals**

p -by-2 matrix

Fixed-effects confidence intervals, returned as a p -by-2 matrix. feCI contains the confidence limits that correspond to the p fixed-effects estimates in the vector `beta` returned by the `fixedEffects` method. The first column of feCI has the lower confidence limits and the second column has the upper confidence limits.

reCI — Random-effects confidence intervals

q -by-2 matrix

Random-effects confidence intervals, returned as a q -by-2 matrix. reCI contains the confidence limits corresponding to the q random-effects estimates in the vector `B` returned by the `randomEffects` method. The first column of reCI has the lower confidence limits and the second column has the upper confidence limits.

Examples**95% Confidence Intervals for Fixed-Effects Coefficients**

Load the sample data.

```
load('weight.mat')
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fixed-effects coefficient estimates.

```
fe = fixedEffects(lme)
```

```
fe = 9×1
    0.6610
    0.0032
    0.3608
   -0.0333
    0.1132
    0.1732
    0.0388
    0.0305
    0.0331
```

The first estimate, 0.6610, corresponds to the constant term. The second row, 0.0032, and the third row, 0.3608, are estimates for the coefficient of initial weight and week, respectively. Rows four to six correspond to the indicator variables for programs B-D, and the last three rows correspond to the interaction of programs B-D and week.

Compute the 95% confidence intervals for the fixed-effects coefficients.

```
fecI = coefCI(lme)
```

```
fecI = 9×2
    0.1480    1.1741
    0.0005    0.0059
    0.1004    0.6211
   -0.2932    0.2267
   -0.1471    0.3734
    0.0395    0.3069
   -0.1503    0.2278
   -0.1585    0.2196
   -0.1559    0.2221
```

Some confidence intervals include 0. To obtain specific p -values for each fixed-effects term, use the `fixedEffects` method. To test for entire terms use the `anova` method.

Confidence Intervals with Specified Options

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and a potentially correlated random effect for intercept and acceleration grouped by model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the fixed-effects coefficient estimates.

```
fe = fixedEffects(lme)
```

```
fe = 3×1
    50.1325
   -0.5833
   -0.1695
```

Compute the 99% confidence intervals for fixed-effects coefficients using the residuals method to determine the degrees of freedom. This is the default method.

```
feCI = coefCI(lme, 'Alpha',0.01)
```

```
feCI = 3×2
    44.2690    55.9961
   -0.9300   -0.2365
   -0.1883   -0.1507
```

Compute the 99% confidence intervals for fixed-effects coefficients using the Satterthwaite approximation to compute the degrees of freedom.

```
feCI = coefCI(lme, 'Alpha',0.01, 'DFMethod', 'satterthwaite')
```

```
feCI = 3×2
    44.0949    56.1701
   -0.9640   -0.2025
   -0.1884   -0.1507
```

The Satterthwaite approximation produces similar confidence intervals than the residual method.

Compute Confidence Intervals for Random Effects

Load the sample data.

```
load('shift.mat')
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if there is significant difference in the performance according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Compute the estimate of the BLUPs for random effects.

```
randomEffects(lme)
```

```
ans = 5×1
    0.5775
    1.1757
   -2.1715
    2.3655
   -1.9472
```

Compute the 95% confidence intervals for random effects.

```
[~,reCI] = coefCI(lme)
```

```
reCI = 5×2
   -1.3916    2.5467
   -0.7934    3.1449
   -4.1407   -0.2024
    0.3964    4.3347
   -3.9164    0.0219
```

Compute the 99% confidence intervals for random effects using the residuals method to determine the degrees of freedom. This is the default method.

```
[~,reCI] = coefCI(lme, 'Alpha', 0.01)
```

```
reCI = 5×2
   -2.1831    3.3382
   -1.5849    3.9364
   -4.9322    0.5891
   -0.3951    5.1261
   -4.7079    0.8134
```

Compute the 99% confidence intervals for random effects using the Satterthwaite approximation to determine the degrees of freedom.

```
[~,reCI] = coefCI(lme, 'Alpha', 0.01, 'DFMethod', 'satterthwaite')
```

```
reCI = 5×2
   -2.6840    3.8390
   -2.0858    4.4372
   -5.4330    1.0900
   -0.8960    5.6270
```

-5.2087 1.3142

The Satterthwaite approximation might produce smaller DF values than the residual method. That is why these confidence intervals are larger than the previous ones computed using the residual method.

coefCI

Class: NonLinearModel

Confidence intervals of coefficient estimates of nonlinear regression model

Syntax

```
ci = coefCI mdl
ci = coefCI(mdl,alpha)
```

Description

`ci = coefCI(mdl)` returns confidence intervals for the coefficients in `mdl`.

`ci = coefCI(mdl,alpha)` returns confidence intervals with confidence level $1 - \alpha$.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

alpha

Scalar from 0 to 1, the probability that the confidence interval does not contain the true value.

Default: 0.05

Output Arguments

ci

k -by-2 matrix of confidence intervals. The j th row of `ci` is the confidence interval of coefficient j of `mdl`. The name of coefficient j of `mdl` is in `mdl.CoeffNames`.

Examples

Default Confidence Intervals

Create a nonlinear model for auto mileage based on the `carbig` data. Then obtain confidence intervals for the resulting model coefficients.

Load the data and create a nonlinear model.

```
load carbig
ds = dataset(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1) + ...
    b(3)*x(:,2) + b(4)*x(:,1).*x(:,2);
```

```

beta0 = [1 1 1 1];
mdl = fitnlm(ds,modelfun,beta0)

mdl =
Nonlinear regression model:
    MPG ~ b1 + b2*Horsepower + b3*Weight + b4*Horsepower*Weight

Estimated Coefficients:
              Estimate          SE          tStat          pValue
    _____
    b1          63.558          2.3429          27.127          1.2343e-91
    b2         -0.25084          0.027279          -9.1952          2.3226e-18
    b3         -0.010772          0.00077381          -13.921          5.1372e-36
    b4          5.3554e-05          6.6491e-06           8.0542          9.9336e-15

```

```

Number of observations: 392, Error degrees of freedom: 388
Root Mean Squared Error: 3.93
R-Squared: 0.748, Adjusted R-Squared 0.746
F-statistic vs. constant model: 385, p-value = 7.26e-116

```

All the coefficients have extremely small p -values. This means a confidence interval around the coefficients will not contain the point θ , unless the confidence level is very high.

Find 95% confidence intervals for the coefficients of the model.

```

ci = coefCI(mdl)

ci = 4x2

    58.9515    68.1644
    -0.3045    -0.1972
    -0.0123    -0.0093
     0.0000     0.0001

```

The confidence interval for b_4 seems to contain θ . Examine it in more detail.

```

ci(4,:)

ans = 1x2
    10-4 ×
    0.4048    0.6663

```

As expected, the confidence interval does not contain the point θ .

More About

Confidence Interval

The coefficient confidence intervals provide a measure of precision for regression coefficient estimates.

A $100(1 - \alpha)\%$ confidence interval gives the range that the corresponding regression coefficient will be in with $100(1 - \alpha)\%$ confidence, meaning that $100(1 - \alpha)\%$ of the intervals resulting from repeated experimentation will contain the true value of the coefficient.

The software finds confidence intervals using the Wald method. The $100*(1 - \alpha)\%$ confidence intervals for regression coefficients are

$$b_i \pm t_{(1 - \alpha/2, n - p)}SE(b_i),$$

where b_i is the coefficient estimate, $SE(b_i)$ is the standard error of the coefficient estimate, and $t_{(1-\alpha/2, n-p)}$ is the $100(1 - \alpha/2)$ percentile of t -distribution with $n - p$ degrees of freedom. n is the number of observations and p is the number of regression coefficients.

coefTest

Package:

Linear hypothesis test on generalized linear regression model coefficients

Syntax

```
p = coefTest mdl
p = coefTest mdl,H
p = coefTest mdl,H,C
[p,F] = coefTest( ___ )
[p,F,r] = coefTest( ___ )
```

Description

`p = coefTest(mdl)` computes the p -value for an F test that all coefficient estimates in `mdl`, except the intercept term, are zero.

`p = coefTest(mdl,H)` performs an F -test that $H \times B = 0$, where B represents the coefficient vector. Use `H` to specify the coefficients to include in the F -test.

`p = coefTest(mdl,H,C)` performs an F -test that $H \times B = C$.

`[p,F] = coefTest(___)` also returns the F -test statistic F using any of the input argument combinations in previous syntaxes.

`[p,F,r] = coefTest(___)` also returns the numerator degrees of freedom r for the test.

Examples

Test Significance of Generalized Linear Regression Model

Fit a generalized linear regression model, and test the coefficients of the fitted model to see if they differ from zero.

Generate sample data using Poisson random numbers with two underlying predictors $X(:,1)$ and $X(:,2)$.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1), rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson')
```

```
mdl =
Generalized linear regression model:
```

```
log(y) ~ 1 + x1 + x2
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0405	0.022122	47.034	0
x1	0.9968	0.003362	296.49	0
x2	1.987	0.0063433	313.24	0

100 observations, 97 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0

Test whether the fitted model has coefficients that differ significantly from zero.

```
p = coefTest mdl
```

```
p = 4.1131e-153
```

The small p -value indicates that the model fits significantly better than a degenerate model consisting of only an intercept term.

Test Significance of Generalized Linear Regression Model Coefficient

Fit a generalized linear regression model, and test the significance of a specified coefficient in the fitted model.

Generate sample data using Poisson random numbers with two underlying predictors $X(:,1)$ and $X(:,2)$.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1), rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson')
```

```
mdl =
Generalized linear regression model:
log(y) ~ 1 + x1 + x2
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0405	0.022122	47.034	0
x1	0.9968	0.003362	296.49	0
x2	1.987	0.0063433	313.24	0

```
100 observations, 97 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0
```

Test the significance of the `x1` coefficient. According to the model display, `x1` is the second predictor. Specify the coefficient by using a numeric index vector.

```
p = coefTest mdl, [0 1 0])
```

```
p = 2.8681e-145
```

The returned p -value indicates that `x1` is statistically significant in the fitted model.

Input Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object | CompactGeneralizedLinearModel object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`, or a `CompactGeneralizedLinearModel` object created using `compact`.

H — Hypothesis matrix

numeric index matrix

Hypothesis matrix, specified as an r -by- s numeric index matrix, where r is the number of coefficients to include in an F -test, and s is the total number of coefficients.

- If you specify H , then the output p is the p -value for an F -test that $H \times B = 0$, where B represents the coefficient vector.
- If you specify H and C , then the output p is the p -value for an F -test that $H \times B = C$.

Example: `[1 0 0 0 0]` tests the first coefficient among five coefficients.

Data Types: `single` | `double`

C — Hypothesized value

numeric vector

Hypothesized value for testing the null hypothesis, specified as a numeric vector with the same number of rows as H .

If you specify H and C , then the output p is the p -value for an F -test that $H \times B = C$, where B represents the coefficient vector.

Data Types: `single` | `double`

Output Arguments

p — p -value for F -test

numeric value in the range $[0,1]$

p -value for the F -test, returned as a numeric value in the range $[0,1]$.

F – Value of test statistic for *F*-test

numeric value

Value of the test statistic for the *F*-test, returned as a numeric value.

r – Numerator degrees of freedom for *F*-test

positive integer

Numerator degrees of freedom for the *F*-test, returned as a positive integer. The *F*-statistic has *r* degrees of freedom in the numerator and `mdl.DFE` degrees of freedom in the denominator.

Algorithms

The *p*-value, *F*-statistic, and numerator degrees of freedom are valid under these assumptions:

- The data comes from a model represented by the formula in the `Formula` property of the fitted model.
- The observations are independent, conditional on the predictor values.

Under these assumptions, let β represent the (unknown) coefficient vector of the linear regression. Suppose H is a full-rank matrix of size *r*-by-*s*, where *r* is the number of coefficients to include in an *F*-test, and *s* is the total number of coefficients. Let c be a column vector with *r* rows. The following is a test statistic for the hypothesis that $H\beta = c$:

$$F = (H\hat{\beta} - c)'(H\hat{V}H)'^{-1}(H\hat{\beta} - c).$$

Here $\hat{\beta}$ is the estimate of the coefficient vector β , stored in the `Coefficients` property, and \hat{V} is the estimated covariance of the coefficient estimates, stored in the `CoefficientCovariance` property. When the hypothesis is true, the test statistic F has an “F Distribution” on page B-45 with *r* and *u* degrees of freedom, where *u* is the degrees of freedom for error, stored in the `DFE` property.

Alternative Functionality

The values of commonly used test statistics are available in the `Coefficients` property of a fitted model.

 “Generalized Linear Models” on page 12-9

Introduced in R2012a

coefTest

Class: GeneralizedLinearMixedModel

Hypothesis test on fixed and random effects of generalized linear mixed-effects model

Syntax

```
pVal = coefTest(glme)
pVal = coefTest(glme,H)
pVal = coefTest(glme,H,C)
pVal = coefTest(glme,H,C,Name,Value)
[pVal,F,DF1,DF2] = coefTest( ___ )
```

Description

`pVal = coefTest(glme)` returns the p -value of an F -test of the null hypothesis that all fixed-effects coefficients of the generalized linear mixed-effects model `glme`, except for the intercept, are equal to 0.

`pVal = coefTest(glme,H)` returns the p -value of an F -test using a specified contrast matrix, `H`. The null hypothesis is $H_0: H\beta = 0$, where β is the fixed-effects vector.

`pVal = coefTest(glme,H,C)` returns the p -value for an F -test using the hypothesized value, `C`. The null hypothesis is $H_0: H\beta = C$, where β is the fixed-effects vector.

`pVal = coefTest(glme,H,C,Name,Value)` returns the p -value for an F -test on the fixed- and/or random-effects coefficients of the generalized linear mixed-effects model `glme`, with additional options specified by one or more name-value pair arguments. For example, you can specify the method to compute the approximate denominator degrees of freedom for the F -test.

`[pVal,F,DF1,DF2] = coefTest(___)` also returns the F -statistic, `F`, and the numerator and denominator degrees of freedom for `F`, respectively `DF1` and `DF2`, using any of the previous syntaxes.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

H — Fixed-effects contrasts

m -by- p matrix

Fixed-effects contrasts, specified as an m -by- p matrix, where p is the number of fixed-effects coefficients in `glme`. Each row of `H` represents one contrast. The columns of `H` (left to right) correspond to the rows of the p -by-1 fixed-effects vector `beta` (top to bottom) whose estimate is returned by the `fixedEffects` method.

Data Types: single | double

C — Hypothesized value*m*-by-1 vector

Hypothesized value for testing the null hypothesis $H\beta = C$, specified as an *m*-by-1 vector. Here, β is the vector of fixed-effects whose estimate is returned by `fixedEffects`.

Data Types: `single` | `double`**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

DFMethod — Method for computing approximate degrees of freedom`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

Value	Description
<code>'residual'</code>	The degrees of freedom value is assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
<code>'none'</code>	The degrees of freedom is set to infinity.

Example: `'DFMethod', 'none'`**REContrast — Random-effects contrasts***m*-by-*q* matrix

Random-effects contrasts, specified as the comma-separated pair consisting of `'REContrast'` and an *m*-by-*q* matrix, where *q* is the number of random effects parameters in `glme`. The columns of the matrix (left to right) correspond to the rows of the *q*-by-1 random-effects vector `B` (top to bottom), whose estimate is returned by the `randomEffects` method.

Data Types: `single` | `double`**Output Arguments****pVal — *p*-value**

scalar value

p-value for the *F*-test on the fixed- and/or random-effects coefficients of the generalized linear mixed-effects model `glme`, returned as a scalar value.

When fitting a GLME model using `fitglme` and one of the maximum likelihood fit methods (`'Laplace'` or `'ApproximateLaplace'`), `coefTest` uses an approximation of the conditional mean squared error of prediction (CMSEP) of the estimated linear combination of fixed- and random-effects to compute *p*-values. This accounts for the uncertainty in the fixed-effects estimates, but not for the uncertainty in the covariance parameter estimates. For tests on fixed effects only, if you specify the `'CovarianceMethod'` name-value pair argument in `fitglme` as `'JointHessian'`, then `coefTest` accounts for the uncertainty in the estimation of covariance parameters.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REML'), `coefTest` bases the inference on the fitted linear mixed effects model from the final pseudo likelihood iteration.

F — F-statistic

scalar value

F-statistic, returned as a scalar value.

DF1 — Numerator degrees of freedom for F

scalar value

Numerator degrees of freedom for the *F*-statistic *F*, returned as a scalar value.

- If you test the null hypothesis $H_0: H\beta = 0$ or $H_0: H\beta = C$, then DF1 is equal to the number of linearly independent rows in *H*.
- If you test the null hypothesis $H_0: H\beta + KB = C$, then DF1 is equal to the number of linearly independent rows in $[H, K]$.

DF2 — Denominator degrees of freedom for F

scalar value

Denominator degrees of freedom for the *F*-statistic *F*, returned as a scalar value. The value of DF2 depends on the option specified by the 'DFMethod' name-value pair argument.

Examples

Test the Significance of Coefficients

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects intercept grouped by `factory`, to

account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglm(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', 'Di
```

Test if there is any significant difference between supplier C and supplier B.

```
H = [0,0,0,0,1,-1];
```

```
[pVal,F,DF1,DF2] = coefTest(glme,H)
```

```
pVal = 0.2793
```

```
F = 1.1842
```

```
DF1 = 1
```

```
DF2 = 94
```

The large p -value indicates that there is no significant difference between supplier C and supplier B at the 5% significance level. Here, `coefTest` also returns the F -statistic, the numerator degrees of freedom, and the approximate denominator degrees of freedom.

Test if there is any significant difference between supplier A and supplier B.

If you specify the `'DummyVarCoding'` name-value pair argument as `'effects'` when fitting the model using `fitglm`, then

$$\beta_A + \beta_B + \beta_C = 0,$$

where β_A , β_B , and β_C correspond to suppliers A, B, and C, respectively. β_A is the effect of A minus the average effect of A, B, and C. To determine the contrast matrix corresponding to a test between supplier A and supplier B,

$$\beta_B - \beta_A = \beta_B - (-\beta_B - \beta_C) = 2\beta_B + \beta_C.$$

From the output of `disp(glme)`, column 5 of the contrast matrix corresponds to β_C , and column 6 corresponds to β_B . Therefore, the contrast matrix for this test is specified as $H = [0, 0, 0, 0, 1, 2]$.

```
H = [0,0,0,0,1,2];
```

```
[pVal,F,DF1,DF2] = coefTest(glme,H)
```

```
pVal = 0.6177
```

```
F = 0.2508
```

```
DF1 = 1
```

```
DF2 = 94
```

The large p -value indicates that there is no significant difference between supplier A and supplier B at the 5% significance level.

coefTest

Package:

Linear hypothesis test on linear regression model coefficients

Syntax

```
p = coefTest mdl
p = coefTest mdl,H
p = coefTest mdl,H,C
[p,F] = coefTest( ___ )
[p,F,r] = coefTest( ___ )
```

Description

`p = coefTest(mdl)` computes the p -value for an F -test that all coefficient estimates in `mdl`, except for the intercept term, are zero.

`p = coefTest(mdl,H)` performs an F -test that $H \times B = 0$, where B represents the coefficient vector. Use H to specify the coefficients to include in the F -test.

`p = coefTest(mdl,H,C)` performs an F -test that $H \times B = C$.

`[p,F] = coefTest(___)` also returns the F -test statistic F using any of the input argument combinations in previous syntaxes.

`[p,F,r] = coefTest(___)` also returns the numerator degrees of freedom r for the test.

Examples

Test Significance of Linear Regression Model

Fit a linear regression model and test the coefficients of the fitted model to see if they are zero.

Load the `carsmall` data set and create a table in which the `Model_Year` predictor is categorical.

```
load carsmall
Model_Year = categorical(Model_Year);
tbl = table(MPG,Weight,Model_Year);
```

Fit a linear regression model of mileage as a function of the weight, weight squared, and model year.

```
mdl = fitlm(tbl,'MPG ~ Model_Year + Weight^2')
```

```
mdl =
Linear regression model:
    MPG ~ 1 + Weight + Model_Year + Weight^2
```

Estimated Coefficients:

Estimate	SE	tStat	pValue
----------	----	-------	--------

(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Model_Year_76	2.0887	0.71491	2.9215	0.0044137
Model_Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

Number of observations: 94, Error degrees of freedom: 89
 Root Mean Squared Error: 2.78
 R-squared: 0.885, Adjusted R-Squared: 0.88
 F-statistic vs. constant model: 172, p-value = 5.52e-41

The last line of the model display shows the F -statistic value of the regression model and the corresponding p -value. The small p -value indicates that the model fits significantly better than a degenerate model consisting of only an intercept term. You can return these two values by using `coefTest`.

```
[p,F] = coefTest mdl)
```

```
p = 5.5208e-41
```

```
F = 171.8844
```

Test Significance of Linear Model Coefficient

Fit a linear regression model and test the significance of a specified coefficient in the fitted model by using `coefTest`. You can also use `anova` to test the significance of each predictor in the model.

Load the `carsmall` data set and create a table in which the `Model_Year` predictor is categorical.

```
load carsmall
Model_Year = categorical(Model_Year);
tbl = table(MPG,Acceleration,Weight,Model_Year);
```

Fit a linear regression model of mileage as a function of the weight, weight squared, and model year.

```
mdl = fitlm(tbl,'MPG ~ Acceleration + Model_Year + Weight')
```

```
mdl =
Linear regression model:
MPG ~ 1 + Acceleration + Weight + Model_Year
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	40.523	2.5293	16.021	5.8302e-28
Acceleration	-0.023438	0.11353	-0.20644	0.83692
Weight	-0.0066799	0.00045796	-14.586	2.5314e-25
Model_Year_76	1.9898	0.80696	2.4657	0.015591
Model_Year_82	7.9661	0.89745	8.8763	6.7725e-14

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 2.93
 R-squared: 0.873, Adjusted R-Squared: 0.867
 F-statistic vs. constant model: 153, p-value = 5.86e-39

The model display includes the p -value for the t -statistic for each coefficient to test the null hypothesis that the corresponding coefficient is zero.

You can examine the significance of the coefficient using `coefTest`. For example, test the significance of the `Acceleration` coefficient. According to the model display, `Acceleration` is the second predictor. Specify the coefficient by using a numeric index vector.

```
[p_Acceleration,F_Acceleration,r_Acceleration] = coefTest mdl,[0 1 0 0 0])
p_Acceleration = 0.8369
F_Acceleration = 0.0426
r_Acceleration = 1
```

`p_Acceleration` is the p -value corresponding to the F -statistic value `F_Acceleration`, and `r_Acceleration` is the numerator degrees of freedom for the F -test. The returned p -value indicates that `Acceleration` is not statistically significant in the fitted model. Note that `p_Acceleration` is equal to the p -value of t -statistic (`tStat`) in the model display, and `F_Acceleration` is the square of `tStat`.

Test the significance of the categorical predictor `Model_Year`. Instead of testing `Model_Year_76` and `Model_Year_82` separately, you can perform a single test for the categorical predictor `Model_Year`. Specify `Model_Year_76` and `Model_Year_82` by using a numeric index matrix.

```
[p_Model_Year,F_Model_Year,r_Model_Year] = coefTest(mdl,[0 0 0 1 0; 0 0 0 0 1])
p_Model_Year = 2.7408e-14
F_Model_Year = 45.2691
r_Model_Year = 2
```

The returned p -value indicates that `Model_Year` is statistically significant in the fitted model.

You can also return these values by using `anova`.

```
anova(mdl)
```

```
ans=4x5 table
```

	SumSq	DF	MeanSq	F	pValue
Acceleration	0.36613	1	0.36613	0.042618	0.83692
Weight	1827.7	1	1827.7	212.75	2.5314e-25
Model_Year	777.81	2	388.9	45.269	2.7408e-14
Error	764.59	89	8.591		

Input Arguments

mdl — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a `LinearModel` object created by using `fitlm` or `stepwiselm`, or a `CompactLinearModel` object created by using `compact`.

H — Hypothesis matrix

numeric index matrix

Hypothesis matrix, specified as an r -by- s numeric index matrix, where r is the number of coefficients to include in an F -test, and s is the total number of coefficients.

- If you specify H , then the output p is the p -value for an F -test that $H \times B = 0$, where B represents the coefficient vector.
- If you specify H and C , then the output p is the p -value for an F -test that $H \times B = C$.

Example: `[1 0 0 0 0]` tests the first coefficient among five coefficients.

Data Types: `single` | `double`

C — Hypothesized value

numeric vector

Hypothesized value for testing the null hypothesis, specified as a numeric vector with the same number of rows as H .

If you specify H and C , then the output p is the p -value for an F -test that $H \times B = C$, where B represents the coefficient vector.

Data Types: `single` | `double`

Output Arguments

p — p -value for F -test

numeric value in the range $[0,1]$

p -value for the F -test, returned as a numeric value in the range $[0,1]$.

F — Value of test statistic for F -test

numeric value

Value of the test statistic for the F -test, returned as a numeric value.

r — Numerator degrees of freedom for F -test

positive integer

Numerator degrees of freedom for the F -test, returned as a positive integer. The F -statistic has r degrees of freedom in the numerator and `mdl.DFE` degrees of freedom in the denominator.

Algorithms

The p -value, F -statistic, and numerator degrees of freedom are valid under these assumptions:

- The data comes from a model represented by the formula in the `Formula` property of the fitted model.
- The observations are independent, conditional on the predictor values.

Under these assumptions, let β represent the (unknown) coefficient vector of the linear regression. Suppose H is a full-rank matrix of size r -by- s , where r is the number of coefficients to include in an F -test, and s is the total number of coefficients. Let c be a column vector with r rows. The following is a test statistic for the hypothesis that $H\beta = c$:

$$F = (H\hat{\beta} - c)'(HVH')^{-1}(H\hat{\beta} - c).$$

Here $\hat{\beta}$ is the estimate of the coefficient vector β , stored in the `Coefficients` property, and V is the estimated covariance of the coefficient estimates, stored in the `CoefficientCovariance` property. When the hypothesis is true, the test statistic F has an “F Distribution” on page B-45 with r and u degrees of freedom, where u is the degrees of freedom for error, stored in the `DFE` property.

Alternative Functionality

- The values of commonly used test statistics are available in the `Coefficients` property of a fitted model.
- `anova` provides tests for each model predictor and groups of predictors.

coefTest

Class: LinearMixedModel

Hypothesis test on fixed and random effects of linear mixed-effects model

Syntax

```
pVal = coefTest(lme)
pVal = coefTest(lme,H)
pVal = coefTest(lme,H,C)
pVal = coefTest(lme,H,C,Name,Value)
[pVal,F,DF1,DF2] = coefTest( ___ )
```

Description

`pVal = coefTest(lme)` returns the p -value for an F -test that all fixed-effects coefficients except for the intercept are 0.

`pVal = coefTest(lme,H)` returns the p -value for an F -test on fixed-effects coefficients of linear mixed-effects model `lme`, using the contrast matrix `H`. It tests the null hypothesis that $H_0: H\beta = 0$, where β is the fixed-effects vector.

`pVal = coefTest(lme,H,C)` returns the p -value for an F -test on fixed-effects coefficients of the linear mixed-effects model `lme`, using the contrast matrix `H`. It tests the null hypothesis that $H_0: H\beta = C$, where β is the fixed-effects vector.

`pVal = coefTest(lme,H,C,Name,Value)` returns the p -value for an F -test on the fixed- and/or random-effects coefficients of the linear mixed-effects model `lme`, with additional options specified by one or more name-value pair arguments. For example, 'REContrast',`K` tells `coefTest` to test the null hypothesis that $H_0: H\beta + KB = C$, where β is the fixed-effects vector and B is the random-effects vector.

`[pVal,F,DF1,DF2] = coefTest(___)` also returns the F -statistic `F`, and the numerator and denominator degrees of freedom for F , respectively `DF1` and `DF2`.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

H — Fixed-effects contrasts

m -by- p matrix

Fixed-effects contrasts, specified as an m -by- p matrix, where p is the number of fixed-effects coefficients in `lme`. Each row of `H` represents one contrast. The columns of `H` (left to right) correspond to the rows of the p -by-1 fixed-effects vector `beta` (top to bottom), returned by the `fixedEffects` method.

Data Types: `single` | `double`

C — Hypothesized value

m-by-1 vector

Hypothesized value for testing the null hypothesis $H\beta = C$, specified as an *m*-by-1 matrix. Here, `beta` is the vector of fixed-effects estimates returned by the `fixedEffects` method.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

DFMethod — Method for computing approximate denominator degrees of freedom

'residual' (default) | 'satterthwaite' | 'none'

Method for computing the approximate denominator degrees of freedom for the *F*-test, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'residual'	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'satterthwaite'	Satterthwaite approximation.
'none'	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod', 'satterthwaite'

REContrast — Random-effects contrasts

m-by-*q* matrix

Random-effects contrasts, specified as the comma-separated pair consisting of 'REContrast' and an *m*-by-*q* matrix *K*, where *q* is the number of random effects parameters in `lme`. The columns of *K* (left to right) correspond to the rows of the random-effects best linear unbiased predictor vector *B* (top to bottom), returned by the `randomEffects` method.

Data Types: `single` | `double`

Output Arguments

pVal — p-value

scalar value

p-value for the *F*-test on the fixed and/or random-effects coefficients of the linear mixed-effects model `lme`, returned as a scalar value.

F — F-statistic

scalar value

F-statistic, returned as a scalar value.

DF1 — Numerator degrees of freedom for F

scalar value

Numerator degrees of freedom for F, returned as a scalar value.

- If you test the null hypothesis $H_0: H\beta = 0$, or $H_0: H\beta = C$, then DF1 is equal to the number of linearly independent rows in H.
- If you test the null hypothesis $H_0: H\beta + KB = C$, then DF1 is equal to the number of linearly independent rows in [H, K].

DF2 — Denominator degrees of freedom for F

scalar value

Denominator degrees of freedom for F, returned as a scalar value. The value of DF2 depends on the option you select for DFMethod.

Examples**Test Fixed-Effects Coefficients for Categorical Data**

Load the sample data.

```
load('shift.mat')
```

The data shows the absolute deviations from the target quality characteristic measured from the products that five operators manufacture during three different shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if there is significant difference in the performance according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)')
```

```
lme =
Linear mixed-effects model fit by ML
```

```
Model information:
  Number of observations      15
  Fixed effects coefficients   3
  Random effects coefficients  5
  Covariance parameters       2
```

```
Formula:
  QCDev ~ 1 + Shift + (1 | Operator)
```

```
Model fit statistics:
  AIC      BIC      LogLikelihood  Deviance
  59.012   62.552   -24.506      49.012
```

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
{'(Intercept)'} }	3.1196	0.88681	3.5178	12	0.0042407
{'Shift_Morning'}	-0.3868	0.48344	-0.80009	12	0.43921
{'Shift_Night' } }	1.9856	0.48344	4.1072	12	0.0014535

Lower	Upper
1.1874	5.0518
-1.4401	0.66653
0.93227	3.0389

Random effects covariance parameters (95% CIs):

Group: Operator (5 Levels)

Name1	Name2	Type	Estimate
{'(Intercept)'} }	{'(Intercept)'} }	{'std'}	1.8297

Lower	Upper
0.94915	3.5272

Group: Error

Name	Estimate	Lower	Upper
{'Res Std'}	0.76439	0.49315	1.1848

Test if all fixed-effects coefficients except for the intercept are 0.

```
pVal = coefTest(lme)
```

```
pVal = 7.5956e-04
```

The small p -value indicates that not all fixed-effects coefficients are 0.

Test the significance of the `Shift` term using a contrast matrix.

```
H = [0 1 0; 0 0 1];
```

```
pVal = coefTest(lme,H)
```

```
pVal = 7.5956e-04
```

Test the significance of the `Shift` term using the anova method.

```
anova(lme)
```

```
ans =
```

```
ANOVA marginal tests: DFMethod = 'Residual'
```

Term	FStat	DF1	DF2	pValue
{'(Intercept)'} }	12.375	1	12	0.0042407
{'Shift' }	13.864	2	12	0.00075956

The p -value for `Shift`, 0.00075956, is the same as the p -value of the previous hypothesis test.

Test if there is any difference between the evening and morning shifts.

```
pVal = coefTest(lme,[0 1 -1])
```

```
pVal = 3.6147e-04
```

This small *p*-value indicates that the performance of the operators are not the same in the morning and the evening shifts.

Hypothesis Tests for Fixed-Effects Coefficients

Load the sample data.

```
load('weight.mat')
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)')
```

```
lme =
Linear mixed-effects model fit by ML
```

Model information:

Number of observations	120
Fixed effects coefficients	9
Random effects coefficients	40
Covariance parameters	4

Formula:

```
y ~ 1 + InitialWeight + Program*Week + (1 + Week | Subject)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
-22.981	13.257	24.49	-48.981

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF
{'(Intercept)' }	0.66105	0.25892	2.5531	111

Group: Error

Name	Estimate	Lower	Upper
{'Res Std'}	0.10261	0.087882	0.11981

Test for the significance of the interaction between Program and Week.

```
H = [0 0 0 0 0 0 1 0 0;
      0 0 0 0 0 0 0 1 0;
      0 0 0 0 0 0 0 0 1];
pVal = coefTest(lme,H)
```

```
pVal = 0.9775
```

The high p -value indicates that the interaction between Program and Week is not statistically significant.

Now, test whether all coefficients involving Program are 0.

```
H = [0 0 1 0 0 0 0 0 0;
      0 0 0 1 0 0 0 0 0;
      0 0 0 0 1 0 0 0 0;
      0 0 0 0 0 0 1 0 0;
      0 0 0 0 0 0 0 1 0;
      0 0 0 0 0 0 0 0 1];
C = [0;0;0;0;0;0];
pVal = coefTest(lme,H,C)
```

```
pVal = 0.0274
```

The p -value of 0.0274 indicates that not all coefficients involving Program are zero.

Hypothesis Tests for Fixed- and Random-Effects Coefficients

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for the region and a random intercept that varies by `Date`.

```
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)')
```

```
lme =
Linear mixed-effects model fit by ML
```

Model information:

Number of observations	468
Fixed effects coefficients	9
Random effects coefficients	52
Covariance parameters	2

Formula:

```
FluRate ~ 1 + Region + (1 | Date)
```

Model fit statistics:

Test the hypothesis that the random effects-term for week 10/9/2005 is zero.

```
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
K = zeros(length(STATS),1);
K(STATS.Level == '10/9/2005') = 1;
pVal = coefTest(lme,[0 0 0 0 0 0 0 0],0,'REContrast',K')
pVal = 0.1692
```

Refit the model this time with a random intercept and slope.

```
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1 + Region|Date)');
```

Test the hypothesis that the combined coefficient of region WNCentral for week 10/9/2005 is zero.

```
[~,~,STATS] = randomEffects(lme); STATS.Level = nominal(STATS.Level);
K = zeros(length(STATS),1);
K(STATS.Level == '10/9/2005' & flu2.Region == 'WNCentral') = 1;
pVal = coefTest(lme,[0 0 0 1 0 0 0 0],0,'REContrast',K')
pVal = 1.3417e-12
```

Also return the F -statistic with the numerator and denominator degrees of freedom.

```
[pVal,F,DF1,DF2] = coefTest(lme,[0 0 0 1 0 0 0 0],0,'REContrast',K')
pVal = 1.3417e-12
F = 53.1837
DF1 = 1
DF2 = 459
```

Repeat the test using the Satterthwaite approximation for the denominator degrees of freedom.

```
[pVal,F,DF1,DF2] = coefTest(lme,[0 0 0 1 0 0 0 0],0,'REContrast',K',...
'DFMethod','satterthwaite')
```

pVal = NaN

F = 53.1837

DF1 = 1

DF2 = 0

LinearMixedModel | anova | coefCI

coefTest

Class: NonLinearModel

Linear hypothesis test on nonlinear regression model coefficients

Syntax

```
p = coefTest mdl
p = coefTest mdl,H
p = coefTest mdl,H,C
[p,F] = coefTest mdl,...
[p,F,r] = coefTest mdl,...
```

Description

`p = coefTest(mdl)` computes the p -value for an F test that all coefficient estimates in `mdl` are zero.

`p = coefTest(mdl,H)` performs an F test that $H*B = 0$, where B represents the coefficient vector.

`p = coefTest(mdl,H,C)` performs an F test that $H*B = C$.

`[p,F] = coefTest(mdl,...)` returns the F test statistic.

`[p,F,r] = coefTest(mdl,...)` returns the numerator degrees of freedom for the test.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

H

Numeric matrix having one column for each coefficient in the model. When H is an input, the output p is the p -value for an F test that $H*B = 0$, where B represents the coefficient vector.

C

Numeric vector with the same number of rows as H . When C is an input, the output p is the p -value for an F test that $H*B = C$, where B represents the coefficient vector.

Output Arguments

p

p -value of the F test (see “More About” on page 32-620).

F

Value of the test statistic for the F test (see “More About” on page 32-620).

r

Numerator degrees of freedom for the F test (see “More About” on page 32-620). The F statistic has r degrees of freedom in the numerator and $mdl.DFE$ degrees of freedom in the denominator.

Examples

Test Nonlinear Regression Model Coefficients

Make a nonlinear model of mileage as a function of the weight from the `carsmall` data set. Test the coefficients to see if all should be zero.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Test the model for significant differences from a constant model.

```
p = coefTest(mdl)
```

```
p = 1.3708e-36
```

There is no doubt that the model contains nonzero terms.

More About

Test Statistics

The p -value, F statistic, and numerator degrees of freedom are valid under these assumptions:

- The data comes from a normal distribution.
- The entries are independent.

Suppose these assumptions hold. Let β represent the unknown coefficient vector of the linear regression. Suppose H is a full-rank matrix of size r -by- s , where s is the number of terms in β . Let c be a vector the same size as β . The following is a test statistic for the hypothesis that $H\beta = c$:

$$F = (H\hat{\beta} - c)(HVH)^{-1}(H\hat{\beta} - c).$$

Here $\hat{\beta}$ is the estimate of the coefficient vector β in `mdl.Coeffs`, and V is the estimated covariance of the coefficient estimates in `mdl.CoeffCov`. When the hypothesis is true, the test statistic F has an “F Distribution” on page B-45 with r and u degrees of freedom.

Alternatives

The values of commonly used test statistics are available in the `mdl.Coefficients` table.

coefstest

Class: RepeatedMeasuresModel

Linear hypothesis test on coefficients of repeated measures model

Syntax

```
tbl = coefstest(rm,A,C,D)
```

Description

`tbl = coefstest(rm,A,C,D)` returns a table `tbl` containing the multivariate analysis of variance (manova) for the repeated measures model `rm`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

A — Specification representing between-subjects model

a-by-*p* matrix

Specification representing the between-subjects model, specified as an *a*-by-*p* numeric matrix, with rank $a \leq p$.

Data Types: single | double

C — Specification representing within-subjects hypothesis

r-by-*c* matrix

Specification representing the within-subjects (within time) hypotheses, specified as an *r*-by-*c* numeric matrix, with rank $c \leq r \leq n - p$.

Data Types: single | double

D — Hypothesized value

0 (default) | scalar value | *a*-by-*c* matrix

Hypothesized value, specified as a scalar value or an *a*-by-*c* matrix.

Data Types: single | double

Output Arguments

tbl — Results of multivariate analysis of variance

table

Results of multivariate analysis of variance for the repeated measures model `rm`, returned as a table containing the following columns.

Statistic	Type of test statistic used
Value	Value of the corresponding test statistic
F	<i>F</i> -statistic value
RSquare	Measure of variance explained
df1	Numerator degrees of freedom for the <i>F</i> -statistic
df2	Denominator degrees of freedom for the <i>F</i> -statistic
pValue	<i>p</i> -value associated with the test statistic value

Examples

Test Coefficients for First and Last Repeated Measures

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Test that the coefficients of all terms in the between-subjects model are the same for the first and last repeated measurement variable.

```
coefstest(rm,eye(8),[1 0 0 0 0 0 0 -1])
```

```
ans=4x7 table
```

Statistic	Value	F	RSquare	df1	df2	pValue
Pillai	0.3355	1.3884	0.3355	8	22	0.25567
Wilks	0.6645	1.3884	0.3355	8	22	0.25567
Hotelling	0.50488	1.3884	0.3355	8	22	0.25567
Roy	0.50488	1.3884	0.3355	8	22	0.25567

The *p*-value of 0.25567 indicates that there is not enough statistical evidence to conclude that the coefficients of all terms in the between-subjects model for the first and last repeated measures variable are different.

Tips

- This test is defined as $A*B*C = D$, where B is the matrix of coefficients in the repeated measures model. A and C are numeric matrices of the proper size for this multiplication. D is a scalar or numeric matrix of the proper size. The default is $D = 0$.

See Also`fitrm | manova`

combine

Class: CompactTreeBagger

Combine two ensembles

Syntax

```
B1 = combine(B1,B2)
```

Description

`B1 = combine(B1,B2)` appends decision trees from ensemble B2 to those stored in B1 and returns ensemble B1. This method requires that the class and variable names be identical in both ensembles.

See Also

append

combnk

Enumeration of combinations

Syntax

```
C = combnk(v,k)
```

Description

`C = combnk(v,k)` returns a matrix containing all possible combinations of the elements of vector `v` taken `k` at a time. Matrix `C` has `k` columns and $n!/((n-k)!k!)$ rows, where `n` is the number of observations in `v`.

Examples

Combinations of Four Characters

Create a character array of every four-letter combination of the characters in the word 'tendrill'.

```
C = combnk('tendrill',4);
```

`C` is a 35-by-4 character array.

Display the last five combinations in the list.

```
last5 = C(31:35,:)
```

```
last5 = 5x4 char array
    'tedr'
    'tenl'
    'teni'
    'tenr'
    'tend'
```

Combinations of Elements from a Numeric Vector

List all two-number combinations of the numbers one through four.

```
C = combnk(1:4,2)
```

```
C = 6x2
```

```
     3     4
     2     4
     2     3
     1     4
     1     3
```

1 2

Because `1:4` is a vector of doubles, `C` is a matrix of doubles.

Input Arguments

v — Set of all elements

vector

Set of all elements, specified as a vector.

Example: `[1 2 3 4 5]`

Example: `'abcd'`

Data Types: `single` | `double` | `logical` | `char`

k — Number of selected choices

nonnegative integer scalar

Number of elements to select, specified as a nonnegative integer scalar. `k` can be any numeric type, but must be real.

There are no restrictions on combining inputs of different types for `combnk(v,k)`.

Example: `3`

Data Types: `single` | `double`

Output Arguments

C — All combinations

matrix

All combinations of `v`, returned as a matrix of the same type as `v`. `C` has `k` columns and $n! / ((n - k)! k!)$ rows, where `n` is the number of observations in `v`.

Each row of `C` contains a combination of `k` items selected from `v`. The elements in each row of `C` are listed in the same order as they appear in `v`.

If `k` is larger than `n`, then `C` is an empty matrix.

Limitations

`combnk` is practical only for situations where `v` has fewer than 15 observations.

Alternative Functionality

MATLAB contains the function `nchoosek`, which can also return all combinations of an element vector and has extended functionality using MATLAB Coder. `nchoosek` is faster than `combnk`.

See Also

`nchoosek` | `perms` | `randperm`

Introduced before R2006a

compact

Class: ClassificationDiscriminant

Compact discriminant analysis classifier

Syntax

```
cobj = compact(obj)
```

Description

`cobj = compact(obj)` creates a compact version of `obj`.

Input Arguments

obj

Discriminant analysis classifier created using `fitcdiscr`.

Output Arguments

cobj

Compact classifier. `cobj` has class `CompactClassificationDiscriminant`. You can predict classifications using `cobj` exactly as you can using `obj`. However, since `cobj` does not contain training data, you cannot perform some actions, such as cross validation.

Examples

Compare the size of the discriminant analysis classifier for Fisher's iris data to the compact version of the classifier:

```
load fisheriris
fullobj = fitcdiscr(meas,species);
cobj = compact(fullobj);
b = whos('fullobj'); % b.bytes = size of fullobj
c = whos('cobj'); % c.bytes = size of cobj
[b.bytes c.bytes] % shows cobj uses 60% of the memory
```

```
ans =
    18578    11498
```

ClassificationDiscriminant | fitcdiscr

Topics

“Discriminant Analysis Classification” on page 20-2

compact

Reduce size of multiclass error-correcting output codes (ECOC) model

Syntax

```
CompactMdl = compact(Mdl)
```

Description

`CompactMdl = compact(Mdl)` returns a compact multiclass error-correcting output codes (ECOC) model (`CompactMdl`), the compact version of the trained ECOC model `Mdl`. `CompactMdl` is a `CompactClassificationECOC` object.

`CompactMdl` does not contain the training data, whereas `Mdl` contains the training data in its `X` and `Y` properties. Therefore, although you can predict class labels using `CompactMdl`, you cannot perform tasks such as cross-validation with the compact ECOC model.

Examples

Reduce Size of Full ECOC Model

Reduce the size of a full ECOC model by removing the training data. Full ECOC models (`ClassificationECOC` models) hold the training data. To improve efficiency, use a smaller classifier.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
```

Train an ECOC model using SVM binary classifiers. Standardize the predictor data using an SVM template `t`, and specify the order of the classes. During training, the software uses default values for empty options in `t`.

```
t = templateSVM('Standardize',true);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`Mdl` is a `ClassificationECOC` model.

Reduce the size of the ECOC model.

```
CompactMdl = compact(Mdl)
```

```
CompactMdl =
  classreg.learning.classif.CompactClassificationECOC
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: [setosa    versicolor    virginica]
      ScoreTransform: 'none'
```

```
BinaryLearners: {3x1 cell}
CodingMatrix: [3x3 double]
```

Properties, Methods

`CompactMdl` is a `CompactClassificationECOC` model. `CompactMdl` does not store all of the properties that `Mdl` stores. In particular, it does not store the training data.

Display the amount of memory each classifier uses.

```
whos('CompactMdl','Mdl')
```

Name	Size	Bytes	Class
CompactMdl	1x1	14444	classreg.learning.classif.CompactClassificationECOC
Mdl	1x1	27551	ClassificationECOC

The full ECOC model (`Mdl`) is approximately double the size of the compact ECOC model (`CompactMdl`).

To label new observations efficiently, you can remove `Mdl` from the MATLAB® Workspace, and then pass `CompactMdl` and new predictor values to `predict`.

Input Arguments

Mdl — Full, trained multiclass ECOC model

`ClassificationECOC` model

Full, trained multiclass ECOC model, specified as a `ClassificationECOC` model trained with `fitcecoc`.

See Also

`ClassificationECOC` | `CompactClassificationECOC` | `fitcecoc` | `predict`

Introduced in R2014b

compact

Compact classification ensemble

Syntax

```
cens = compact(ens)
```

Description

`cens = compact(ens)` creates a compact version of `ens`. You can predict classifications using `cens` exactly as you can using `ens`. However, since `cens` does not contain training data, you cannot perform some actions, such as cross validation.

Input Arguments

ens

A classification ensemble created with `fitcensemble`.

Output Arguments

cens

A compact classification ensemble. `cens` has class `CompactClassificationEnsemble`.

Examples

View Size of Compact Classification Ensemble

Compare the size of a classification ensemble for the Fisher iris data to the compact version of the ensemble.

Load the Fisher iris data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using `AdaBoostM2`.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Create a compact version of `ens` and compare ensemble sizes.

```
cens = compact(ens);
b = whos('ens'); % b.bytes = size of ens
c = whos('cens'); % c.bytes = size of cens
[b.bytes c.bytes] % Shows cens uses less memory
```

```
ans = 1×2
```

429869

389494

The compact version of the ensemble uses less memory than the full ensemble. Note that the ensemble sizes can vary slightly, depending on your operating system.

ClassificationTree | fitcensemble

Topics

“Framework for Ensemble Learning” on page 18-30

compact

Class: ClassificationNaiveBayes

Compact naive Bayes classifier

Syntax

```
CMdl = compact(Mdl)
```

Description

`CMdl = compact(Mdl)` returns a compact naive Bayes classifier (`CMdl`), which is the compact version of the trained naive Bayes classifier `Mdl`.

`CMdl` stores less than `Mdl`, e.g., `CMdl` does not store the training data.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

Output Arguments

CMdl — Compact naive Bayes classifier

CompactClassificationNaiveBayes model

Compact naive Bayes classifier, returned as a `CompactClassificationNaiveBayes` model.

Predict class labels using `CMdl` exactly as you would using `Mdl`. However, since `CMdl` does not contain training data, you cannot perform certain tasks, such as cross validation.

Examples

Reduce the Size of Naive Bayes Classifiers

Full naive Bayes classifiers (i.e., `ClassificationNaiveBayes` models) hold the training data. For efficiency, you might not want to predict new labels using a large classifier. This example shows how to reduce the size of a full naive Bayes classifier.

Load the `ionosphere` data set.

```
load ionosphere
X = X(:,3:end); % Remove two predictors for stability
```

Train a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to specify the order of the labels.

```
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'})
```

```
Mdl =
  ClassificationNaiveBayes
      ResponseName: 'Y'
      CategoricalPredictors: []
          ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      NumObservations: 351
      DistributionNames: {1x32 cell}
      DistributionParameters: {2x32 cell}
```

Properties, Methods

Mdl is a `ClassificationNaiveBayes` model.

Reduce the size of the naive Bayes classifier.

```
CMdl = compact(Mdl)
```

```
CMdl =
  classreg.learning.classif.CompactClassificationNaiveBayes
      ResponseName: 'Y'
      CategoricalPredictors: []
          ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      DistributionNames: {1x32 cell}
      DistributionParameters: {2x32 cell}
```

Properties, Methods

CMdl is a `CompactClassificationNaiveBayes` model.

Display how much memory each classifier uses.

```
whos('Mdl','CMdl')
```

Name	Size	Bytes	Class
CMdl	1x1	14892	classreg.learning.classif.CompactClassificationNaiveBayes
Mdl	1x1	111006	ClassificationNaiveBayes

The full naive Bayes classifier (Mdl) is much larger than the compact naive Bayes classifier (CMdl).

You can remove Mdl from the MATLAB® Workspace, and pass CMdl and new predictor values to `predict` to efficiently label new observations.

compact

Reduce size of support vector machine (SVM) classifier

Syntax

```
CompactSVMModel = compact(SVMModel)
```

Description

`CompactSVMModel = compact(SVMModel)` returns a compact support vector machine (SVM) classifier (`CompactSVMModel`), the compact version of the trained SVM classifier `SVMModel`. `CompactSVMModel` is a `CompactClassificationSVM` object.

`CompactSVMModel` does not contain the training data, whereas `SVMModel` contains the training data in its `X` and `Y` properties. Therefore, although you can predict class labels using `CompactSVMModel`, you cannot perform tasks such as cross-validation with the compact SVM classifier.

Examples

Reduce Size of SVM Classifiers

Reduce the size of a full SVM classifier by removing the training data. Full SVM classifiers (that is, `ClassificationSVM` classifiers) hold the training data. To improve efficiency, use a smaller classifier.

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the predictor data and specify the order of the classes.

```
SVMModel = fitcsvm(X,Y,'Standardize',true,...
    'ClassNames',{'b','g'})
```

```
SVMModel =
    ClassificationSVM
        ResponseName: 'Y'
    CategoricalPredictors: []
            ClassNames: {'b' 'g'}
        ScoreTransform: 'none'
    NumObservations: 351
            Alpha: [90x1 double]
            Bias: -0.1343
    KernelParameters: [1x1 struct]
            Mu: [1x34 double]
            Sigma: [1x34 double]
    BoxConstraints: [351x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [351x1 logical]
        Solver: 'SMO'
```

Properties, Methods

`SVMModel` is a `ClassificationSVM` classifier.

Reduce the size of the SVM classifier.

```
CompactSVMModel = compact(SVMModel)
```

```
CompactSVMModel =
  classreg.learning.classif.CompactClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
          Alpha: [90x1 double]
          Bias: -0.1343
  KernelParameters: [1x1 struct]
      Mu: [1x34 double]
      Sigma: [1x34 double]
  SupportVectors: [90x34 double]
  SupportVectorLabels: [90x1 double]
```

Properties, Methods

`CompactSVMModel` is a `CompactClassificationSVM` classifier.

Display the amount of memory each classifier uses.

```
whos('SVMModel', 'CompactSVMModel')
```

Name	Size	Bytes	Class
CompactSVMModel	1x1	30890	classreg.learning.classif.CompactClassificationSVM
SVMModel	1x1	140980	ClassificationSVM

The full SVM classifier (`SVMModel`) is more than four times larger than the compact SVM classifier (`CompactSVMModel`).

To label new observations efficiently, you can remove `SVMModel` from the MATLAB® Workspace, and then pass `CompactSVMModel` and new predictor values to `predict`.

To further reduce the size of your compact SVM classifier, use the `discardSupportVectors` function to discard support vectors.

Input Arguments

SVMModel — Full, trained SVM classifier

`ClassificationSVM` classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained with `fitsvm`.

See Also

`ClassificationSVM` | `CompactClassificationSVM` | `discardSupportVectors` | `fitsvm`

Introduced in R2014a

compact

Class: ClassificationTree

Compact tree

Syntax

```
ctree = compact(tree)
```

Description

`ctree = compact(tree)` creates a compact version of `tree`.

Input Arguments

tree

A classification tree created using `fitctree`.

Output Arguments

ctree

A compact decision tree. `ctree` has class `CompactClassificationTree`. You can predict classifications using `ctree` exactly as you can using `tree`. However, since `ctree` does not contain training data, you cannot perform some actions, such as cross validation.

Examples

Create a Compact Classification Tree

Compare the size of the classification tree for Fisher's iris data to the compact version of the tree.

```
load fisheriris
fulltree = fitctree(meas,species);
ctree = compact(fulltree);
b = whos('fulltree'); % b.bytes = size of fulltree
c = whos('ctree'); % c.bytes = size of ctree
[b.bytes c.bytes] % shows ctree uses half the memory
```

```
ans = 1x2
```

```
11594
```

```
4929
```

See Also

[ClassificationTree](#) | [CompactClassificationTree](#) | [fitctree](#) | [predict](#)

compact

Compact linear regression model

Syntax

```
compactMdl = compact mdl
```

Description

`compactMdl = compact(mdl)` returns the compact linear regression model `compactMdl`, which is the compact version of the full, fitted linear regression model `mdl`.

Examples

Compact Linear Regression Model

Fit a linear regression model to data and reduce the size of a full, fitted linear regression model by discarding the sample data and some information related to the fitting process.

Load the `largedata4reg` data set, which contains 15,000 observations and 45 predictor variables.

```
load largedata4reg
```

Fit a linear regression model to the data.

```
mdl = fitlm(X,Y);
```

Compact the model.

```
compactMdl = compact(mdl);
```

The compact model discards the original sample data and some information related to the fitting process.

Compare the size of the full model `mdl` and the compact model `compactMdl`.

```
vars = whos('compactMdl','mdl');  
[vars(1).bytes,vars(2).bytes]
```

```
ans = 1×2
```

```
81538    11408530
```

The compact model consumes less memory than the full model.

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a `LinearModel` object created using `fitlm` or `stepwiselm`.

Output Arguments

compactMdl — Compact linear regression model

`CompactLinearModel` object

Compact linear regression model, returned as a `CompactLinearModel` object.

A `CompactLinearModel` object consumes less memory than a `LinearModel` object because a compact model does not store the input data used to fit the model or information related to the fitting process. You can still use a compact model to predict responses using new input data, but some `LinearModel` object functions do not work with a compact model.

compact

Compact generalized linear regression model

Syntax

```
compactMdl = compact mdl
```

Description

`compactMdl = compact(mdl)` returns the compact generalized linear regression model `compactMdl`, which is the compact version of the full, fitted generalized linear regression model `mdl`.

Examples

Compact Generalized Linear Regression Model

Fit a generalized linear regression model to data and reduce the size of a full, fitted model by discarding the sample data and some information related to the fitting process.

Load the `largedata4reg` data set, which contains 15,000 observations and 45 predictor variables.

```
load largedata4reg
```

Fit a generalized linear regression model to the data using the first 15 predictor variables.

```
mdl = fitglm(X(:,1:15),Y);
```

Compact the model.

```
compactMdl = compact(mdl);
```

The compact model discards the original sample data and some information related to the fitting process, so it uses less memory than the full model.

Compare the size of the full model `mdl` and the compact model `compactMdl`.

```
vars = whos('compactMdl','mdl');  
[vars(1).bytes,vars(2).bytes]
```

```
ans = 1×2
```

```
15518    4382502
```

The compact model consumes less memory than the full model.

Input Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`.

Output Arguments

compactMdl — Compact generalized linear regression model

`CompactGeneralizedLinearModel` object

Compact generalized linear regression model, returned as a `CompactGeneralizedLinearModel` object.

A `CompactGeneralizedLinearModel` object consumes less memory than a `GeneralizedLinearModel` object because a compact model does not store the input data used to fit the model or information related to the fitting process. You can still use a compact model to predict responses using new input data, but some `GeneralizedLinearModel` object functions that require the input data do not work with a compact model.

`CompactGeneralizedLinearModel` | `GeneralizedLinearModel` | `fitglm` | `stepwiseglm`

Introduced in R2016b

compact

Create compact regression ensemble

Syntax

```
cens = compact(ens)
```

Description

`cens = compact(ens)` creates a compact version of `ens`. You can predict regressions using `cens` exactly as you can using `ens`. However, since `cens` does not contain training data, you cannot perform some actions, such as cross validation.

Input Arguments

ens

A regression ensemble created with `fitrensemble`.

Output Arguments

cens

A compact regression ensemble. `cens` is of class `CompactRegressionEnsemble`.

Examples

View Size of Compact Regression Ensemble

Compare the size of a regression ensemble for the `carsmall` data to the size of the compact version of the ensemble.

Load the `carsmall` data set and select acceleration, number of cylinders, displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Acceleration Cylinders Displacement Horsepower Weight];
```

Train an ensemble of regression trees.

```
ens = fitrensemble(X,MPG);
```

Create a compact version of `ens` and compare ensemble sizes.

```
cens = compact(ens);
b = whos('ens');
c = whos('cens');
[b.bytes c.bytes] % b.bytes = size of ens and c.bytes = size of cens

ans = 1×2
```

466319

434511

The compact ensemble uses less memory.

[CompactRegressionEnsemble](#) | [RegressionEnsemble](#)

compact

Class: RegressionGP

Create compact Gaussian process regression model

Syntax

```
cgprMdl = compact(gprMdl)
```

Description

`cgprMdl = compact(gprMdl)` returns a compact version of the trained Gaussian process regression (GPR) model, `gprMdl`.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object

Gaussian process regression model, specified as a RegressionGP object.

Output Arguments

cgprMdl — Compact Gaussian process regression model

CompactRegressionGP object

Compact Gaussian process regression model, returned as a CompactRegressionGP object.

Examples

Compute Predictions and Regression Loss for Test Data

Generate example training data.

```
rng(1) % For reproducibility
n = 100000;
X = linspace(0,1,n)';
X = [X,X.^2];
y = 1 + X*[1;2] + sin(20*X*[1;-2]) + 0.2*randn(n,1);
```

Train a GPR model using the subset of regressors ('sr') approximation method and predict using the subset of data ('sd') method. Use 50 points in the active set and sparse greedy matrix approximation ('sigma') method for active set selection. Because the scales of the first and second predictors are different, it is good practice to standardize the data.

```
gprMdl = fitrgp(X,y,'KernelFunction','squaredExponential','FitMethod',...
'sr','PredictMethod','sd','Basis','none','ActiveSetSize',50,...
'ActiveSetMethod','sigma','Standardize',1,'KernelParameters',[1;1]);
```

`fitrgp` accepts any combination of fitting, prediction, and active set selection methods. In some cases it might not be possible to compute the standard deviations of the predicted responses, hence the prediction intervals. See “Tips” on page 32-648. And, in some cases, using the exact method might be expensive because of the size of the training data.

Create a compact GPR object.

```
cgprMdl = compact(gprMdl);
```

Generate the test data.

```
n = 4000;  
Xnew = linspace(0,1,n)';  
Xnew = [Xnew,Xnew.^2];  
ynew = 1 + Xnew*[1;2] + sin(20*Xnew*[1;-2]) + 0.2*randn(n,1);
```

Use the compact object to predict the response in test data and the prediction intervals.

```
[ypred,~,yci] = predict(cgprMdl,Xnew);
```

Plot the true response, predicted response, and prediction intervals.

```
figure;  
plot(ynew,'r');  
hold on;  
plot(ypred,'b')  
plot(yci(:,1),'k--');  
plot(yci(:,2),'k--');  
legend('Data','Pred','Lower 95%','Upper 95%','Location','Best');  
xlabel('x');  
ylabel('y');  
hold off
```

Compute the mean squared error loss on the test data using the trained GPR model.

```
L = loss(cgprMdl, Xnew, ynew)
```

```
L = 0.0497
```

Tips

- The compact object does not contain the training data that `fitrgp` uses in training the GPR model, `gprMdl`.
- You can use the compact object to make predictions (see `predict`) or compute the regression error (see `loss`).
- Computation of standard deviations, `ysd`, and prediction intervals, `yint`, is not supported when `PredictMethod` is `'bcd'`.
- If `gprMdl` is a `CompactRegressionGP` object, you cannot compute standard deviations, `ysd`, or prediction intervals, `yint`, for `PredictMethod` equal to `'sr'` or `'fic'`. To compute `ysd` and `yint` for `PredictMethod` equal to `'sr'` or `'fic'`, use the full regression (`RegressionGP`) object.

`CompactRegressionGP` | `fitrgp` | `loss` | `predict`

Introduced in R2015b

compact

Class: RegressionSVM

Compact support vector machine regression model

Syntax

```
compactMdl = compact mdl
```

Description

`compactMdl = compact(mdl)` returns a compact support vector machine (SVM) regression model, `compactMdl`, which is the compact version of the full, trained SVM regression model `mdl`.

`compactMdl` does not contain the training data, whereas `mdl` contains the training data in its properties `mdl.X` and `mdl.Y`.

Input Arguments

mdl — Full, trained SVM regression model

RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model returned by `fitrsvm`.

Output Arguments

compactMdl — Compact SVM regression model

CompactRegressionSVM model

Compact SVM regression model, returned as a CompactRegressionSVM model.

Predict response values using `compactMdl` exactly as you would using `mdl`. However, since `compactMdl` does not contain training data, you cannot perform certain tasks, such as cross validation.

Examples

Compact an SVM Regression Model

This example shows how to reduce the size of a full, trained SVM regression model by discarding the training data and some information related to the training process.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name 'abalone.data'. Read the data into a table.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);  
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model using a Gaussian kernel function and an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 'auto', 'Standardize', true)
```

```
mdl =
```

```
RegressionSVM
  PredictorNames: {1x8 cell}
  ResponseName: 'Var9'
  CategoricalPredictors: 1
  ResponseTransform: 'none'
  Alpha: [3635x1 double]
  Bias: 10.8144
  KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
  NumObservations: 4177
  BoxConstraints: [4177x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [4177x1 logical]
  Solver: 'SMO'
```

Properties, Methods

Compact the model.

```
compactMdl = compact(mdl)
```

```
compactMdl =
```

```
classreg.learning.regr.CompactRegressionSVM
  PredictorNames: {1x8 cell}
  ResponseName: 'Var9'
  CategoricalPredictors: 1
  ResponseTransform: 'none'
  Alpha: [3635x1 double]
  Bias: 10.8144
  KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
  SupportVectors: [3635x10 double]
```

Properties, Methods

The compacted model discards the training data and some information related to the training process.

Compare the size of the full model `mdl` and the compact model `compactMdl`.

```
vars = whos('compactMdl', 'mdl');
[vars(1).bytes, vars(2).bytes]
```

```
ans =
    323793    775968
```

The compacted model consumes about half the memory of the full model.

Reduce Memory Consumption of SVM Regression Model

This example shows how to reduce the memory consumption of a full, trained SVM regression model by compacting the model and discarding the support vectors.

Load the `carsmall` sample data.

```
load carsmall
rng default % for reproducibility
```

Train a linear SVM regression model using `Weight` as the predictor variable and `MPG` as the response variable. Standardize the data.

```
mdl = fitrsvm(Weight,MPG,'Standardize',true);
```

Note that `MPG` contains several NaN values. When training a model, `fitrsvm` will remove rows that contain NaN values from both the predictor and response data. As a result, the trained model uses only 94 of the 100 total observations contained in the sample data.

Compact the regression model to discard the training data and some information related to the training process.

```
compactMdl = compact(mdl);
```

`compactMdl` is a `CompactRegressionSVM` model that has the same parameters, support vectors, and related estimates as `mdl`, but no longer stores the training data.

Discard the support vectors and related estimates for the compacted model.

```
mdlOut = discardSupportVectors(compactMdl);
```

`mdlOut` is a `CompactRegressionSVM` model that has the same parameters as `mdl` and `compactMdl`, but no longer stores the support vectors and related estimates.

Compare the sizes of the three SVM regression models, `compactMdl`, `mdl`, and `mdlOut`.

```
vars = whos('compactMdl','mdl','mdlOut');
[vars(1).bytes,vars(2).bytes,vars(3).bytes]
```

```
ans =
    3601    13727    2305
```

The compacted model `compactMdl` consumes 3601 bytes of memory, while the full model `mdl` consumes 13727 bytes of memory. The model `mdlOut`, which also discards the support vectors, consumes 2305 bytes of memory.

`CompactRegressionSVM` | `RegressionSVM` | `fitrsvm`

Introduced in R2015b

compact

Class: RegressionTree

Compact regression tree

Syntax

```
ctree = compact(tree)
```

Description

`ctree = compact(tree)` creates a compact version of `tree`.

Input Arguments

tree

A regression tree created using `fitrtree`.

Output Arguments

ctree

A compact regression tree. `ctree` has class `CompactRegressionTree`. You can predict regressions using `ctree` exactly as you can using `tree`. However, since `ctree` does not contain training data, you cannot perform some actions, such as cross validation.

Examples

Reduce Memory Consumption of Regression Tree Model

Compare the size of a full regression tree model to the compacted model.

Load the `carsmall` data set. Consider Acceleration, Displacement, Horsepower, and Weight as predictor variables.

```
load carsmall
X = [Acceleration Cylinders Displacement Horsepower Weight];
```

Grow a regression tree using the entire data set.

```
Mdl = fitrtree(X,MPG)

Mdl =
  RegressionTree
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
      NumObservations: 94
```

Properties, Methods

`Mdl` is a `RegressionTree` model. It is a full model, that is, it stores information such as the predictor and response data `fitrtree` used in training. For a properties list of full regression tree models, see `RegressionTree`.

Create a compact version of the full regression tree. That is, one that contains enough information to make predictions only.

```
CMdl = compact(Mdl)
```

```
CMdl =
  classreg.learning.regr.CompactRegressionTree
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
```

Properties, Methods

`CMdl` is a `CompactRegressionTree` model. For a properties list of compact regression tree models, see `CompactRegressionTree`.

Inspect the amounts of memory that the full and compact regression trees consume.

```
mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]
```

```
ans = 1×2
```

```
12233    6730
```

```
cMdlInfo.bytes/mdlInfo.bytes
```

```
ans = 0.5502
```

In this case, the compact regression tree model consumes about 25% less memory than the full model consumes.

`CompactRegressionTree` | `RegressionTree` | `fitrtree` | `predict`

compact

Class: TreeBagger

Compact ensemble of decision trees

Description

`CMdl = compact(Mdl)` creates a compact version of `Mdl`, a `TreeBagger` model object. You can predict regressions using `CMdl` exactly as you can using `Mdl`. However, since `CMdl` does not contain training data, you cannot perform some actions, such as make out-of-bag predictions using `oobPredict`.

Input Arguments

Mdl

A regression ensemble created with `TreeBagger`.

Output Arguments

CMdl

A compact regression ensemble. `CMdl` is of class `CompactTreeBagger`.

Examples

Reduce Size of Bag of Trees

Create a compact bag of trees for efficiently making predictions on new data.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a bag of 100 classification trees using all measurements and the `AdaBoostM1` method.

```
Mdl = TreeBagger(100,X,Y,'Method','classification')
```

```
Mdl =
```

```
TreeBagger
```

```
Ensemble with 100 bagged decision trees:
```

```
      Training X:      [351x34]
      Training Y:      [351x1]
      Method:          classification
      NumPredictors:    34
      NumPredictorsToSample: 6
      MinLeafSize:      1
      InBagFraction:    1
      SampleWithReplacement: 1
      ComputeOOBPrediction: 0
```

```

Compute00BPredictorImportance:      0
      Proximity:                    []
      ClassNames:                    'b'      'g'

```

Properties, Methods

`Mdl` is a `TreeBagger` model object that contains the training data, among other things.

Create a compact version of `Mdl`.

```
CMdl = compact(Mdl)
```

```

CMdl =
  CompactTreeBagger
Ensemble with 100 bagged decision trees:
      Method:      classification
  NumPredictors:      34
  ClassNames: 'b' 'g'

```

Properties, Methods

`CMdl` is a `CompactTreeBagger` model object. `CMdl` is almost the same as `Mdl`. One exception is that it does not store the training data.

Compare the amounts of space consumed by `Mdl` and `CMdl`.

```

mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]

```

```
ans = 1x2
```

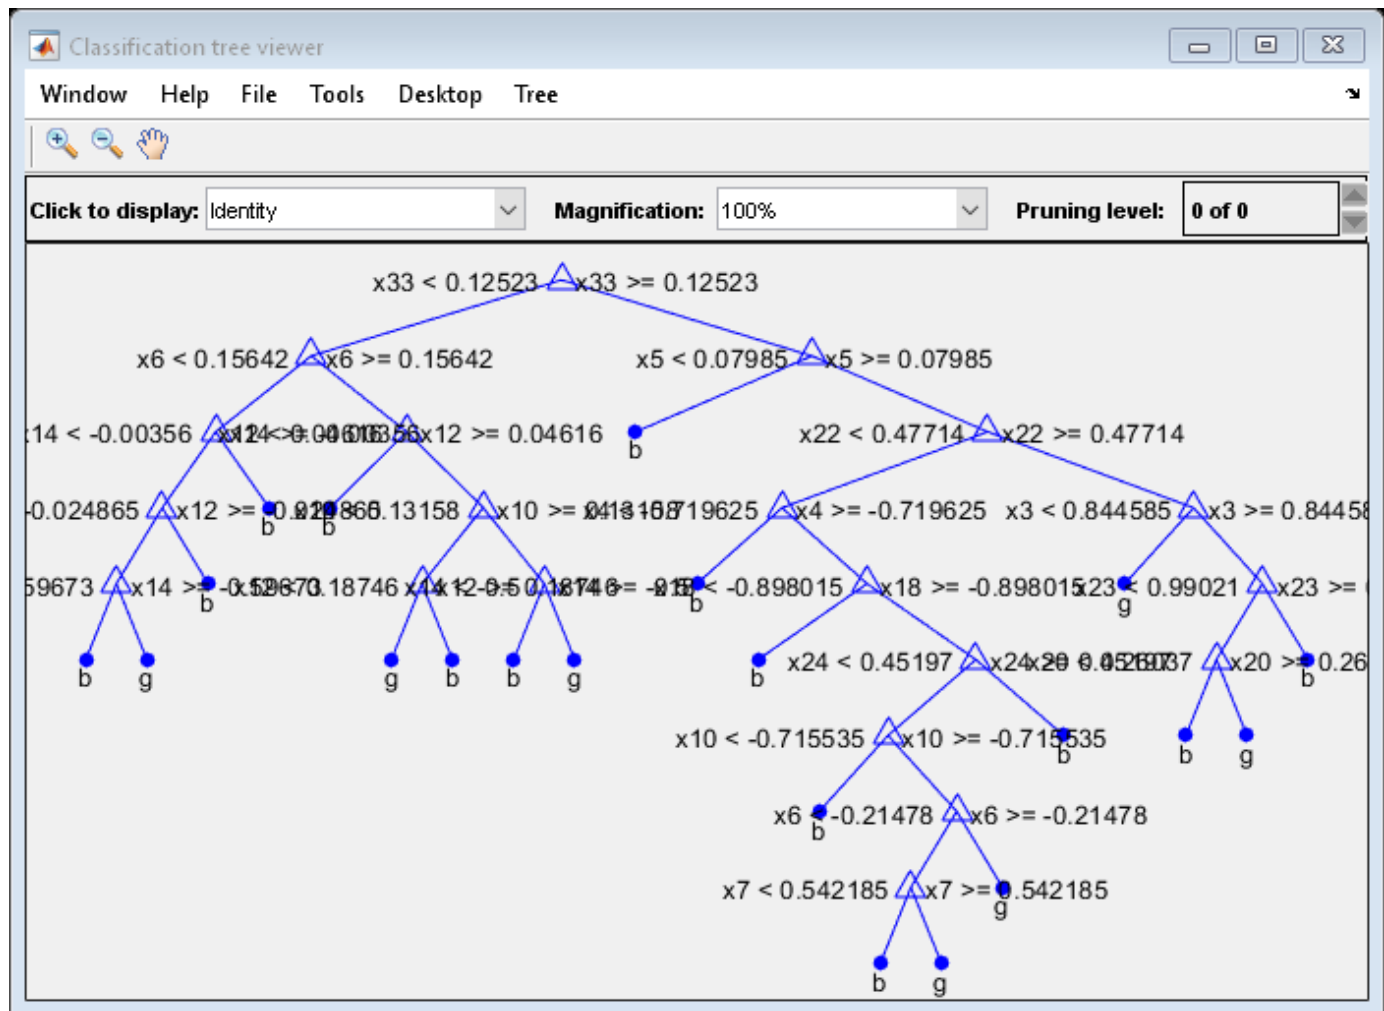

```
    1069822    931016
```

`Mdl` consumes more space than `CMdl`.

`CMdl.Trees` stores the trained classification trees (`CompactClassificationTree` model objects) that compose `Mdl`.

Display a graph of the first tree in the compact model.

```
view(CMdl.Trees{1}, 'Mode', 'graph');
```

By default, TreeBagger grows deep trees.

Predict the label of the mean of X using the compact ensemble.

```
predMeanX = predict(CMdl,mean(X))
```

```
predMeanX = 1x1 cell array
    {'g'}
```

“Bootstrap Aggregation (Bagging) of Classification Trees Using TreeBagger” on page 18-119

CompactClassificationDiscriminant

Package: `classreg.learning.classif`

Compact discriminant analysis class

Description

A `CompactClassificationDiscriminant` object is a compact version of a discriminant analysis classifier. The compact version does not include the data for training the classifier. Therefore, you cannot perform some tasks with a compact classifier, such as cross validation. Use a compact classifier for making predictions (classifications) of new data.

Construction

`cobj = compact(obj)` constructs a compact classifier from a full classifier.

`cobj = makecdiscr(Mu, Sigma)` constructs a compact discriminant analysis classifier from the class means `Mu` and covariance matrix `Sigma`. For syntax details, see `makecdiscr`.

Input Arguments

obj

Discriminant analysis classifier, created using `fitcdiscr`.

Properties

BetweenSigma

p-by-p matrix, the between-class covariance, where p is the number of predictors.

CategoricalPredictors

Categorical predictor indices, which is always empty (`[]`).

ClassNames

List of the elements in the training data `Y` with duplicates removed. `ClassNames` can be a categorical array, cell array of character vectors, character array, logical vector, or a numeric vector.

`ClassNames` has the same data type as the data in the argument `Y`. (The software treats string arrays as cell arrays of character vectors.)

Coeffs

k-by-k structure of coefficient matrices, where k is the number of classes. `Coeffs(i, j)` contains coefficients of the linear or quadratic boundaries between classes `i` and `j`. Fields in `Coeffs(i, j)`:

- `DiscrimType`
- `Class1 — ClassNames(i)`

- `Class2` — `ClassNames(j)`
- `Const` — A scalar
- `Linear` — A vector with `p` components, where `p` is the number of columns in `X`
- `Quadratic` — `p`-by-`p` matrix, exists for quadratic `DiscrimType`

The equation of the boundary between class `i` and class `j` is

$$\text{Const} + \text{Linear} * x + x' * \text{Quadratic} * x = 0,$$

where `x` is a column vector of length `p`.

If `fitcdiscr` had the `FillCoeffs` name-value pair set to `'off'` when constructing the classifier, `Coeffs` is empty (`[]`).

Cost

Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response.

Change a `Cost` matrix using dot notation: `obj.Cost = costMatrix`.

Delta

Value of the Delta threshold for a linear discriminant model, a nonnegative scalar. If a coefficient of `obj` has magnitude smaller than `Delta`, `obj` sets this coefficient to `0`, and so you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be `0` for quadratic discriminant models.

Change `Delta` using dot notation: `obj.Delta = newDelta`.

DeltaPredictor

Row vector of length equal to the number of predictors in `obj`. If `DeltaPredictor(i) < Delta` then coefficient `i` of the model is `0`.

If `obj` is a quadratic discriminant model, all elements of `DeltaPredictor` are `0`.

DiscrimType

Character vector specifying the discriminant type. One of:

- `'linear'`
- `'quadratic'`
- `'diagLinear'`
- `'diagQuadratic'`
- `'pseudoLinear'`
- `'pseudoQuadratic'`

Change `DiscrimType` using dot notation: `obj.DiscrimType = newDiscrimType`.

You can change between linear types, or between quadratic types, but cannot change between linear and quadratic types.

Gamma

Value of the Gamma regularization parameter, a scalar from 0 to 1. Change Gamma using dot notation: `obj.Gamma = newGamma`.

- If you set 1 for linear discriminant, the discriminant sets its type to 'diagLinear'.
- If you set a value between MinGamma and 1 for linear discriminant, the discriminant sets its type to 'linear'.
- You cannot set values below the value of the MinGamma property.
- For quadratic discriminant, you can set either 0 (for DiscrimType 'quadratic') or 1 (for DiscrimType 'diagQuadratic').

LogDetSigma

Logarithm of the determinant of the within-class covariance matrix. The type of LogDetSigma depends on the discriminant type:

- Scalar for linear discriminant analysis
- Vector of length K for quadratic discriminant analysis, where K is the number of classes

MinGamma

Nonnegative scalar, the minimal value of the Gamma parameter so that the correlation matrix is invertible. If the correlation matrix is not singular, MinGamma is 0.

Mu

Class means, specified as a K-by-p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of Mu represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the ClassNames attribute.

PredictorNames

Cell array of names for the predictor variables, in the order in which they appear in the training data X.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of Prior corresponds to the order of the classes in ClassNames.

Add or change a Prior vector using dot notation: `obj.Prior = priorVector`.

ResponseName

Character vector describing the response variable Y.

ScoreTransform

Character vector representing a built-in transformation function, or a function handle for transforming scores. 'none' means no transformation; equivalently, 'none' means $@(x)x$. For a list

of built-in transformation functions and the syntax of custom transformation functions, see `fitcdiscr`.

Implement dot notation to add or change a `ScoreTransform` function using one of the following:

- `cobj.ScoreTransform = 'function'`
- `cobj.ScoreTransform = @function`

Sigma

Within-class covariance matrix or matrices. The dimensions depend on `DiscrimType`:

- `'linear'` (default) — Matrix of size p -by- p , where p is the number of predictors
- `'quadratic'` — Array of size p -by- p -by- K , where K is the number of classes
- `'diagLinear'` — Row vector of length p
- `'diagQuadratic'` — Array of size 1 -by- p -by- K
- `'pseudoLinear'` — Matrix of size p -by- p
- `'pseudoQuadratic'` — Array of size p -by- p -by- K

Methods

<code>edge</code>	Classification edge
<code>logP</code>	Log unconditional probability density for discriminant analysis classifier
<code>loss</code>	Classification error
<code>mahal</code>	Mahalanobis distance to class means
<code>margin</code>	Classification margins
<code>nLinearCoeffs</code>	Number of nonzero linear coefficients
<code>predict</code>	Predict labels using discriminant analysis classification model

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Construct a Compact Discriminant Analysis Classifier

Load the sample data.

```
load fisheriris
```

Construct a discriminant analysis classifier for the sample data.

```
fullobj = fitcdiscr(meas,species);
```

Construct a compact discriminant analysis classifier, and compare its size to that of the full classifier.

```
cobj = compact(fullobj);
b = whos('fullobj'); % b.bytes = size of fullobj
```

```

c = whos('cobj'); % c.bytes = size of cobj
[b.bytes c.bytes] % shows cobj uses 60% of the memory

ans = 1x2

      18123      11510

```

The compact classifier is smaller than the full classifier.

Construct Classifier Using Means and Covariances

Construct a compact discriminant analysis classifier from the means and covariances of the Fisher iris data.

```

load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147;
cpct = makecdiscr(mu,sigstar,...
    'ClassNames',{'setosa','versicolor','virginica'});

```

More About

Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).
 - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
 - For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \underset{y=1, \dots, K}{\operatorname{argmin}} \sum_{k=1}^K \hat{P}(k|x)C(y|k),$$

where

- \hat{y} is the predicted classification.

- K is the number of classes.
- $\widehat{P}(k|x)$ is the posterior probability on page 20-6 of class k for observation x .
- $C(y|k)$ is the cost on page 20-7 of classifying an observation as y when its true class is k .

For details, see “Prediction Using Discriminant Analysis Models” on page 20-6.

Regularization

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, γ and δ , that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let Σ represent the covariance matrix of the data X , and let \widehat{X} be the centered data (the data X minus the mean by class). Define

$$D = \text{diag}(\widehat{X}^T * \widehat{X}).$$

The regularized covariance matrix $\widetilde{\Sigma}$ is

$$\widetilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq \text{MinGamma}$, $\widetilde{\Sigma}$ is nonsingular.

Let μ_k be the mean vector for those elements of X in class k , and let μ_0 be the global mean vector (the mean of the rows of X). Let C be the correlation matrix of the data X , and let \widetilde{C} be the regularized correlation matrix:

$$\widetilde{C} = (1 - \gamma)C + \gamma I,$$

where I is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point x is

$$(x - \mu_0)^T \widetilde{\Sigma}^{-1} (\mu_k - \mu_0) = [(x - \mu_0)^T D^{-1/2}] [\widetilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)].$$

The parameter δ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $[\widetilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)]$ is set to zero if it is smaller in magnitude than the threshold δ . Therefore, for class k , if component j is thresholded to zero, component j of x does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(i)$, all classes k have

$$|\widetilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)| \leq \delta.$$

Therefore, when $\delta \geq \text{DeltaPredictor}(i)$, the regularized classifier does not use predictor i .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train a discriminant analysis model by using `fitcdiscr` or create a compact discriminant analysis model by using `makecdiscr`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
 - The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

“Discriminant Analysis Classification” on page 20-2

Introduced in R2011b

CompactClassificationECOC

Compact multiclass model for support vector machines (SVMs) and other classifiers

Description

`CompactClassificationECOC` is a compact version of the multiclass error-correcting output codes (ECOC) model. The compact classifier does not include the data used for training the multiclass ECOC model. Therefore, you cannot perform certain tasks, such as cross-validation, using the compact classifier. Use a compact multiclass ECOC model for tasks such as classifying new data (`predict`).

Creation

You can create a `CompactClassificationECOC` model in two ways:

- Create a compact ECOC model from a trained `ClassificationECOC` model by using the `compact` object function.
- Create a compact ECOC model by using the `fitcecoc` function and specifying the 'Learners' name-value pair argument as 'linear', 'kernel', a `templateLinear` or `templateKernel` object, or a cell array of such objects.

Properties

After you create a `CompactClassificationECOC` model object, you can use dot notation to access its properties. For an example, see “Train and Cross-Validate ECOC Classifier” on page 32-671.

ECOC Properties

BinaryLearners — Trained binary learners

cell vector of model objects

Trained binary learners, specified as a cell vector of model objects. The number of binary learners depends on the number of classes in Y and the coding design.

The software trains `BinaryLearner{j}` according to the binary problem specified by `CodingMatrix(:,j)`. For example, for multiclass learning using SVM learners, each element of `BinaryLearners` is a `CompactClassificationSVM` classifier.

Data Types: `cell`

BinaryLoss — Binary learner loss function

'binodeviance' | 'exponential' | 'hamming' | 'hinge' | 'linear' | 'logit' | 'quadratic'

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets `BinaryLoss` to 'hamming'. To potentially increase accuracy, specify a binary loss function other than the default during a prediction or loss computation by using the 'BinaryLoss' name-value pair argument of `predict` or `loss`.

Data Types: char

CodingMatrix — Class assignment codes

numeric matrix

Class assignment codes for the binary learners, specified as a numeric matrix. `CodingMatrix` is a K -by- L matrix, where K is the number of classes and L is the number of binary learners.

The elements of `CodingMatrix` are -1 , 0 , or 1 , and the values correspond to dichotomous class assignments. This table describes how learner j assigns observations in class i to a dichotomous class corresponding to the value of `CodingMatrix(i, j)`.

Value	Dichotomous Class Assignment
-1	Learner j assigns observations in class i to a negative class.
0	Before training, learner j removes observations in class i from the data set.
1	Learner j assigns observations in class i to a positive class.

Data Types: double | single | int8 | int16 | int32 | int64

LearnerWeights — Binary learner weights

numeric row vector

Binary learner weights, specified as a numeric row vector. The length of `LearnerWeights` is equal to the number of binary learners (`length(Mdl.BinaryLearners)`).

`LearnerWeights(j)` is the sum of the observation weights that binary learner j uses to train its classifier.

The software uses `LearnerWeights` to fit posterior probabilities by minimizing the Kullback-Leibler divergence. The software ignores `LearnerWeights` when it uses the quadratic programming method of estimating posterior probabilities.

Data Types: double | single

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

vector of positive integers | []

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: single | double

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels Y . (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data X , specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in X .

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as the number of classes in `ClassNames`, and the order of the elements corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

ScoreTransform — Score transformation function to apply to predicted scores

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter this code and replace *function* with a value in the table.

```
Mdl.ScoreTransform = 'function';
```

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

Object Functions

compareHoldout	Compare accuracies of two classification models using new data
discardSupportVectors	Discard support vectors of linear SVM binary learners in ECOC model
edge	Classification edge for multiclass error-correcting output codes (ECOC) model
loss	Classification loss for multiclass error-correcting output codes (ECOC) model
margin	Classification margins for multiclass error-correcting output codes (ECOC) model
predict	Classify observations using multiclass error-correcting output codes (ECOC) model
selectModels	Choose subset of multiclass ECOC models composed of binary ClassificationLinear learners
update	Update model parameters for code generation

Examples

Reduce Size of Full ECOC Model

Reduce the size of a full ECOC model by removing the training data. Full ECOC models (`ClassificationECOC` models) hold the training data. To improve efficiency, use a smaller classifier.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
```

Train an ECOC model using SVM binary classifiers. Standardize the predictor data using an SVM template `t`, and specify the order of the classes. During training, the software uses default values for empty options in `t`.

```
t = templateSVM('Standardize',true);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`Mdl` is a `ClassificationECOC` model.

Reduce the size of the ECOC model.

```
CompactMdl = compact(Mdl)
```

```
CompactMdl =
  classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
  CategoricalPredictors: []
        ClassNames: [setosa   versicolor   virginica]
    ScoreTransform: 'none'
  BinaryLearners: {3x1 cell}
    CodingMatrix: [3x3 double]
```

Properties, Methods

`CompactMdl` is a `CompactClassificationECOC` model. `CompactMdl` does not store all of the properties that `Mdl` stores. In particular, it does not store the training data.

Display the amount of memory each classifier uses.

```
whos('CompactMdl','Mdl')
```

Name	Size	Bytes	Class
CompactMdl	1x1	14444	classreg.learning.classif.CompactClassificationECOC
Mdl	1x1	27551	ClassificationECOC

The full ECOC model (`Mdl`) is approximately double the size of the compact ECOC model (`CompactMdl`).

To label new observations efficiently, you can remove `Mdl` from the MATLAB® Workspace, and then pass `CompactMdl` and new predictor values to `predict`.

Train and Cross-Validate ECOC Classifier

Train and cross-validate an ECOC classifier using different binary learners and the one-versus-all coding design.

Load Fisher's iris data set. Specify the predictor data X and the response data Y . Determine the class names and the number of classes.

```
load fisheriris
X = meas;
Y = species;
classNames = unique(species(~strcmp(species, ''))) % Remove empty classes

classNames = 3x1 cell
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
K = numel(classNames) % Number of classes
```

```
K = 3
```

You can use `classNames` to specify the order of the classes during training.

For a one-versus-all coding design, this example has $K = 3$ binary learners. Specify templates for the binary learners such that:

- Binary learner 1 and 2 are naive Bayes classifiers. By default, each predictor is conditionally, normally distributed given its label.
- Binary learner 3 is an SVM classifier. Specify to use the Gaussian kernel.

```
rng(1); % For reproducibility
tNB = templateNaiveBayes();
tSVM = templateSVM('KernelFunction','gaussian');
tLearners = {tNB tNB tSVM};
```

`tNB` and `tSVM` are template objects for naive Bayes and SVM learning, respectively. The objects indicate which options to use during training. Most of their properties are empty, except those specified by name-value pair arguments. During training, the software fills in the empty properties with their default values.

Train and cross-validate an ECOC classifier using the binary learner templates and the one-versus-all coding design. Specify the order of the classes. By default, naive Bayes classifiers use posterior probabilities as scores, whereas SVM classifiers use distances from the decision boundary. Therefore, to aggregate the binary learners, you must specify to fit posterior probabilities.

```
CVMdl = fitcecoc(X,Y,'ClassNames',classNames,'CrossVal','on',...
    'Learners',tLearners,'FitPosterior',true);
```

`CVMdl` is a `ClassificationPartitionedECOC` cross-validated model. By default, the software implements 10-fold cross-validation. The scores across the binary learners have the same form (that is, they are posterior probabilities), so the software can aggregate the results of the binary classifications properly.

Inspect one of the trained folds using dot notation.

```
CVMdl.Trained{1}
```

```
ans =
  classreg.learning.classif.CompactClassificationECOC
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  BinaryLearners: {3x1 cell}
  CodingMatrix: [3x3 double]
```

Properties, Methods

Each fold is a `CompactClassificationECOC` model trained on 90% of the data.

You can access the results of the binary learners using dot notation and cell indexing. Display the trained SVM classifier (the third binary learner) in the first fold.

```
CVMdl.Trained{1}.BinaryLearners{3}
```

```
ans =
  classreg.learning.classif.CompactClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: [-1 1]
  ScoreTransform: '@(S)sigmoid(S,-4.016609e+00,-3.242911e-01)'
      Alpha: [33x1 double]
      Bias: -0.1346
  KernelParameters: [1x1 struct]
  SupportVectors: [33x4 double]
  SupportVectorLabels: [33x1 double]
```

Properties, Methods

Estimate the generalization error.

```
genError = kfoldLoss(CVMdl)
```

```
genError = 0.0333
```

On average, the generalization error is approximately 3%.

Algorithms

Random Coding Design Matrices

For a given number of classes K , the software generates random coding design matrices as follows.

- 1 The software generates one of these matrices:

- a Dense random — The software assigns 1 or -1 with equal probability to each element of the K -by- L_d coding design matrix, where $L_d \approx \lceil 10 \log_2 K \rceil$.
 - b Sparse random — The software assigns 1 to each element of the K -by- L_s coding design matrix with probability 0.25, -1 with probability 0.25, and 0 with probability 0.5, where $L_s \approx \lceil 15 \log_2 K \rceil$.
- 2 If a column does not contain at least one 1 and at least one -1, then the software removes that column.
 - 3 For distinct columns u and v , if $u = v$ or $u = -v$, then the software removes v from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal, pairwise row distance based on the Hamming measure ([4]) given by

$$\Delta(k_1, k_2) = 0.5 \sum_{l=1}^L |m_{k_1 l}| |m_{k_2 l}| |m_{k_1 l} - m_{k_2 l}|,$$

where $m_{k,l}$ is an element of coding design matrix j .

Support Vector Storage

By default and for efficiency, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties for all linear SVM binary learners. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors', true)
Mdl = fitcecoc(X, Y, 'Learners', t);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train an ECOC model by using `fitcecoc`, the following restrictions apply.

- You cannot fit posterior probabilities by using the 'FitPosterior' name-value pair argument.
- All binary learners must be either SVM classifiers or linear classification models. For the 'Learners' name-value pair argument, you can specify:
 - 'svm' or 'linear'
 - An SVM template object or a cell array of such objects (see `templateSVM`)
 - A linear classification model template object or a cell array of such objects (see `templateLinear`)
- When you generate code using a coder configurer for `predict` and `update`, the following additional restrictions apply for binary learners.
 - If you use a cell array of SVM template objects, the value of 'Standardize' for SVM learners must be consistent. For example, if you specify 'Standardize', `true` for one SVM learner, you must specify the same value for all SVM learners.
 - If you use a cell array of SVM template objects, and you use one SVM learner with a linear kernel ('KernelFunction', 'linear') and another with a different type of kernel function, then you must specify 'SaveSupportVectors', `true` for the learner with a linear kernel.

For details, see `ClassificationECOCoderConfigurer`. For information on name-value pair arguments that you cannot modify when you retrain a model, see “Tips” on page 32-5748.

- Code generation limitations for SVM classifiers and linear classification models also apply to ECOC classifiers, depending on the choice of binary learners. For more details, see “Code Generation” on page 32-700 of the `CompactClassificationSVM` class and “Code Generation” on page 32-390 of the `ClassificationLinear` class.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2014b

CompactClassificationEnsemble

Package: `classreg.learning.classif`

Compact classification ensemble class

Description

Compact version of a classification ensemble (of class `ClassificationEnsemble`). The compact version does not include the data for training the classification ensemble. Therefore, you cannot perform some tasks with a compact classification ensemble, such as cross validation. Use a compact classification ensemble for making predictions (classifications) of new data.

Construction

`ens = compact(fullEns)` constructs a compact decision ensemble from a full decision ensemble.

Input Arguments

`fullEns`

A classification ensemble created by `fitcensemble`.

Properties

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

`ClassNames`

List of the elements in `Y` with duplicates removed. `ClassNames` can be a numeric vector, vector of categorical variables, logical vector, character array, or cell array of character vectors. `ClassNames` has the same data type as the data in the argument `Y`. (The software treats string arrays as cell arrays of character vectors.)

`CombineWeights`

Character vector describing how `ens` combines weak learner weights, either `'WeightedSum'` or `'WeightedAverage'`.

`Cost`

Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response. This property is read-only.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

NumTrained

Number of trained weak learners in `ens`, a scalar.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in `X`.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

ResponseName

Character vector with the name of the response variable `Y`.

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```
ens.ScoreTransform = 'function'
```

or

```
ens.ScoreTransform = @function
```

Trained

A cell vector of trained classification models.

- If `Method` is 'LogitBoost' or 'GentleBoost', then `CompactClassificationEnsemble` stores trained learner j in the `CompactRegressionLearner` property of the object stored in `Trained{j}`. That is, to access trained learner j , use `ens.Trained{j}.CompactRegressionLearner`.
- Otherwise, cells of the cell vector contain the corresponding, compact classification models.

TrainedWeights

Numeric vector of trained weights for the weak learners in `ens`. `TrainedWeights` has `T` elements, where `T` is the number of weak learners in `learners`.

UsePredForLearner

Logical matrix of size P-by-NumTrained, where P is the number of predictors (columns) in the training data X. UsePredForLearner(i, j) is true when learner j uses predictor i, and is false otherwise. For each learner, the predictors have the same order as the columns in the training data X.

If the ensemble is not of type Subspace, all entries in UsePredForLearner are true.

Methods

edge	Classification edge
loss	Classification error
margin	Classification margins
predict	Classify observations using ensemble of classification models
predictorImportance	Estimates of predictor importance for classification ensemble of decision trees
removeLearners	Remove members of compact classification ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Reduce Size of Classification Ensemble

Create a compact classification ensemble for efficiently making predictions on new data.

Load the ionosphere data set.

```
load ionosphere
```

Train a boosted ensemble of 100 classification trees using all measurements and the AdaBoostM1 method.

```
Mdl = fitensemble(X,Y,'Method','AdaBoostM1')
```

```
Mdl =
  classreg.learning.classif.ClassificationEnsemble
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
    NumObservations: 351
      NumTrained: 100
          Method: 'AdaBoostM1'
      LearnerNames: {'Tree'}
ReasonForTermination: 'Terminated normally after completing the requested number of training
          FitInfo: [100x1 double]
  FitInfoDescription: {2x1 cell}
```

Properties, Methods

`Mdl` is a `ClassificationEnsemble` model object that contains the training data, among other things.

Create a compact version of `Mdl`.

```
CMdl = compact(Mdl)
```

```
CMdl =  
  classreg.learning.classif.CompactClassificationEnsemble  
    ResponseName: 'Y'  
    CategoricalPredictors: []  
    ClassNames: {'b' 'g'}  
    ScoreTransform: 'none'  
    NumTrained: 100
```

Properties, Methods

`CMdl` is a `CompactClassificationEnsemble` model object. `CMdl` is almost the same as `Mdl`. One exception is that `CMdl` does not store the training data.

Compare the amounts of space consumed by `Mdl` and `CMdl`.

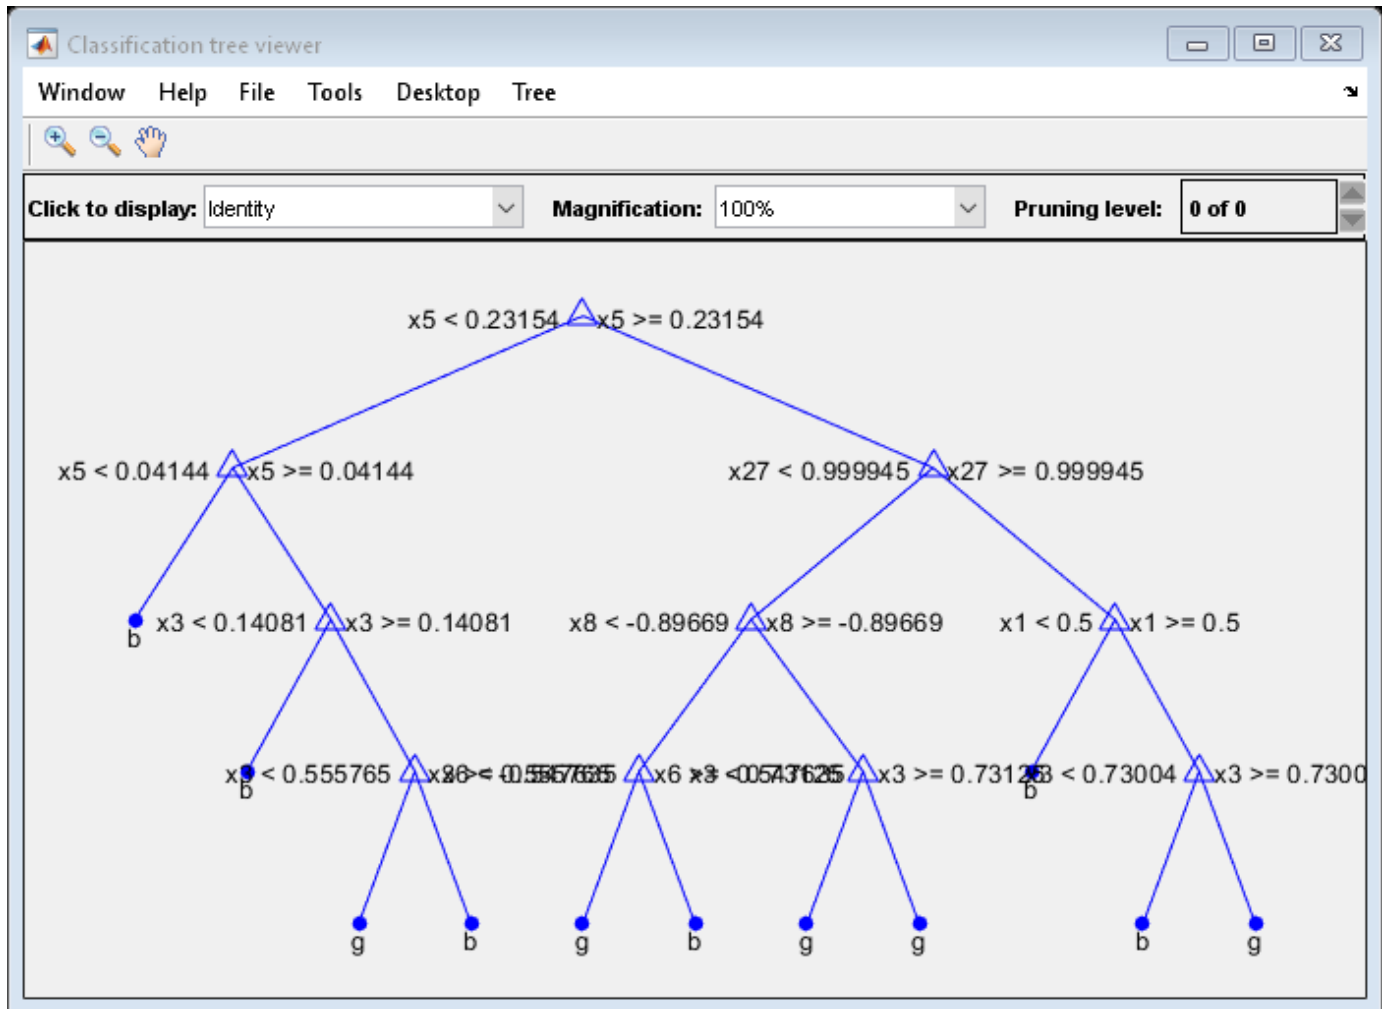

```
mdlInfo = whos('Mdl');  
cMdlInfo = whos('CMdl');  
[mdlInfo.bytes cMdlInfo.bytes]  
  
ans = 1×2  
      860835      614718
```

`Mdl` consumes more space than `CMdl`.

`CMdl.Trained` stores the trained classification trees (`CompactClassificationTree` model objects) that compose `Mdl`.

Display a graph of the first tree in the compact ensemble.

```
view(CMdl.Trained{1}, 'Mode', 'graph');
```

By default, `fitensemble` grows shallow trees for boosted ensembles of trees.

Predict the label of the mean of X using the compact ensemble.

```
predMeanX = predict(CMdl,mean(X))
```

```
predMeanX = 1x1 cell array
    {'g'}
```

Tip

For an ensemble of classification trees, the `Trained` property of `ens` stores an `ens.NumTrained-by-1` cell vector of compact classification models. For a textual or graphical display of tree t in the cell vector, enter:

- `view(ens.Trained{t}.CompactRegressionLearner)` for ensembles aggregated using `LogitBoost` or `GentleBoost`.
- `view(ens.Trained{t})` for all other aggregation methods.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train an ensemble by using `fitcensemble`, code generation limitations for the weak learners used in the ensemble also apply to the ensemble. For more details, see the Code Generation sections of `ClassificationKNN`, `CompactClassificationDiscriminant`, and `CompactClassificationTree`.
- For fixed-point code generation, you must train an ensemble using tree learners.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a

CompactClassificationNaiveBayes

Package: `classreg.learning.classif`

Compact naive Bayes classifier

Description

`CompactClassificationNaiveBayes` is a compact naive Bayes on page 32-688 classifier.

The compact classifier does not include the data used for training the naive Bayes classifier. Therefore, you cannot perform tasks, such as cross validation, using the compact classifier.

Use a compact naive Bayes classifier to label new data (i.e., predicting the labels of new data) more efficiently.

Construction

`CMdl = compact(Mdl)` returns a compact naive Bayes classifier (`CMdl`) from a full, trained naive Bayes classifier (`Mdl`).

Input Arguments

Mdl — Fully trained naive Bayes classifier

`ClassificationNaiveBayes` model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

Properties

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

CategoricalLevels — Multivariate multinomial levels

cell vector of numeric vectors

Multivariate multinomial levels, specified as a cell vector of numeric vectors. `CategoricalLevels` has length equal to the number of predictors (`size(X,2)`).

The cells of `CategoricalLevels` correspond to predictors that you specified as `'mvmn'` (i.e., having a multivariate multinomial distribution) during training. Cells that do not correspond to a multivariate multinomial distribution are empty (`[]`).

If predictor j is multivariate multinomial, then `CategoricalLevels{j}` is a list of all distinct values of predictor j in the sample (NaNs removed from `unique(X(:,j))`).

Data Types: cell

ClassNames — Distinct class names

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Distinct class names, specified as a categorical or character array, logical or numeric vector, or cell vector of character vectors.

ClassNames is the same data type as **Y**, and has K elements or rows for character arrays. (The software treats string arrays as cell arrays of character vectors.)

Data Types: categorical | char | logical | single | double | cell

Cost — Misclassification cost

square matrix

Misclassification cost, specified as a K -by- K square matrix.

The value of $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of **Cost** correspond to the order of the classes in **ClassNames**.

The value of **Cost** does not influence training. You can reset **Cost** after training **Mdl** using dot notation, e.g., `Mdl.Cost = [0 0.5; 1 0];`.

Data Types: double | single

DistributionNames — Predictor distributions

'normal' (default) | 'kernel' | 'mn' | 'mvmn' | cell array of character vectors

Predictor distributions **fitcnb** uses to model the predictors, specified as a character vector or cell array of character vectors.

This table summarizes the available distributions.

Value	Description
'kernel'	Kernel smoothing density estimate.
'mn'	Multinomial bag-of-tokens model on page 32-414. Indicates that all predictors have this distribution.
'mvmn'	Multivariate multinomial distribution.
'normal'	Normal (Gaussian) distribution.

If **Distribution** is a 1-by- P cell array of character vectors, then the software models feature j using the distribution in element j of the cell array.

Data Types: char | cell

DistributionParameters — Distribution parameter estimates

cell array

Distribution parameter estimates, specified as a cell array. **DistributionParameters** is a K -by- D cell array, where cell (k, d) contains the distribution parameter estimates for instances of predictor d in class k . The order of the rows corresponds to the order of the classes in the property **ClassNames**, and the order of the predictors corresponds to the order of the columns of **X**.

If class k has no observations for predictor j , then $\text{Distribution}\{k, j\}$ is empty ($[]$).

The elements of $\text{DistributionParameters}$ depends on the distributions of the predictors. This table describes the values in $\text{DistributionParameters}\{k, j\}$.

Distribution of Predictor j	Value
kernel	A <code>KernelDistribution</code> model. Display properties using cell indexing and dot notation. For example, to display the estimated bandwidth of the kernel density for predictor 2 in the third class, use <code>Mdl.DistributionParameters{3,2}.Bandwidth</code> .
mn	A scalar representing the probability that token j appears in class k . For details, see “Algorithms” on page 32-415.
mvmn	A numeric vector containing the probabilities for each possible level of predictor j in class k . The software orders the probabilities by the sorted order of all unique levels of predictor j (stored in the property <code>CategoricalLevels</code>). For more details, see “Algorithms” on page 32-415.
normal	A 2-by-1 numeric vector. The first element is the sample mean and the second element is the sample standard deviation.

Data Types: cell

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Kernel — Kernel smoother types

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | cell array of character vectors

Kernel smoother types, specified as a character vector or cell array of character vectors. `Kernel` has length equal to the number of predictors (`size(X,2)`). `Kernel{j}` corresponds to predictor j , and contains a character vector describing the type of kernel smoother. This table describes the supported kernel smoother types. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
'box'	Box (uniform)	$f(x) = 0.5I\{ x \leq 1\}$
'epanechnikov'	Epanechnikov	$f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$

Value	Kernel	Formula
'normal'	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$
'triangle'	Triangular	$f(x) = (1 - x)I\{ x \leq 1\}$

If a cell is empty ([]), then the software did not fit a kernel distribution to the corresponding predictor.

Data Types: char | cell

PredictorNames — Predictor names

cell array of character vectors

Predictor names, specified as a cell array of character vectors. The order of the elements in PredictorNames corresponds to the order in X.

Data Types: cell

Prior — Class prior probabilities

numeric vector

Class prior probabilities, specified as a numeric row vector. Prior is a 1-by-K vector, and the order of its elements correspond to the elements of ClassNames.

fitcnb normalizes the prior probabilities you set using the name-value pair parameter 'Prior' so that $\text{sum}(\text{Prior}) = 1$.

The value of Prior does not change the best-fitting model. Therefore, you can reset Prior after training Mdl using dot notation, e.g., `Mdl.Prior = [0.2 0.8];`

Data Types: double | single

ResponseName — Response name

character vector

Response name, specified as a character vector.

Data Types: char

ScoreTransform — Classification score transformation function

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Classification score transformation function, specified as a character vector or function handle.

To change the score transformation function to e.g., *function*, use dot notation.

- For a built-in function, enter this code and replace *function* with a value in the table.

```
Mdl.ScoreTransform = 'function';
```

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$

Value	Description
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

Support — Kernel smoother density support

cell vector

Kernel smoother density support, specified as a cell vector. **Support** has length equal to the number of predictors (`size(X,2)`). The cells represent the regions to apply the kernel density.

This table describes the supported options.

Value	Description
1-by-2 numeric row vector	For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support.
'positive'	The density support is all positive real values.
'unbounded'	The density support is all real values.

If a cell is empty ([]), then the software did not fit a kernel distribution to the corresponding predictor.

Width — Kernel smoother window width

numeric matrix

Kernel smoother window width, specified as a numeric matrix. **Width** is a K -by- P matrix, where K is the number of classes in the data, and P is the number of predictors (`size(X,2)`).

$Width(k,j)$ is the kernel smoother window width for the kernel smoothing density of predictor j within class k . NaNs in column j indicate that the software did not fit predictor j using a kernel density.

Methods

edge	Classification edge for naive Bayes classifiers
logP	Log unconditional probability density for naive Bayes classifier
loss	Classification error for naive Bayes classifier
margin	Classification margins for naive Bayes classifiers
predict	Predict labels using naive Bayes classification model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Reduce the Size of Naive Bayes Classifiers

Full naive Bayes classifiers (i.e., `ClassificationNaiveBayes` models) hold the training data. For efficiency, you might not want to predict new labels using a large classifier. This example shows how to reduce the size of a full naive Bayes classifier.

Load the `ionosphere` data set.

```
load ionosphere
X = X(:,3:end); % Remove two predictors for stability
```

Train a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to specify the order of the labels.

```
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'})
```

```
Mdl =
  ClassificationNaiveBayes
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      NumObservations: 351
  DistributionNames: {1x32 cell}
  DistributionParameters: {2x32 cell}
```

Properties, Methods

`Mdl` is a `ClassificationNaiveBayes` model.

Reduce the size of the naive Bayes classifier.

```
CMdl = compact(Mdl)
```

```
CMdl =
  classreg.learning.classif.CompactClassificationNaiveBayes
      ResponseName: 'Y'
```

```

CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    DistributionNames: {1x32 cell}
    DistributionParameters: {2x32 cell}

```

Properties, Methods

`CMdl` is a `CompactClassificationNaiveBayes` model.

Display how much memory each classifier uses.

```
whos('Mdl','CMdl')
```

Name	Size	Bytes	Class
CMdl	1x1	14892	classreg.learning.classif.CompactClassificationNaiveBayes
Mdl	1x1	111006	ClassificationNaiveBayes

The full naive Bayes classifier (`Mdl`) is much larger than the compact naive Bayes classifier (`CMdl`).

You can remove `Mdl` from the MATLAB® Workspace, and pass `CMdl` and new predictor values to `predict` to efficiently label new observations.

Train and Cross Validate Naive Bayes Classifiers

Load the ionosphere data set.

```
load ionosphere
X = X(:,3:end); % Remove two predictors for stability
```

Train and cross validate a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to specify the order of the classes.

```
rng(1); % For reproducibility
CVMdl = fitcnb(X,Y,'ClassNames',{'b','g'},'CrossVal','on')

CVMdl =
classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'NaiveBayes'
    PredictorNames: {1x32 cell}
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
```

Properties, Methods

`CVMdl` is not a `ClassificationNaiveBayes` model, but a `ClassificationPartitionedModel` cross-validated, naive Bayes model. By default, the software implements 10-fold cross validation.

Alternatively, you can cross validate a trained `ClassificationNaiveBayes` model by passing it to `crossval`.

Inspect one of the trained folds using dot notation.

```
CVMdl.Trained{1}
ans =
  classreg.learning.classif.CompactClassificationNaiveBayes
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
  DistributionNames: {1x32 cell}
  DistributionParameters: {2x32 cell}
```

Properties, Methods

Each fold is a `CompactClassificationNaiveBayes` model trained on 90% of the data.

Estimate the generalization error.

```
genError = kfoldLoss(CVMdl)
genError = 0.1795
```

On average, the generalization error is approximately 17%.

One way to attempt reducing an unsatisfactory generalization error is to specify different conditional distributions for the predictors, or tune the parameters of the conditional distributions.

More About

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor j is the nonnegative number of occurrences of token j in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm:

- 1 Estimates the densities of the predictors within each class.
- 2 Models posterior probabilities according to Bayes rule. That is, for all $k = 1, \dots, K$,

$$\widehat{P}(Y = k | X_1, \dots, X_P) = \frac{\pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)}{\sum_{k=1}^K \pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)},$$

where:

- Y is the random variable corresponding to the class index of an observation.
 - X_1, \dots, X_P are the random predictors of an observation.
 - $\pi(Y = k)$ is the prior probability that a class index is k .
- 3** Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability

$\widehat{P}(Y = k | X_1, \dots, X_P) \propto \pi(Y = k) P_{mn}(X_1, \dots, X_P | Y = k)$, where $P_{mn}(X_1, \dots, X_P | Y = k)$ is the probability mass function of a multinomial distribution.

Algorithms

- If you specify 'DistributionNames', 'mn' when training MdL using `fitcnb`, then the software fits a multinomial distribution using the bag-of-tokens model on page 32-1656. The software stores the probability that token j appears in class k in the property `DistributionParameters{k,j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{token } j \mid \text{class } k) = \frac{1 + c_{j|k}}{P + c_k},$$

where:

- $c_{j|k} = n_k \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i: y_i \in \text{class } k} w_i}$; which is the weighted number of occurrences of token j in class k .
 - n_k is the number of observations in class k .
 - w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
 - $c_k = \sum_{j=1}^P c_{j|k}$; which is the total weighted number of occurrences of all tokens in class k .
- If you specify 'DistributionNames', 'mvmn' when training MdL using `fitcnb`, then:
 - 1** For each predictor, the software collects a list of the unique levels, stores the sorted list in `CategoricalLevels`, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
 - 2** For predictor j in class k , the software counts instances of each categorical level using the list stored in `CategoricalLevels{j}`.
 - 3** The software stores the probability that predictor j , in class k , has level L in the property `DistributionParameters{k,j}`, for all levels in `CategoricalLevels{j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{predictor } j = L | \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

where:

- $m_{j|k}(L) = n_k \frac{\sum_{i: y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i: y_i \in \text{class } k} w_i}$; which is the weighted number of observations for which predictor j equals L in class k .
- n_k is the number of observations in class k .
- $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
- w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
- m_j is the number of distinct levels in predictor j .
- m_k is the weighted number of observations in class k .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train a naive Bayes model by using `fitcnb`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the 'CategoricalPredictors' name-value pair argument.
 - The value of the 'DistributionNames' name-value pair argument cannot contain 'mn' or 'mvmn'.
 - The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
 - The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

Topics

“Naive Bayes Classification” on page 21-2

“Grouping Variables” on page 2-45

CompactClassificationSVM

Compact support vector machine (SVM) for one-class and binary classification

Description

`CompactClassificationSVM` is a compact version of the support vector machine (SVM) classifier. The compact classifier does not include the data used for training the SVM classifier. Therefore, you cannot perform some tasks, such as cross-validation, using the compact classifier. Use a compact SVM classifier for tasks such as predicting the labels of new data.

Creation

Create a `CompactClassificationSVM` model from a full, trained `ClassificationSVM` classifier by using `compact`.

Properties

SVM Properties

Alpha — Trained classifier coefficients

numeric vector

This property is read-only.

Trained classifier coefficients, specified as an s -by-1 numeric vector. s is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`.

`Alpha` contains the trained classifier coefficients from the dual problem, that is, the estimated Lagrange multipliers. If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitsvm`, then for a given set of duplicate observations that are support vectors, `Alpha` contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one observation from the set of duplicates and a coefficient of 0 to all other duplicate observations in the set.

Data Types: `single` | `double`

Beta — Linear predictor coefficients

numeric vector

This property is read-only.

Linear predictor coefficients, specified as a numeric vector. The length of `Beta` is equal to the number of predictors used to train the model.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. `Beta` stores one value for each predictor variable, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then `Beta` is a numeric vector containing five values.

If `KernelParameters.Function` is 'linear', then the classification score for the observation x is

$$f(x) = (x/s)\beta + b.$$

`Mdl` stores β , b , and s in the properties `Beta`, `Bias`, and `KernelParameters.Scale`, respectively.

To estimate classification scores manually, you must first apply any transformations to the predictor data that were applied during training. Specifically, if you specify 'Standardize', `true` when using `fitcsvm`, then you must standardize the predictor data manually by using the mean `Mdl.Mu` and standard deviation `Mdl.Sigma`, and then divide the result by the kernel scale in `Mdl.KernelParameters.Scale`.

All SVM functions, such as `resubPredict` and `predict`, apply any required transformation before estimation.

If `KernelParameters.Function` is not 'linear', then `Beta` is empty (`[]`).

Data Types: `single` | `double`

Bias — Bias term

scalar

This property is read-only.

Bias term, specified as a scalar.

Data Types: `single` | `double`

KernelParameters — Kernel parameters

structure array

This property is read-only.

Kernel parameters, specified as a structure array. The kernel parameters property contains the fields listed in this table.

Field	Description
Function	Kernel function used to compute the elements of the Gram matrix on page 32-1689. For details, see 'KernelFunction'.
Scale	Kernel scale parameter used to scale all elements of the predictor data on which the model is trained. For details, see 'KernelScale'.

To display the values of `KernelParameters`, use dot notation. For example, `Mdl.KernelParameters.Scale` displays the kernel scale parameter value.

The software accepts `KernelParameters` as inputs and does not modify them.

Data Types: `struct`

SupportVectorLabels — Support vector class labels

s -by-1 numeric vector

This property is read-only.

Support vector class labels, specified as an s -by-1 numeric vector. s is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`.

A value of +1 in `SupportVectorLabels` indicates that the corresponding support vector is in the positive class (`ClassNames{2}`). A value of -1 indicates that the corresponding support vector is in the negative class (`ClassNames{1}`).

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations that are support vectors, `SupportVectorLabels` contains one unique support vector label.

Data Types: `single` | `double`

SupportVectors — Support vectors

s-by-*p* numeric matrix

This property is read-only.

Support vectors in the trained classifier, specified as an *s*-by-*p* numeric matrix. *s* is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`, and *p* is the number of predictor variables in the predictor data.

`SupportVectors` contains rows of the predictor data *X* that MATLAB considers to be support vectors. If you specify `'Standardize', true` when training the SVM classifier using `fitcsvm`, then `SupportVectors` contains the standardized rows of *X*.

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations that are support vectors, `SupportVectors` contains one unique support vector.

Data Types: `single` | `double`

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

vector of positive integers | []

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: `single` | `double`

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used in training the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

Cost — Misclassification cost

numeric square matrix

This property is read-only.

Misclassification cost, specified as a numeric square matrix, where $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i .

During training, the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

- For two-class learning, Cost always has this form: $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$. The rows correspond to the true class and the columns correspond to the predicted class. The order of the rows and columns of Cost corresponds to the order of the classes in `ClassNames`.
- For one-class learning, $\text{Cost} = 0$.

For more details, see Algorithms on page 32-489.

Data Types: `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

This property is read-only.

Expanded predictor names, specified as a cell array of character vectors.

If the model uses dummy variable encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

Mu — Predictor means

numeric vector | []

This property is read-only.

Predictor means, specified as a numeric vector. If you specify `'Standardize', 1` or `'Standardize', true` when you train an SVM classifier using `fitcsvm`, then the length of `Mu` is equal to the number of predictors.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. `Mu` stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set `'Standardize', false` when you train the SVM classifier using `fitcsvm`, then `Mu` is an empty vector (`[]`).

Data Types: `single` | `double`

PredictorNames — Predictor variable names

cell array of character vectors

This property is read-only.

Predictor variable names, specified as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the training data.

Data Types: `cell`

Prior – Prior probabilities

numeric vector

This property is read-only.

Prior probabilities for each class, specified as a numeric vector. The order of the elements of `Prior` corresponds to the elements of `Mdl.ClassNames`.

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

For more details, see Algorithms on page 32-489.

Data Types: `single` | `double`

ScoreTransform – Score transformation

character vector | function handle

Score transformation, specified as a character vector or function handle. `ScoreTransform` represents a built-in transformation function or a function handle for transforming predicted classification scores.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter a character vector.

```
Mdl.ScoreTransform = 'function';
```

This table describes the available built-in functions.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: `char` | `function_handle`

Sigma — Predictor standard deviations

[] (default) | numeric vector

This property is read-only.

Predictor standard deviations, specified as a numeric vector.

If you specify 'Standardize', true when you train the SVM classifier using `fitcsvm`, then the length of `Sigma` is equal to the number of predictor variables.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. `Sigma` stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set 'Standardize', false when you train the SVM classifier using `fitcsvm`, then `Sigma` is an empty vector ([]).

Data Types: `single` | `double`

Object Functions

<code>compareHoldout</code>	Compare accuracies of two classification models using new data
<code>discardSupportVectors</code>	Discard support vectors for linear support vector machine (SVM) classifier
<code>edge</code>	Find classification edge for support vector machine (SVM) classifier
<code>fitPosterior</code>	Fit posterior probabilities for compact support vector machine (SVM) classifier
<code>loss</code>	Find classification error for support vector machine (SVM) classifier
<code>margin</code>	Find classification margins for support vector machine (SVM) classifier
<code>predict</code>	Classify observations using support vector machine (SVM) classifier
<code>update</code>	Update model parameters for code generation

Examples**Reduce Size of SVM Classifiers**

Reduce the size of a full SVM classifier by removing the training data. Full SVM classifiers (that is, `ClassificationSVM` classifiers) hold the training data. To improve efficiency, use a smaller classifier.

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the predictor data and specify the order of the classes.

```
SVMMModel = fitcsvm(X,Y,'Standardize',true,...
    'ClassNames',{'b','g'})
```

```
SVMMModel =
    ClassificationSVM
        ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'b' 'g'}
        ScoreTransform: 'none'
```

```

    NumObservations: 351
        Alpha: [90x1 double]
        Bias: -0.1343
    KernelParameters: [1x1 struct]
        Mu: [1x34 double]
        Sigma: [1x34 double]
    BoxConstraints: [351x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [351x1 logical]
    Solver: 'SM0'

```

Properties, Methods

`SVMModel` is a `ClassificationSVM` classifier.

Reduce the size of the SVM classifier.

```
CompactSVMModel = compact(SVMModel)
```

```

CompactSVMModel =
  classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
  CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    Alpha: [90x1 double]
    Bias: -0.1343
  KernelParameters: [1x1 struct]
    Mu: [1x34 double]
    Sigma: [1x34 double]
  SupportVectors: [90x34 double]
  SupportVectorLabels: [90x1 double]

```

Properties, Methods

`CompactSVMModel` is a `CompactClassificationSVM` classifier.

Display the amount of memory each classifier uses.

```
whos('SVMModel', 'CompactSVMModel')
```

Name	Size	Bytes	Class
CompactSVMModel	1x1	30890	classreg.learning.classif.CompactClassificationSVM
SVMModel	1x1	140980	ClassificationSVM

The full SVM classifier (`SVMModel`) is more than four times larger than the compact SVM classifier (`CompactSVMModel`).

To label new observations efficiently, you can remove `SVMModel` from the MATLAB® Workspace, and then pass `CompactSVMModel` and new predictor values to `predict`.

To further reduce the size of your compact SVM classifier, use the `discardSupportVectors` function to discard support vectors.

Train and Cross-Validate SVM Classifier

Load the ionosphere data set.

```
load ionosphere
```

Train and cross-validate an SVM classifier. Standardize the predictor data and specify the order of the classes.

```
rng(1); % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Standardize',true,...
    'ClassNames',{'b','g'},'CrossVal','on')

CVSVMModel =
    classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'SVM'
    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
```

Properties, Methods

CVSVMModel is a ClassificationPartitionedModel cross-validated SVM classifier. By default, the software implements 10-fold cross-validation.

Alternatively, you can cross-validate a trained ClassificationSVM classifier by passing it to crossval.

Inspect one of the trained folds using dot notation.

```
CVSVMModel.Trained{1}

ans =
    classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    Alpha: [78x1 double]
    Bias: -0.2209
    KernelParameters: [1x1 struct]
    Mu: [1x34 double]
    Sigma: [1x34 double]
    SupportVectors: [78x34 double]
    SupportVectorLabels: [78x1 double]
```

Properties, Methods

Each fold is a `CompactClassificationSVM` classifier trained on 90% of the data.

Estimate the generalization error.

```
genError = kfoldLoss(CVSVMModel)
```

```
genError = 0.1168
```

On average, the generalization error is approximately 12%.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train an SVM model by using `fitsvm`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the 'CategoricalPredictors' name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
 - The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
 - The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function. For generating code that predicts posterior probabilities given new observations, pass a trained SVM model to `fitPosterior` or `fitSVMPosterior`. The `ScoreTransform` property of the returned model contains an anonymous function that represents the score-to-posterior-probability function and is configured for code generation.
 - For fixed-point code generation, the value of the 'ScoreTransform' name-value pair argument cannot be 'invlogit'.

For more information, see "Introduction to Code Generation" on page 31-2.

Introduced in R2014a

CompactClassificationTree

Package: `classreg.learning.classif`

Compact classification tree

Description

Compact version of a classification tree (of class `ClassificationTree`). The compact version does not include the data for training the classification tree. Therefore, you cannot perform some tasks with a compact classification tree, such as cross validation. Use a compact classification tree for making predictions (classifications) of new data.

Construction

`ctree = compact(tree)` constructs a compact decision tree from a full decision tree.

Input Arguments

tree

A decision tree constructed using `fitctree`.

Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

CategoricalSplits

An n -by-2 cell array, where n is the number of categorical splits in `tree`. Each row in `CategoricalSplits` gives left and right values for a categorical split. For each branch node with categorical split j based on a categorical predictor variable z , the left child is chosen if z is in `CategoricalSplits(j,1)` and the right child is chosen if z is in `CategoricalSplits(j,2)`. The splits are in the same order as nodes of the tree. Find the nodes for these splits by selecting 'categorical' cuts from top to bottom in the `CutType` property.

Children

An n -by-2 array containing the numbers of the child nodes for each node in `tree`, where n is the number of nodes. Leaf nodes have child node 0.

ClassCount

An n -by- k array of class counts for the nodes in `tree`, where n is the number of nodes and k is the number of classes. For any node number i , the class counts `ClassCount(i,:)` are counts of observations (from the data used in fitting the tree) from each class satisfying the conditions for node i .

ClassNames

List of the elements in *Y* with duplicates removed. **ClassNames** can be a numeric vector, vector of categorical variables, logical vector, character array, or cell array of character vectors. **ClassNames** has the same data type as the data in the argument *Y*. (The software treats string arrays as cell arrays of character vectors.)

If the value of a property has at least one dimension of length *k*, then **ClassNames** indicates the order of the elements along that dimension (e.g., **Cost** and **Prior**).

ClassProbability

An *n*-by-*k* array of class probabilities for the nodes in **tree**, where *n* is the number of nodes and *k* is the number of classes. For any node number *i*, the class probabilities **ClassProbability**(*i*, :) are the estimated probabilities for each class for a point satisfying the conditions for node *i*.

Cost

Square matrix, where **Cost**(*i*, *j*) is the cost of classifying a point into class *j* if its true class is *i* (the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of **Cost** corresponds to the order of the classes in **ClassNames**. The number of rows and columns in **Cost** is the number of unique classes in the response. This property is read-only.

CutCategories

An *n*-by-2 cell array of the categories used at branches in **tree**, where *n* is the number of nodes. For each branch node *i* based on a categorical predictor variable *x*, the left child is chosen if *x* is among the categories listed in **CutCategories**{*i*, 1}, and the right child is chosen if *x* is among those listed in **CutCategories**{*i*, 2}. Both columns of **CutCategories** are empty for branch nodes based on continuous predictors and for leaf nodes.

CutPoint contains the cut points for 'continuous' cuts, and **CutCategories** contains the set of categories.

CutPoint

An *n*-element vector of the values used as cut points in **tree**, where *n* is the number of nodes. For each branch node *i* based on a continuous predictor variable *x*, the left child is chosen if $x < \text{CutPoint}(i)$ and the right child is chosen if $x \geq \text{CutPoint}(i)$. **CutPoint** is NaN for branch nodes based on categorical predictors and for leaf nodes.

CutPoint contains the cut points for 'continuous' cuts, and **CutCategories** contains the set of categories.

CutType

An *n*-element cell array indicating the type of cut at each node in **tree**, where *n* is the number of nodes. For each node *i*, **CutType**{*i*} is:

- 'continuous' — If the cut is defined in the form $x < v$ for a variable *x* and cut point *v*.
- 'categorical' — If the cut is defined by whether a variable *x* takes a value in a set of categories.
- '' — If *i* is a leaf node.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictor

An n -element cell array of the names of the variables used for branching in each node in `tree`, where n is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty character vector.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictorIndex

An n -element array of numeric indices for the variables used for branching in each node in `tree`, where n is the number of nodes. For more information, see `CutPredictor`.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

IsBranchNode

An n -element logical vector that is `true` for each branch node and `false` for each leaf node of `tree`.

NodeClass

An n -element cell array with the names of the most probable classes in each node of `tree`, where n is the number of nodes in the tree. Every element of this array is a character vector equal to one of the class names in `ClassNames`.

NodeError

An n -element vector of the errors of the nodes in `tree`, where n is the number of nodes. `NodeError(i)` is the misclassification probability for node i .

NodeProbability

An n -element vector of the probabilities of the nodes in `tree`, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

NodeRisk

An n -element vector of the risk of the nodes in the tree, where n is the number of nodes. The risk for each node is the measure of impurity (Gini index or deviance) for this node weighted by the node probability. If the tree is grown by `twoing`, the risk for each node is zero.

NodeSize

An n -element vector of the sizes of the nodes in `tree`, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

NumNodes

The number of nodes in `tree`.

Parent

An n -element vector containing the number of the parent node for each node in `tree`, where n is the number of nodes. The parent of the root node is 0.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in `X`.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

PruneAlpha

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to M , then `PruneAlpha` has $M + 1$ elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

PruneList

An n -element numeric vector with the pruning levels in each node of `tree`, where n is the number of nodes. The pruning levels range from 0 (no pruning) to M , where M is the distance between the deepest leaf and the root node.

ResponseName

Character vector describing the response variable `Y`.

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```
ctree.ScoreTransform = 'function'
or
ctree.ScoreTransform = @function
```

SurrogateCutCategories

An n -element cell array of the categories used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutCategories{k}` is a cell array. The length of

`SurrogateCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutCategories{k}` is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutVar`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutCategories` contains an empty cell.

SurrogateCutFlip

An n -element cell array of the numeric cut assignments used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrSurrogateCutFlip{k}` is a numeric vector. The length of `SurrogateCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or $+1$. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and the cut assignment for this surrogate split is $+1$, or if $Z \geq C$ and the cut assignment for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and the cut assignment for this surrogate split is $+1$, or if $Z < C$ and the cut assignment for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutFlip` contains an empty array.

SurrogateCutPoint

An n -element cell array of the numeric values used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutPoint{k}` is a numeric vector. The length of `SurrogateCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutPoint{k}` is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z < C$ and `SurrogateCutFlip` for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables returned by `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPoint` contains an empty cell.

SurrogateCutType

An n -element cell array indicating types of surrogate splits at each node in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutType{k}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutType` contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form $Z < V$ for a variable Z and cut point V or 'categorical' if the cut is defined by whether Z takes a value in a set of categories.

SurrogateCutPredictor

An n -element cell array of the names of the variables used for surrogate splits in each node in `tree`, where n is the number of nodes in `tree`. Every element of `SurrogateCutPredictor` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPredictor` contains an empty cell.

SurrogatePredictorAssociation

An n -element cell array of the predictive measures of association for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogatePredictorAssociation{k}` is a numeric vector. The length of `SurrogatePredictorAssociation{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogatePredictorAssociation{k}` gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogatePredictorAssociation` contains an empty cell.

Methods

<code>edge</code>	Classification edge
<code>loss</code>	Classification error
<code>margin</code>	Classification margins
<code>surrogateAssociation</code>	Mean predictive measure of association for surrogate splits in classification tree
<code>predict</code>	Predict labels using classification tree
<code>predictorImportance</code>	Estimates of predictor importance for classification tree
<code>view</code>	View classification tree

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Construct a Compact Classification Tree

Construct a compact classification tree for the Fisher iris data.

```
load fisheriris
tree = fitctree(meas,species);
ctree = compact(tree);
```

Compare the size of the resulting tree to that of the original tree.

```
t = whos('tree'); % t.bytes = size of tree in bytes
c = whos('ctree'); % c.bytes = size of ctree in bytes
[c.bytes t.bytes]
```

```
ans = 1×2
      4929      11594
```

The compact tree is smaller than the original tree.

More About

Impurity and Node Error

`ClassificationTree` splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i)\log_2 p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and therefore similar to the parent node. The split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train a classification tree using `fitctree`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the `'CategoricalPredictors'` name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
 - The value of the `'ClassNames'` name-value pair argument cannot be a categorical array.
 - The value of the `'ScoreTransform'` name-value pair argument cannot be an anonymous function. For fixed-point code generation, the `'ScoreTransform'` value cannot be `'invlogit'`.
 - You cannot use surrogate splits, that is, the value of the `'Surrogate'` name-value pair argument must be `'off'`.

Compact linear regression model

Description

`CompactLinearModel` is a compact version of a full linear regression model object `LinearModel`. Because a compact model does not store the input data used to fit the model or information related to the fitting process, a `CompactLinearModel` object consumes less memory than a `LinearModel` object. You can still use a compact model to predict responses using new input data, but some `LinearModel` object functions do not work with a compact model.

Creation

Create a `CompactLinearModel` model from a full, trained `LinearModel` model by using `compact`.

Properties

Coefficient Estimates

CoefficientCovariance — Covariance matrix of coefficient estimates

numeric matrix

This property is read-only.

Covariance matrix of coefficient estimates, specified as a p -by- p matrix of numeric values. p is the number of coefficients in the fitted model.

For details, see “Coefficient Standard Errors and Confidence Intervals” on page 11-57.

Data Types: `single` | `double`

CoefficientNames — Coefficient names

cell array of character vectors

This property is read-only.

Coefficient names, specified as a cell array of character vectors, each containing the name of the corresponding term.

Data Types: `cell`

Coefficients — Coefficient values

table

This property is read-only.

Coefficient values, specified as a table. `Coefficients` contains one row for each coefficient and these columns:

- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — *t*-statistic for a test that the coefficient is zero
- **pValue** — *p*-value for the *t*-statistic

Use `anova` (only for a linear regression model) or `coefTest` to perform other tests on the coefficients. Use `coefCI` to find the confidence intervals of the coefficient estimates.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the estimated coefficient vector in the model `mdl`:

```
beta = mdl.Coefficients.Estimate
```

Data Types: `table`

NumCoefficients — Number of model coefficients

positive integer

This property is read-only.

Number of model coefficients, specified as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

Data Types: `double`

NumEstimatedCoefficients — Number of estimated coefficients

positive integer

This property is read-only.

Number of estimated coefficients in the model, specified as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

Data Types: `double`

Summary Statistics

DFE — Degrees of freedom for error

positive integer

This property is read-only.

Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer.

Data Types: `double`

LogLikelihood — Loglikelihood

numeric value

This property is read-only.

Loglikelihood of response values, specified as a numeric value, based on the assumption that each response value follows a normal distribution. The mean of the normal distribution is the fitted (predicted) response value, and the variance is the MSE.

Data Types: `single` | `double`

ModelCriterion — Criterion for model comparison

structure

This property is read-only.

Criterion for model comparison, specified as a structure with these fields:

- **AIC** — Akaike information criterion. $AIC = -2 \cdot \log L + 2 \cdot m$, where $\log L$ is the loglikelihood and m is the number of estimated parameters.
- **AICc** — Akaike information criterion corrected for the sample size. $AICc = AIC + (2 \cdot m \cdot (m + 1)) / (n - m - 1)$, where n is the number of observations.
- **BIC** — Bayesian information criterion. $BIC = -2 \cdot \log L + m \cdot \log(n)$.
- **CAIC** — Consistent Akaike information criterion. $CAIC = -2 \cdot \log L + m \cdot (\log(n) + 1)$.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property using dot notation. For example, obtain the AIC value `aic` in the model `mdl`:

```
aic = mdl.ModelCriterion.AIC
```

Data Types: `struct`

MSE — Mean squared error

numeric value

This property is read-only.

Mean squared error (residuals), specified as a numeric value.

$$MSE = SSE / DFE,$$

where MSE is the mean squared error, SSE is the sum of squared errors, and DFE is the degrees of freedom.

Data Types: `single` | `double`

RMSE — Root mean squared error

numeric value

This property is read-only.

Root mean squared error (residuals), specified as a numeric value.

$$RMSE = \sqrt{MSE},$$

where $RMSE$ is the root mean squared error and MSE is the mean squared error.

Data Types: `single` | `double`

Rsquared — R-squared value for model

structure

This property is read-only.

R-squared value for the model, specified as a structure with two fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients

The R-squared value is the proportion of the total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$\text{Rsquared} = \text{SSR}/\text{SST},$$

where SST is the total sum of squares, and SSR is the regression sum of squares.

For details, see “Coefficient of Determination (R-Squared)” on page 11-60.

To obtain either of these values as a scalar, index into the property using dot notation. For example, obtain the adjusted R-squared value in the model mdl:

```
r2 = mdl.Rsquared.Adjusted
```

Data Types: `struct`

SSE — Sum of squared errors

numeric value

This property is read-only.

Sum of squared errors (residuals), specified as a numeric value.

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR},$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

SSR — Regression sum of squares

numeric value

This property is read-only.

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR},$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

SST — Total sum of squares

numeric value

This property is read-only.

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of the response vector y from the mean (y).

The Pythagorean theorem implies

$$SST = SSE + SSR,$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

Fitting Method

Robust — Robust fit information

structure

This property is read-only.

Robust fit information, specified as a structure with the fields described in this table.

Field	Description
<code>WgtFun</code>	Robust weighting function, such as <code>'bisquare'</code> (see <code>'RobustOpts'</code>)
<code>Tune</code>	Tuning constant. This field is empty (<code>[]</code>) if <code>WgtFun</code> is <code>'ols'</code> or if <code>WgtFun</code> is a function handle for a custom weight function with the default tuning constant 1.
<code>Weights</code>	Vector of weights used in the final iteration of robust fit. This field is empty for a <code>CompactLinearModel</code> object.

This structure is empty unless you fit the model using robust regression.

Data Types: `struct`

Input Data

Formula — Model information

`LinearFormula` object

This property is read-only.

Model information, specified as a `LinearFormula` object.

Display the formula of the fitted model `mdl` using dot notation:

```
mdl.Formula
```

NumObservations — Number of observations

positive integer

This property is read-only.

Number of observations the fitting function used in fitting, specified as a positive integer.

`NumObservations` is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `'Exclude'` name-value pair argument) or rows with missing values.

Data Types: `double`

NumPredictors — Number of predictor variables

positive integer

This property is read-only.

Number of predictor variables used to fit the model, specified as a positive integer.

Data Types: double

NumVariables — Number of variables

positive integer

This property is read-only.

Number of variables in the input data, specified as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector.

`NumVariables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: double

PredictorNames — Names of predictors used to fit model

cell array of character vectors

This property is read-only.

Names of predictors used to fit the model, specified as a cell array of character vectors.

Data Types: cell

ResponseName — Response variable name

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: char

VariableInfo — Information about variables

table

This property is read-only.

Information about variables contained in `Variables`, specified as a table with one row for each variable and the columns described in this table.

Column	Description
Class	Variable class, specified as a cell array of character vectors, such as 'double' and 'categorical'

Column	Description
Range	Variable range, specified as a cell array of vectors <ul style="list-style-type: none"> • Continuous variable — Two-element vector $[min, max]$, the minimum and maximum values • Categorical variable — Vector of distinct variable values
InModel	Indicator of which variables are in the fitted model, specified as a logical vector. The value is <code>true</code> if the model includes the variable.
IsCategorical	Indicator of categorical variables, specified as a logical vector. The value is <code>true</code> if the variable is categorical.

`VariableInfo` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `table`

VariableNames — Names of variables

cell array of character vectors

This property is read-only.

Names of variables, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in the table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` contains the values specified by the `'VarNames'` name-value pair argument of the fitting method. The default value of `'VarNames'` is `{'x1', 'x2', ..., 'xn', 'y'}`.

`VariableNames` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `cell`

Object Functions

Predict Responses

`feval` Predict responses of linear regression model using one input for each predictor
`predict` Predict responses of linear regression model
`random` Simulate responses with random noise for linear regression model

Evaluate Linear Model

`anova` Analysis of variance for linear regression model
`coefCI` Confidence intervals of coefficient estimates of linear regression model
`coefTest` Linear hypothesis test on linear regression model coefficients

Visualize Linear Model

`plotEffects` Plot main effects of predictors in linear regression model
`plotInteraction` Plot interaction effects of two predictors in linear regression model

plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
plotSlice	Plot of slices through fitted linear regression surface

Examples

Compact Linear Regression Model

Fit a linear regression model to data and reduce the size of a full, fitted linear regression model by discarding the sample data and some information related to the fitting process.

Load the `largedata4reg` data set, which contains 15,000 observations and 45 predictor variables.

```
load largedata4reg
```

Fit a linear regression model to the data.

```
mdl = fitlm(X,Y);
```

Compact the model.

```
compactMdl = compact(mdl);
```

The compact model discards the original sample data and some information related to the fitting process.

Compare the size of the full model `mdl` and the compact model `compactMdl`.

```
vars = whos('compactMdl','mdl');
[vars(1).bytes,vars(2).bytes]
```

```
ans = 1x2
```

```
81538    11408530
```

The compact model consumes less memory than the full model.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `random` functions support code generation.
- When you fit a model by using `fitlm` or `stepwiselm`, you cannot supply training data in a table that contains a logical vector, character array, categorical array, string array, or cell array of character vectors. Also, you cannot use the `'CategoricalVars'` name-value pair argument. Code generation does not support categorical predictors. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2016a

CompactGeneralizedLinearModel

Compact generalized linear regression model class

Description

`CompactGeneralizedLinearModel` is a compact version of a full generalized linear regression model object `GeneralizedLinearModel`. Because a compact model does not store the input data used to fit the model or information related to the fitting process, a `CompactGeneralizedLinearModel` object consumes less memory than a `GeneralizedLinearModel` object. You can still use a compact model to predict responses using new input data, but some `GeneralizedLinearModel` object functions do not work with a compact model.

Creation

Create a `CompactGeneralizedLinearModel` model from a full, trained `GeneralizedLinearModel` model by using `compact`.

`fitglm` returns `CompactGeneralizedLinearModel` when you work with tall arrays, and returns `GeneralizedLinearModel` when you work with in-memory tables and arrays.

Properties

Coefficient Estimates

CoefficientCovariance — Covariance matrix of coefficient estimates

numeric matrix

This property is read-only.

Covariance matrix of coefficient estimates, specified as a p -by- p matrix of numeric values. p is the number of coefficients in the fitted model.

For details, see “Coefficient Standard Errors and Confidence Intervals” on page 11-57.

Data Types: `single` | `double`

CoefficientNames — Coefficient names

cell array of character vectors

This property is read-only.

Coefficient names, specified as a cell array of character vectors, each containing the name of the corresponding term.

Data Types: `cell`

Coefficients — Coefficient values

table

This property is read-only.

Coefficient values, specified as a table. `Coefficients` contains one row for each coefficient and these columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — t -statistic for a test that the coefficient is zero
- `pValue` — p -value for the t -statistic

Use `anova` (only for a linear regression model) or `coefTest` to perform other tests on the coefficients. Use `coefCI` to find the confidence intervals of the coefficient estimates.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the estimated coefficient vector in the model `mdl`:

```
beta = mdl.Coefficients.Estimate
```

Data Types: `table`

NumCoefficients — Number of model coefficients

positive integer

This property is read-only.

Number of model coefficients, specified as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

Data Types: `double`

NumEstimatedCoefficients — Number of estimated coefficients

positive integer

This property is read-only.

Number of estimated coefficients in the model, specified as a positive integer.

`NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

Data Types: `double`

Summary Statistics

Deviance — Deviance of fit

numeric value

This property is read-only.

Deviance of the fit, specified as a numeric value. The deviance is useful for comparing two models when one model is a special case of the other model. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of estimated parameters between the two models. For more information, see “Deviance” on page 32-727.

Data Types: `single` | `double`

DFE — Degrees of freedom for error

positive integer

This property is read-only.

Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer.

Data Types: double

Dispersion — Scale factor of variance of response

numeric scalar

This property is read-only.

Scale factor of the variance of the response, specified as a numeric scalar.

If the 'DispersionFlag' name-value pair argument of `fitglm` or `stepwiseglm` is `true`, then the function estimates the `Dispersion` scale factor in computing the variance of the response. The variance of the response equals the theoretical variance multiplied by the scale factor. For example, the variance function for the binomial distribution is $p(1-p)/n$, where p is the probability parameter and n is the sample size parameter. If `Dispersion` is near 1, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If `Dispersion` is larger than 1, the data set is “overdispersed” relative to the binomial distribution.

Data Types: double

DispersionEstimated — Flag to indicate use of dispersion scale factor

logical value

This property is read-only.

Flag to indicate whether `fitglm` used the `Dispersion` scale factor to compute standard errors for the coefficients in `Coefficients.SE`, specified as a logical value. If `DispersionEstimated` is `false`, `fitglm` used the theoretical value of the variance.

- `DispersionEstimated` can be `false` only for the binomial and Poisson distributions.
- Set `DispersionEstimated` by setting the 'DispersionFlag' name-value pair argument of `fitglm` or `stepwiseglm`.

Data Types: logical

LogLikelihood — Loglikelihood

numeric value

This property is read-only.

Loglikelihood of the model distribution at the response values, specified as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

Data Types: single | double

ModelCriterion — Criterion for model comparison

structure

This property is read-only.

Criterion for model comparison, specified as a structure with these fields:

- **AIC** — Akaike information criterion. $AIC = -2 \cdot \log L + 2 \cdot m$, where $\log L$ is the loglikelihood and m is the number of estimated parameters.
- **AICc** — Akaike information criterion corrected for the sample size. $AICc = AIC + (2 \cdot m \cdot (m + 1)) / (n - m - 1)$, where n is the number of observations.
- **BIC** — Bayesian information criterion. $BIC = -2 \cdot \log L + m \cdot \log(n)$.
- **CAIC** — Consistent Akaike information criterion. $CAIC = -2 \cdot \log L + m \cdot (\log(n) + 1)$.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property using dot notation. For example, obtain the AIC value `aic` in the model `mdl`:

```
aic = mdl.ModelCriterion.AIC
```

Data Types: `struct`

Rquared — R-squared value for model

`structure`

This property is read-only.

R-squared value for the model, specified as a structure with five fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients
- **LLR** — Loglikelihood ratio
- **Deviance** — Deviance
- **AdjGeneralized** — Adjusted generalized R-squared

The R-squared value is the proportion of the total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$R_{\text{squared}} = \text{SSR} / \text{SST}$$

To obtain any of these values as a scalar, index into the property using dot notation. For example, obtain the adjusted R-squared value in the model `mdl`:

```
r2 = mdl.Rsquared.Adjusted
```

Data Types: `struct`

SSE — Sum of squared errors

`numeric value`

This property is read-only.

Sum of squared errors (residuals), specified as a numeric value.

Data Types: `single` | `double`

SSR — Regression sum of squares

numeric value

This property is read-only.

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

Data Types: `single` | `double`

SST — Total sum of squares

numeric value

This property is read-only.

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of the response vector y from the mean (\bar{y}).

Data Types: `single` | `double`

Input Data

Distribution — Generalized distribution information

structure

This property is read-only.

Generalized distribution information, specified as a structure with the fields described in this table.

Field	Description
Name	Name of the distribution: 'normal', 'binomial', 'poisson', 'gamma', or 'inverse gaussian'
DevianceFunction	Function that computes the components of the deviance as a function of the fitted parameter values and the response values
VarianceFunction	Function that computes the theoretical variance for the distribution as a function of the fitted parameter values. When <code>DispersionEstimated</code> is <code>true</code> , <code>Dispersion</code> multiplies the variance function in the computation of the coefficient standard errors.

Data Types: `struct`

Formula — Model information

`LinearFormula` object

This property is read-only.

Model information, specified as a `LinearFormula` object.

Display the formula of the fitted model `mdl` using dot notation:

`mdl.Formula`

Link — Link function

structure

This property is read-only.

Link function, specified as a structure with the fields described in this table.

Field	Description
Name	Name of the link function, specified as a character vector. If you specify the link function using a function handle, then Name is ''.
LinkFunction	Function f that defines the link function, specified as a function handle
DevianceFunction	Derivative of f , specified as a function handle
VarianceFunction	Inverse of f , specified as a function handle

The link function is a function f that links the distribution parameter μ to the fitted linear combination Xb of the predictors:

$$f(\mu) = Xb.$$

Data Types: struct

NumObservations — Number of observations

positive integer

This property is read-only.

Number of observations the fitting function used in fitting, specified as a positive integer. **NumObservations** is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the 'Exclude' name-value pair argument) or rows with missing values.

Data Types: double

NumPredictors — Number of predictor variables

positive integer

This property is read-only.

Number of predictor variables used to fit the model, specified as a positive integer.

Data Types: double

NumVariables — Number of variables

positive integer

This property is read-only.

Number of variables in the input data, specified as a positive integer. **NumVariables** is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector.

NumVariables also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: double

PredictorNames — Names of predictors used to fit model

cell array of character vectors

This property is read-only.

Names of predictors used to fit the model, specified as a cell array of character vectors.

Data Types: cell

ResponseName — Response variable name

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: char

VariableInfo — Information about variables

table

This property is read-only.

Information about variables contained in `Variables`, specified as a table with one row for each variable and the columns described in this table.

Column	Description
Class	Variable class, specified as a cell array of character vectors, such as 'double' and 'categorical'
Range	Variable range, specified as a cell array of vectors <ul style="list-style-type: none"> Continuous variable — Two-element vector $[min, max]$, the minimum and maximum values Categorical variable — Vector of distinct variable values
InModel	Indicator of which variables are in the fitted model, specified as a logical vector. The value is <code>true</code> if the model includes the variable.
IsCategorical	Indicator of categorical variables, specified as a logical vector. The value is <code>true</code> if the variable is categorical.

`VariableInfo` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: table

VariableNames — Names of variables

cell array of character vectors

This property is read-only.

Names of variables, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in the table or dataset.

- If the fit is based on a predictor matrix and response vector, `VariableNames` contains the values specified by the 'VarNames' name-value pair argument of the fitting method. The default value of 'VarNames' is {'x1', 'x2', ..., 'xn', 'y'}.

`VariableNames` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: cell

Object Functions

Predict Responses

`feval` Predict responses of generalized linear regression model using one input for each predictor
`predict` Predict responses of generalized linear regression model
`random` Simulate responses with random noise for generalized linear regression model

Evaluate Generalized Linear Model

`coefCI` Confidence intervals of coefficient estimates of generalized linear regression model
`coefTest` Linear hypothesis test on generalized linear regression model coefficients
`devianceTest` Analysis of deviance for generalized linear regression model

Visualize Generalized Linear Model and Summary Statistics

`plotPartialDependence` Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
`plotSlice` Plot of slices through fitted generalized linear regression surface

Examples

Compact Generalized Linear Regression Model

Fit a generalized linear regression model to data and reduce the size of a full, fitted model by discarding the sample data and some information related to the fitting process.

Load the `largedata4reg` data set, which contains 15,000 observations and 45 predictor variables.

```
load largedata4reg
```

Fit a generalized linear regression model to the data using the first 15 predictor variables.

```
mdl = fitglm(X(:,1:15),Y);
```

Compact the model.

```
compactMdl = compact(mdl);
```

The compact model discards the original sample data and some information related to the fitting process, so it uses less memory than the full model.

Compare the size of the full model `mdl` and the compact model `compactMdl`.

```
vars = whos('compactMdl','mdl');  
[vars(1).bytes,vars(2).bytes]
```

```
ans = 1x2
```

```
    15518    4382502
```

The compact model consumes less memory than the full model.

More About

Deviance

Deviance of a model M_1 is twice the difference between the loglikelihood of the model M_1 and the saturated model M_s . A saturated model is the model with the maximum number of parameters that you can estimate.

For example, if you have n observations (y_i , $i = 1, 2, \dots, n$) with potentially different values for $X_i^T\beta$, then you can define a saturated model with n parameters. Let $L(b,y)$ denote the maximum value of the likelihood function for a model with the parameters b . Then the deviance of the model M_1 is

$$-2(\log L(b_1, y) - \log L(b_s, y)),$$

where b_1 and b_s contain the estimated parameters for the model M_1 and the saturated model, respectively. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where n is the number of parameters in the saturated model and p is the number of parameters in the model M_1 .

Assume you have two different generalized linear regression models M_1 and M_2 , and M_1 has a subset of the terms in M_2 . You can assess the fit of the models by comparing the deviances D_1 and D_2 of the two models. The difference of the deviances is

$$\begin{aligned} D &= D_2 - D_1 = -2(\log L(b_2, y) - \log L(b_s, y)) + 2(\log L(b_1, y) - \log L(b_s, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, the difference D has a chi-square distribution with degrees of freedom ν equal to the difference in the number of parameters estimated in M_1 and M_2 . You can obtain the p -value for this test by using `1 - chi2cdf(D, \nu)`.

Typically, you examine D using a model M_2 with a constant term and no predictors. Therefore, D has a chi-square distribution with $p - 1$ degrees of freedom. If the dispersion is estimated, the difference divided by the estimated dispersion has an F distribution with $p - 1$ numerator degrees of freedom and $n - p$ denominator degrees of freedom.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `random` functions support code generation.
- When you fit a model by using `fitglm` or `stepwiseglm`, the following restrictions apply.
 - Code generation does not support categorical predictors. You cannot supply training data in a table that contains a logical vector, character array, categorical array, string array, or cell array

of character vectors. Also, you cannot use the 'CategoricalVars' name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.

- The `Link`, `Derivative`, and `Inverse` fields of the 'Link' name-value pair argument cannot be anonymous functions. That is, you cannot generate code using a generalized linear model that was created using anonymous functions for links. Instead, define functions for link components.

For more information, see “Introduction to Code Generation” on page 31-2.

“Generalized Linear Models” on page 12-9

Introduced in R2016b

CompactRegressionEnsemble

Package: `classreg.learning.regr`

Compact regression ensemble class

Description

Compact version of a regression ensemble (of class `RegressionEnsemble`). The compact version does not include the data for training the regression ensemble. Therefore, you cannot perform some tasks with a compact regression ensemble, such as cross validation. Use a compact regression ensemble for making predictions (regressions) of new data.

Construction

`ens = compact(fullEns)` constructs a compact decision ensemble from a full decision ensemble.

Input Arguments

`fullEns`

A regression ensemble created by `fitensemble`.

Properties

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

`CombineWeights`

A character vector describing how the ensemble combines learner predictions.

`ExpandedPredictorNames`

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

`NumTrained`

Number of trained learners in the ensemble, a positive scalar.

`PredictorNames`

A cell array of names for the predictor variables, in the order in which they appear in `X`.

ResponseName

A character vector with the name of the response variable Y.

ResponseTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$.

Add or change a ResponseTransform function using dot notation:

```
ens.ResponseTransform = @function
```

Trained

The trained learners, a cell array of compact regression models.

TrainedWeights

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

Methods

loss	Regression error
predict	Predict responses using ensemble of regression models
predictorImportance	Estimates of predictor importance for regression ensemble
removeLearners	Remove members of compact regression ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Reduce Size of Regression Ensemble

Create a compact regression ensemble for efficiently making predictions on new data.

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (`Weight`) and number of cylinders (`Cylinders`).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Train a boosted ensemble of 100 regression trees using the LSBoost. Specify that `Cylinders` is a categorical variable.

```
Mdl = fitensemble(X,Y,'PredictorNames',{'W','C'},...
    'CategoricalPredictors',2)
```

```
Mdl =
  classreg.learning.regr.RegressionEnsemble
    PredictorNames: {'W' 'C'}
    ResponseName: 'Y'
  CategoricalPredictors: 2
    ResponseTransform: 'none'
    NumObservations: 94
    NumTrained: 100
    Method: 'LSBoost'
    LearnerNames: {'Tree'}
  ReasonForTermination: 'Terminated normally after completing the requested number of training iterations'
    FitInfo: [100x1 double]
  FitInfoDescription: {2x1 cell}
  Regularization: []
```

Properties, Methods

Mdl is a **RegressionEnsemble** model object that contains the training data, among other things.

Create a compact version of **Mdl**.

```
CMdl = compact(Mdl)
```

```
CMdl =
  classreg.learning.regr.CompactRegressionEnsemble
    PredictorNames: {'W' 'C'}
    ResponseName: 'Y'
  CategoricalPredictors: 2
    ResponseTransform: 'none'
    NumTrained: 100
```

Properties, Methods

CMdl is a **CompactRegressionEnsemble** model object. **CMdl** is almost the same as **Mdl**. One exception is that **CMdl** does not store the training data.

Compare the amounts of space consumed by **Mdl** and **CMdl**.

```
mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]
```

```
ans = 1x2
```

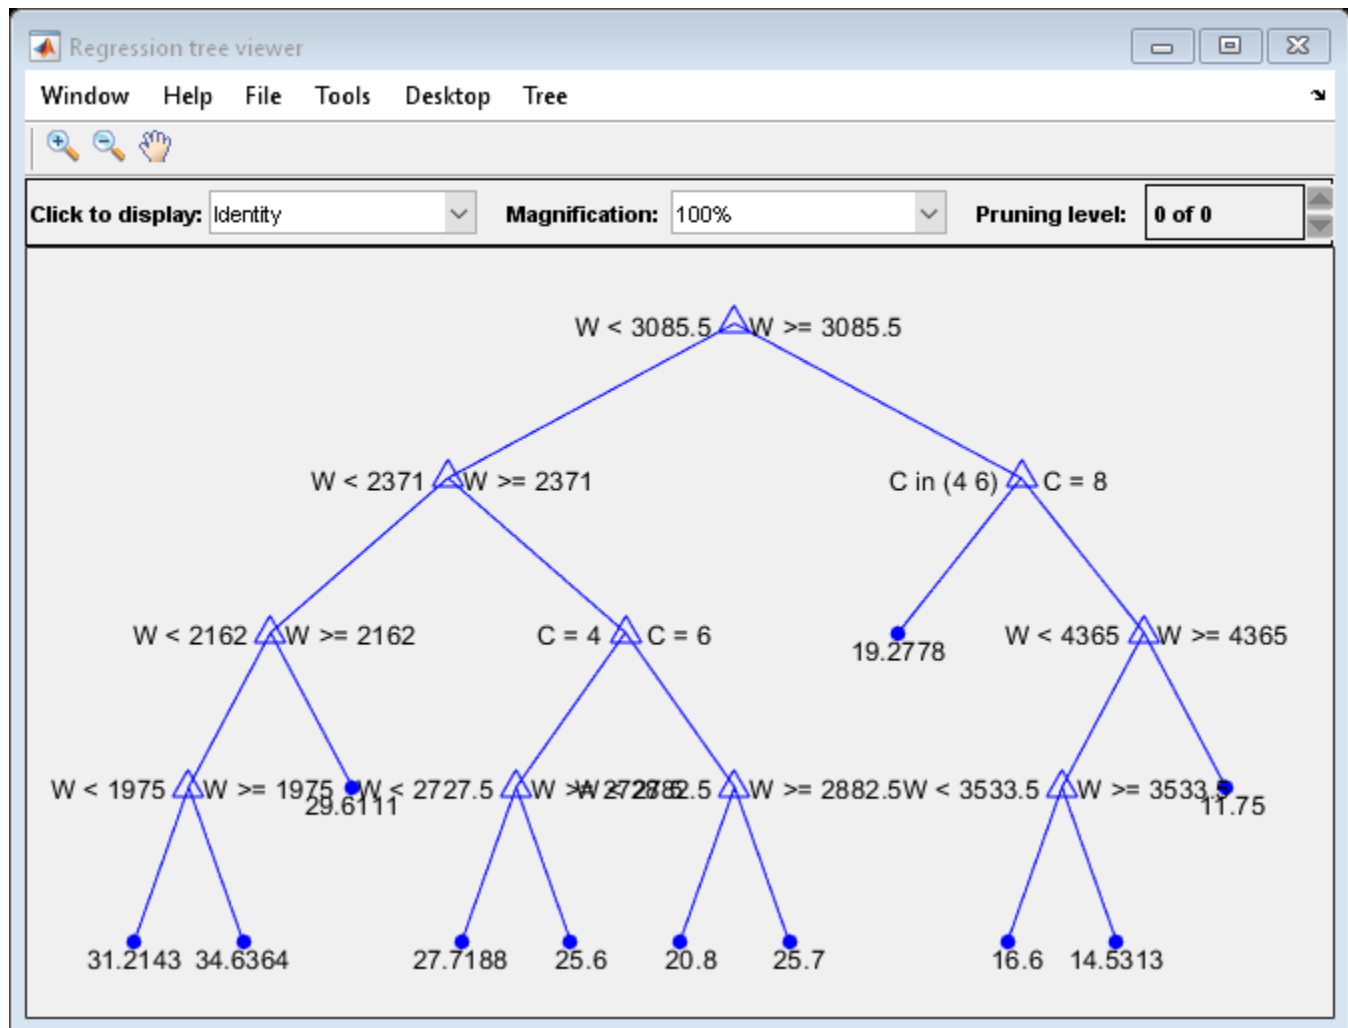

```
    497305    472380
```

Mdl consumes more space than **CMdl**.

CMdl.Trained stores the trained regression trees (**CompactRegressionTree** model objects) that compose **Mdl**.

Display a graph of the first tree in the compact ensemble.

```
view(CMdl.Trained{1}, 'Mode', 'graph');
```

By default, `fitensemble` grows shallow trees for boosted ensembles of trees.

Predict the fuel economy of a typical car using the compact ensemble.

```
typicalX = [mean(X(:,1)) mode(X(:,2))];
predMeanX = predict(CMdl,typicalX)

predMeanX = 26.2520
```

Tip

For a compact ensemble of regression trees, the `Trained` property of `ens` stores a cell vector of `ens.NumTrained CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(ens.Trained{t})
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train an ensemble by using `fitensemble`, code generation limitations for regression trees also apply to ensembles of regression trees. For more details, see “Code Generation” on page 32-751 of the `CompactRegressionTree` class.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a

CompactRegressionGP

Package: `classreg.learning.regr`

Compact Gaussian process regression model class

Description

`CompactRegressionGP` is a compact Gaussian process regression (GPR) model. The compact model consumes less memory than a full model, because it does not include the data used for training the GPR model.

Because the compact model does not include the training data, you cannot perform some tasks, such as cross-validation, using the compact model. However, you can use the compact model for making predictions or calculate regression loss for new data (use `predict` and `loss`).

Construction

`compactMdl = compact(gprMdl)` returns a compact GPR model, `compactMdl`, from a full, trained GPR model, `gprMdl`. For more information, see `compact`.

Input Arguments

gprMdl — Full, trained Gaussian process regression model

RegressionGP model

Full, trained Gaussian process regression model, specified as a `RegressionGP` model, returned by `fitrgp`.

Properties

Fitting

FitMethod — Method used to estimate the parameters

'none' | 'exact' | 'sd' | 'sr' | 'fic'

Method used to estimate the basis function coefficients, β ; noise standard deviation, σ ; and kernel parameters, θ , of the GPR model, stored as a character vector. It can be one of the following.

Fit Method	Description
'none'	No estimation. <code>fitrgp</code> uses the initial parameter values as the parameter values.
'exact'	Exact Gaussian process regression.
'sd'	Subset of data points approximation.
'sr'	Subset of regressors approximation.
'fic'	Fully independent conditional approximation.

BasisFunction — Explicit basis function

'none' | 'constant' | 'linear' | 'pureQuadratic' | function handle

Explicit basis function used in the GPR model, stored as a character vector or a function handle. It can be one of the following. If n is the number of observations, the basis function adds the term $\mathbf{H}^*\boldsymbol{\beta}$ to the model, where \mathbf{H} is the basis matrix and $\boldsymbol{\beta}$ is a p -by-1 vector of basis coefficients.

Explicit Basis	Basis Matrix
'none'	Empty matrix.
'constant'	$H = 1$ (n -by-1 vector of 1s, where n is the number of observations)
'linear'	$H = [1, X]$
'pureQuadratic'	$H = [1, X, X_2]$, where $X_2 = \begin{bmatrix} x_{11}^2 & x_{12}^2 & \dots & x_{1d}^2 \\ x_{21}^2 & x_{22}^2 & \dots & x_{2d}^2 \\ \vdots & \vdots & \vdots & \vdots \\ x_{n1}^2 & x_{n2}^2 & \dots & x_{nd}^2 \end{bmatrix}.$
Function handle	Function handle, <code>hfcn</code> , that <code>fitrgp</code> calls as: $H = hfcn(X)$, where X is an n -by- d matrix of predictors and H is an n -by- p matrix of basis functions.

Data Types: char | function_handle

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: single | double

Beta — Estimated coefficients

vector

Estimated coefficients for the explicit basis functions, stored as a vector. You can define the explicit basis function by using the `BasisFunction` name-value pair argument in `fitrgp`.

Data Types: double

Sigma — Estimated noise standard deviation

scalar value

Estimated noise standard deviation of the GPR model, stored as a scalar value.

Data Types: double

ModelParameters – Parameters used for training

GPParams object

Parameters used for training the GPR model, stored as a GPParams object.

Kernel Function**KernelFunction – Form of the covariance function**

'squaredExponential' | 'matern32' | 'matern52' | 'ardsquaredexponential' |
'ardmatern32' | 'ardmatern52' | function handle

Form of the covariance function used in the GPR model, stored as a character vector containing the name of the built-in covariance function or a function handle. It can be one of the following.

Function	Description
'squaredexponential'	Squared exponential kernel.
'matern32'	Matern kernel with parameter 3/2.
'matern52'	Matern kernel with parameter 5/2.
'ardsquaredexponential'	Squared exponential kernel with a separate length scale per predictor.
'ardmatern32'	Matern kernel with parameter 3/2 and a separate length scale per predictor.
'ardmatern52'	Matern kernel with parameter 5/2 and a separate length scale per predictor.
Function handle	A function handle that <code>fitrgp</code> can call like this: $K_{mn} = kfcn(X_m, X_n, \theta)$ where X_m is an m -by- d matrix, X_n is an n -by- d matrix and K_{mn} is an m -by- n matrix of kernel products such that $K_{mn}(i,j)$ is the kernel product between $X_m(i,:)$ and $X_n(j,:)$. θ is the r -by-1 unconstrained parameter vector for <code>kfcn</code> .

Data Types: char | function_handle

KernelInformation – Information about the parameters of the kernel function

structure

Information about the parameters of the kernel function used in the GPR model, stored as a structure with the following fields.

Field Name	Description
Name	Name of the kernel function
KernelParameters	Vector of the estimated kernel parameters
KernelParameterNames	Names associated with the elements of KernelParameters.

Data Types: struct

Prediction**PredictMethod — Method used to make predictions**`'exact' | 'bcd' | 'sd' | 'sr' | 'fic'`

Method that `predict` uses to make predictions from the GPR model, stored as a character vector. It can be one of the following.

PredictMethod	Description
'exact'	Exact Gaussian process regression
'bcd'	Block Coordinate Descent
'sd'	Subset of Data points approximation
'sr'	Subset of Regressors approximation
'fic'	Fully Independent Conditional approximation

Alpha — Weights

numeric vector

Weights used to make predictions from the trained GPR model, stored as a numeric vector. `predict` computes the predictions for a new predictor matrix X_{new} by using the product

$$K(X_{new}, A) * \alpha .$$

$K(X_{new}, A)$ is the matrix of kernel products between X_{new} and active set vector A and α is a vector of weights.

Data Types: double

ResponseTransform — Transformation applied to predicted response`'none'` (default)

Transformation applied to the predicted response, stored as a character vector describing how the response values predicted by the model are transformed. In `RegressionGP`, `ResponseTransform` is `'none'` by default, and `RegressionGP` does not use `ResponseTransform` when making predictions.

Active Set Selection**ActiveSetVectors — Subset of training data**

matrix

Subset of training data used to make predictions from the GPR model, stored as a matrix.

`predict` computes the predictions for a new predictor matrix X_{new} by using the product

$$K(X_{new}, A) * \alpha .$$

$K(X_{new}, A)$ is the matrix of kernel products between X_{new} and active set vector A and α is a vector of weights.

`ActiveSetVectors` is equal to the training data X for exact GPR fitting and a subset of the training data X for sparse GPR methods. When there are categorical predictors in the model, `ActiveSetVectors` contains dummy variables for the corresponding predictors.

Data Types: double

ActiveSetMethod — Method used to select the active set

'sgma' | 'entropy' | 'likelihood' | 'random'

Method used to select the active set for sparse methods ('sd', 'sr', or 'fic'), stored as a character vector. It can be one of the following.

ActiveSetMethod	Description
'sgma'	Sparse greedy matrix approximation
'entropy'	Differential entropy-based selection
'likelihood'	Subset of regressors log likelihood-based selection
'random'	Random selection

The selected active set is used in parameter estimation or prediction, depending on the choice of FitMethod and PredictMethod in fitrgp.

ActiveSetSize — Size of the active set

integer value

Size of the active set for sparse methods ('sd', 'sr', or 'fic'), stored as an integer value.

Data Types: double

Methods

loss Regression error for Gaussian process regression model
 predict Predict response of Gaussian process regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The predict function supports code generation.
- When you train a Gaussian process regression model by using fitrgp and you supply training data in a table, the predictors must be numeric (double or single). Code generation does not support categorical predictors (logical, categorical, char, string, or cell). Also, you cannot use the 'CategoricalPredictors' name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using dummyvar before fitting the model.

For more information, see “Introduction to Code Generation” on page 31-2.

Topics

Class Attributes (MATLAB)

Property Attributes (MATLAB)

Introduced in R2015b

CompactRegressionSVM

Package: `classreg.learning.regr`

Compact support vector machine regression model

Description

`CompactRegressionSVM` is a compact support vector machine (SVM) regression model. It consumes less memory than a full, trained support vector machine model (`RegressionSVM` model) because it does not store the data used to train the model.

Because the compact model does not store the training data, you cannot use it to perform certain tasks, such as cross validation. However, you can use a compact SVM regression model to predict responses using new input data.

Construction

`compactMdl = compact mdl` returns a compact SVM regression model `compactMdl` from a full, trained SVM regression model, `mdl`. For more information, see `compact`.

Input Arguments

mdl — Full, trained SVM regression model

`RegressionSVM` model

Full, trained SVM regression model, specified as a `RegressionSVM` model returned by `fitrsvm`.

Properties

Alpha — Dual problem coefficients

vector of numeric values

Dual problem coefficients, specified as a vector of numeric values. `Alpha` contains m elements, where m is the number of support vectors in the trained SVM regression model. The dual problem introduces two Lagrange multipliers for each support vector. The values of `Alpha` are the differences between the two estimated Lagrange multipliers for the support vectors. For more details, see “Understanding Support Vector Machine Regression” on page 25-2.

If you specified to remove duplicates using `RemoveDuplicates`, then, for a particular set of duplicate observations that are support vectors, `Alpha` contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one observation from the set of duplicates and a coefficient of 0 to all other duplicate observations in the set.

Data Types: `single` | `double`

Beta — Primal linear problem coefficients

vector of numeric values | ' [] '

Primal linear problem coefficients, stored as a numeric vector of length p , where p is the number of predictors in the SVM regression model.

The values in `Beta` are the linear coefficients for the primal optimization problem.

If the model is obtained using a kernel function other than `'linear'`, this property is empty (`[]`).

The `predict` method computes predicted response values for the model as $YFIT = (X/S) \times \text{Beta} + \text{Bias}$, where `S` is the value of the kernel scale stored in the `KernelParameters.Scale` property.

Data Types: `double`

Bias — Bias term

scalar value

Bias term in the SVM regression model, stored as a scalar value.

Data Types: `double`

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

KernelParameters — Kernel function parameters

structure

Kernel function parameters, stored as a structure with the following fields.

Field	Description
Function	Kernel function name (a character vector).
Scale	Numeric scale factor used to divide predictor values.

You can specify values for `KernelParameters.Function` and `KernelParameters.Scale` by using the `KernelFunction` and `KernelScale` name-value pair arguments in `fitrsvm`, respectively.

Data Types: `struct`

Mu — Predictor means

vector of numeric values | `[]`

Predictor means, stored as a vector of numeric values.

If the training data is standardized, then `Mu` is a numeric vector of length p , where p is the number of predictors used to train the model. In this case, the `predict` method centers predictor matrix `X` by subtracting the corresponding element of `Mu` from each column.

If the training data is not standardized, then `Mu` is empty (`[]`).

Data Types: `single` | `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names, stored as a cell array of character vectors containing the name of each predictor in the order in which they appear in `X`. `PredictorNames` has a length equal to the number of columns in `X`.

Data Types: `cell`

ResponseName — Response variable name

character vector

Response variable name, stored as a character vector.

Data Types: `char`

ResponseTransform — Response transformation function

'none' | function handle

Response transformation function, specified as 'none' or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

Sigma — Predictor standard deviations

vector of numeric values | `[]`

Predictor standard deviations, stored as a vector of numeric values.

If the training data is standardized, then `Sigma` is a numeric vector of length p , where p is the number of predictors used to train the model. In this case, the `predict` method scales the predictor matrix `X` by dividing each column by the corresponding element of `Sigma`, after centering each element using `Mu`.

If the training data is not standardized, then `Sigma` is empty (`[]`).

Data Types: `single` | `double`

SupportVectors — Support vectors

matrix of numeric values

Support vectors, stored as an m -by- p matrix of numeric values. m is the number of support vectors (`sum(Mdl.IsSupportVector)`), and p is the number of predictors in `X`.

If you specified to remove duplicates using `RemoveDuplicates`, then for a given set of duplicate observations that are support vectors, `SupportVectors` contains one unique support vector.

Data Types: `single` | `double`

Methods

<code>discardSupportVectors</code>	Discard support vectors
<code>loss</code>	Regression error for support vector machine regression model
<code>predict</code>	Predict responses using support vector machine regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Compact an SVM Regression Model

This example shows how to reduce the size of a full, trained SVM regression model by discarding the training data and some information related to the training process.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`. Read the data into a `table`.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for `sex`, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model using a Gaussian kernel function and an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale','auto','Standardize',true)
```

```
mdl =
```

```
RegressionSVM
  PredictorNames: {1x8 cell}
  ResponseName: 'Var9'
  CategoricalPredictors: 1
  ResponseTransform: 'none'
  Alpha: [3635x1 double]
  Bias: 10.8144
  KernelParameters: [1x1 struct]
  Mu: [1x10 double]
  Sigma: [1x10 double]
  NumObservations: 4177
  BoxConstraints: [4177x1 double]
  ConvergenceInfo: [1x1 struct]
```

```

    IsSupportVector: [4177x1 logical]
        Solver: 'SMO'

```

Properties, Methods

Compact the model.

```
compactMdl = compact mdl
```

```
compactMdl =
```

```

classreg.learning.regr.CompactRegressionSVM
    PredictorNames: {1x8 cell}
    ResponseName: 'Var9'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
    Alpha: [3635x1 double]
    Bias: 10.8144
    KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
    SupportVectors: [3635x10 double]

```

Properties, Methods

The compacted model discards the training data and some information related to the training process.

Compare the size of the full model `mdl` and the compact model `compactMdl`.

```
vars = whos('compactMdl', 'mdl');
[vars(1).bytes, vars(2).bytes]
```

```
ans =
```

```

    323793    775968

```

The compacted model consumes about half the memory of the full model.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train an SVM regression model by using `fitrsvm`, the following restrictions apply.
 - Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the `'CategoricalPredictors'` name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
 - The value of the `'ResponseTransform'` name-value pair argument cannot be an anonymous function. For fixed-point code generation, the `'ResponseTransform'` value must be `'none'`.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2015b

CompactRegressionTree

Package: `classreg.learning.regr`

Compact regression tree

Description

Compact version of a regression tree (of class `RegressionTree`). The compact version does not include the data for training the regression tree. Therefore, you cannot perform some tasks with a compact regression tree, such as cross validation. Use a compact regression tree for making predictions (regressions) of new data.

Construction

`ctree = compact(tree)` constructs a compact decision tree from a full decision tree.

Input Arguments

tree — Full, trained regression tree

`RegressionTree` object

Full, trained regression tree, specified as a `RegressionTree` object constructed by `fitrtree`.

Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

CategoricalSplits

An n -by-2 cell array, where n is the number of categorical splits in `tree`. Each row in `CategoricalSplits` gives left and right values for a categorical split. For each branch node with categorical split j based on a categorical predictor variable z , the left child is chosen if z is in `CategoricalSplits(j,1)` and the right child is chosen if z is in `CategoricalSplits(j,2)`. The splits are in the same order as nodes of the tree. Nodes for these splits can be found by running `cuttype` and selecting 'categorical' cuts from top to bottom.

Children

An n -by-2 array containing the numbers of the child nodes for each node in `tree`, where n is the number of nodes. Leaf nodes have child node 0.

CutCategories

An n -by-2 cell array of the categories used at branches in `tree`, where n is the number of nodes. For each branch node i based on a categorical predictor variable x , the left child is chosen if x is among the categories listed in `CutCategories{i,1}`, and the right child is chosen if x is among those

listed in `CutCategories{i,2}`. Both columns of `CutCategories` are empty for branch nodes based on continuous predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPoint

An n -element vector of the values used as cut points in `tree`, where n is the number of nodes. For each branch node i based on a continuous predictor variable x , the left child is chosen if `CutPoint<v(i)` and the right child is chosen if `x>=CutPoint(i)`. `CutPoint` is NaN for branch nodes based on categorical predictors and for leaf nodes.

CutType

An n -element cell array indicating the type of cut at each node in `tree`, where n is the number of nodes. For each node i , `CutType{i}` is:

- 'continuous' — If the cut is defined in the form $x < v$ for a variable x and cut point v .
- 'categorical' — If the cut is defined by whether a variable x takes a value in a set of categories.
- '' — If i is a leaf node.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictor

An n -element cell array of the names of the variables used for branching in each node in `tree`, where n is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty character vector.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictorIndex

An n -element array of numeric indices for the variables used for branching in each node in `tree`, where n is the number of nodes. For more information, see `CutPredictor`.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

IsBranchNode

An n -element logical vector `ib` that is `true` for each branch node and `false` for each leaf node of `tree`.

NodeError

An n -element vector e of the errors of the nodes in `tree`, where n is the number of nodes. $e(i)$ is the misclassification probability for node i .

NodeMean

An n -element numeric array with mean values in each node of `tree`, where n is the number of nodes in the tree. Every element in `NodeMean` is the average of the true Y values over all observations in the node.

NodeProbability

An n -element vector p of the probabilities of the nodes in `tree`, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

NodeRisk

An n -element vector of the risk of the nodes in the tree, where n is the number of nodes. The risk for each node is the node error weighted by the node probability.

NodeSize

An n -element vector `sizes` of the sizes of the nodes in `tree`, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

NumNodes

The number of nodes n in `tree`.

Parent

An n -element vector p containing the number of the parent node for each node in `tree`, where n is the number of nodes. The parent of the root node is \emptyset .

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X .

PruneAlpha

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to M , then `PruneAlpha` has $M + 1$ elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

PruneList

An n -element numeric vector with the pruning levels in each node of `tree`, where n is the number of nodes. The pruning levels range from 0 (no pruning) to M , where M is the distance between the deepest leaf and the root node.

ResponseName

Name of the response variable Y , a character vector.

ResponseTransform

Function handle for transforming the raw response values (mean squared error). The function handle must accept a matrix of response values and return a matrix of the same size. The default 'none' means $@(x)x$, or no transformation.

Add or change a ResponseTransform function using dot notation:

```
ctree.ResponseTransform = @function
```

SurrogateCutCategories

An n -element cell array of the categories used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutCategories{k}` is a cell array. The length of `SurrogateCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutCategories{k}` is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutCategories` contains an empty cell.

SurrogateCutFlip

An n -element cell array of the numeric cut assignments used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutFlip{k}` is a numeric vector. The length of `SurrogateCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or $+1$. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and the cut assignment for this surrogate split is $+1$, or if $Z \geq C$ and the cut assignment for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and the cut assignment for this surrogate split is $+1$, or if $Z < C$ and the cut assignment for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutFlip` contains an empty array.

SurrogateCutPoint

An n -element cell array of the numeric values used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutPoint{k}` is a numeric vector. The length of `SurrogateCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutPoint{k}` is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z < C$ and `SurrogateCutFlip` for this surrogate split is -1 . The order of the surrogate split variables at each

node is matched to the order of variables returned by `SurrogateCutVar`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPoint` contains an empty cell.

SurrogateCutType

An n -element cell array indicating types of surrogate splits at each node in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutType{k}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutType` contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form $Z < V$ for a variable Z and cut point V or 'categorical' if the cut is defined by whether Z takes a value in a set of categories.

SurrogateCutPredictor

An n -element cell array of the names of the variables used for surrogate splits in each node in `tree`, where n is the number of nodes in `tree`. Every element of `SurrogateCutPredictor` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPredictor` contains an empty cell.

SurrogatePredictorAssociation

An n -element cell array of the predictive measures of association for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogatePredictorAssociation{k}` is a numeric vector. The length of `SurrogatePredictorAssociation{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogatePredictorAssociation{k}` gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogatePredictorAssociation` contains an empty cell.

Methods

<code>loss</code>	Regression error
<code>surrogateAssociation</code>	Mean predictive measure of association for surrogate splits in regression tree
<code>predict</code>	Predict responses using regression tree
<code>predictorImportance</code>	Estimates of predictor importance for regression tree
<code>view</code>	View regression tree

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Construct and Compact a Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree for the sample data.

```
tree = fitrtree([Weight, Cylinders],MPG,...
    'MinParentSize',20,...
    'PredictorNames',{'W','C'});
```

Make a compact version of the tree.

```
ctree = compact(tree);
```

Compare the size of the compact tree to that of the full tree.

```
t = whos('tree'); % t.bytes = size of tree in bytes
c = whos('ctree'); % c.bytes = size of ctree in bytes
[c.bytes t.bytes]
```

```
ans = 1×2
```

```
4143    7390
```

The compact tree is smaller than the full tree.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train a regression tree model by using `fitrtree`, the following restrictions apply.
 - Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the `'CategoricalPredictors'` name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
 - The value of the `'ResponseTransform'` name-value pair argument cannot be an anonymous function. For fixed-point code generation, the `'ResponseTransform'` value must be `'none'`.
 - You cannot use surrogate splits, that is, the value of the `'Surrogate'` name-value pair argument must be `'off'`.

For more information, see “Introduction to Code Generation” on page 31-2.

CompactTreeBagger class

Compact ensemble of decision trees grown by bootstrap aggregation

Description

`CompactTreeBagger` class is a lightweight class that contains the trees grown using `TreeBagger`. `CompactTreeBagger` does not preserve any information about how `TreeBagger` grew the decision trees. It does not contain the input data used for growing trees, nor does it contain training parameters such as minimal leaf size or number of variables sampled for each decision split at random. You can only use `CompactTreeBagger` for predicting the response of the trained ensemble given new data *X*, and other related functions.

`CompactTreeBagger` lets you save the trained ensemble to disk, or use it in any other way, while discarding training data and various parameters of the training configuration irrelevant for predicting response of the fully grown ensemble. This reduces storage and memory requirements, especially for ensembles trained on large data sets.

Construction

`CompactTreeBagger` Create `CompactTreeBagger` object

`CMdl = compact(Mdl)` creates a compact version of `Mdl`, a `TreeBagger` model object. You can predict regressions using `CMdl` exactly as you can using `Mdl`. However, since `CMdl` does not contain training data, you cannot perform some actions, such as make out-of-bag predictions using `oobPredict`.

Methods

<code>combine</code>	Combine two ensembles
<code>error</code>	Error (misclassification probability or MSE)
<code>margin</code>	Classification margin
<code>mdsprox</code>	Multidimensional scaling of proximity matrix
<code>meanMargin</code>	Mean classification margin
<code>outlierMeasure</code>	Outlier measure for data
<code>predict</code>	Predict responses using ensemble of bagged decision trees
<code>proximity</code>	Proximity matrix for data
<code>setDefaultYfit</code>	Set default value for <code>predict</code>

Properties

ClassNames

The `ClassNames` property is a cell array containing the class names for the response variable *Y* supplied to `TreeBagger`. This property is empty for regression trees.

DefaultYfit

The `DefaultYfit` property controls what predicted value `CompactTreeBagger` returns when no prediction is possible, for example when the `predict` method needs to predict for an observation which has only false values in the matrix supplied through `'useifort'` argument.

For classification, you can set this property to either `''` or `'MostPopular'`. If you choose `'MostPopular'` (default), the property value becomes the name of the most probable class in the training data.

For regression, you can set this property to any numeric scalar. The default is the mean of the response for the training data.

DeltaCriterionDecisionSplit

The `DeltaCriterionDecisionSplit` property is a numeric array of size 1-by-*Nvars* of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.

Method

The `Method` property is `'classification'` for classification ensembles and `'regression'` for regression ensembles.

NumPredictorSplit

The `NumPredictorSplit` property is a numeric array of size 1-by-*Nvars*, where every element gives a number of splits on this predictor summed over all trees.

NumTrees

The `NumTrees` property is a scalar equal to the number of decision trees in the ensemble.

PredictorNames

The `PredictorNames` property is a cell array containing the names of the predictor variables (features). These names are taken from the optional `'names'` parameter that supplied to `TreeBagger`. The default names are `'x1'`, `'x2'`, etc.

SurrogateAssociation

The `SurrogateAssociation` property is a matrix of size *Nvars*-by-*Nvars* with predictive measures of variable association, averaged across the entire ensemble of grown trees. If you grew the ensemble setting `'surrogate'` to `'on'`, this matrix for each tree is filled with predictive measures of association averaged over the surrogate splits. If you grew the ensemble setting `'surrogate'` to `'off'` (default), `SurrogateAssociation` is diagonal.

Trees

The `Trees` property is a cell array of size `NumTrees`-by-1 containing the trees in the ensemble.

Examples

Reduce Size of Bag of Trees

Create a compact bag of trees for efficiently making predictions on new data.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a bag of 100 classification trees using all measurements and the `AdaBoostM1` method.

```
Mdl = TreeBagger(100,X,Y,'Method','classification')
```

```
Mdl =
  TreeBagger
Ensemble with 100 bagged decision trees:
      Training X:      [351x34]
      Training Y:      [351x1]
      Method:          classification
      NumPredictors:   34
      NumPredictorsToSample: 6
      MinLeafSize:     1
      InBagFraction:   1
      SampleWithReplacement: 1
      ComputeOOBPrediction: 0
      ComputeOOBPredictorImportance: 0
      Proximity:       []
      ClassNames:     'b'      'g'
```

Properties, Methods

`Mdl` is a `TreeBagger` model object that contains the training data, among other things.

Create a compact version of `Mdl`.

```
CMdl = compact(Mdl)
```

```
CMdl =
  CompactTreeBagger
Ensemble with 100 bagged decision trees:
      Method:          classification
      NumPredictors:   34
      ClassNames:     'b' 'g'
```

Properties, Methods

`CMdl` is a `CompactTreeBagger` model object. `CMdl` is almost the same as `Mdl`. One exception is that it does not store the training data.

Compare the amounts of space consumed by `Mdl` and `CMdl`.

```
mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]
```

```
ans = 1x2
```

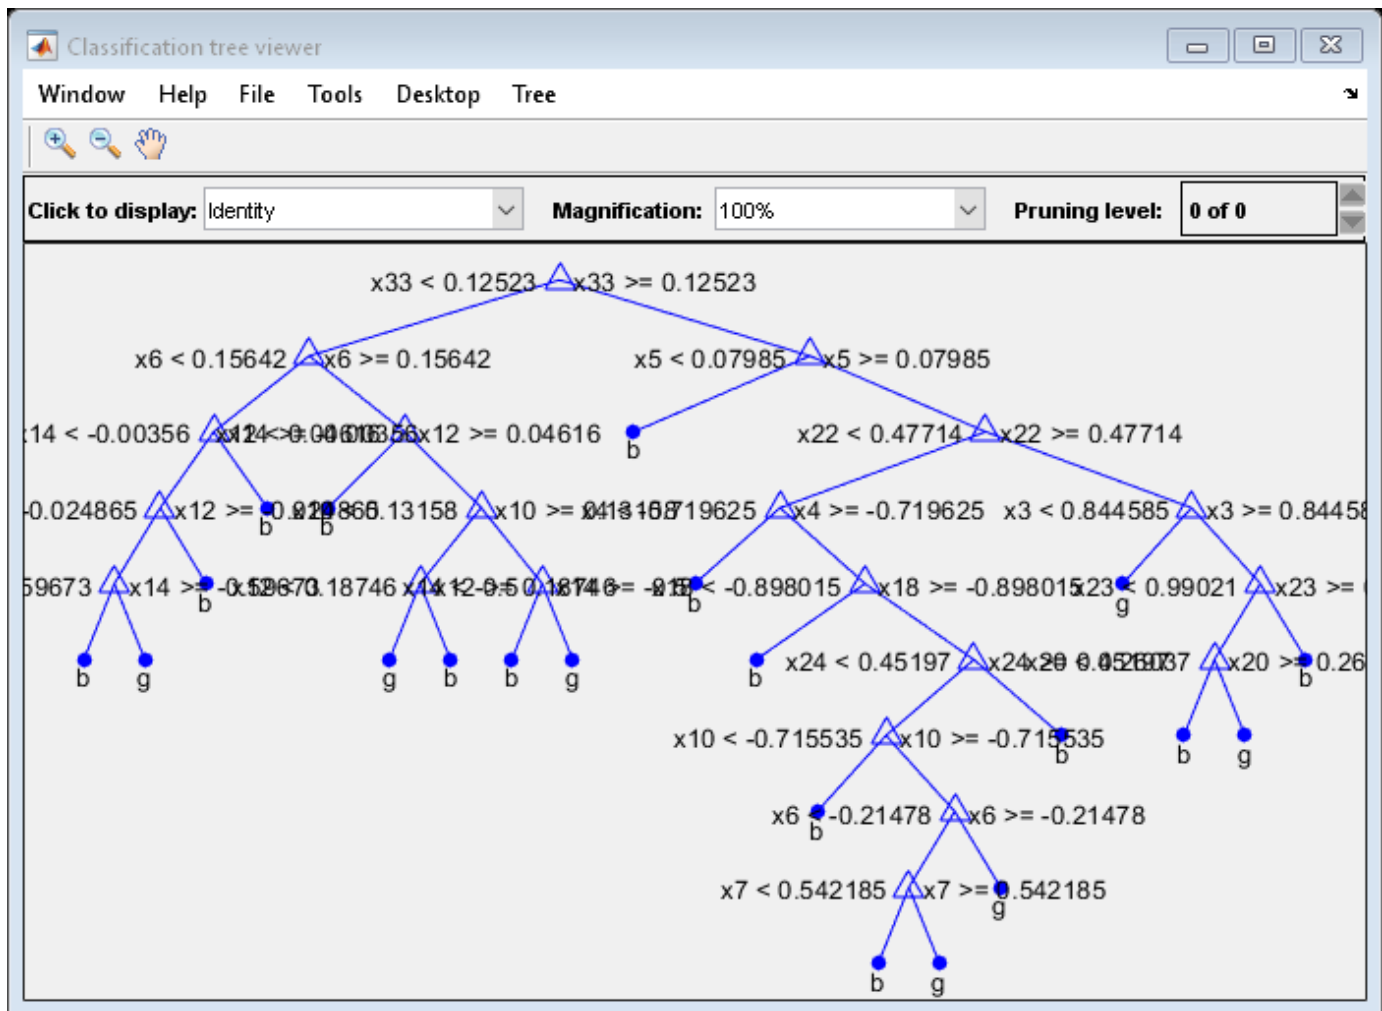

1069822 931016

Mdl consumes more space than CMdl.

CMdl.Trees stores the trained classification trees (CompactClassificationTree model objects) that compose Mdl.

Display a graph of the first tree in the compact model.

```
view(CMdl.Trees{1}, 'Mode', 'graph');
```

By default, TreeBagger grows deep trees.

Predict the label of the mean of X using the compact ensemble.

```
predMeanX = predict(CMdl, mean(X))
```

```
predMeanX = 1x1 cell array
    {'g'}
```

Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes \(MATLAB\)](#) in the MATLAB Object-Oriented Programming documentation.

Tip

The `Trees` property of `CMDL` stores a cell vector of `CMDL.NumTrees` `CompactClassificationTree` or `CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(CMDL.Trees{t})
```

CompactTreeBagger

Class: CompactTreeBagger

Create CompactTreeBagger object

Description

When you use the `TreeBagger` constructor to grow trees, it creates a `CompactTreeBagger` object. You can obtain the compact object from the full `TreeBagger` object using the `TreeBagger/compact` method. You do not create an instance of `CompactTreeBagger` directly.

compare

Class: GeneralizedLinearMixedModel

Compare generalized linear mixed-effects models

Syntax

```
results = compare(glme, altglme)
results = compare(glme, altglme, Name, Value)
```

Description

`results = compare(glme, altglme)` returns the results of a likelihood ratio test on page 32-762 that compares the generalized linear mixed-effects models `glme` and `altglme`. To conduct a valid likelihood ratio test, both models must use the same response vector in the fit, and `glme` must be nested in `altglme`. Always input the smaller model first, and the larger model second.

`compare` tests the following null and alternate hypotheses:

- H_0 : Observed response vector is generated by `glme`.
- H_1 : Observed response vector is generated by model `altglme`.

`results = compare(glme, altglme, Name, Value)` returns the results of a likelihood ratio test using additional options specified by one or more `Name, Value` pair arguments. For example, you can check if the first input model, `glme`, is nested in the second input model, `altglme`.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

You can create a GeneralizedLinearMixedModel object by fitting a generalized linear mixed-effects model to your sample data using `fitglme`. To conduct a valid likelihood ratio test on two models that have response distributions other than normal, you must fit both models using the 'ApproximateLaplace' or 'Laplace' fit method. Models with response distributions other than normal that are fitted using 'MPL' or 'REMP' cannot be compared using a likelihood ratio test.

altglme — Alternative generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Alternative generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. `altglme` must fit to the same response vector as `glme`, but with different model specifications. `glme` must be nested in `altglme`, such that you can obtain `glme` from `altglme` by setting some of the model parameters of `altglme` to fixed values such as 0.

You can create a GeneralizedLinearMixedModel object by fitting a generalized linear mixed-effects model to your sample data using `fitglme`. To conduct a valid likelihood ratio test on two

models that have response distributions other than normal, you must fit both models using the 'ApproximateLaplace' or 'Laplace' fit method. Models with response distributions other than normal that are fitted using 'MPL' or 'REMP' cannot be compared using a likelihood ratio test.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

CheckNesting – Indicator to check nesting between two models

`true` (default) | `false`

Indicator to check nesting on page 32-763 between two models, specified as the comma-separated pair consisting of 'CheckNesting' and either `true` or `false`. If 'CheckNesting' is `true`, then `compare` checks if the smaller model `glme` is nested in the larger model `altglme`. If the nesting requirements are not satisfied, then `compare` returns an error. If 'CheckNesting' is `false`, then `compare` does not perform this check.

Example: 'CheckNesting', `true`

Output Arguments

results – Results of likelihood ratio test

table

Results of the likelihood ratio test, returned as a table with two rows. The first row is for `glme`, and the second row is for `altglme`. The columns of `results` contain the following.

Column Name	Description
Model	Name of the model
DF	Degrees of freedom
AIC	Akaike information criterion for the model
BIC	Bayesian information criterion for the model
LogLik	Maximized log likelihood for the model
LRStat	Likelihood ratio test statistic for comparing <code>altglme</code> and <code>glme</code>
deltaDF	DF for <code>altglme</code> minus DF for <code>glme</code>
pValue	p -value for the likelihood ratio test

Examples

Compare Mixed-Effects Models

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to

decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a fixed-effects-only model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Specify the response distribution as Poisson, the link function as log, and the fit method as Laplace. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

```
FEglme = fitglm(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier', 'Distribution',
```

Fit a second model that uses the same fixed-effects predictors, response distribution, link function, and fit method. This time, include a random-effects intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglm(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', 'Di
```

Compare the two models using a theoretical likelihood ratio test. Specify 'CheckNesting' as true, so `compare` returns a warning if the nesting requirements are not satisfied.

```
results = compare(FEglme,glme,'CheckNesting',true)

results =
  Theoretical Likelihood Ratio Test

  Model    DF    AIC    BIC    LogLik    LRStat    deltaDF
FEglme    6    431.02  446.65  -209.51    16.672    1
glme      7    416.35  434.58  -201.17    16.672    1

pValue

4.4435e-05
```

Since `compare` did not return an error, the nesting requirements are satisfied. The small p -value indicates that `compare` rejects the null hypothesis that the observed response vector is generated by the model `FEglme`, and instead accepts the alternate model `glme`. The smaller AIC and BIC values for `glme` also support the conclusion that `glme` provides a better fitting model for the response.

More About

Likelihood Ratio Test

A *likelihood ratio test* compares the specifications of two nested models by assessing the significance of restrictions to an extended model with unrestricted parameters. Under the null hypothesis H_0 , the likelihood ratio test statistic has an approximate chi-squared reference distribution with degrees of freedom `deltaDF`.

When comparing two models, `compare` computes the p -value for the likelihood ratio test by comparing the observed likelihood ratio test statistic with this chi-squared reference distribution. A small p -value leads to a rejection of H_0 in favor of H_1 , and acceptance of the alternate model `altglme`. On the other hand, a large p -value indicates that we cannot reject H_0 , and reflects insufficient evidence to accept the model `altglme`.

The p -values obtained using the likelihood ratio test can be conservative when testing for the presence or absence of random-effects terms, and anti-conservative when testing for the presence or absence of fixed-effects terms. Instead, use the `fixedEffects` or `coefTest` methods to test for fixed effects.

To conduct a valid likelihood ratio test on GLME models, both models must be fitted using a Laplace or approximate Laplace fit method. Models fitted using a maximum pseudo likelihood (MPL) or restricted maximum pseudo likelihood (REMPL) method cannot be compared using a likelihood ratio test. When comparing models fitted using MPL, the maximized log likelihood of the pseudodata from the final pseudo likelihood iteration is used in the likelihood ratio test. If you compare models with non-normal distributions fitted using MPL, then `compare` gives a warning that the likelihood ratio test is using maximized log likelihood of pseudodata from the final pseudo likelihood iteration. To use the true maximized log likelihood in the likelihood ratio test, fit both `glme` and `altglme` using approximate Laplace or Laplace prior to model comparison.

Nesting Requirements

To conduct a valid likelihood ratio test, `glme` must be nested in `altglme`. The `'CheckNesting'`, `true` name-value pair argument checks the following requirements, and returns an error if any are not satisfied:

- You must fit both models (`glme` and `altglme`) using the `'ApproximateLaplace'` or `'Laplace'` fit method. You cannot compare GLME models fitted using `'MPL'` or `'REMP'` using a likelihood ratio test.
- You must fit both models using the same response vector, response distribution, and link function.
- The smaller model (`glme`) must be nested within the larger model (`altglme`), such that you can obtain `glme` from `altglme` by setting some of the model parameters of `altglme` to fixed values such as 0.
- The maximized log likelihood of the larger model (`altglme`) must be greater than or equal to the maximized log likelihood of the smaller model (`glme`).
- The weight vectors used to fit `glme` and `altglme` must be identical.
- The random-effects design matrix of the larger model (`altglme`) must contain the random-effects design matrix of the smaller model (`glme`).
- The fixed-effects design matrix of the larger model (`altglme`) must contain the fixed-effects design matrix of the smaller model (`glme`).

Akaike and Bayesian Information Criteria

The *Akaike information criterion* (AIC) is $AIC = -2\log L_M + 2(param)$.

$\log L_M$ depends on the method used to fit the model.

- If you use `'Laplace'` or `'ApproximateLaplace'`, then $\log L_M$ is the maximized log likelihood.
- If you use `'MPL'`, then $\log L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use `'REMP'`, then $\log L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

$param$ is the total number of parameters estimated in the model. For most GLME models, $param$ is equal to $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance, excluding the residual variance, and p is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then $param$ is equal to $(nc + p)$.

The *Bayesian information criterion* (BIC) is $BIC = -2*\log L_M + \ln(n_{eff})(param)$.

$\log L_M$ depends on the method used to fit the model.

- If you use `'Laplace'` or `'ApproximateLaplace'`, then $\log L_M$ is the maximized log likelihood.
- If you use `'MPL'`, then $\log L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use `'REMP'`, then $\log L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

n_{eff} is the effective number of observations.

- If you use 'MPL', 'Laplace', or 'ApproximateLaplace', then $n_{eff} = n$, where n is the number of observations.
- If you use 'REML', then $n_{eff} = n - p$.

$param$ is the total number of parameters estimated in the model. For most GLME models, $param$ is equal to $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance, excluding the residual variance, and p is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then $param$ is equal to $(nc + p)$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, p . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

For models fitted using 'MPL' and 'REML', AIC and BIC are based on the log likelihood (or restricted log likelihood) of pseudo data from the final pseudo likelihood iteration. Therefore, a direct comparison of AIC and BIC values between models fitted using 'MPL' and 'REML' is not appropriate.

compare

Class: LinearMixedModel

Compare linear mixed-effects models

Syntax

```
results = compare(lme, altlme)
results = compare( ____, Name, Value)

[results, siminfo] = compare(lme, altlme, 'NSim', nsim)
[results, siminfo] = compare( ____, Name, Value)
```

Description

`results = compare(lme, altlme)` returns the results of a likelihood ratio test on page 32-773 that compares the linear mixed-effects models `lme` and `altlme`. Both models must use the same response vector in the fit and `lme` must be nested in `altlme` for a valid theoretical likelihood ratio test. Always input the smaller model first, and the larger model second.

`compare` tests the following null and alternate hypotheses:

H_0 : Observed response vector is generated by `lme`.

H_1 : Observed response vector is generated by model `altlme`.

It is recommended that you fit `lme` and `altlme` using the maximum likelihood (ML) method prior to model comparison. If you use the restricted maximum likelihood (REML) method, then both models must have the same fixed-effects design matrix.

To test for fixed effects, use `compare` with the simulated likelihood ratio test on page 32-774 when `lme` and `altlme` are fit using ML or use the `fixedEffects`, `anova`, or `coefTest` methods.

`results = compare(____, Name, Value)` also returns the results of a likelihood ratio test that compares linear mixed-effects models `lme` and `altlme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can check if the first input model is nested in the second input model.

`[results, siminfo] = compare(lme, altlme, 'NSim', nsim)` returns the results of a simulated likelihood ratio test that compares linear mixed-effects models `lme` and `altlme`.

You can fit `lme` and `altlme` using ML or REML. Also, `lme` does not have to be nested in `altlme`. If you use the restricted maximum likelihood (REML) method to fit the models, then both models must have the same fixed-effects design matrix.

`[results, siminfo] = compare(____, Name, Value)` also returns the results of a simulated likelihood ratio test that compares linear mixed-effects models `lme` and `altlme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can change the options for performing the simulated likelihood ratio test, or change the confidence level of the confidence interval for the p -value.

Input Arguments

lme — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

altlme — Alternative linear mixed-effects model

`LinearMixedModel` object

Alternative linear mixed-effects model fit to the same response vector but with different model specifications, specified as a `LinearMixedModel` object. `lme` must be nested in `altlme`, that is, `lme` should be obtained from `altlme` by setting some parameters to fixed values, such as 0. You can create a linear mixed-effects object using `fitlme` or `fitlmematrix`.

nsim — Number of replications for simulations

positive integer number

Number of replications for simulations in the simulated likelihood ratio test, specified as a positive integer number. You must specify `nsim` to do a simulated likelihood ratio test.

Example: `'NSim', 1000`

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Options — Options for performing simulated likelihood ratio test

structure

Options for performing the simulated likelihood ratio test in parallel, specified as the comma-separated pair consisting of `'Options'`, and a structure created by `statset('LinearMixedModel')`.

These options require Parallel Computing Toolbox.

`compare` uses the following fields.

- 'UseParallel'
 - False for serial computation. Default.
 - True for parallel computation.

You need Parallel Computing Toolbox for parallel computation.
- 'UseSubstreams'
 - False for not using a separate substream of the random number generator for each iteration. Default.
 - True for using a separate substream of the random number generator for each iteration. You can only use this option with random stream types that support substreams.
- 'Streams'
 - If 'UseSubstreams' is True, then 'Streams' must be a single random number stream, or a scalar cell array containing a single stream.
 - If 'UseSubstreams' is False and
 - 'UseParallel' is False, then 'Streams' must be a single random number stream, or a scalar cell array containing a single stream.
 - 'UseParallel' is True, then 'Streams' must be equal to the number of processors used. If a parallel pool is open, then the 'Streams' is the same length as the size of the parallel pool. If 'UseParallel' is True, a parallel pool might open up for you. But since 'Streams' must be equal to the number of processors used, it is best to open a pool explicitly using the `parpool` command, before calling `compare` with the 'UseParallel', 'True' option.

For information on parallel statistical computing at the command line, enter

`help parallelstats`

Data Types: `struct`

CheckNesting — Indicator to check nesting between two models

`false` (default) | `true`

Indicator to check nesting on page 32-774 between two models, specified as the comma-separated pair consisting of 'CheckNesting' and one of the following.

<code>false</code>	Default. No checks.
<code>true</code>	<code>compare</code> checks if the smaller model <code>lme</code> is nested in the bigger model <code>altlme</code> .

`lme` must be nested in the alternate model `altlme` for a valid theoretical likelihood ratio test on page 32-773. `compare` returns an error message if the nesting requirements are not satisfied.

Although valid for both tests, the nesting requirements are weaker for the simulated likelihood ratio test on page 32-774.

Example: `'CheckNesting', true`

Data Types: `single | double`

Output Arguments

results — Results of likelihood ratio test or simulated likelihood ratio test

dataset array

Results of the likelihood ratio test or simulated likelihood ratio test, returned as a dataset array with two rows. The first row is for `lme`, and the second row is for `altlme`. The columns of `results` depend on whether the test is a likelihood ratio or a simulated likelihood ratio test.

- If you use the likelihood ratio test on page 32-773, then `results` contains the following columns.

<code>Model</code>	Name of the model
<code>DF</code>	Degrees of freedom, that is, the number of free parameters in the model
<code>AIC</code>	Akaike information criterion for the model
<code>BIC</code>	Bayesian information criterion for the model
<code>LogLik</code>	Maximized log likelihood for the model
<code>LRStat</code>	Likelihood ratio test statistic for comparing <code>altlme</code> versus <code>lme</code>
<code>deltaDF</code>	DF for <code>altlme</code> minus DF for <code>lme</code>
<code>pValue</code>	p -value for the likelihood ratio test

- If you use the simulated likelihood ratio test on page 32-774, then `results` contains the following columns.

<code>Model</code>	Name of the model
<code>DF</code>	Degrees of freedom, that is, the number of free parameters in the model
<code>LogLik</code>	Maximized log likelihood for the model
<code>LRStat</code>	Likelihood ratio test statistic for comparing <code>altlme</code> versus <code>lme</code>
<code>pValue</code>	p -value for the likelihood ratio test
<code>Lower</code>	Lower limit of the confidence interval for <code>pValue</code>
<code>Upper</code>	Upper limit of the confidence interval for <code>pValue</code>

siminfo — Simulation output

structure

Simulation output, returned as a structure with the following fields.

<code>nsim</code>	Value set for <code>nsim</code> .
<code>alpha</code>	Value set for 'Alpha'.
<code>pValueSim</code>	Simulation-based <i>p</i> -value.
<code>pValueSimCI</code>	Confidence interval for <code>pValueSim</code> . The first element of the vector is the lower limit and the second element of the vector contains the upper limit.
<code>deltaDF</code>	The number of free parameters in <code>altlme</code> minus the number of free parameters in <code>lme</code> . DF for <code>altlme</code> minus DF for <code>lme</code> .
<code>TH0</code>	A vector of simulated likelihood ratio test statistics under the null hypothesis that the model <code>lme</code> generated the observed response vector <code>y</code> .

Examples

Test for Random Effects

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model, with a varying intercept and varying slope for each region, grouped by `Date`.

```
altlme = fitlme(flu2,'FluRate ~ 1 + Region + (1 + Region|Date)');
```

Fit a linear mixed-effects model with fixed effects for the region and a random intercept that varies by `Date`.

```
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)');
```

Compare the two models. Also check if `lme2` is nested in `lme`.

```
compare(lme,altlme,'CheckNesting',true)
```

```
ans =
    Theoretical Likelihood Ratio Test
```

Model	DF	AIC	BIC	LogLik	LRStat	deltaDF	pValue
lme	11	318.71	364.35	-148.36			
altlme	55	-305.51	-77.346	207.76	712.22	44	0

The small p -value of 0 indicates that model `altlme` is significantly better than the simpler model `lme`.

Test for Fixed and Random Effects

Load the sample data.

```
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

```
lmeBig = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term `(1 | Soil)`.

```
lmeSmall = fitlme(ds, 'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)');
```

Compare the two models using the simulated likelihood ratio test with 1000 replications. You must use this test to test for both fixed- and random-effect terms. Note that both models are fit using the default fitting method, ML. That's why, there is no restriction on the fixed-effects design matrices. If you use restricted maximum likelihood (REML) method, both models must have identical fixed-effects design matrices.

```
[table, siminfo] = compare(lmeSmall, lmeBig, 'nsim', 1000)
```

```
table =
    Simulated Likelihood Ratio Test: Nsim = 1000, Alpha = 0.05

    Model      DF      AIC      BIC      LogLik      LRStat      pValue
    lmeSmall    10     511.06     532     -245.53
    lmeBig      23     522.57     570.74     -238.29     14.491     0.57343

    Lower      Upper
```

```
0.54211    0.60431
```

```
siminfo = struct with fields:
    nsim: 1000
    alpha: 0.0500
    pvalueSim: 0.5734
    pvalueSimCI: [0.5421 0.6043]
    deltaDF: 13
    TH0: [1000x1 double]
```

The high p -value suggests that the larger model, `lme` is not significantly better than the smaller model, `lme2`. The smaller values of “Akaike and Bayesian Information Criteria” on page 32-775 for `lme2` also support this.

Models with Correlated and Uncorrelated Random Effects

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

First, prepare the design matrices.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Refit the model with uncorrelated random effects for intercept and acceleration. First prepare the random effects design and the random effects grouping variables.

```
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};

lme2 = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept'}},{'Acceleration'}},'RandomEffectGroups',...
{'Model_Year','Model_Year'});
```

Compare `lme` and `lme2` using the simulated likelihood ratio test.

```
compare(lme2,lme,'CheckNesting',true,'NSim',1000)
```

```
ans =
```

```
SIMULATED LIKELIHOOD RATIO TEST: NSIM = 1000, ALPHA = 0.05
```

Model	DF	AIC	BIC	LogLik	LRStat	pValue	Lower
lme2	6	2194.5	2218.3	-1091.3			
lme	7	2193.5	2221.3	-1089.7	3.0323	0.094905	0.077462

```
Upper
```

```
0.11477
```

The high P -value indicates that `lme2` is not a significantly better fit than `lme`.

Simulated Likelihood Ratio Test Using Parallel Computing

Load the sample data.

```
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term `(1|Soil)`.

```
lme2 = fitlme(ds, 'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)');
```

Create the options structure for `LinearMixedModel`.

```
opt = statset('LinearMixedModel')
```

```
opt = struct with fields:
    Display: 'off'
    MaxFunEvals: []
```

```

      MaxIter: 10000
      TolBnd: []
      TolFun: 1.0000e-06
      TolTypeFun: []
      TolX: 1.0000e-12
      TolTypeX: []
      GradObj: []
      Jacobian: []
      DerivStep: []
      FunValCheck: []
      Robust: []
      RobustWgtFun: []
      WgtFun: []
      Tune: []
      UseParallel: []
      UseSubstreams: []
      Streams: {}
      OutputFcn: []

```

Change the options for parallel testing.

```
opt.UseParallel = true;
```

Start a parallel environment.

```
mypool = parpool();
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

Compare `lme2` and `lme` using the simulated likelihood ratio test with 1000 replications and parallel computing.

```
compare(lme2,lme,'nsim',1000,'Options',opt)
```

```
ans =
  Simulated Likelihood Ratio Test: Nsim = 1000, Alpha = 0.05

  Model    DF    AIC      BIC      LogLik    LRStat    pValue    Lower
  lme2     10    511.06    532     -245.53
  lme      23    522.57    570.74    -238.29    14.491    0.54346    0.51201

  Upper

  0.57465
```

The high p -value suggests that the larger model, `lme` is not significantly better than the smaller model, `lme2`. The smaller values of AIC and BIC for `lme2` also support this.

More About

Likelihood Ratio Test

Under the null hypothesis H_0 , the observed likelihood ratio test statistic has an approximate chi-squared reference distribution with degrees of freedom `deltaDF`. When comparing two models,

`compare` computes the p -value for the likelihood ratio test by comparing the observed likelihood ratio test statistic with this chi-squared reference distribution.

The p -values obtained using the likelihood ratio test can be conservative when testing for the presence or absence of random-effects terms and anticonservative when testing for the presence or absence of fixed-effects terms. Hence, use the `fixedEffects`, `anova`, or `coefTest` method or the simulated likelihood ratio test while testing for fixed effects.

Simulated Likelihood Ratio Test

To perform the simulated likelihood ratio test, `compare` first generates the reference distribution of the likelihood ratio test statistic under the null hypothesis. Then, it assesses the statistical significance of the alternate model by comparing the observed likelihood ratio test statistic to this reference distribution.

`compare` produces the simulated reference distribution of the likelihood ratio test statistic under the null hypothesis as follows:

- Generate random data `ysim` from the fitted model `lme`.
- Fit the model specified in `lme` and alternate model `altlme` to the simulated data `ysim`.
- Calculate the likelihood ratio test statistic using results from step 2 and store the value.
- Repeat step 1 to 3 `nsim` times.

Then, `compare` computes the p -value for the simulated likelihood ratio test by comparing the observed likelihood ratio test statistic with the simulated reference distribution. The p -value estimate is the ratio of the number of times the simulated likelihood ratio test statistic is equal to or exceeds the observed value plus one, to the number of replications plus one.

Suppose the observed likelihood ratio statistic is T , and the simulated reference distribution is stored in vector T_{H_0} . Then,

$$p - value = \frac{\left[\sum_{j=1}^{nsim} I(T_{H_0}(j) \geq T) \right] + 1}{nsim + 1} .$$

To account for the uncertainty in the simulated reference distribution, `compare` computes a $100 \cdot (1 - \alpha)\%$ confidence interval for the true p -value.

You can use the simulated likelihood ratio test to compare arbitrary linear mixed-effects models. That is, when you are using the simulated likelihood ratio test, `lme` does not have to be nested within `altlme`, and you can fit `lme` and `altlme` using either maximum likelihood (ML) or restricted maximum likelihood (REML) methods. If you use the restricted maximum likelihood (REML) method to fit the models, then both models must have the same fixed-effects design matrix.

Nesting Requirements

The `'CheckNesting'`, `'True'` name-value pair argument checks the following requirements.

For a simulated likelihood ratio test:

- You must use the same method to fit both models (`lme` and `altlme`). `compare` cannot compare a model fit using ML to a model fit using REML.

- You must fit both models to the same response vector.
- If you use REML to fit `lme` and `altlme`, then both models must have the same fixed-effects design matrix.
- The maximized log likelihood or restricted log likelihood of the bigger model (`altlme`) must be greater than or equal to that of the smaller model (`lme`).

For a theoretical test, 'CheckNesting', 'True' checks all the requirements listed for a simulated likelihood ratio test and the following:

- Weight vectors you use to fit `lme` and `altlme` must be identical.
- If you use ML to fit `lme` and `altlme`, the fixed-effects design matrix of the bigger model (`altlme`) must contain that of the smaller model (`lme`).
- The random-effects design matrix of the bigger model (`altlme`) must contain that of the smaller model (`lme`).

Akaike and Bayesian Information Criteria

Akaike information criterion (AIC) is $AIC = -2 \cdot \log L_M + 2 \cdot (nc + p + 1)$, where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, and $nc + p + 1$ is the number of parameters estimated in the model. p is the number of fixed-effects coefficients, and nc is the total number of parameters in the random-effects covariance excluding the residual variance.

Bayesian information criterion (BIC) is $BIC = -2 \cdot \log L_M + \ln(n_{eff}) \cdot (nc + p + 1)$, where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, n_{eff} is the effective number of observations, and $(nc + p + 1)$ is the number of parameters estimated in the model.

- If the fitting method is maximum likelihood (ML), then $n_{eff} = n$, where n is the number of observations.
- If the fitting method is restricted maximum likelihood (REML), then $n_{eff} = n - p$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, p . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

Deviance

`LinearMixedModel` computes the deviance of model M as minus two times the loglikelihood of that model. Let L_M denote the maximum value of the likelihood function for model M . Then, the deviance of model M is

$$-2 \cdot \log L_M.$$

A lower value of deviance indicates a better fit. Suppose M_1 and M_2 are two different models, where M_1 is nested in M_2 . Then, the fit of the models can be assessed by comparing the deviances Dev_1 and Dev_2 of these models. The difference of the deviances is

$$Dev = Dev_1 - Dev_2 = 2(\log LM_2 - \log LM_1).$$

Usually, the asymptotic distribution of this difference has a chi-square distribution with degrees of freedom ν equal to the number of parameters that are estimated in one model but fixed (typically at

0) in the other. That is, it is equal to the difference in the number of parameters estimated in M_1 and M_2 . You can get the p -value for this test using $1 - \text{chi2cdf}(\text{Dev}, V)$, where $\text{Dev} = \text{Dev}_2 - \text{Dev}_1$.

However, in mixed-effects models, when some variance components fall on the boundary of the parameter space, the asymptotic distribution of this difference is more complicated. For example, consider the hypotheses

$$H_0: D = \begin{pmatrix} D_{11} & 0 \\ 0 & 0 \end{pmatrix}, D \text{ is a } q\text{-by-}q \text{ symmetric positive semidefinite matrix.}$$

$H_1: D$ is a $(q+1)$ -by- $(q+1)$ symmetric positive semidefinite matrix.

That is, H_1 states that the last row and column of D are different from zero. Here, the bigger model M_2 has $q + 1$ parameters and the smaller model M_1 has q parameters. And Dev has a 50:50 mixture of χ^2_q and $\chi^2_{(q+1)}$ distributions (Stram and Lee, 1994).

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options', statset('UseParallel', true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

compareHoldout

Package:

Compare accuracies of two classification models using new data

Syntax

```
h = compareHoldout(C1,C2,T1,T2,ResponseVarName)
```

```
h = compareHoldout(C1,C2,T1,T2,Y)
```

```
h = compareHoldout(C1,C2,X1,X2,Y)
```

```
h = compareHoldout( ____,Name,Value)
```

```
[h,p,e1,e2] = compareHoldout( ____ )
```

Description

`compareHoldout` statistically assesses the accuracies of two classification models. The function first compares their predicted labels against the true labels, and then it detects whether the difference between the misclassification rates is statistically significant.

You can determine whether the accuracies of the classification models differ or whether one model performs better than another. `compareHoldout` can conduct several McNemar test on page 32-792 variations, including the asymptotic test, the exact-conditional test, and the mid- p -value test. For cost-sensitive assessment on page 32-791, available tests include a chi-square test (requires Optimization Toolbox) and a likelihood ratio test.

`h = compareHoldout(C1,C2,T1,T2,ResponseVarName)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels in the `ResponseVarName` variable. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model C1 uses the predictor data in T1, and the second classification model C2 uses the predictor data in T2. The tables T1 and T2 must contain the same response variable but can contain different sets of predictors. By default, the software conducts the mid- p -value McNemar test to compare the accuracies.

`h = 1` indicates rejecting the null hypothesis at the 5% significance level. `h = 0` indicates not rejecting the null hypothesis at the 5% level.

The following are examples of tests you can conduct:

- Compare the accuracies of a simple classification model and a model that is more complex by passing the same set of predictor data (that is, $T1 = T2$).
- Compare the accuracies of two potentially different models using two potentially different sets of predictors.
- Perform various types of Feature Selection on page 15-49. For example, you can compare the accuracy of a model trained using a set of predictors to the accuracy of one trained on a subset or different set of those predictors. You can choose the set of predictors arbitrarily, or use a feature selection technique such as PCA or sequential feature selection (see `pca` and `sequentialfs`).

`h = compareHoldout(C1,C2,T1,T2,Y)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels Y. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model C1 uses the predictor data T1, and the second classification model C2 uses the predictor data T2. By default, the software conducts the mid-*p*-value McNemar test to compare the accuracies.

`h = compareHoldout(C1,C2,X1,X2,Y)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels Y. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model C1 uses the predictor data X1, and the second classification model C2 uses the predictor data X2. By default, the software conducts the mid-*p*-value McNemar test to compare the accuracies.

`h = compareHoldout(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input argument combinations in previous syntaxes. For example, you can specify the type of alternative hypothesis, specify the type of test, and supply a cost matrix.

`[h,p,e1,e2] = compareHoldout(___)` returns the *p*-value for the hypothesis test (*p*) and the respective classification losses on page 32-794 of each set of predicted class labels (*e1* and *e2*) using any of the input arguments in the previous syntaxes.

Examples

Compare Accuracies of Full and Reduced Classification Models

Train two *k*-nearest neighbor classifiers, one using a subset of the predictors used for the other. Conduct a statistical test comparing the accuracies of the two models on a test set.

Load the `carsmall` data set.

```
load carsmall
```

Create two tables of input data, where the second table excludes the predictor `Acceleration`. Specify `Model_Year` as the response variable.

```
T1 = table(Acceleration,Displacement,Horsepower,MPG,Model_Year);
T2 = T1(:,2:end);
```

Create a partition that splits the data into training and test sets. Keep 30% of the data for testing.

```
rng(1) % For reproducibility
CVP = cvpartition(Model_Year,'holdout',0.3);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train the ClassificationKNN models using the T1 and T2 data.

```
C1 = fitcknn(T1(idxTrain,:), 'Model_Year');
C2 = fitcknn(T2(idxTrain,:), 'Model_Year');
```

C1 and C2 are trained ClassificationKNN models.

Test whether the two models have equal predictive accuracies on the test set.

```
h = compareHoldout(C1,C2,T1(idxTest,:),T2(idxTest,:), 'Model_Year')
h = logical
    0
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Compare Accuracies of Two Different Classification Models

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a test set.

Load the `ionosphere` data set.

```
load ionosphere
```

Create a partition that evenly splits the data into training and test sets.

```
rng(1) % For reproducibility
CVP = cvpartition(Y, 'holdout', 0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```
C1 = fitsvm(X(idxTrain,:),Y(idxTrain), 'Standardize', true, ...
    'KernelFunction', 'RBF', 'KernelScale', 'auto');
t = templateTree('Reproducible', true); % For reproducibility of random predictor selections
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain), 'Method', 'Bag', ...
    'Learners', t);
```

C1 is a trained ClassificationSVM model. C2 is a trained ClassificationBaggedEnsemble model.

Test whether the two models have equal predictive accuracies. Use the same test-set predictor data for each model.

```
h = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest))
h = logical
    0
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Compare Classification Model to More Complex Model

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy on test data than the more complex model.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and test sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
C2 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');
```

C1 and C2 are trained `ClassificationSVM` models.

Test the null hypothesis that the simpler model (C1) is at most as accurate as the more complex model (C2). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid- p -value test (the cost-insensitive testing default). Request to return p -values and misclassification rates.

```
Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);

[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater',...
    'Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})
```

```
ans=4x2 table
           Asymp           MidP
           _____ _____
h           1             1
p    7.2801e-09    2.7649e-10
e1     0.13714     0.13714
e2     0.33143     0.33143
```

The p -value is close to zero for both tests, providing strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No matter what test you specify, `compareHoldout` returns the same type of misclassification measure for both models.

Conduct Cost-Sensitive Comparison of Two Classification Models

For data sets with imbalanced class representations, or for data sets with imbalanced false-positive and false-negative costs, you can statistically compare the predictive performance of two classification models by including a cost matrix in the analysis.

Load the `arrhythmia` data set. Determine the class representations in the data.

```
load arrhythmia;
Y = categorical(Y);
tabulate(Y);
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

There are 16 classes, however some are not represented in the data set (for example, class 13). Most observations are classified as not having arrhythmia (class 1). The data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status (class 16) from the data set.

```
idx = (Y ~= '16');
Y = Y(idx);
X = X(idx,:);
Y(Y ~= '1') = 'WithArrhythmia';
Y(Y == '1') = 'NoArrhythmia';
Y = removecats(Y);
```

Create a partition that evenly splits the data into training and test sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the "no arrhythmia" class is five times worse than misclassifying a patient without arrhythmia into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate the predicted class. When you conduct a cost-sensitive analysis, a good practice is to specify the order of the classes.

```
cost = [0 1;5 0];
ClassNames = {'NoArrhythmia','WithArrhythmia'};
```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and another that uses LogitBoost. Because the data set contains missing values, specify to use surrogate splits. Train the models using the cost matrix.

```
t = templateTree('Surrogate','on');
numTrees = 50;
C1 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1', ...
    'NumLearningCycles',numTrees,'Learners',t, ...
    'Cost',cost,'ClassNames',ClassNames);
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','LogitBoost', ...
    'NumLearningCycles',numTrees,'Learners',t, ...
    'Cost',cost,'ClassNames',ClassNames);
```

C1 and C2 are trained ClassificationEnsemble models.

Test whether the AdaBoostM1 ensemble (C1) and the LogitBoost ensemble (C2) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return p -values and misclassification costs.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest), ...
    'Cost',cost)
```

```
h = logical
    0
```

```
p = 0.4488
```

```
e1 = 0.5302
```

```
e2 = 0.4698
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Select Features Using Statistical Accuracy Comparison

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the out-of-sample accuracy between the two models.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and test sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an ensemble of 100 boosted classification trees using AdaBoostM1 and the entire set of predictors. Inspect the importance measure for each predictor.

```
t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'Learners',t);
predImp = predictorImportance(C2);
```

```
figure;
bar(predImp);
h = gca;
h.XTick = 1:2:h.XLim(2)
```

```
h =
  Axes with properties:
      XLim: [-0.2000 35.2000]
      YLim: [0 0.0090]
      XScale: 'linear'
      YScale: 'linear'
  GridLineStyle: '-'
  Position: [0.1300 0.1100 0.7750 0.8150]
  Units: 'normalized'
```

Show all properties

```
title('Predictor Importance');
xlabel('Predictor');
ylabel('Importance measure');
```

Identify the top five predictors in terms of their importance.

```
[~,idxSort] = sort(predImp, 'descend');
idx5 = idxSort(1:5);
```

Train another ensemble of 100 boosted classification trees using AdaBoostM1 and the five predictors with the greatest importance.

```
C1 = fitensemble(X(idxTrain,idx5),Y(idxTrain),'Method','AdaBoostM1',...
    'Learners',t);
```

Test whether the two models have equal predictive accuracies. Specify the reduced test-set predictor data for C1 and the full test-set predictor data for C2.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,idx5),X(idxTest,:),Y(idxTest))
```

```
h = logical
    0
```

```
p = 0.7744
```

```
e1 = 0.0914
```

```
e2 = 0.0857
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble, C1.

Input Arguments

C1 – First trained classification model

trained classification model object | trained, compact classification model object

First trained classification model, specified as any trained classification model object or compact classification model object described in this table.

Trained Model Type	Model Object	Returned By
Classification tree	ClassificationTree	fitctree
Discriminant analysis	ClassificationDiscriminant	fitcdiscr
Ensemble of bagged classification models	ClassificationBaggedEnsemble	fitcensemble
Ensemble of classification models	ClassificationEnsemble	fitcensemble
Multiclass, error-correcting output codes (ECOC)	ClassificationECOC	fitcecoc
kNN	ClassificationKNN	fitcknn
Naive Bayes	ClassificationNaiveBayes	fitcnb
Support vector machine (SVM)	ClassificationSVM	fitsvm
Compact discriminant analysis	CompactClassificationDiscriminant	compact
Compact ECOC	CompactClassificationECOC	compact
Compact ensemble of classification models	CompactClassificationEnsemble	compact
Compact naive Bayes	CompactClassificationNaiveBayes	compact
Compact SVM	CompactClassificationSVM	compact
Compact classification tree	CompactClassificationTree	compact

C2 – Second trained classification model

trained classification model object | trained, compact classification model object

Second trained classification model, specified as any trained classification model object or compact classification model object that is a valid choice for C1.

T1 – Test-set predictor data for first classification model

table

Test-set predictor data for the first classification model, C1, specified as a table. Each row of T1 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T1 can contain an additional column for the response variable. T1 must contain all the predictors used to train C1. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows and the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify `ResponseVarName` or `Y`.

Data Types: `table`

T2 — Test-set predictor data for second classification model

`table`

Test-set predictor data for the second classification model, C2, specified as a table. Each row of T2 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T2 can contain an additional column for the response variable. T2 must contain all the predictors used to train C2. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows and the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify `ResponseVarName` or `Y`.

Data Types: `table`

X1 — Test-set predictor data for first classification model

`numeric matrix`

Test-set predictor data for the first classification model, C1, specified as a numeric matrix.

Each row of X1 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C1 must compose X1.

The number of rows in X1 and X2 must equal the number of rows in Y.

Data Types: `double` | `single`

X2 — Test-set predictor data for second classification model

`numeric matrix`

Test-set predictor data for the second classification model, C2, specified as a numeric matrix.

Each row of X2 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C2 must compose X2.

The number of rows in X2 and X1 must equal the number of rows in Y.

Data Types: `double` | `single`

ResponseVarName — Response variable name

`name of a variable in T1 and T2`

Response variable name, specified as the name of a variable in T1 and T2. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify `ResponseVarName`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable is stored as `T1.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of T1 and T2, including `Response`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

Y — True class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

True class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

When you specify Y, `compareHoldout` treats all variables in the matrices X1 and X2 or the tables T1 and T2 as predictor variables.

If Y is a character array, then each element must correspond to one row of the array.

The number of rows in the predictor data must equal the number of rows in Y.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Note NaNs, <undefined> values, empty character vectors (' '), empty strings (""), and <missing> values indicate missing values. `compareHoldout` removes missing values in Y and the corresponding rows of X1 and X2. Additionally, `compareHoldout` predicts classes whether X1 and X2 have missing observations.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`compareHoldout(C1,C2,X1,X2,Y,'Alternative','greater','Test','asymptotic','Cost',[0 2;1 0])` tests whether the first set of predicted class labels is more accurate than the second set, conducts the asymptotic McNemar test, and penalizes misclassifying observations with the true label `ClassNames{1}` twice as much as misclassifying observations with the true label `ClassNames{2}`.

Alpha — Hypothesis test significance level

0.05 (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the interval (0,1).

Example: 'Alpha', 0.1

Data Types: `single` | `double`

Alternative — Alternative hypothesis to assess

'unequal' (default) | 'greater' | 'less'

Alternative hypothesis to assess, specified as the comma-separated pair consisting of 'Alternative' and one of the values listed in this table.

Value	Alternative Hypothesis
'unequal' (default)	For predicting Y, the set of predictions resulting from C1 applied to X1 and C2 applied to X2 have unequal accuracies.
'greater'	For predicting Y, the set of predictions resulting from C1 applied to X1 is more accurate than C2 applied to X2.
'less'	For predicting Y, the set of predictions resulting from C1 applied to X1 is less accurate than C2 applied to X2.

Example: 'Alternative', 'greater'

ClassNames — Class names

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class names, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. You must set ClassNames using the data type of Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use ClassNames to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use ClassNames to specify the order of the dimensions of Cost.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train and test models using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default is the set of all distinct class names in Y.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | string | logical | single | double | cell

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array.

- If you specify the square matrix Cost, then Cost(i, j) is the cost of classifying a point into class j if its true class is i. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.
- If you specify the structure S, then S must have two fields:
 - S.ClassNames, which contains the class names as a variable of the same data type as Y. You can use this field to specify the order of the classes.
 - S.ClassificationCosts, which contains the cost matrix, with rows and columns ordered as in S.ClassNames.

If you specify Cost, then compareHoldout cannot conduct one-sided, exact, or mid-p tests. You must also specify 'Alternative', 'unequal', 'Test', 'asymptotic'. For cost-sensitive testing options, see the CostTest name-value pair argument.

A best practice is to supply the same cost matrix used to train the classification models.

The default is $\text{Cost}(i,j) = 1$ if $i \neq j$, and $\text{Cost}(i,j) = 0$ if $i = j$.

Example: 'Cost',[0 1 2 ; 1 0 2; 2 2 0]

Data Types: single | double | struct

CostTest — Cost-sensitive test type

'likelihood' (default) | 'chisquare'

Cost-sensitive test type, specified as the comma-separated pair consisting of 'CostTest' and 'chisquare' or 'likelihood'. If you do not specify a cost matrix using the Cost name-value pair argument, compareHoldout ignores CostTest.

This table summarizes the available options for cost-sensitive testing.

Value	Asymptotic Test Type	Requirements
'chisquare'	Chi-square test	Optimization Toolbox to implement quadprog
'likelihood'	Likelihood ratio test	None

For more details, see “Cost-Sensitive Testing” on page 32-791.

Example: 'CostTest','chisquare'

Test — Test to conduct

'asymptotic' | 'exact' | 'midp'

Test to conduct, specified as the comma-separated pair consisting of 'Test' and 'asymptotic', 'exact', or 'midp'.

This table summarizes the available options for cost-insensitive testing.

Value	Description
'asymptotic'	Asymptotic McNemar test
'exact'	Exact-conditional McNemar test
'midp' (default)	Mid- <i>p</i> -value McNemar test

For more details, see “McNemar Tests” on page 32-792.

For cost-sensitive testing, Test must be 'asymptotic'. When you specify the Cost name-value pair argument and choose a cost-sensitive test using the CostTest name-value pair argument, 'asymptotic' is the default.

Example: 'Test','asymptotic'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

$h = 1$ indicates the rejection of the null hypothesis at the Alpha significance level.

$h = 0$ indicates failure to reject the null hypothesis at the Alpha significance level.

Data Types: `logical`

p — p-value

scalar in the interval [0,1]

p-value of the test, returned as a scalar in the interval [0,1]. *p* is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`compareHoldout` estimates *p* using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see “McNemar Tests” on page 32-792. For details on test statistics derived from cost-sensitive tests, see “Cost-Sensitive Testing” on page 32-791.

Data Types: `double`

e1 — Classification loss

numeric scalar

Classification loss, returned as a numeric scalar. `e1` summarizes the accuracy of the first set of class labels predicting the true class labels (*Y*). `compareHoldout` applies the first test-set predictor data (*X1*) to the first classification model (*C1*) to estimate the first set of class labels. Then, the function compares the estimated labels to *Y* to obtain the classification loss.

For cost-insensitive testing, `e1` is the misclassification rate. That is, `e1` is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, `e1` is the misclassification cost. That is, `e1` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

For more information, see “Classification Loss” on page 32-794.

Data Types: `double`

e2 — Classification loss

numeric scalar

Classification loss, returned as a numeric scalar. `e2` summarizes the accuracy of the second set of class labels predicting the true class labels (*Y*). `compareHoldout` applies the second test-set predictor data (*X2*) to the second classification model (*C2*) to estimate the second set of class labels. Then, the function compares the estimated labels to *Y* to obtain the classification loss.

For cost-insensitive testing, `e2` is the misclassification rate. That is, `e2` is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, `e2` is the misclassification cost. That is, `e2` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

For more information, see “Classification Loss” on page 32-794.

Data Types: `double`

Limitations

- `compareHoldout` does not compare ECOC models composed of linear or kernel classification models (that is, `ClassificationLinear` or `ClassificationKernel` model objects). To compare `ClassificationECOC` models composed of linear or kernel classification models, use `testcholdout` instead.
- Similarly, `compareHoldout` does not compare `ClassificationLinear` or `ClassificationKernel` model objects. To compare these models, use `testcholdout` instead.

More About

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. By conducting a cost-sensitive analysis, you can account for the cost imbalance when you train the classification models and when you statistically compare them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss. Use misclassification cost instead to compare classification models.

Misclassification costs are often imbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick. Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick typically causes some inconvenience, but does not pose significant danger. In this situation, you assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- n_{ijk} and $\hat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with the following characteristics. k is the true class, i is the label assigned by the first classification model, and j is the label assigned by the second classification model. The unknown true value of $\hat{\pi}_{ijk}$ is π_{ijk} . The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. Additionally, $\sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \hat{\pi}_{ijk} = 1$.
- c_{ij} is the relative cost of assigning label j to an observation with true class i . $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one (i,j) pair, $c_{ij} > 0$.
- All subscripts take on integer values from 1 through K , which is the number of classes.
- The expected difference in the misclassification costs of the two classification models is

$$\delta = \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K (c_{ki} - c_{kj}) \pi_{ijk}.$$

- The hypothesis test is

$$H_0: \delta = 0$$

$$H_1: \delta \neq 0$$

The available cost-sensitive tests are appropriate for two-tailed testing.

Available asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

- Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any $n_{ijk} = 0$. The test statistic is

$$t_{\chi^2}^* = \sum_i \sum_{j \neq k} \frac{(n_{ijk} + 1 - (n_{test} + K^3) \hat{\pi}_{ijk}^{(1)})^2}{n_{ijk} + 1}.$$

If $1 - F_{\chi^2}(t_{\chi^2}^*; 1) < \alpha$, then reject H_0 .

- $\hat{\pi}_{ijk}^{(1)}$ are estimated by minimizing $t_{\chi^2}^*$ under the constraint that $\delta = 0$.
- $F_{\chi^2}(x; 1)$ is the χ^2 cdf with one degree of freedom evaluated at x .
- Likelihood ratio test — The likelihood ratio test is based on N_{ijk} , which are binomial random variables with sample size n_{test} and success probability π_{ijk} . The random variables represent the random number of observations with: true class k , label i assigned by the first classification model, and label j assigned by the second classification model. Jointly, the distribution of the random variables is multinomial.

The test statistic is

$$t_{LRT}^* = 2 \log \left[\frac{P\left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \hat{\pi}_{ijk} = \hat{\pi}_{ijk}^{(2)} \right)}{P\left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \hat{\pi}_{ijk} = \hat{\pi}_{ijk}^{(3)} \right)} \right].$$

If $1 - F_{\chi^2}(t_{LRT}^*; 1) < \alpha$, then reject H_0 .

- $\hat{\pi}_{ijk}^{(2)} = \frac{n_{ijk}}{n_{test}}$ is the unrestricted MLE of π_{ijk} .
- $\hat{\pi}_{ijk}^{(3)} = \frac{n_{ijk}}{n_{test} + \lambda(c_{ki} - c_{kj})}$ is the MLE under the null hypothesis that $\delta = 0$. λ is the solution to

$$\sum_{i,j,k} \frac{n_{ijk}(c_{ki} - c_{kj})}{n_{test} + \lambda(c_{ki} - c_{kj})} = 0.$$
- $F_{\chi^2}(x; 1)$ is the χ^2 cdf with one degree of freedom evaluated at x .

McNemar Tests

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

- 1 Partition the data into training and test sets.
- 2 Train both classification models using the training set.
- 3 Predict class labels using the test set.
- 4 Summarize the results in a two-by-two table similar to this figure.

		Model 2		
		Correct	Incorrect	
Model 1	Correct	n_{11}	n_{12}	$n_{1\bullet}$
	Incorrect	n_{21}	n_{22}	$n_{2\bullet}$
		$n_{\bullet 1}$	$n_{\bullet 2}$	n_{test}

n_{ii} are the number of concordant pairs, that is, the number of observations that both models classify the same way (correctly or incorrectly). n_{ij} , $i \neq j$, are the number of discordant pairs, that is, the number of observations that models classify differently (correctly or incorrectly).

The misclassification rates for Models 1 and 2 are $\hat{\pi}_{2\bullet} = n_{2\bullet}/n$ and $\hat{\pi}_{\bullet 2} = n_{\bullet 2}/n$, respectively. A two-sided test for comparing the accuracy of the two models is

$$H_0: \pi_{\bullet 2} = \pi_{2\bullet}$$

$$H_1: \pi_{\bullet 2} \neq \pi_{2\bullet}$$

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to $H_0: \pi_{12} = \pi_{21}$. Also, under the null hypothesis, $N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5)$ [1].

These facts are the basis for the available McNemar test variants: the asymptotic, exact-conditional, and mid-p-value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance level α) are:

- For one-sided tests, the test statistic is

$$t_{a1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}$$

If $1 - \Phi(|t_1^*|) < \alpha$, where Φ is the standard Gaussian cdf, then reject H_0 .

- For two-sided tests, the test statistic is

$$t_{a2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}$$

If $1 - F_{\chi^2}(t_2^*; m) < \alpha$, where $F_{\chi^2}(x; m)$ is the χ_m^2 cdf evaluated at x , then reject H_0 .

The asymptotic test requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution.

- The total number of discordant pairs, $n_d = n_{12} + n_{21}$, must be greater than 10 ([1], Ch. 10.1.4).
- In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed α , as suggested in simulation studies in [18]. However, the asymptotic McNemar test performs well in terms of statistical power.
- Exact-Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance level α) are ([36], [38]):

- For one-sided tests, the test statistic is

$$t_1^* = n_{12}.$$

If $F_{\text{Bin}}(t_1^*; n_d, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ is the binomial cdf with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic is

$$t_2^* = \min(n_{12}, n_{21}).$$

If $F_{\text{Bin}}(t_2^*; n_d, 0.5) < \alpha/2$, then reject H_0 .

The exact-conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid- p -value test ([1], Ch. 3.6.3).

- Mid- p -value test — The mid- p -value McNemar test statistics and rejection regions (for significance level α) are ([32]):
- For one-sided tests, the test statistic is

$$t_1^* = n_{12}.$$

If $F_{\text{Bin}}(t_1^* - 1; n_{12} + n_{21}, 0.5) + 0.5f_{\text{Bin}}(t_1^*; n_{12} + n_{21}, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ and $f_{\text{Bin}}(x; n, p)$ are the binomial cdf and pdf, respectively, with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic is

$$t_2^* = \min(n_{12}, n_{21}).$$

If $F_{\text{Bin}}(t_2^* - 1; n_{12} + n_{21} - 1, 0.5) + 0.5f_{\text{Bin}}(t_2^*; n_{12} + n_{21}, 0.5) < \alpha/2$, then reject H_0 .

The mid- p -value test addresses the over-conservative behavior of the exact-conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are the misclassification rate and cost.

`compareHoldout` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (that is, the unrestricted classification losses). n_{ijk} is the number of test-sample observations with: true class k , label i assigned by the first classification model, and label j assigned by the second classification model. The corresponding estimated proportion is $\hat{\pi}_{ijk} = \frac{n_{ijk}}{n_{test}}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. The indices are taken from 1 through K , the number of classes.

- The misclassification rate, or classification error, is a scalar in the interval $[0,1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk}$$

For the misclassification rate of the second classification model (e_2), switch the indices i and j in the formula.

Classification accuracy decreases as the misclassification rate increases to 1.

- The misclassification cost is a nonnegative scalar that is a measure of classification quality relative to the values of the specified cost matrix. Its interpretation depends on the specified costs of misclassification. The misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, C) in which the weights are the respective estimated proportions of misclassified observations. The misclassification cost for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk} c_{ki}$$

where c_{kj} is the cost of classifying an observation into class j if its true class is k . For the misclassification cost of the second classification model (e_2), switch the indices i and j in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as the misclassification cost increases.

Tips

- One way to perform cost-insensitive feature selection is:
 - 1 Train the first classification model (C1) using the full predictor set.
 - 2 Train the second classification model (C2) using the reduced predictor set.
 - 3 Specify X1 as the full test-set predictor data and X2 as the reduced test-set predictor data.
 - 4 Enter `compareHoldout(C1,C2,X1,X2,Y,'Alternative','less')`. If `compareHoldout` returns 1, then there is enough evidence to suggest that the classification model that uses fewer predictors performs better than the model that uses the full predictor set.

Alternatively, you can assess whether there is a significant difference between the accuracies of the two models. To perform this assessment, remove the 'Alternative', 'less' specification in step 4. `compareHoldout` conducts a two-sided test, and `h = 0` indicates that there is not enough evidence to suggest a difference in the accuracy of the two models.

- Cost-sensitive tests perform numerical optimization, which requires additional computational resources. The likelihood ratio test conducts numerical optimization indirectly by finding the root of a Lagrange multiplier in an interval. For some data sets, if the root lies close to the boundaries of the interval, then the method can fail. Therefore, if you have an Optimization Toolbox license, consider conducting the cost-sensitive chi-square test instead. For more details, see `CostTest` and “Cost-Sensitive Testing” on page 32-791.

Alternative Functionality

To directly compare the accuracy of two sets of class labels in predicting a set of true class labels, use `testcholdout`.

Introduced in R2015a

confusionchart

Create confusion matrix chart for classification problem

Syntax

```
confusionchart(trueLabels,predictedLabels)
confusionchart(m)
confusionchart(m,classLabels)
confusionchart(parent, ___)
confusionchart( ___,Name,Value)
cm = confusionchart( ___)
```

Description

`confusionchart(trueLabels,predictedLabels)` creates a confusion matrix chart from true labels `trueLabels` and predicted labels `predictedLabels` and returns a `ConfusionMatrixChart` object. The rows of the confusion matrix correspond to the true class and the columns correspond to the predicted class. Diagonal and off-diagonal cells correspond to correctly and incorrectly classified observations, respectively. Use `cm` to modify the confusion matrix chart after it is created. For a list of properties, see `ConfusionMatrixChart Properties`.

`confusionchart(m)` creates a confusion matrix chart from the numeric confusion matrix `m`. Use this syntax if you already have a numeric confusion matrix in the workspace.

`confusionchart(m,classLabels)` specifies class labels that appear along the x-axis and y-axis. Use this syntax if you already have a numeric confusion matrix and class labels in the workspace.

`confusionchart(parent, ___)` creates the confusion chart in the figure, panel, or tab specified by `parent`.

`confusionchart(___,Name,Value)` specifies additional `ConfusionMatrixChart` properties using one or more name-value pair arguments. Specify the properties after all other input arguments. For a list of properties, see `ConfusionMatrixChart Properties`.

`cm = confusionchart(___)` returns the `ConfusionMatrixChart` object. Use `cm` to modify properties of the chart after creating it. For a list of properties, see `ConfusionMatrixChart Properties`.

Examples

Create Confusion Matrix Chart

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of character vectors that contains the corresponding iris species.

Train a k -nearest neighbor (KNN) classifier, where the number of nearest neighbors in the predictors (k) is 5. A good practice is to standardize numeric predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1);
```

Predict the labels of the training data.

```
predictedY = resubPredict(Mdl);
```

Create a confusion matrix chart from the true labels Y and the predicted labels predictedY .

```
cm = confusionchart(Y,predictedY);
```

The confusion matrix displays the total number of observations in each cell. The rows of the confusion matrix correspond to the true class, and the columns correspond to the predicted class. Diagonal and off-diagonal cells correspond to correctly and incorrectly classified observations, respectively.

By default, `confusionchart` sorts the classes into their natural order as defined by `sort`. In this example, the class labels are character vectors, so `confusionchart` sorts the classes alphabetically. Use `sortClasses` to sort the classes by a specified order or by the confusion matrix values.

The `NormalizedValues` property contains the values of the confusion matrix. Display these values using dot notation.

```
cm.NormalizedValues
```

```
ans = 3x3
```

```

50  0  0
 0  47 3
 0  4  46

```

Modify the appearance and behavior of the confusion matrix chart by changing property values. Add a title.

```
cm.Title = 'Iris Flower Classification Using KNN';
```

Add column and row summaries.

```
cm.RowSummary = 'row-normalized';
cm.ColumnSummary = 'column-normalized';
```

A row-normalized row summary displays the percentages of correctly and incorrectly classified observations for each true class. A column-normalized column summary displays the percentages of correctly and incorrectly classified observations for each predicted class.

Sort Classes by Precision or Recall

Create a confusion matrix chart and sort the classes of the chart according to the class-wise true positive rate (recall) or the class-wise positive predictive value (precision).

Load and inspect the arrhythmia data set.

```
load arrhythmia
isLabels = unique(Y);
nLabels = numel(isLabels)
```

```
nLabels = 13
```

```
tabulate(categorical(Y))
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

The data contains 16 distinct labels that describe various degrees of arrhythmia, but the response (Y) includes only 13 distinct labels.

Train a classification tree and predict the resubstitution response of the tree.

```
Mdl = fitctree(X,Y);
predictedY = resubPredict(Mdl);
```

Create a confusion matrix chart from the true labels Y and the predicted labels predictedY. Specify 'RowSummary' as 'row-normalized' to display the true positive rates and false positive rates in the row summary. Also, specify 'ColumnSummary' as 'column-normalized' to display the positive predictive values and false discovery rates in the column summary.

```
fig = figure;
cm = confusionchart(Y,predictedY,'RowSummary','row-normalized','ColumnSummary','column-normalized');
```

Resize the container of the confusion chart so percentages appear in the row summary.

```
fig_Position = fig.Position;
fig_Position(3) = fig_Position(3)*1.5;
fig.Position = fig_Position;
```

To sort the confusion matrix according to the true positive rate, normalize the cell values across each row by setting the Normalization property to 'row-normalized' and then use sortClasses. After sorting, reset the Normalization property back to 'absolute' to display the total number of observations in each cell.

```
cm.Normalization = 'row-normalized';
sortClasses(cm, 'descending-diagonal')
cm.Normalization = 'absolute';
```

To sort the confusion matrix according to the positive predictive value, normalize the cell values across each column by setting the Normalization property to 'column-normalized' and then use `sortClasses`. After sorting, reset the Normalization property back to 'absolute' to display the total number of observations in each cell.

```
cm.Normalization = 'column-normalized';
sortClasses(cm, 'descending-diagonal')
cm.Normalization = 'absolute';
```

Confusion Matrix for Classification Using Tall Arrays

Perform classification on a tall array of the Fisher iris data set. Compute a confusion matrix chart for the known and predicted tall labels by using the `confusionchart` function.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Load Fisher's iris data set.

```
load fisheriris
```

Convert the in-memory arrays `meas` and `species` to tall arrays.

```
tx = tall(meas);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
ty = tall(species);
```

Find the number of observations in the tall array.

```
numObs = gather(length(ty)); % gather collects tall array into memory
```

Set the seeds of the random number generators using `rng` and `tallrng` for reproducibility, and randomly select training samples. The results can vary depending on the number of workers and the

execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```
rng('default')
tallrng('default')
numTrain = floor(numObs/2);
[txTrain,trIdx] = datasample(tx,numTrain,'Replace',false);
tyTrain = ty(trIdx);
```

Fit a decision tree classifier model on the training samples.

```
mdl = fitctree(txTrain,tyTrain);
```

Evaluating tall expression using the Parallel Pool 'local':

```
- Pass 1 of 2: Completed in 7.9 sec
- Pass 2 of 2: Completed in 6.2 sec
```

Evaluation completed in 19 sec

Evaluating tall expression using the Parallel Pool 'local':

```
- Pass 1 of 4: Completed in 3.6 sec
- Pass 2 of 4: Completed in 6.6 sec
- Pass 3 of 4: Completed in 15 sec
- Pass 4 of 4: Completed in 8.9 sec
```

Evaluation completed in 39 sec

Evaluating tall expression using the Parallel Pool 'local':

```
- Pass 1 of 4: Completed in 2 sec
- Pass 2 of 4: Completed in 4.8 sec
- Pass 3 of 4: Completed in 14 sec
- Pass 4 of 4: Completed in 7.7 sec
```

Evaluation completed in 32 sec

Evaluating tall expression using the Parallel Pool 'local':

```
- Pass 1 of 4: Completed in 1.7 sec
- Pass 2 of 4: Completed in 4.5 sec
- Pass 3 of 4: Completed in 11 sec
- Pass 4 of 4: Completed in 7.3 sec
```

Evaluation completed in 27 sec

Evaluating tall expression using the Parallel Pool 'local':

```
- Pass 1 of 4: Completed in 1.6 sec
- Pass 2 of 4: Completed in 4.4 sec
- Pass 3 of 4: Completed in 11 sec
- Pass 4 of 4: Completed in 8.1 sec
```

Evaluation completed in 30 sec

Predict labels for the test samples by using the trained model.

```
txTest = tx(~trIdx,:);
label = predict(mdl,txTest);
```

Create the confusion matrix chart for the resulting classification.

```
tyTest = ty(~trIdx);
cm = confusionchart(tyTest,label)
```

Evaluating tall expression using the Parallel Pool 'local':

```
- Pass 1 of 1: Completed in 1.7 sec
```

Evaluation completed in 2.7 sec

Evaluating tall expression using the Parallel Pool 'local':

```
- Pass 1 of 1: Completed in 3.9 sec
```

Evaluation completed in 5 sec

```
cm =
ConfusionMatrixChart with properties:
    NormalizedValues: [3x3 double]
    ClassLabels: {3x1 cell}

Show all properties
```

The confusion matrix chart shows that three measurements in the versicolor class are misclassified. All the measurements belonging to setosa and virginica are classified correctly.

Input Arguments

trueLabels — True labels of classification problem

categorical vector | numeric vector | string vector | character array | cell array of character vectors | logical vector

True labels of classification problem, specified as a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector. If `trueLabels` is a vector, then each element corresponds to one observation. If `trueLabels` is a character array, then it must be two-dimensional with each row corresponding to the label of one observation.

predictedLabels — Predicted labels of classification problem

categorical vector | numeric vector | string vector | character array | cell array of character vectors | logical vector

Predicted labels of classification problem, specified as a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector. If `predictedLabels` is a vector, then each element corresponds to one observation. If `predictedLabels` is a character array, then it must be two-dimensional with each row corresponding to the label of one observation.

m — Confusion matrix

matrix

Confusion matrix, specified as a matrix. `m` must be square and its elements must be positive integers. The element $m(i, j)$ is the number of times an observation of the i th true class was predicted to be of the j th class. Each colored cell of the confusion matrix chart corresponds to one element of the confusion matrix `m`.

classLabels — Class labels

categorical vector | numeric vector | string vector | character array | cell array of character vectors | logical vector

Class labels of the confusion matrix chart, specified as a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector. If `classLabels` is a vector, then it must have the same number of elements as the confusion matrix has rows and columns. If `classLabels` is a character array, then it must be two-dimensional with each row corresponding to the label of one class.

parent — Parent container

Figure object | Panel object | Tab object

Parent container in which to plot, specified as a Figure, Panel, or Tab object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `cm = confusionchart(trueLabels, predictedLabels, 'Title', 'My Title Text', 'ColumnSummary', 'column-normalized')`

Note The properties listed here are only a subset. For a complete list, see `ConfusionMatrixChart` Properties.

Title — Title

' ' (default) | character vector | string scalar

Title of the confusion matrix chart, specified as a character vector or string scalar.

Example: `cm = confusionchart(__, 'Title', 'My Title Text')`

Example: `cm.Title = 'My Title Text'`

ColumnSummary — Column summary

'off' (default) | 'absolute' | 'column-normalized' | 'total-normalized'

Column summary of the confusion matrix chart, specified as one of the following:

Option	Description
'off'	Do not display a column summary.
'absolute'	Display the total number of correctly and incorrectly classified observations for each predicted class.
'column-normalized'	Display the number of correctly and incorrectly classified observations for each predicted class as percentages of the number of observations of the corresponding predicted class. The percentages of correctly classified observations can be thought of as class-wise precisions (or positive predictive values).
'total-normalized'	Display the number of correctly and incorrectly classified observations for each predicted class as percentages of the total number of observations.

Example: `cm = confusionchart(__, 'ColumnSummary', 'column-normalized')`

Example: `cm.ColumnSummary = 'column-normalized'`

RowSummary – Row summary

'off' (default) | 'absolute' | 'row-normalized' | 'total-normalized'

Row summary of the confusion matrix chart, specified as one of the following:

Option	Description
'off'	Do not display a row summary.
'absolute'	Display the total number of correctly and incorrectly classified observations for each true class.
'row-normalized'	Display the number of correctly and incorrectly classified observations for each true class as percentages of the number of observations of the corresponding true class. The percentages of correctly classified observations can be thought of as class-wise recalls (or true positive rates).
'total-normalized'	Display the number of correctly and incorrectly classified observations for each true class as percentages of the total number of observations.

Example: `cm = confusionchart(__, 'RowSummary', 'row-normalized')`

Example: `cm.RowSummary = 'row-normalized'`

Normalization – Normalization of cell values

'absolute' (default) | 'column-normalized' | 'row-normalized' | 'total-normalized'

Normalization of cell values, specified as one of the following:

Option	Description
'absolute'	Display the total number of observations in each cell.
'column-normalized'	Normalize each cell value by the number of observations that has the same predicted class.
'row-normalized'	Normalize each cell value by the number of observations that has the same true class.
'total-normalized'	Normalize each cell value by the total number of observations.

Modifying the normalization of cell values also affects the colors of the cells.

Example: `cm = confusionchart(__, 'Normalization', 'total-normalized')`

Example: `cm.Normalization = 'total-normalized'`

Limitations

- MATLAB code generation is not supported for `ConfusionMatrixChart` objects.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Properties

`ConfusionMatrixChart` Properties

Introduced in R2018b

ConfusionMatrixChart Properties

Confusion matrix chart appearance and behavior

Description

ConfusionMatrixChart properties control the appearance and behavior of a ConfusionMatrixChart object. By changing property values, you can modify certain aspects of the confusion matrix chart. For example, you can add a title:

```
cm = confusionchart([1 3 5; 2 4 6; 11 7 3]);
cm.Title = 'My Confusion Matrix Title';
```

Properties

Labels

Title — Title

' ' (default) | character vector | string scalar

Title of the confusion matrix chart, specified as a character vector or string scalar.

Example: `cm = confusionchart(__, 'Title', 'My Title Text')`

Example: `cm.Title = 'My Title Text'`

XLabel — Label for x-axis

'Predicted class' (default) | string scalar | character vector

Label for the x-axis, specified as a string scalar or character vector.

Example: `cm = confusionchart(__, 'XLabel', 'My Label')`

Example: `cm.XLabel = 'My Label'`

YLabel — Label for y-axis

'True class' (default) | string scalar | character vector

Label for the x-axis, specified as a string scalar or character vector.

Example: `cm = confusionchart(__, 'YLabel', 'My Label')`

Example: `cm.YLabel = 'My Label'`

ClassLabels — Class labels

categorical vector | numeric vector | string vector | character array | cell array of character vectors | logical vector

This property is read-only.

Class labels of the confusion matrix chart, stored as a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector.

Row and Column Summaries**ColumnSummary – Column summary**

'off' (default) | 'absolute' | 'column-normalized' | 'total-normalized'

Column summary of the confusion matrix chart, specified as one of the following:

Option	Description
'off'	Do not display a column summary.
'absolute'	Display the total number of correctly and incorrectly classified observations for each predicted class.
'column-normalized'	Display the number of correctly and incorrectly classified observations for each predicted class as percentages of the number of observations of the corresponding predicted class. The percentages of correctly classified observations can be thought of as class-wise precisions (or positive predictive values).
'total-normalized'	Display the number of correctly and incorrectly classified observations for each predicted class as percentages of the total number of observations.

Example: `cm = confusionchart(__, 'ColumnSummary', 'column-normalized')`

Example: `cm.ColumnSummary = 'column-normalized'`

RowSummary – Row summary

'off' (default) | 'absolute' | 'row-normalized' | 'total-normalized'

Row summary of the confusion matrix chart, specified as one of the following:

Option	Description
'off'	Do not display a row summary.
'absolute'	Display the total number of correctly and incorrectly classified observations for each true class.
'row-normalized'	Display the number of correctly and incorrectly classified observations for each true class as percentages of the number of observations of the corresponding true class. The percentages of correctly classified observations can be thought of as class-wise recalls (or true positive rates).
'total-normalized'	Display the number of correctly and incorrectly classified observations for each true class as percentages of the total number of observations.

Example: `cm = confusionchart(__, 'RowSummary', 'row-normalized')`

Example: `cm.RowSummary = 'row-normalized'`

Data**NormalizedValues — Values of the confusion matrix**

numeric matrix

This property is read-only.

Values of the confusion matrix, stored as a numeric matrix. This property equals the values of the confusion matrix normalized using the method of the `Normalization` property. The software recalculates the normalized values of the confusion matrix each time you modify the `Normalization` property.

Normalization — Normalization of cell values

'absolute' (default) | 'column-normalized' | 'row-normalized' | 'total-normalized'

Normalization of cell values, specified as one of the following:

Option	Description
'absolute'	Display the total number of observations in each cell.
'column-normalized'	Normalize each cell value by the number of observations that has the same predicted class.
'row-normalized'	Normalize each cell value by the number of observations that has the same true class.
'total-normalized'	Normalize each cell value by the total number of observations.

Modifying the normalization of cell values also affects the colors of the cells.

Example: `cm = confusionchart(__, 'Normalization', 'total-normalized')`

Example: `cm.Normalization = 'total-normalized'`

Color and Styling**GridVisible — State of grid visibility**

'on' (default) | on/off logical value

State of grid visibility, specified as 'on' or 'off', or as numeric or logical 1 (true) or 0 (false). A value of 'on' is equivalent to true, and 'off' is equivalent to false. Thus, you can use the value of this property as a logical value. The value is stored as an on/off logical value of type `matlab.lang.OnOffSwitchState`.

- 'on' — Display grid lines between the chart cells.
- 'off' — Do not display grid lines between the chart cells.

Example: `cm = confusionchart(__, 'GridVisible', 'off')`

Example: `cm.GridVisible = 'off'`

DiagonalColor — Color for diagonal cells

[0 0.4471 0.7412] (default) | RGB triplet | hexadecimal color code | 'r' | 'g' | 'b' | ...

Color for diagonal cells, specified as an RGB triplet, a hexadecimal color code, a color name, or a short name. The color of each diagonal cell is proportional to the cell value and the `DiagonalColor`

property, normalized to the largest cell value of the confusion matrix chart. Cells with positive values are colored with a minimum amount of color, proportional to the `DiagonalColor` property.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

The software chooses an appropriate text color for cell labels automatically, depending on the color of the chart cells.

Example: `cm = confusionchart(__, 'DiagonalColor', 'blue')`

Example: `cm.DiagonalColor = 'blue'`

OffDiagonalColor — Color for off-diagonal cells

`[0.8510 0.3255 0.0980]` (default) | RGB triplet | hexadecimal color code | 'r' | 'g' | 'b' | ...

Color for off-diagonal cells, specified as an RGB triplet, a hexadecimal color code, a color name, or a short name. The color of each diagonal cell is proportional to the cell value and the `OffDiagonalColor` property, normalized to the largest cell value of the confusion matrix chart. Cells with positive values are colored with a minimum amount of color, proportional to the `OffDiagonalColor` property.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

The software chooses an appropriate text color for cell labels automatically, depending on the color of the chart cells.

Example: `cm = confusionchart(__, 'OffDiagonalColor', 'blue')`

Example: `cm.OffDiagonalColor = 'blue'`

FontColor — Text color for title, axis labels, and class labels

[0.1500 0.1500 0.1500] (default) | RGB triplet | hexadecimal color code | 'r' | 'g' | 'b' | ...

Text color for title, axis labels, and class labels, specified as an RGB triplet, a hexadecimal color code, a color name, or a short name.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7].
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

The software chooses an appropriate text color for cell labels automatically, depending on the color of the chart cells.

Example: `cm = confusionchart(__, 'FontColor', 'blue')`

Example: `cm.FontColor = 'blue'`

Font**FontName — Font name**

system supported font name

Font name, specified as a system supported font name. The default font depends on the specific operating system and locale.

Example: `cm = confusionchart(__, 'FontName', 'Cambria')`

Example: `cm.FontName = 'Cambria'`

FontSize — Font size

positive scalar

Font size used for the title, axis labels, class labels, and cell labels, specified as a positive scalar. The default font depends on the specific operating system and locale.

The title and axis labels use a slightly larger font size (scaled up by 10%). If there is not enough room to display the cell labels within the cells, then the cell labels use a smaller font size. If the cell labels become too small, then they are hidden.

Example: `cm = confusionchart(__, 'FontSize', 12)`

Example: `cm.FontSize = 12`

Position**PositionConstraint — Position to hold constant**

'outerposition' | 'innerposition'

Position property to hold constant when adding, removing, or changing decorations, specified as one of the following values:

- 'outerposition' — The `OuterPosition` property remains constant when you add, remove, or change decorations such as a title or an axis label. If any positional adjustments are needed, MATLAB adjusts the `InnerPosition` property.
- 'innerposition' — The `InnerPosition` property remains constant when you add, remove, or change decorations such as a title or an axis label. If any positional adjustments are needed, MATLAB adjusts the `OuterPosition` property.

Note Setting this property has no effect when the parent container is a `TiledChartLayout`.

OuterPosition — Outer size and position

[0 0 1 1] (default) | four-element vector

Outer size and position within the parent container (a figure, panel, or tab), specified as a four-element vector of the form [left bottom width height]. The outer position includes the title, axis labels, and class labels.

- The `left` and `bottom` elements define the distance from the lower left corner of the container to the lower left corner of the chart.
- The `width` and `height` elements are the chart dimensions, which include the chart cells, plus a margin for the surrounding text.

The default value of `[0 0 1 1]` is the whole interior of the container.

By default, the values are normalized to the container. To change the units, set the `Units` property.

Example: `cm = confusionchart(__, 'OuterPosition', [0.1 0.1 0.8 0.8])`

Example: `cm.OuterPosition = [0.1 0.1 0.8 0.8]`

InnerPosition — Inner size and position

`[0.1300 0.1100 0.7750 0.8150]` (default) | four-element vector

Inner size and position of the chart within the parent container (a figure, panel, or tab) returned as a four-element vector of the form `[left bottom width height]`. The inner position does not include the title, axis labels, or class labels.

- The `left` and `bottom` elements define the distance from the lower left corner of the container to the lower left corner of the chart.
- The `width` and `height` elements are the chart dimensions, which include only the chart cells.

Example: `cm = confusionchart(__, 'InnerPosition', [0.1 0.1 0.8 0.8])`

Example: `cm.InnerPosition = [0.1 0.1 0.8 0.8]`

Position — Inner size and position

four-element vector

Inner size and position of the chart within the parent container (a figure, panel, or tab) returned as a four-element vector of the form `[left bottom width height]`. This property is equivalent to the `InnerPosition` property.

Units — Position units

'normalized' (default) | 'inches' | 'centimeters' | 'points' | 'pixels' | 'characters'

Position units, specified as one of these values:

Units	Description
'normalized'	Normalized with respect to the container, which is typically the figure or a panel. The lower left corner of the container maps to $(0, 0)$, and the upper right corner maps to $(1, 1)$.
'inches'	Inches.
'centimeters'	Centimeters.
'characters'	Based on the default uicontrol font of the graphics root object: <ul style="list-style-type: none"> • Character width = width of letter x. • Character height = distance between the baselines of two lines of text.
'points'	Typography points. One point equals 1/72 inch.

Units	Description
'pixels'	Pixels. Starting in R2015b, distances in pixels are independent of your system resolution on Windows® and Macintosh systems: <ul style="list-style-type: none"> • On Windows systems, a pixel is 1/96th of an inch. • On Macintosh systems, a pixel is 1/72nd of an inch. On Linux® systems, the size of a pixel is determined by your system resolution.

When specifying the units as a name-value pair during object creation, you must set the `Units` property before specifying the properties that you want to use these units for, such as `OuterPosition`.

Visible — State of visibility

'on' (default) | on/off logical value

State of visibility, specified as 'on' or 'off', or as numeric or logical 1 (true) or 0 (false). A value of 'on' is equivalent to true, and 'off' is equivalent to false. Thus, you can use the value of this property as a logical value. The value is stored as an on/off logical value of type `matlab.lang.OnOffSwitchState`.

- 'on' — Display the chart.
- 'off' — Hide the chart without deleting it. You still can access the properties of an invisible chart.

Parent/Child

Parent — Parent container

figure object | panel object | tab object

Parent container, specified as a figure, panel, or tab object.

HandleVisibility — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of the chart object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — Object handle is always visible.
- 'off' — Object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. To temporarily hide the handle during the execution of that function, set the `HandleVisibility` to 'off'.
- 'callback' — Object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the object at the command line, but allows callback functions to access it.

If the object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles, regardless of their `HandleVisibility` property setting.

Functions

`categorical` | `confusionchart` | `sortClasses`

Introduced in R2018b

confusionmat

Compute confusion matrix for classification problem

Syntax

```
C = confusionmat(group,grouphat)
C = confusionmat(group,grouphat,'Order',grouporder)
[C,order] = confusionmat(____)
```

Description

`C = confusionmat(group,grouphat)` returns the confusion matrix `C` determined by the known and predicted groups in `group` and `grouphat`, respectively.

`C = confusionmat(group,grouphat,'Order',grouporder)` uses `grouporder` to order the rows and columns of `C`.

`[C,order] = confusionmat(____)` also returns the order of the rows and columns of `C` in the variable `order` using any of the input arguments in previous syntaxes.

Examples

Display Confusion Matrix

Display the confusion matrix for data with two misclassifications and one missing classification.

Create vectors for the known groups and the predicted groups.

```
g1 = [3 2 2 3 1 1]'; % Known groups
g2 = [4 2 3 NaN 1 1]'; % Predicted groups
```

Return the confusion matrix.

```
C = confusionmat(g1,g2)
```

```
C = 4×4
```

```
     2     0     0     0
     0     1     1     0
     0     0     0     1
     0     0     0     0
```

The indices of the rows and columns of the confusion matrix `C` are identical and arranged by default in the sorted order of `[g1;g2]`, that is, `(1,2,3,4)`.

The confusion matrix shows that the two data points known to be in group 1 are classified correctly. For group 2, one of the data points is misclassified into group 3. Also, one of the data points known to be in group 3 is misclassified into group 4. `confusionmat` treats the NaN value in the grouping variable `g2` as a missing value and does not include it in the rows and columns of `C`.

Plot the confusion matrix as a confusion matrix chart by using `confusionchart`.

```
confusionchart(C)
```

You do not need to calculate the confusion matrix first and then plot it. Instead, plot a confusion matrix chart directly from the true and predicted labels by using `confusionchart`.

```
cm = confusionchart(g1,g2)
```

```
cm =
ConfusionMatrixChart with properties:
```

```
NormalizedValues: [4x4 double]
ClassLabels: [4x1 double]
```

```
Show all properties
```

The `ConfusionMatrixChart` object stores the numeric confusion matrix in the `NormalizedValues` property and the classes in the `ClassLabels` property. Display these properties using dot notation.

```
cm.NormalizedValues
```

```
ans = 4x4
```

```

     2     0     0     0
     0     1     1     0
     0     0     0     1
     0     0     0     0
```

```
cm.ClassLabels
```

```
ans = 4x1
```

```

     1
     2
```

```
3
4
```

Specify Group Order of Confusion Matrix

Display the confusion matrix for data with two misclassifications and one missing classification, and specify the group order.

Create vectors for the known groups and the predicted groups.

```
g1 = [3 2 2 3 1 1]'; % Known groups
g2 = [4 2 3 NaN 1 1]'; % Predicted groups
```

Specify the group order and return the confusion matrix.

```
C = confusionmat(g1,g2,'Order',[4 3 2 1])
```

```
C = 4×4
```

```
0 0 0 0
1 0 0 0
0 1 1 0
0 0 0 2
```

The indices of the rows and columns of the confusion matrix *C* are identical and arranged in the order specified by the group order, that is, (4, 3, 2, 1).

The second row of the confusion matrix *C* shows that one of the data points known to be in group 3 is misclassified into group 4. The third row of *C* shows that one of the data points belonging to group 2 is misclassified into group 3, and the fourth row shows that the two data points known to be in group 1 are classified correctly. `confusionmat` treats the NaN value in the grouping variable *g2* as a missing value and does not include it in the rows and columns of *C*.

Confusion Matrix for Classification

Perform classification on a sample of the `fisheriris` data set and display the confusion matrix for the resulting classification.

Load Fisher's iris data set.

```
load fisheriris
```

Randomize the measurements and groups in the data.

```
rng(0,'twister'); % For reproducibility
numObs = length(species);
p = randperm(numObs);
meas = meas(p,:);
species = species(p);
```

Train a discriminant analysis classifier by using measurements in the first half of the data.

```
half = floor(numObs/2);
training = meas(1:half,:);
trainingSpecies = species(1:half);
Mdl = fitcdiscr(training,trainingSpecies);
```

Predict labels for the measurements in the second half of the data by using the trained classifier.

```
sample = meas(half+1:end,:);
grouphat = predict(Mdl,sample);
```

Specify the group order and display the confusion matrix for the resulting classification.

```
group = species(half+1:end);
[C,order] = confusionmat(group,grouphat,'Order',{'setosa','versicolor','virginica'})
```

```
C = 3×3
```

```
    29     0     0
     0    22     2
     0     0    22
```

```
order = 3×1 cell
    {'setosa' }
    {'versicolor' }
    {'virginica' }
```

The confusion matrix shows that the measurements belonging to setosa and virginica are classified correctly, while two of the measurements belonging to versicolor are misclassified as virginica. The output order contains the order of the rows and columns of the confusion matrix in the sequence specified by the group order {'setosa', 'versicolor', 'virginica'}.

Confusion Matrix for Classification Using Tall Arrays

Perform classification on a tall array of the fisheriris data set, compute a confusion matrix for the known and predicted tall labels by using the confusionmat function, and plot the confusion matrix by using the confusionchart function.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the mapreducer function.

Load Fisher's iris data set.

```
load fisheriris
```

Convert the in-memory arrays meas and species to tall arrays.

```
tx = tall(meas);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
ty = tall(species);
```

Find the number of observations in the tall array.

```
numObs = gather(length(ty)); % gather collects tall array into memory
```

Set the seeds of the random number generators using `rng` and `tallrng` for reproducibility, and randomly select training samples. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```
rng('default')
tallrng('default')
numTrain = floor(numObs/2);
[txTrain, trIdx] = datasample(tx, numTrain, 'Replace', false);
tyTrain = ty(trIdx);
```

Fit a decision tree classifier model on the training samples.

```
mdl = fitctree(txTrain, tyTrain);
```

```
Evaluating tall expression using the Parallel Pool 'local':

```

```
- Pass 2 of 4: Completed in 4.8 sec
```

```
- Pass 3 of 4: Completed in 10 sec
```

```
- Pass 4 of 4: Completed in 7.3 sec
```

```
Evaluation completed in 27 sec
```

```
Evaluating tall expression using the Parallel Pool 'local':
```

```
- Pass 1 of 4: Completed in 1.6 sec
```

```
- Pass 2 of 4: Completed in 4.3 sec
```

```
- Pass 3 of 4: Completed in 10 sec
```

```
- Pass 4 of 4: Completed in 7.9 sec
```

```
Evaluation completed in 28 sec
```

Predict labels for the test samples by using the trained model.

```
txTest = tx(~trIdx, :);
label = predict(mdl, txTest);
```

Compute the confusion matrix for the resulting classification.

```
tyTest = ty(~trIdx);
[C, order] = confusionmat(tyTest, label)
```

```
C =
```

```
MxNx... tall array
```

```
? ? ? ...
? ? ? ...
? ? ? ...
: : :
: : :
```

```
order =
```

```
MxNx... tall array
```

```
? ? ? ...
? ? ? ...
? ? ? ...
: : :
: : :
```

Use the `gather` function to perform the deferred calculation and return the result of `confusionmat` in memory.

```
gather(C)
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 3.2 sec
Evaluation completed in 4.7 sec
```

```
ans = 3x3
```

```
25    0    0
 1   24    3
 0    0   22
```

```
gather(order)
```

```
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0.091 sec
```

```
ans = 3x1 cell
```

```
{'setosa' }
{'versicolor'}
{'virginica' }
```

The confusion matrix shows that three measurements in the `versicolor` class are misclassified. All the measurements belonging to `setosa` and `virginica` are classified correctly.

To compute and plot the confusion matrix, use `confusionchart` on page 32-797 instead.

```
cm = confusionchart(tyTest,label)
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 1.4 sec
Evaluation completed in 2.4 sec
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 2.2 sec
Evaluation completed in 2.9 sec
```

```
cm =
ConfusionMatrixChart with properties:

    ClassLabels: {3x1 cell}

Show all properties
```

Input Arguments

group — Known groups

numeric vector | logical vector | character array | string array | cell array of character vectors | categorical vector

Known groups for categorizing observations, specified as a numeric vector, logical vector, character array, string array, cell array of character vectors, or categorical vector.

`group` is a grouping variable of the same type as `groupcat`. The `group` argument must have the same number of observations as `groupcat`, as described in “Grouping Variables” on page 2-45. The `confusionmat` function treats character arrays and string arrays as cell arrays of character vectors. Additionally, `confusionmat` treats NaN, empty, and 'undefined' values in `group` as missing values and does not count them as distinct groups or categories.

Example: {'Male', 'Female', 'Female', 'Male', 'Female'}

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

grouphat — Predicted groups

numeric vector | logical vector | character array | string array | cell array of character vectors | categorical vector

Predicted groups for categorizing observations, specified as a numeric vector, logical vector, character array, string array, cell array of character vectors, or categorical vector.

`grouphat` is a grouping variable of the same type as `group`. The `grouphat` argument must have the same number of observations as `group`, as described in “Grouping Variables” on page 2-45. The `confusionmat` function treats character arrays and string arrays as cell arrays of character vectors. Additionally, `confusionmat` treats NaN, empty, and 'undefined' values in `grouphat` as missing values and does not count them as distinct groups or categories.

Example: `[1 0 0 1 0]`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

grouporder — Group order

numeric vector | logical vector | character array | string array | cell array of character vectors | categorical vector

Group order, specified as a numeric vector, logical vector, character array, string array, cell array of character vectors, or categorical vector.

`grouporder` is a grouping variable containing all the distinct elements in `group` and `grouphat`. Specify `grouporder` to define the order of the rows and columns of `C`. If `grouporder` contains elements that are not in `group` or `grouphat`, the corresponding entries in `C` are 0.

By default, the group order depends on the data type of `s = [group;grouphat]`:

- For numeric and logical vectors, the order is the sorted order of `s`.
- For categorical vectors, the order is the order returned by `categories(s)`.
- For other data types, the order is the order of first appearance in `s`.

Example: `'order',{'setosa','versicolor','virginica'}`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

Output Arguments

C — Confusion matrix

matrix

Confusion matrix, returned as a square matrix with size equal to the total number of distinct elements in the `group` and `grouphat` arguments. $C(i, j)$ is the count of observations known to be in group `i` but predicted to be in group `j`.

The rows and columns of `C` have identical ordering of the same group indices. By default, the group order depends on the data type of `s = [group;grouphat]`:

- For numeric and logical vectors, the order is the sorted order of `s`.
- For categorical vectors, the order is the order returned by `categories(s)`.

- For other data types, the order is the order of first appearance in `s`.

To change the order, specify `grouporder`,

The `confusionmat` function treats `NaN`, empty, and `'undefined'` values in the grouping variables as missing values and does not include them in the rows and columns of `C`.

order — Order of rows and columns

numeric vector | logical vector | categorical vector | cell array of character vectors

Order of rows and columns in `C`, returned as a numeric vector, logical vector, categorical vector, or cell array of character vectors. If `group` and `groupcat` are character arrays, string arrays, or cell arrays of character vectors, then the variable `order` is a cell array of character vectors. Otherwise, `order` is of the same type as `group` and `groupcat`.

Alternative Functionality

- Use `confusionchart` to calculate and plot a confusion matrix. Additionally, `confusionchart` displays summary statistics about your data and sorts the classes of the confusion matrix according to the class-wise precision (positive predictive value), class-wise recall (true positive rate), or total number of correctly classified observations.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Introduced in R2008b

controlchart

Shewhart control charts

Syntax

```
controlchart(X)
controlchart(x,group)
controlchart(X,group)
[stats,plotdata] = controlchart(x,[group])
controlchart(x,group,'name',value)
```

Description

`controlchart(X)` produces an xbar chart of the measurements in matrix *X*. Each row of *X* is considered to be a subgroup of measurements containing replicate observations taken at the same time. The rows should be in time order. If *X* is a time series object, the time samples should contain replicate observations.

The chart plots the means of the subgroups in time order, a center line (CL) at the average of the means, and upper and lower control limits (UCL, LCL) at three standard errors from the center line. The standard error is the estimated process standard deviation divided by the square root of the subgroup size. Process standard deviation is estimated from the average of the subgroup standard deviations. Out of control measurements are marked as violations and drawn with a red circle. Data cursor mode is enabled, so clicking any data point displays information about that point.

`controlchart(x,group)` accepts a grouping variable `group` for a vector of measurements *x*. `group` is a categorical variable, numeric vector, character vector, string array, or cell array of character vectors the same length as *x*. Consecutive measurements *x*(*n*) sharing the same value of `group`(*n*) for $1 \leq n \leq \text{length}(x)$ are defined to be a subgroup. Subgroups can have different numbers of observations.

`controlchart(X,group)` accepts a grouping variable `group` for a matrix of measurements in *X*. In this case, `group` is only used to label the time axis; it does not change the default grouping by rows.

`[stats,plotdata] = controlchart(x,[group])` returns a structure `stats` of subgroup statistics and parameter estimates, and a structure `plotdata` of plotted values. `plotdata` contains one record for each chart.

The fields in `stats` and `plotdata` depend on the chart type.

The fields in `stats` are selected from the following:

- `mean` — Subgroup means
- `std` — Subgroup standard deviations
- `range` — Subgroup ranges
- `n` — Subgroup size, or total inspection size or area
- `i` — Individual data values
- `ma` — Moving averages

- `mr` — Moving ranges
- `count` — Count of defects or defective items
- `mu` — Estimated process mean
- `sigma` — Estimated process standard deviation
- `p` — Estimated proportion defective
- `m` — Estimated mean defects per unit

The fields in `plotdata` are the following:

- `pts` — Plotted point values
- `cl` — Center line
- `lcl` — Lower control limit
- `ucl` — Upper control limit
- `se` — Standard error of plotted point
- `n` — Subgroup size
- `ooc` — Logical that is true for points that are out of control

`controlchart(x,group,'name',value)` specifies one or more of the following optional parameter name/value pairs, with *name* in single quotes:

- `charttype` — The name of a chart type chosen from among the following:
 - `'xbar'` — Xbar or mean
 - `'s'` — Standard deviation
 - `'r'` — Range
 - `'ewma'` — Exponentially weighted moving average
 - `'i'` — Individual observation
 - `'mr'` — Moving range of individual observations
 - `'ma'` — Moving average of individual observations
 - `'p'` — Proportion defective
 - `'np'` — Number of defectives
 - `'u'` — Defects per unit
 - `'c'` — Count of defects

Alternatively, a parameter can be a string array or cell array listing multiple compatible chart types. There are four sets of compatible types:

- `'xbar'`, `'s'`, `'r'`, and `'ewma'`
- `'i'`, `'mr'`, and `'ma'`
- `'p'` and `'np'`
- `'u'` and `'c'`
- `display` — Either `'on'` (default) to display the control chart, or `'off'` to omit the display
- `label` — A character vector, string array, or cell array of character vectors, one per subgroup. This label is displayed as part of the data cursor for a point on the plot.

- `lambda` — A parameter between 0 and 1 controlling how much the current prediction is influenced by past observations in an EWMA plot. Higher values of '`lambda`' give less weight to past observations and more weight to the current observation. The default is 0.4.
- `limits` — A three-element vector specifying the values of the lower control limit, center line, and upper control limits. Default is to estimate the center line and to compute control limits based on the estimated value of sigma. Not permitted if there are multiple chart types.
- `mean` — Value for the process mean, or an empty value (default) to estimate the mean from X. This is the `p` parameter for `p` and `np` charts, the mean defects per unit for `u` and `c` charts, and the normal `mu` parameter for other charts.
- `nsigma` — The number of sigma multiples from the center line to a control limit. Default is 3.
- `parent` — The handle of the axes to receive the control chart plot. Default is to create axes in a new figure. Not permitted if there are multiple chart types.
- `rules` — The name of a control rule, or a string array or cell array containing multiple control rule names. These rules, together with the control limits, determine if a point is marked as out of control. The default is to apply no control rules, and to use only the control limits to decide if a point is out of control. See `controlrules` for more information. Control rules are applied to charts that measure the process level (`xbar`, `i`, `c`, `u`, `p`, and `np`) rather than the variability (`r`, `s`), and they are not applied to charts based on moving statistics (`ma`, `mr`, `ewma`).
- `sigma` — Either a value for sigma, or a method of estimating sigma chosen from among '`std`' (the default) to use the average within-subgroup standard deviation, '`range`' to use the average subgroup range, and '`variance`' to use the square root of the pooled variance. When creating `i`, `mr`, or `ma` charts for data not in subgroups, the estimate is always based on a moving range.
- `specs` — A vector specifying specification limits. Typically this is a two-element vector of lower and upper specification limits. Since specification limits typically apply to individual measurements, this parameter is primarily suitable for `i` charts. These limits are not plotted on `r`, `s`, or `mr` charts.
- `unit` — The total number of inspected items for `p` and `np` charts, and the size of the inspected unit for `u` and `c` charts. In both cases X must be the count of the number of defects or defectives found. Default is 1 for `u` and `c` charts. This argument is required (no default) for `p` and `np` charts.
- `width` — The width of the window used for computing the moving ranges and averages in `mr` and `ma` charts, and for computing the sigma estimate in `i`, `mr`, and `ma` charts. Default is 5.

Examples

XBar and R Charts

Load the sample data.

```
load parts
```

Create xbar and r control charts for the data.

```
st = controlchart(runout, 'charttype', {'xbar' 'r'});
```

Display the process mean and standard deviation.

```
fprintf('Parameter estimates: mu = %g, sigma = %g\n',st.mu,st.sigma);
```

```
Parameter estimates: mu = -0.0863889, sigma = 0.130215
```

controlrules

Topics

“Grouping Variables” on page 2-45

Introduced in R2006b

controlrules

Western Electric and Nelson control rules

Syntax

```
R = controlrules('rules',x,cl,se)
[R,RULES] = controlrules('rules',x,cl,se)
```

Description

`R = controlrules('rules',x,cl,se)` determines which points in the vector `x` violate the control rules in `rules`. `cl` is a vector of center-line values. `se` is a vector of standard errors. (Typically, control limits on a control chart are at the values $cl - 3*se$ and $cl + 3*se$.) `rules` is the name of a control rule, or a string array or cell array containing multiple control rule names. If `x` has n values and `rules` contains m rules, then `R` is an n -by- m logical array, with `R(i,j)` assigned the value 1 if point i violates rule j , 0 if it does not.

The following are accepted values for `rules` (specified inside single quotes):

- `we1` — 1 point above $cl + 3*se$
- `we2` — 2 of 3 above $cl + 2*se$
- `we3` — 4 of 5 above $cl + se$
- `we4` — 8 of 8 above cl
- `we5` — 1 below $cl - 3*se$
- `we6` — 2 of 3 below $cl - 2*se$
- `we7` — 4 of 5 below $cl - se$
- `we8` — 8 of 8 below cl
- `we9` — 15 of 15 between $cl - se$ and $cl + se$
- `we10` — 8 of 8 below $cl - se$ or above $cl + se$
- `n1` — 1 point below $cl - 3*se$ or above $cl + 3*se$
- `n2` — 9 of 9 on the same side of cl
- `n3` — 6 of 6 increasing or decreasing
- `n4` — 14 alternating up/down
- `n5` — 2 of 3 below $cl - 2*se$ or above $cl + 2*se$, same side
- `n6` — 4 of 5 below $cl - se$ or above $cl + se$, same side
- `n7` — 15 of 15 between $cl - se$ and $cl + se$
- `n8` — 8 of 8 below $cl - se$ or above $cl + se$, either side
- `we` — All Western Electric rules
- `n` — All Nelson rules

For multi-point rules, a rule violation at point i indicates that the set of points ending at point i triggered the rule. Point i is considered to have violated the rule only if it is one of the points violating the rule's condition.

Any points with NaN as their x , cl , or se values are not considered to have violated rules, and are not counted in the rules for other points.

Control rules can be specified in the `controlchart` function as values for the 'rules' parameter.

`[R,RULES] = controlrules('rules',x,cl,se)` returns a cell array of text RULES listing the rules applied.

Examples

Use Western Electric Control Rule

Load the sample data.

```
load parts;
```

Create an Xbar chart using the `we2` rule to mark out of control measurements.

```
st = controlchart(runout,'rules','we2');
x = st.mean;
cl = st.mu;
se = st.sigma./sqrt(st.n);
hold on
plot(cl+2*se,'m')
```

You can see the out of control points marked with a red circle.

Use `controlrules` to identify the measurements that violate the control rule.

```
R = controlrules('we2',x,cl,se);  
I = find(R)
```

```
I = 6×1
```

```
    21  
    23  
    24  
    25  
    26  
    27
```

`controlchart`

Introduced in R2006b

cophenet

Cophenetic correlation coefficient

Syntax

```
c = cophenet(Z,Y)
[c,d] = cophenet(Z,Y)
```

Description

`c = cophenet(Z,Y)` computes the cophenetic correlation coefficient for the hierarchical cluster tree represented by `Z`. `Z` is the output of the `linkage` function. `Y` contains the distances or dissimilarities used to construct `Z`, as output by the `pdist` function. `Z` is a matrix of size $(m-1)$ -by-3, with distance information in the third column. `Y` is a vector of size $m*(m-1)/2$.

`[c,d] = cophenet(Z,Y)` returns the cophenetic distances `d` in the same lower triangular distance vector format as `Y`.

The cophenetic correlation for a cluster tree is defined as the linear correlation coefficient between the cophenetic distances obtained from the tree, and the original distances (or dissimilarities) used to construct the tree. Thus, it is a measure of how faithfully the tree represents the dissimilarities among observations.

The cophenetic distance between two observations is represented in a dendrogram by the height of the link at which those two observations are first joined. That height is the distance between the two subclusters that are merged by that link.

The output value, `c`, is the cophenetic correlation coefficient. The magnitude of this value should be very close to 1 for a high-quality solution. This measure can be used to compare alternative cluster solutions obtained using different algorithms.

The cophenetic correlation between `Z(:,3)` and `Y` is defined as

$$c = \frac{\sum_{i < j} (Y_{ij} - y)(Z_{ij} - z)}{\sqrt{\sum_{i < j} (Y_{ij} - y)^2 \sum_{i < j} (Z_{ij} - z)^2}}$$

where:

- Y_{ij} is the distance between objects i and j in `Y`.
- Z_{ij} is the cophenetic distance between objects i and j , from `Z(:,3)`.
- y and z are the average of `Y` and `Z(:,3)`, respectively.

Examples

```
X = [rand(10,3); rand(10,3)+1; rand(10,3)+2];
Y = pdist(X);
Z = linkage(Y,'average');
```

```
% Compute Spearman's rank correlation between the
```

```
% dissimilarities and the cophenetic distances
[c,D] = cophenet(Z,Y);
r = corr(Y',D', 'type', 'spearman')
r =
    0.8279
```

Introduced before R2006a

copulacdf

Copula cumulative distribution function

Syntax

```
y = copulacdf('Gaussian',u,rho)
```

```
y = copulacdf('t',u,rho,nu)
```

```
y = copulacdf(family,u,alpha)
```

Description

`y = copulacdf('Gaussian',u,rho)` returns the cumulative probability of the Gaussian copula, with linear correlation parameters `rho` evaluated at the points in `u`.

`y = copulacdf('t',u,rho,nu)` returns the cumulative probability of the t copula, with linear correlation parameters, `rho`, and degrees of freedom parameter `nu` evaluated at the points in `u`.

`y = copulacdf(family,u,alpha)` returns the cumulative probability of the bivariate Archimedean copula of the type specified by `family`, with scalar parameter `alpha` evaluated at the points in `u`.

Examples

Compute the Clayton Copula cdf

Define two 10-by-10 matrices containing the values at which to compute the cdf.

```
u = linspace(0,1,10);  
[u1,u2] = meshgrid(u,u);
```

Compute the cdf of a Clayton copula that has an alpha parameter equal to 1, at the values in `u`.

```
y = copulacdf('Clayton',[u1(:),u2(:)],1);
```

Plot the cdf as a surface, and label the axes.

```
surf(u1,u2,reshape(y,10,10))  
xlabel('u1')  
ylabel('u2')
```

Input Arguments

u — Values at which to evaluate cdf

matrix of scalar values in the range [0,1]

Values at which to evaluate the cdf, specified as a matrix of scalar values in the range [0,1]. If u is an n -by- p matrix, then its values represent n points in the p -dimensional unit hypercube. If u is an n -by-2 matrix, then its values represent n points in the unit square.

If you specify a bivariate Archimedean copula type ('Clayton', 'Frank', or 'Gumbel'), then u must be an n -by-2 matrix.

Data Types: single | double

rho — Linear correlation parameters

scalar values | matrix of scalar values

Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If u is an n -by- p matrix, then ρ is a p -by- p correlation matrix.
- If u is an n -by-2 matrix, then ρ can be a scalar correlation coefficient.

Data Types: single | double

nu — Degrees of freedom

positive integer value

Degrees of freedom for the t copula, specified as a positive integer value.

Data Types: single | double

family — Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

'Clayton'	Clayton copula
'Frank'	Frank copula
'Gumbel'	Gumbel copula

alpha — Bivariate Archimedean copula parameter

scalar value

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for α depend on the specified copula family.

Copula Family	Permitted Alpha Values
'Clayton'	$[0, \infty)$
'Frank'	$(-\infty, \infty)$
'Gumbel'	$[1, \infty)$

Data Types: single | double

Output Arguments**y — Cumulative distribution function**

vector of scalar values

Cumulative distribution function of the copula, evaluated at the points in u , returned as a vector of scalar values.**See Also**

copulaparam | copulapdf | copularnd | copulastat

Topics

"Generate Correlated Data Using Rank Correlation" on page 5-105

"Copulas: Generate Correlated Samples" on page 5-118

Introduced in R2006a

copulafit

Fit copula to data

Syntax

```
rhohat = copulafit('Gaussian',u)

[rhohat,nuhat] = copulafit('t',u)
[rhohat,nuhat,nuci] = copulafit('t',u)

paramhat = copulafit(family,u)
[paramhat,paramci] = copulafit(family,u)

___ = copulafit( ___,Name,Value)
```

Description

`rhohat = copulafit('Gaussian',u)` returns an estimate, `rhohat`, of the matrix of linear correlation parameters for a Gaussian copula, given the data in `u`.

`[rhohat,nuhat] = copulafit('t',u)` returns an estimate, `rhohat`, of the matrix of linear correlation parameters for a t copula, and an estimate of the degrees of freedom parameter, `nuhat`, given the data in `u`.

`[rhohat,nuhat,nuci] = copulafit('t',u)` also returns an approximate 95% confidence interval, `nuci`, for the degrees of freedom estimated in `nuhat`.

`paramhat = copulafit(family,u)` returns an estimate, `paramhat`, of the copula parameter for a bivariate Archimedean copula of the type specified by `family`, given the data in `u`.

`[paramhat,paramci] = copulafit(family,u)` also returns an approximate 95% confidence interval, `paramci`, for the copula parameter estimated in `paramhat`.

`___ = copulafit(___,Name,Value)` returns any of the previous syntaxes, with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence interval to compute, or specify control parameters for the iterative parameter estimation algorithm using a options structure.

Examples

Fit a t Copula to Data

Load and plot simulated stock return data.

```
load stockreturns
x = stocks(:,1);
y = stocks(:,2);

figure;
scatterhist(x,y)
```

Transform the data to the copula scale (unit square) using a kernel estimator of the cumulative distribution function.

```
u = ksdensity(x,x,'function','cdf');  
v = ksdensity(y,y,'function','cdf');
```

```
figure;  
scatterhist(u,v)  
xlabel('u')  
ylabel('v')
```

Fit a t copula to the data.

```
rng default % For reproducibility
[Rho,nu] = copulafit('t',[u v],'Method','ApproximateML')
```

Rho =

```
    1.0000    0.7220
    0.7220    1.0000
```

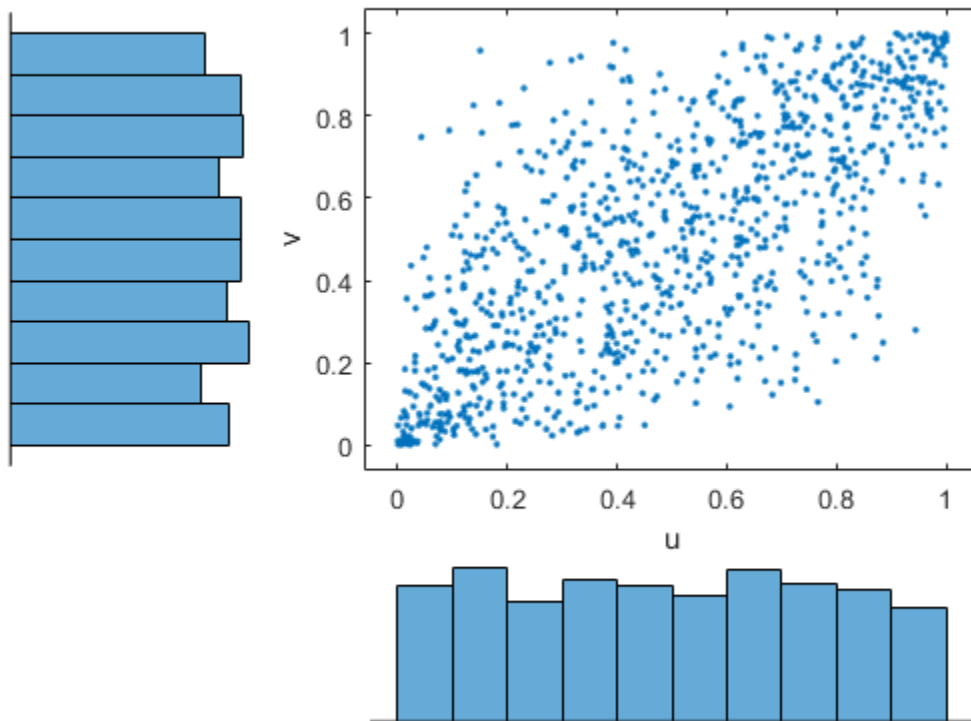

nu =

```
3.0531e+06
```

Generate a random sample from the t copula.

```
r = copularnd('t',Rho,nu,1000);
u1 = r(:,1);
v1 = r(:,2);
```

```
figure;
scatterhist(u1,v1)
xlabel('u')
ylabel('v')
set(get(gca,'children'),'marker','.')
```

Transform the random sample back to the original scale of the data.

```
x1 = ksdensity(x,u1,'function','icdf');  
y1 = ksdensity(y,v1,'function','icdf');
```

```
figure;  
scatterhist(x1,y1)  
set(get(gca,'children'),'marker','.')
```

Input Arguments

u – Copula values

matrix of scalar values in the range (0,1)

Copula values, specified as a matrix of scalar values in the range (0,1). If u is an n -by- p matrix, then its values represent n points in the p -dimensional unit hypercube. If u is an n -by-2 matrix, then its values represent n points in the unit square.

If you specify a bivariate Archimedean copula type ('Clayton', 'Frank', or 'Gumbel'), then u must be an n -by-2 matrix.

Data Types: single | double

family – Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

'Clayton'	Clayton copula
'Frank'	Frank copula
'Gumbel'	Gumbel copula

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Alpha', 0.01, 'Method', 'ApproximateML'` computes 99% confidence intervals for the estimated copula parameter and uses an approximation method to fit the copula.

Alpha — Significance level for confidence intervals

0.05 (default) | scalar value in the range (0,1)

Significance level for confidence intervals, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). `copulafit` returns approximate $100 \times (1-\text{Alpha})\%$ confidence intervals.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Method — Method for fitting *t* copula

`'ML'` (default) | `'ApproximateML'`

Method for fitting *t* copula, specified as the comma-separated pair consisting of `'Method'` and either `'ML'` or `'ApproximateML'`.

If you specify `'ApproximateML'`, then `copulafit` fits a *t* copula for large samples by maximizing an objective function that approximates the profile log likelihood for the degrees of freedom parameter [1]. This method can be significantly faster than maximum likelihood (`'ML'`), but the estimates and confidence limits may not be accurate for small to moderate sample sizes.

Example: `'Method', 'ApproximateML'`

Options — Control parameter specifications

structure

Control parameter specifications, specified as the comma-separated pair consisting of `'Options'` and an options structure created by `statset`. To see the fields and default values used by `copulafit`, type `statset('copulafit')` at the command prompt.

This name-value pair is not applicable when you specify the copula type as `'Gaussian'`.

Data Types: `struct`

Output Arguments

rho_hat — Estimated correlation parameters for the fitted Gaussian copula

matrix of scalar values

Estimated correlation parameters for the fitted Gaussian copula, given the data in `u`, returned as a matrix of scalar values.

nu_hat — Estimated degrees of freedom parameter for the fitted *t* copula

scalar value

Estimated degrees of freedom parameter for the fitted *t* copula, returned as a scalar value.

nuci — Approximate confidence interval for the degrees of freedom parameter

1-by-2 matrix of scalar values

Approximate confidence interval for the degrees of freedom parameter, returned as a 1-by-2 matrix of scalar values. The first column contains the lower boundary, and the second column contains the upper boundary. By default, `copulafit` returns the approximate 95% confidence interval. You can specify a different confidence interval using the 'Alpha' name-value pair.

paramhat — Estimated copula parameter for the fitted Archimedean copula

scalar value

Estimated copula parameter for the fitted Archimedean copula, returned as a scalar value.

paramci — Approximate confidence interval for the copula parameter

1-by-2 matrix of scalar values

Approximate confidence interval for the copula parameter, returned as a 1-by-2 matrix of scalar values. The first column contains the lower boundary, and the second column contains the upper boundary. By default, `copulafit` returns the approximate 95% confidence interval. You can specify a different confidence interval using the 'Alpha' name-value pair.

Algorithms

By default, `copulafit` uses maximum likelihood to fit a copula to `u`. When `u` contains data transformed to the unit hypercube by parametric estimates of their marginal cumulative distribution functions, this is known as the *Inference Functions for Margins (IFM)* method. When `u` contains data transformed by the empirical cdf (see `ecdf`), this is known as *Canonical Maximum Likelihood (CML)*.

Introduced in R2007b

copulaparam

Copula parameters as function of rank correlation

Syntax

```
rho = copulaparam('Gaussian',r)
rho = copulaparam('t',r,nu)
alpha = copulaparam(family,r)
___ = copulaparam( ___,Name,Value)
```

Description

`rho = copulaparam('Gaussian',r)` returns the linear correlation parameters, `rho`, that correspond to a Gaussian copula with Kendall's rank correlation, `r`.

`rho = copulaparam('t',r,nu)` returns the linear correlation parameters, `rho`, that correspond to a t copula with Kendall's rank correlation, `r`, and degrees of freedom, `nu`.

`alpha = copulaparam(family,r)` returns the copula parameter, `alpha`, that corresponds to a bivariate Archimedean copula of the type specified by `family`, with Kendall's rank correlation, `r`.

`___ = copulaparam(___,Name,Value)` returns the correlation parameter using any of the previous syntaxes, with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify whether the input rank correlation value is Spearman's ρ or Kendall's τ .

Examples

Generate Correlated Data Using the Inverse cdf

Generate correlated random data from a beta distribution using a bivariate Gaussian copula with Kendall's τ rank correlation equal to -0.5.

Compute the linear correlation parameter from the rank correlation value.

```
rng default % For reproducibility
tau = -0.5;
rho = copulaparam('Gaussian',tau)

rho = -0.7071
```

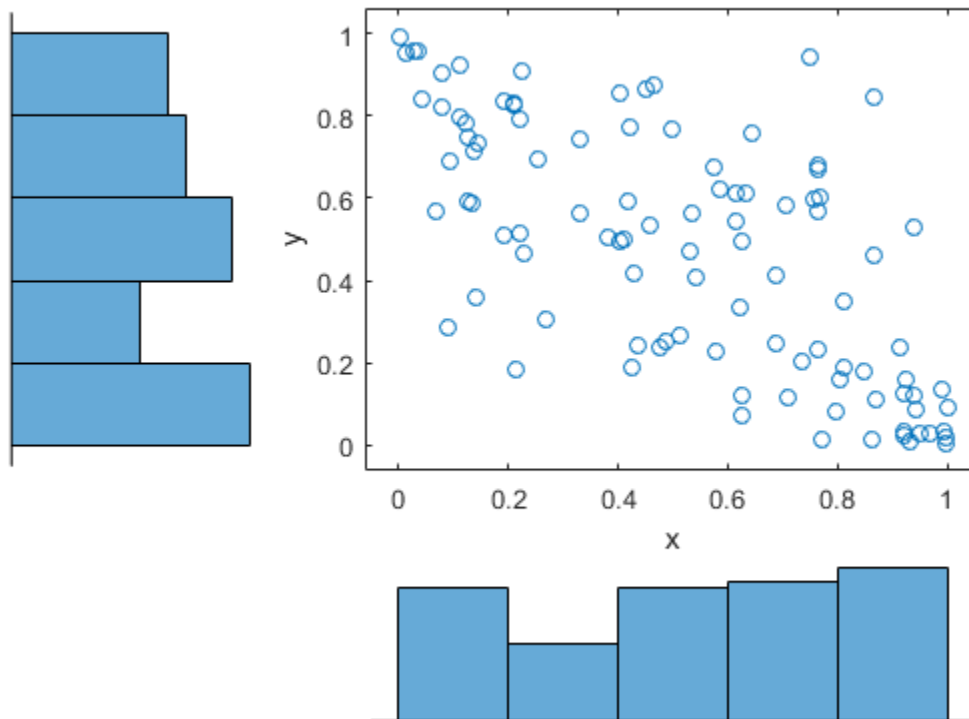

Use a Gaussian copula to generate a two-column matrix of dependent random values.

```
u = copularnd('gaussian',rho,100);
```

Each column contains 100 random values between 0 and 1, inclusive, sampled from a continuous uniform distribution.

Create a `scatterhist` plot to visualize the random numbers generated using the copula.

```
figure
scatterhist(u(:,1),u(:,2))
```

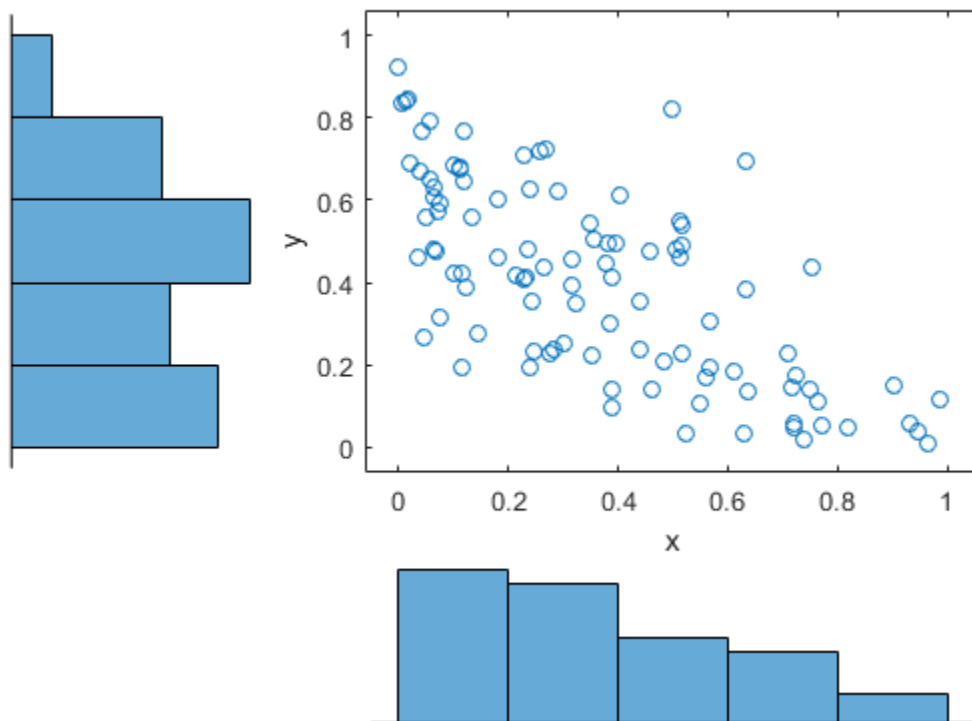

The histograms show that the data in each column of the copula has a marginal uniform distribution. The scatterplot shows that the data in the two columns is negatively correlated.

Use the inverse cdf function `betainv` to transform each column of the uniform marginal distributions into random numbers from a beta distribution. In the first column, the first shape parameter A is equal to 1, and a second shape parameter B is equal to 2. In the second column, the first shape parameter A is equal to 1.5, and a second shape parameter B is equal to 2.

```
b = [betainv(u(:,1),1,2), betainv(u(:,2),1.5,2)];
```

Create a `scatterhist` plot to visualize the correlated beta distribution data.

```
figure
scatterhist(b(:,1),b(:,2))
```

The histograms show the marginal beta distributions for each variable. The scatterplot shows the negative correlation.

Verify that the sample has a rank correlation approximately equal to the initial value for Kendall's *tau*.

```
tau_sample = corr(b, 'type', 'kendall')
```

```
tau_sample = 2x2
```

```
    1.0000    -0.5135
   -0.5135     1.0000
```

The sample rank correlation of -0.5135 is approximately equal to the -0.5 initial value for *tau*.

Input Arguments

r — Copula rank correlation

scalar value | matrix of scalar values

Copula rank correlation, returned as a scalar value or matrix of scalar values.

- If *r* is a scalar correlation coefficient, then *rho* is a scalar correlation coefficient corresponding to a bivariate copula.
- If *r* is a *p*-by-*p* correlation matrix, then *rho* is a *p*-by-*p* correlation matrix.

If the copula is specified as one of the bivariate Archimedean copula types ('Clayton', 'Frank', or 'Gumbel'), then r is a scalar value.

nu — Degrees of freedom

positive integer value

Degrees of freedom for the t copula, specified as a positive integer value.

Data Types: single | double

family — Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

'Clayton'	Clayton copula
'Frank'	Frank copula
'Gumbel'	Gumbel copula

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: 'type', 'Spearman' computes Spearman's rank correlation.

type — Type of rank correlation

'Kendall' (default) | 'Spearman'

Type of rank correlation, specified as the comma-separated pair consisting of 'type' and one of the following.

- 'Kendall' — Indicates that the input value for r is a Kendall's τ correlation value
- 'Spearman' — Indicates that the input value for r is a Spearman's ρ rank correlation value

copulaparam uses an approximation to Spearman's rank correlation for copula families that do not have an existing analytic formula. The approximation is based on a smooth fit to values computed at discrete values of the copula parameters. For a t copula, the approximation is accurate for degrees of freedom larger than 0.05.

Example: 'type', 'Spearman'

Output Arguments

rho — Linear correlation parameter

scalar value | matrix of scalar values

Linear correlation parameter, returned as a scalar value or matrix of scalar values.

- If r is a scalar correlation coefficient, then rho is a scalar correlation coefficient corresponding to a bivariate copula.
- If r is a p -by- p correlation matrix, then rho is a p -by- p correlation matrix.

alpha — Bivariate Archimedean copula parameter

scalar value

Bivariate Archimedean copula parameter, returned as a scalar value. Permitted values for alpha depend on the specified copula family.

Copula Family	Permitted Alpha Values
'Clayton'	$[0, \infty)$
'Frank'	$(-\infty, \infty)$
'Gumbel'	$[1, \infty)$

Data Types: single | double

Topics

“Generate Correlated Data Using Rank Correlation” on page 5-105

“Copulas: Generate Correlated Samples” on page 5-118

Introduced in R2006a

copulapdf

Copula probability density function

Syntax

```
y = copulapdf('Gaussian',u,rho)
```

```
y = copulapdf('t',u,rho,nu)
```

```
y = copulapdf(family,u,alpha)
```

Description

`y = copulapdf('Gaussian',u,rho)` returns the probability density of the Gaussian copula with linear correlation parameters, `rho`, evaluated at the points in `u`.

`y = copulapdf('t',u,rho,nu)` returns the probability density of the t copula with linear correlation parameters, `rho`, and degrees of freedom parameter, `nu`, evaluated at the points in `u`.

`y = copulapdf(family,u,alpha)` returns the probability density of the bivariate Archimedean copula of the type specified by `family`, with scalar parameter, `alpha`, evaluated at the points in `u`.

Examples

Compute the Clayton Copula pdf

Define two 10-by-10 matrices containing the values at which to compute the pdf.

```
u = linspace(0,1,10);  
[u1,u2] = meshgrid(u,u);
```

Compute the pdf of a Clayton copula that has an alpha parameter equal to 1, at the values in `u`.

```
y = copulapdf('Clayton',[u1(:),u2(:)],1);
```

Plot the pdf as a surface, and label the axes.

```
surf(u1,u2,reshape(y,10,10))  
xlabel('u1')  
ylabel('u2')
```

Input Arguments

u — Values at which to evaluate pdf

matrix of scalar values in the range [0,1]

Values at which to evaluate the pdf, specified as a matrix of scalar values in the range [0,1]. If *u* is an *n*-by-*p* matrix, then its values represent *n* points in the *p*-dimensional unit hypercube. If *u* is an *n*-by-2 matrix, then its values represent *n* points in the unit square.

If you specify a bivariate Archimedean copula type ('Clayton', 'Frank', or 'Gumbel'), then *u* must be an *n*-by-2 matrix.

Data Types: single | double

rho — Linear correlation parameters

scalar values | matrix of scalar values

Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If *u* is an *n*-by-*p* matrix, then *rho* is a *p*-by-*p* correlation matrix.
- If *u* is an *n*-by-2 matrix, then *rho* can be a scalar correlation coefficient.

Data Types: single | double

nu — Degrees of freedom

positive integer value

Degrees of freedom for the t copula, specified as a positive integer value.

Data Types: single | double

family — Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

'Clayton'	Clayton copula
'Frank'	Frank copula
'Gumbel'	Gumbel copula

alpha — Bivariate Archimedean copula parameter

scalar value

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for α depend on the specified copula family.

Copula Family	Permitted Alpha Values
'Clayton'	$[0, \infty)$
'Frank'	$(-\infty, \infty)$
'Gumbel'	$[1, \infty)$

Data Types: single | double

Output Arguments**y — Probability density function**

vector of scalar values

Probability density function, evaluated at the values in u , returned as a vector of scalar values.**See Also**

copulacdf | copulaparam | copularnd | copulastat

Introduced in R2006a

copulastat

Copula rank correlation

Syntax

```
r = copulastat('Gaussian',rho)
```

```
r = copulastat('t',rho,nu)
```

```
r = copulastat(family,alpha)
```

```
r = copulstat( ____,Name,Value)
```

Description

`r = copulastat('Gaussian',rho)` returns the Kendall's rank correlation, r , that corresponds to a Gaussian copula with linear correlation parameters ρ .

`r = copulastat('t',rho,nu)` returns the Kendall's rank correlation, r , that corresponds to a t copula with linear correlation parameters, ρ , and degrees of freedom parameter, ν .

`r = copulastat(family,alpha)` returns the Kendall's rank correlation, r , that corresponds to a bivariate Archimedean copula that has the type specified by `family` and scalar parameter `alpha`.

`r = copulstat(____,Name,Value)` returns the copula rank correlation with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can return Spearman's ρ rank correlation.

Examples

Compute the Gaussian Copula Rank Correlation

Compute the rank correlation for a Gaussian copula with the specified linear correlation parameter ρ .

```
rho = -.7071;  
tau = copulastat('gaussian',rho)
```

```
tau = -0.5000
```

Use the copula to generate dependent random values from a beta distribution that has parameters a and b equal to 2.

```
rng default % For reproducibility  
u = copularnd('gaussian',rho,100);  
b = betainv(u,2,2);
```

Verify that the sample has a rank correlation approximately equal to `tau`.

```
tau_sample = corr(b,'type','k')
```

```
tau_sample = 2x2
    1.0000    -0.5135
   -0.5135     1.0000
```

Input Arguments

rho — Linear correlation parameters

scalar values | matrix of scalar values

Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If **rho** is a scalar correlation coefficient, then **r** is a scalar correlation coefficient corresponding to a bivariate copula.
- If **rho** is a p -by- p correlation matrix, then **r** is a p -by- p correlation matrix.

Data Types: single | double

nu — Degrees of freedom

positive integer value

Degrees of freedom for the t copula, specified as a positive integer value.

Data Types: single | double

family — Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

'Clayton'	Clayton copula
'Frank'	Frank copula
'Gumbel'	Gumbel copula

alpha — Bivariate Archimedean copula parameter

scalar value

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for **alpha** depend on the specified copula family.

Copula Family	Permitted Alpha Values
'Clayton'	$[0, \infty)$
'Frank'	$(-\infty, \infty)$
'Gumbel'	$[1, \infty)$

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'type', 'Spearman'` computes Spearman's rank correlation.

type — Type of rank correlation

`'Kendall'` (default) | `'Spearman'`

Type of rank correlation, specified as the comma-separated pair consisting of `'type'` and one of the following.

- `'Kendall'` — Compute Kendall's τ .
- `'Spearman'` — Compute Spearman's ρ (rank correlation).

`copulastat` uses an approximation to Spearman's rank correlation for copula families that do not have an existing analytic formula. The approximation is based on a smooth fit to values computed at discrete values of the copula parameters. For a t copula, the approximation is accurate for degrees of freedom larger than 0.05.

Example: `'type', 'Spearman'`

Output Arguments

r — Copula rank correlation

scalar value | matrix of scalar values

Copula rank correlation, returned as a scalar value or matrix of scalar values.

- If ρ is a scalar correlation coefficient, then r is a scalar correlation coefficient corresponding to a bivariate copula.
- If ρ is a p -by- p correlation matrix, then r is a p -by- p correlation matrix.

Topics

"Generate Correlated Data Using Rank Correlation" on page 5-105

"Copulas: Generate Correlated Samples" on page 5-118

Introduced in R2006a

copularnd

Copula random numbers

Syntax

```
u = copularnd('Gaussian',rho,n)
```

```
u = copularnd('t',rho,nu,n)
```

```
u = copularnd(family,alpha,n)
```

Description

`u = copularnd('Gaussian',rho,n)` returns n random vectors generated from a Gaussian copula with linear correlation parameters `rho`.

`u = copularnd('t',rho,nu,n)` returns n random vectors generated from a t copula with linear correlation parameters `rho` and degrees of freedom `nu`.

`u = copularnd(family,alpha,n)` returns n random vectors generated from a bivariate Archimedean copula that has the type specified by `family` and the scalar parameter `alpha`.

Examples

Generate Correlated Data Using the Inverse cdf

Generate correlated random data from a beta distribution using a bivariate Gaussian copula with Kendall's τ rank correlation equal to -0.5.

Compute the linear correlation parameter from the rank correlation value.

```
rng default % For reproducibility
tau = -0.5;
rho = copulaparam('Gaussian',tau)

rho = -0.7071
```

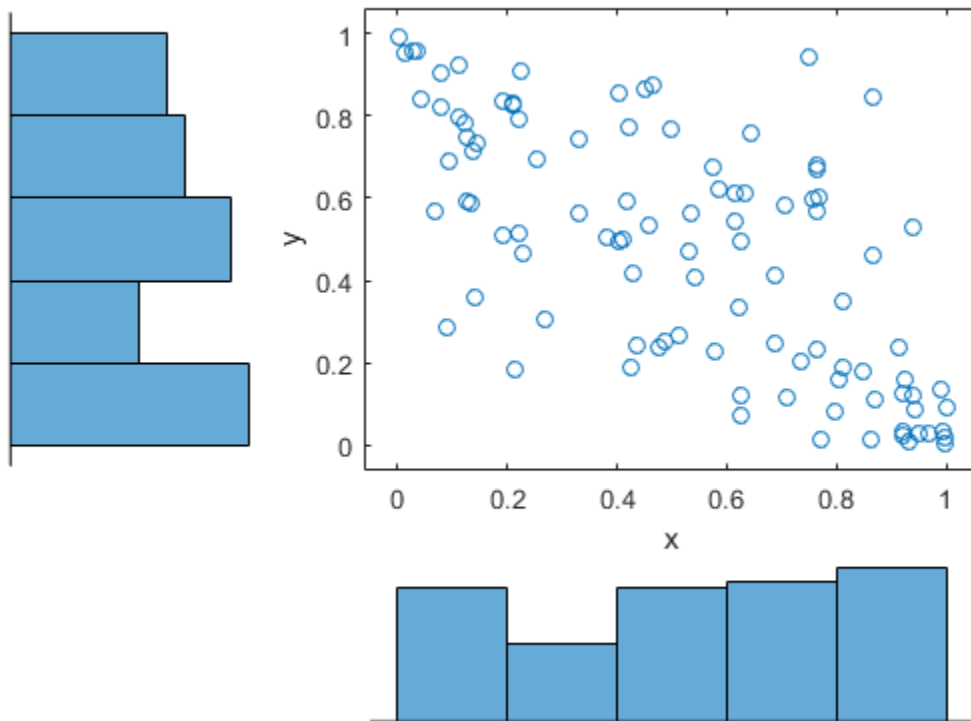

Use a Gaussian copula to generate a two-column matrix of dependent random values.

```
u = copularnd('gaussian',rho,100);
```

Each column contains 100 random values between 0 and 1, inclusive, sampled from a continuous uniform distribution.

Create a `scatterhist` plot to visualize the random numbers generated using the copula.

```
figure
scatterhist(u(:,1),u(:,2))
```

The histograms show that the data in each column of the copula has a marginal uniform distribution. The scatterplot shows that the data in the two columns is negatively correlated.

Use the inverse cdf function `betainv` to transform each column of the uniform marginal distributions into random numbers from a beta distribution. In the first column, the first shape parameter A is equal to 1, and a second shape parameter B is equal to 2. In the second column, the first shape parameter A is equal to 1.5, and a second shape parameter B is equal to 2.

```
b = [betainv(u(:,1),1,2), betainv(u(:,2),1.5,2)];
```

Create a `scatterhist` plot to visualize the correlated beta distribution data.

```
figure
scatterhist(b(:,1),b(:,2))
```

The histograms show the marginal beta distributions for each variable. The scatterplot shows the negative correlation.

Verify that the sample has a rank correlation approximately equal to the initial value for Kendall's τ .

```
tau_sample = corr(b, 'type', 'kendall')
```

```
tau_sample = 2x2
```

```
    1.0000    -0.5135
   -0.5135     1.0000
```

The sample rank correlation of -0.5135 is approximately equal to the -0.5 initial value for τ .

Input Arguments

rho — Linear correlation parameters

scalar values | matrix of scalar values

Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If rho is a p -by- p correlation matrix, then the output argument u is an n -by- p matrix.
- If rho is a scalar correlation coefficient, then the output argument u is an n -by-2 matrix.

Data Types: single | double

n — Number of random vectors to return

positive scalar value

Number of random vectors to return, specified as a positive scalar value.

- If you specify the copula type as 'Gaussian' or 't', and rho is a p -by- p correlation matrix, then u is an n -by- p matrix.
- If you specify the copula type as 'Gaussian' or 't', and rho is a scalar correlation coefficient, then u is an n -by-2 matrix.
- If you specify the copula type as 'Clayton', 'Frank', or 'Gumbel', then u is an n -by-2 matrix.

Data Types: single | double

nu — Degrees of freedom

positive integer value

Degrees of freedom for the t copula, specified as a positive integer value.

Data Types: single | double

family — Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

'Clayton'	Clayton copula
'Frank'	Frank copula
'Gumbel'	Gumbel copula

alpha — Bivariate Archimedean copula parameter

scalar value

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for alpha depend on the specified copula family.

Copula Family	Permitted Alpha Values
'Clayton'	$[0, \infty)$
'Frank'	$(-\infty, \infty)$
'Gumbel'	$[1, \infty)$

Data Types: single | double

Output Arguments**u — Copula random numbers**

matrix of scalar values

Copula random numbers, returned as a matrix of scalar values. Each column of u is a sample from a $\text{Uniform}(0, 1)$ marginal distribution.

- If you specify the copula type as 'Gaussian' or 't', and rho is a p -by- p correlation matrix, then u is an n -by- p matrix.

- If you specify the copula type as 'Gaussian' or 't', and rho is a scalar correlation coefficient, then u is an n -by-2 matrix.
- If you specify the copula type as 'Clayton', 'Frank', or 'Gumbel', then u is an n -by-2 matrix.

Topics

“Generate Correlated Data Using Rank Correlation” on page 5-105

“Copulas: Generate Correlated Samples” on page 5-118

Introduced in R2006a

cordexch

Coordinate exchange

Syntax

```
dCE = cordexch(nfactors,nruns)
[dCE,X] = cordexch(nfactors,nruns)
[dCE,X] = cordexch(nfactors,nruns,'model')
[dCE,X] = cordexch(...,'name',value)
```

Description

`dCE = cordexch(nfactors,nruns)` uses a coordinate-exchange algorithm to generate a D -optimal design `dCE` with `nruns` runs (the rows of `dCE`) for a linear additive model with `nfactors` factors (the columns of `dCE`). The model includes a constant term.

`[dCE,X] = cordexch(nfactors,nruns)` also returns the associated design matrix `X`, whose columns are the model terms evaluated at each treatment (row) of `dCE`.

`[dCE,X] = cordexch(nfactors,nruns,'model')` uses the linear regression model specified in `model`. `model` is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with n terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ..., n
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n - 1$, n)
- 4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Alternatively, `model` can be a matrix specifying polynomial terms of arbitrary order. In this case, `model` should have one column for each factor and one row for each term in the model. The entries in any row of `model` are powers for the factors in the columns. For example, if a model has factors `X1`, `X2`, and `X3`, then a row `[0 1 2]` in `model` specifies the term $(X1.^0) .*(X2.^1) .*(X3.^2)$. A row of all zeros in `model` specifies a constant term, which can be omitted.

`[dCE,X] = cordexch(...,'name',value)` specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify `name` inside single quotes.

name	Value
bounds	Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.
categorical	Indices of categorical predictors.
display	Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.
excludefun	Handle to a function that excludes undesirable runs. If the function is f , it must support the syntax $b = f(S)$, where S is a matrix of treatments with nfactors columns and b is a vector of Boolean values with the same number of rows as S . $b(i)$ is true if the method should exclude i th row S .
init	Initial design as a nruns-by-nfactors matrix. The default is a randomly selected set of points.
levels	Vector of number of levels for each factor. Not used when bounds is specified as a cell array.
maxiter	Maximum number of iterations. The default is 10.
tries	Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.
options	<p>A structure that specifies whether to run in parallel, and specifies the random stream or streams. This option requires Parallel Computing Toolbox.</p> <p>Create the options structure with <code>statset</code>. Structure fields:</p> <ul style="list-style-type: none"> • <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>. • <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>cordexch</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> • <code>UseParallel</code> is <code>true</code> • <code>UseSubstreams</code> is <code>false</code> <p>In that case, use a cell array the same size as the Parallel pool.</p>

Examples

Suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$y = \beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_3x_3 + \beta_{12}x_1x_2 + \beta_{13}x_1x_3 + \beta_{23}x_2x_3 + \varepsilon$$

Use `cordexch` to generate a D -optimal design with seven runs:

```
nfactors = 3;
nruns = 7;
```

```
[dCE,X] = cordexch(nfactors,nruns,'interaction','tries',10)
dCE =
    -1     1     1
    -1    -1    -1
     1     1     1
    -1     1    -1
     1    -1     1
     1    -1    -1
    -1    -1     1
X =
     1    -1     1     1    -1    -1     1
     1    -1    -1    -1     1     1     1
     1     1     1     1     1     1     1
     1    -1     1    -1    -1     1    -1
     1     1    -1     1    -1     1    -1
     1     1    -1    -1    -1    -1     1
     1    -1    -1     1     1    -1    -1
```

Columns of the design matrix X are the model terms evaluated at each row of the design dCE . The terms appear in order from left to right: constant term, linear terms (1, 2, 3), interaction terms (12, 13, 23). Use X to fit the model, as described in “Linear Regression” on page 11-8, to response data measured at the design points in dCE .

Algorithms

Both `cordexch` and `rowexch` use iterative search algorithms. They operate by incrementally changing an initial design matrix X to increase $D = |X^T X|$ at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally, D -optimal designs. Run each algorithm multiple times and select the best result for your final design. Both functions have a 'tries' parameter that automates this repetition and comparison.

Unlike the row-exchange algorithm used by `rowexch`, `cordexch` does not use a candidate set. (Or rather, the candidate set is the entire design space.) At each step, the coordinate-exchange algorithm exchanges a single element of X with a new element evaluated at a neighboring point in design space. The absence of a candidate set reduces demands on memory, but the smaller scale of the search means that the coordinate-exchange algorithm is more likely to become trapped in a local minimum.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced before R2006a

corr

Linear or rank correlation

Syntax

```
rho = corr(X)
rho = corr(X,Y)
[rho,pval] = corr(X,Y)
[rho,pval] = corr( ___,Name,Value)
```

Description

`rho = corr(X)` returns a matrix of the pairwise linear correlation coefficient between each pair of columns in the input matrix `X`.

`rho = corr(X,Y)` returns a matrix of the pairwise correlation coefficient between each pair of columns in the input matrices `X` and `Y`.

`[rho,pval] = corr(X,Y)` also returns `pval`, a matrix of p -values for testing the hypothesis of no correlation against the alternative hypothesis of a nonzero correlation.

`[rho,pval] = corr(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntaxes. For example, `'Type','Kendall'` specifies computing Kendall's tau correlation coefficient.

Examples

Find Correlation Between Two Matrices

Find the correlation between two matrices and compare it to the correlation between two column vectors.

Generate sample data.

```
rng('default')
X = randn(30,4);
Y = randn(30,4);
```

Introduce correlation between column two of the matrix `X` and column four of the matrix `Y`.

```
Y(:,4) = Y(:,4)+X(:,2);
```

Calculate the correlation between columns of `X` and `Y`.

```
[rho,pval] = corr(X,Y)
```

```
rho = 4x4
```

```
-0.1686    -0.0363    0.2278    0.3245
 0.3022    0.0332   -0.0866    0.7653
```

```
-0.3632  -0.0987  -0.0200  -0.3693
-0.1365  -0.1804   0.0853   0.0279
```

```
pval = 4×4
```

```
0.3731  0.8489  0.2260  0.0802
0.1045  0.8619  0.6491  0.0000
0.0485  0.6039  0.9166  0.0446
0.4721  0.3400  0.6539  0.8837
```

As expected, the correlation coefficient between column two of X and column four of Y , $\rho(2,4)$, is the highest, and it represents a high positive correlation between the two columns. The corresponding p -value, $pval(2,4)$, is zero to the four digits shown. Because the p -value is less than the significance level of 0.05 , it indicates rejection of the hypothesis that no correlation exists between the two columns.

Calculate the correlation between X and Y using `corrcoef`.

```
[r,p] = corrcoef(X,Y)
```

```
r = 2×2
```

```
1.0000  -0.0329
-0.0329  1.0000
```

```
p = 2×2
```

```
1.0000  0.7213
0.7213  1.0000
```

The MATLAB® function `corrcoef`, unlike the `corr` function, converts the input matrices X and Y into column vectors, $X(:)$ and $Y(:)$, before computing the correlation between them. Therefore, the introduction of correlation between column two of matrix X and column four of matrix Y no longer exists, because those two columns are in different sections of the converted column vectors.

The value of the off-diagonal elements of r , which represents the correlation coefficient between X and Y , is low. This value indicates little to no correlation between X and Y . Likewise, the value of the off-diagonal elements of p , which represents the p -value, is much higher than the significance level of 0.05 . This value indicates that not enough evidence exists to reject the hypothesis of no correlation between X and Y .

Test Alternative Hypotheses for Correlation

Test alternative hypotheses for positive, negative, and nonzero correlation between the columns of two matrices. Compare values of the correlation coefficient and p -value in each case.

Generate sample data.

```
rng('default')
X = randn(50,4);
Y = randn(50,4);
```

Introduce positive correlation between column one of the matrix X and column four of the matrix Y.

```
Y(:,4) = Y(:,4)+0.7*X(:,1);
```

Introduce negative correlation between column two of X and column two of Y.

```
Y(:,2) = Y(:,2)-2*X(:,2);
```

Test the alternative hypothesis that the correlation is greater than zero.

```
[rho,pval] = corr(X,Y,'Tail','right')
```

```
rho = 4x4
```

0.0627	-0.1438	-0.0035	0.7060
-0.1197	-0.8600	-0.0440	0.1984
-0.1119	0.2210	-0.3433	0.1070
-0.3526	-0.2224	0.1023	0.0374

```
pval = 4x4
```

0.3327	0.8405	0.5097	0.0000
0.7962	1.0000	0.6192	0.0836
0.7803	0.0615	0.9927	0.2298
0.9940	0.9397	0.2398	0.3982

As expected, the correlation coefficient between column one of X and column four of Y, $\text{rho}(1,4)$, has the highest positive value, representing a high positive correlation between the two columns. The corresponding p -value, $\text{pval}(1,4)$, is zero to the four digits shown, which is lower than the significance level of 0.05. These results indicate rejection of the null hypothesis that no correlation exists between the two columns and lead to the conclusion that the correlation is greater than zero.

Test the alternative hypothesis that the correlation is less than zero.

```
[rho,pval] = corr(X,Y,'Tail','left')
```

```
rho = 4x4
```

0.0627	-0.1438	-0.0035	0.7060
-0.1197	-0.8600	-0.0440	0.1984
-0.1119	0.2210	-0.3433	0.1070
-0.3526	-0.2224	0.1023	0.0374

```
pval = 4x4
```

0.6673	0.1595	0.4903	1.0000
0.2038	0.0000	0.3808	0.9164
0.2197	0.9385	0.0073	0.7702
0.0060	0.0603	0.7602	0.6018

As expected, the correlation coefficient between column two of X and column two of Y, $\text{rho}(2,2)$, has the negative number with the largest absolute value (-0.86), representing a high negative correlation between the two columns. The corresponding p -value, $\text{pval}(2,2)$, is zero to the four digits shown, which is lower than the significance level of 0.05. Again, these results indicate rejection of the null hypothesis and lead to the conclusion that the correlation is less than zero.

Test the alternative hypothesis that the correlation is not zero.

```
[rho,pval] = corr(X,Y)
```

```
rho = 4×4
```

```
    0.0627    -0.1438   -0.0035    0.7060
   -0.1197   -0.8600   -0.0440    0.1984
   -0.1119    0.2210   -0.3433    0.1070
   -0.3526   -0.2224    0.1023    0.0374
```

```
pval = 4×4
```

```
    0.6654    0.3190    0.9807    0.0000
    0.4075    0.0000    0.7615    0.1673
    0.4393    0.1231    0.0147    0.4595
    0.0120    0.1206    0.4797    0.7964
```

The p -values, $pval(1,4)$ and $pval(2,2)$, are both zero to the four digits shown. Because the p -values are lower than the significance level of 0.05, the correlation coefficients $rho(1,4)$ and $rho(2,2)$ are significantly different from zero. Therefore, the null hypothesis is rejected; the correlation is not zero.

Input Arguments

X — Input matrix

matrix

Input matrix, specified as an n -by- k matrix. The rows of X correspond to observations, and the columns correspond to variables.

Example: `X = randn(10,5)`

Data Types: `single` | `double`

Y — Input matrix

matrix

Input matrix, specified as an n -by- k_2 matrix when X is specified as an n -by- k_1 matrix. The rows of Y correspond to observations, and the columns correspond to variables.

Example: `Y = randn(20,7)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `corr(X,Y, 'Type', 'Kendall', 'Rows', 'complete')` returns Kendall's tau correlation coefficient using only the rows that contain no missing values.

Type — Type of correlation

'Pearson' (default) | 'Kendall' | 'Spearman'

Type of correlation, specified as the comma-separated pair consisting of 'Type' and one of these values.

Value	Description
'Pearson'	"Pearson's Linear Correlation Coefficient" on page 32-873
'Kendall'	"Kendall's Tau Coefficient" on page 32-873
'Spearman'	"Spearman's Rho" on page 32-874

`corr` computes the p -values for Pearson's correlation using a Student's t distribution for a transformation of the correlation. This correlation is exact when X and Y come from a normal distribution. `corr` computes the p -values for Kendall's tau and Spearman's rho using either the exact permutation distributions (for small sample sizes) or large-sample approximations.

Example: 'Type', 'Spearman'

Rows — Rows to use in computation

'all' (default) | 'complete' | 'pairwise'

Rows to use in computation, specified as the comma-separated pair consisting of 'Rows' and one of these values.

Value	Description
'all'	Use all rows of the input regardless of missing values (NaNs).
'complete'	Use only rows of the input with no missing values.
'pairwise'	Compute $\rho(i, j)$ using rows with no missing values in column i or j .

The 'complete' value, unlike the 'pairwise' value, always produces a positive definite or positive semidefinite rho. Also, the 'complete' value generally uses fewer observations to estimate rho when rows of the input (X or Y) contain missing values.

Example: 'Rows', 'pairwise'

Tail — Alternative hypothesis

'both' (default) | 'right' | 'left'

Alternative hypothesis, specified as the comma-separated pair consisting of 'Tail' and one of the values in the table. 'Tail' specifies the alternative hypothesis against which to compute p -values for testing the hypothesis of no correlation.

Value	Description
'both'	Test the alternative hypothesis that the correlation is not θ .
'right'	Test the alternative hypothesis that the correlation is greater than θ
'left'	Test the alternative hypothesis that the correlation is less than θ .

`corr` computes the p -values for the two-tailed test by doubling the more significant of the two one-tailed p -values.

Example: 'Tail', 'left'

Output Arguments

rho — Pairwise linear correlation coefficient

matrix

Pairwise linear correlation coefficient, returned as a matrix.

- If you input only a matrix X , rho is a symmetric k -by- k matrix, where k is the number of columns in X . The entry $\text{rho}(a, b)$ is the pairwise linear correlation coefficient between column a and column b in X .
- If you input matrices X and Y , rho is a k_1 -by- k_2 matrix, where k_1 and k_2 are the number of columns in X and Y , respectively. The entry $\text{rho}(a, b)$ is the pairwise linear correlation coefficient between column a in X and column b in Y .

pval — p-values

matrix

p -values, returned as a matrix. Each element of pval is the p -value for the corresponding element of rho .

If $\text{pval}(a, b)$ is small (less than 0.05), then the correlation $\text{rho}(a, b)$ is significantly different from zero.

More About

Pearson's Linear Correlation Coefficient

Pearson's linear correlation coefficient is the most commonly used linear correlation coefficient. For column X_a in matrix X and column Y_b in matrix Y , having means $\bar{X}_a = \sum_{i=1}^n (X_{a,i})/n$, and

$\bar{Y}_b = \sum_{j=1}^n (Y_{b,j})/n$, Pearson's linear correlation coefficient $\text{rho}(a,b)$ is defined as:

$$\text{rho}(a,b) = \frac{\sum_{i=1}^n (X_{a,i} - \bar{X}_a)(Y_{b,i} - \bar{Y}_b)}{\left\{ \sum_{i=1}^n (X_{a,i} - \bar{X}_a)^2 \sum_{j=1}^n (Y_{b,j} - \bar{Y}_b)^2 \right\}^{1/2}},$$

where n is the length of each column.

Values of the correlation coefficient can range from -1 to $+1$. A value of -1 indicates perfect negative correlation, while a value of $+1$ indicates perfect positive correlation. A value of 0 indicates no correlation between the columns.

Kendall's Tau Coefficient

Kendall's tau is based on counting the number of (i,j) pairs, for $i < j$, that are concordant—that is, for which $X_{a,i} - X_{a,j}$ and $Y_{b,i} - Y_{b,j}$ have the same sign. The equation for Kendall's tau includes an adjustment for ties in the normalizing constant and is often referred to as tau-b.

For column X_a in matrix X and column Y_b in matrix Y , Kendall's tau coefficient is defined as:

$$\tau = \frac{2K}{n(n-1)},$$

where $K = \sum_{i=1}^{n-1} \sum_{j=i+1}^n \xi^*(X_{a,i}, X_{a,j}, Y_{b,i}, Y_{b,j})$, and

$$\xi^*(X_{a,i}, X_{a,j}, Y_{b,i}, Y_{b,j}) = \begin{cases} 1 & \text{if } (X_{a,i} - X_{a,j})(Y_{b,i} - Y_{b,j}) > 0 \\ 0 & \text{if } (X_{a,i} - X_{a,j})(Y_{b,i} - Y_{b,j}) = 0 \\ -1 & \text{if } (X_{a,i} - X_{a,j})(Y_{b,i} - Y_{b,j}) < 0 \end{cases}.$$

Values of the correlation coefficient can range from -1 to $+1$. A value of -1 indicates that one column ranking is the reverse of the other, while a value of $+1$ indicates that the two rankings are the same. A value of 0 indicates no relationship between the columns.

Spearman's Rho

Spearman's rho is equivalent to "Pearson's Linear Correlation Coefficient" on page 32-873 applied to the rankings of the columns X_a and Y_b .

If all the ranks in each column are distinct, the equation simplifies to:

$$\text{rho}(a, b) = 1 - \frac{6 \sum d^2}{n(n^2 - 1)},$$

where d is the difference between the ranks of the two columns, and n is the length of each column.

Tips

The difference between `corr(X, Y)` and the MATLAB function `corrcoef(X, Y)` is that `corrcoef(X, Y)` returns a matrix of correlation coefficients for two column vectors X and Y . If X and Y are not column vectors, `corrcoef(X, Y)` converts them to column vectors.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitation:

Only the 'Pearson' type is supported.

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

`corrcoef` | `corrcoef` | `partialcorr` | `tiedrank`

Introduced before R2006a

corrcoef

Convert covariance matrix to correlation matrix

Syntax

```
R = corrcoef(C)
[R,sigma] = corrcoef(C)
```

Description

`R = corrcoef(C)` returns the correlation matrix `R` corresponding to the covariance matrix `C`.

`[R,sigma] = corrcoef(C)` also returns `sigma`, a vector of standard deviations.

Examples

Compare Correlation Matrices Obtained by Two Different Methods

Compare the correlation matrix obtained by applying `corrcoef` on a covariance matrix with the correlation matrix obtained by direct computation using `corrcoef` on an input matrix.

Load the `hospital` data set and create a matrix containing the `Weight` and `BloodPressure` measurements. Note that `hospital.BloodPressure` has two columns of data.

```
load hospital
X = [hospital.Weight hospital.BloodPressure];
```

Compute the covariance matrix.

```
C = cov(X)
```

```
C = 3×3
```

```
    706.0404    27.7879    41.0202
    27.7879    45.0622    23.8194
    41.0202    23.8194    48.0590
```

Compute the correlation matrix from the covariance matrix by using `corrcoef`.

```
R1 = corrcoef(C)
```

```
R1 = 3×3
```

```
    1.0000    0.1558    0.2227
    0.1558    1.0000    0.5118
    0.2227    0.5118    1.0000
```

Compute the correlation matrix directly by using `corrcoef`, and then compare `R1` with `R2`.

```
R2 = corrcoef(X)
```

R2 = 3×3

```

1.0000    0.1558    0.2227
0.1558    1.0000    0.5118
0.2227    0.5118    1.0000

```

The correlation matrices R1 and R2 are the same.

Find Standard Deviations from Covariance Matrix

Find the vector of standard deviations from the covariance matrix, and show the relationship between the standard deviations and the covariance matrix.

Load the `hospital` data set and create a matrix containing the `Weight`, `BloodPressure`, and `Age` measurements. Note that `hospital.BloodPressure` has two columns of data.

```

load hospital
X = [hospital.Weight hospital.BloodPressure hospital.Age];

```

Compute the covariance matrix of X.

```
C = cov(X)
```

C = 4×4

```

706.0404    27.7879    41.0202    17.5152
27.7879    45.0622    23.8194     6.4966
41.0202    23.8194    48.0590     4.0315
17.5152     6.4966     4.0315    52.0622

```

C is square, symmetric, and positive semidefinite. The diagonal elements of C are the variances of the four variables in X.

Compute the correlation matrix and standard deviations of X from the covariance matrix C.

```
[R,s1] = corrcoef(C)
```

R = 4×4

```

1.0000    0.1558    0.2227    0.0914
0.1558    1.0000    0.5118    0.1341
0.2227    0.5118    1.0000    0.0806
0.0914    0.1341    0.0806    1.0000

```

s1 = 4×1

```

26.5714
 6.7128
 6.9325
 7.2154

```

Compute the square root of the diagonal elements in C, and then compare s1 with s2.

```
s2 = sqrt(diag(C))
```

```
s2 = 4×1
```

```
26.5714  
6.7128  
6.9325  
7.2154
```

s1 and s2 are equal and correspond to the standard deviation of the variables in X.

Input Arguments

C — Covariance matrix

matrix

Covariance on page 32-878 matrix, specified as a square, symmetric, and positive semidefinite matrix.

For a matrix X that has N observations (rows) and n random variables (columns), C is an n -by- n matrix. The n diagonal elements of C are the variances on page 32-879 of the n random variables in X , and a zero diagonal element in C indicates a constant variable in X .

Data Types: `single` | `double`

Output Arguments

R — Correlation matrix

matrix

Correlation matrix, returned as a matrix that corresponds to the covariance matrix C .

Data Types: `single` | `double`

sigma — Standard deviations

vector

Standard deviations, returned as an n -by-1 vector.

The elements of `sigma` are the standard deviations of the variables in X , the N -by- n matrix that produces C . Row i in `sigma` corresponds to the standard deviation of column i in X .

Data Types: `single` | `double`

More About

Covariance

For two random variable vectors A and B , the covariance is defined as

$$\text{cov}(A, B) = \frac{1}{N-1} \sum_{i=1}^N (A_i - \mu_A) * (B_i - \mu_B)$$

where N is the length of each column, μ_A and μ_B are the mean values of A and B , respectively, and $*$ denotes the complex conjugate.

The *covariance matrix* of two random variables is the matrix of pairwise covariance calculations between each variable,

$$C = \begin{pmatrix} \text{cov}(A, A) & \text{cov}(A, B) \\ \text{cov}(B, A) & \text{cov}(B, B) \end{pmatrix}.$$

For a matrix X , in which each column is a random variable composed of observations, the covariance matrix is the pairwise covariance calculation between each column combination. In other words, $C(i, j) = \text{cov}(X(:, i), X(:, j))$.

Variance

For a random variable vector A composed of N scalar observations, the variance is defined as

$$V = \frac{1}{N-1} \sum_{i=1}^N |A_i - \mu|^2$$

where μ is the mean of A ,

$$\mu = \frac{1}{N} \sum_{i=1}^N A_i.$$

Some definitions of variance use a normalization factor of N instead of $N-1$, but the mean always has the normalization factor N .

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

cholcov | corr | corrcoef | cov

Introduced in R2007b

covarianceParameters

Class: GeneralizedLinearMixedModel

Extract covariance parameters of generalized linear mixed-effects model

Syntax

```
psi = covarianceParameters(glme)
[psi,dispersion] = covarianceParameters(glme)
[psi,dispersion,stats] = covarianceParameters(glme)
[ ___ ] = covarianceParameters(glme,Name,Value)
```

Description

`psi = covarianceParameters(glme)` returns the estimated prior covariance parameters of random-effects predictors in the generalized linear mixed-effects model `glme`.

`[psi,dispersion] = covarianceParameters(glme)` also returns an estimate of the dispersion parameter.

`[psi,dispersion,stats] = covarianceParameters(glme)` also returns a cell array `stats` containing the covariance parameter estimates and related statistics.

`[___] = covarianceParameters(glme,Name,Value)` returns any of the above output arguments using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence level for the confidence limits of covariance parameters.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range [0,1]

Significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

Output Arguments

psi — Estimated prior covariance parameters

cell array

Estimated prior covariance parameters for the random-effects predictors, returned as a cell array of length R , where R is the number of grouping variables used in the model. `psi{r}` contains the covariance matrix of random effects associated with grouping variable g_r , where $r = 1, 2, \dots, R$. The order of grouping variables in `psi` is the same as the order entered when fitting the model. For more information on grouping variables, see “Grouping Variables” on page 2-45.

dispersion — Dispersion parameter

scalar value

Dispersion parameter, returned as a scalar value.

stats — Covariance parameter estimates and related statistics

cell array

Covariance parameter estimates and related statistics, returned as a cell array of length $(R + 1)$, where R is the number of grouping variables used in the model. The first R cells of `stats` each contain a dataset array with the following columns.

Column Name	Description
Group	Grouping variable name
Name1	Name of the first predictor variable
Name2	Name of the second predictor variable
Type	If Name1 and Name2 are the same, then Type is <code>std</code> (standard deviation). If Name1 and Name2 are different, then Type is <code>corr</code> (correlation).
Estimate	If Name1 and Name2 are the same, then Estimate is the standard deviation of the random effect associated with predictor Name1 or Name2. If Name1 and Name2 are different, then Estimate is the correlation between the random effects associated with predictors Name1 and Name2.
Lower	Lower limit of the confidence interval for the covariance parameter
Upper	Upper limit of the confidence interval for the covariance parameter

Cell $R + 1$ contains related statistics for the dispersion parameter.

It is recommended that the presence or absence of covariance parameters in `glme` be tested using the `compare` method, which uses a likelihood ratio test.

When fitting a GLME model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), `covarianceParameters` derives the confidence intervals in `stats` based on a Laplace approximation to the log likelihood of the generalized linear mixed-effects model.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REMP'), `covarianceParameters` derives the confidence intervals in `stats` based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Obtain Estimated Covariance Parameters

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', 'Di
```

Compute and display the estimate of the prior covariance parameter for the random-effects predictor.

```
[psi,dispersion,stats] = covarianceParameters(glme);
psi{1}
```

```
ans = 0.0985
```

`psi{1}` is an estimate of the prior covariance matrix of the first grouping variable. In this example, there is only one grouping variable (`factory`), so `psi{1}` is an estimate of σ_b^2 .

Display the dispersion parameter.

```
dispersion
```

```
dispersion = 1
```

Display the estimated standard deviation of the random effect associated with the predictor. The first cell of `stats` contains statistics for `factory`, while the second cell contains statistics for the dispersion parameter.

```
stats{1}
```

```
ans =
  Covariance Type: Isotropic

  Group      Name1              Name2              Type
  factory    {'(Intercept)'}    {'(Intercept)'}    {'std'}
```

Estimate	Lower	Upper
0.31381	0.19253	0.51148

The estimated standard deviation of the random effect associated with the predictor is 0.31381. The 95% confidence interval is [0.19253 , 0.51148]. Because the confidence interval does not contain 0, the random intercept is significant at the 5% significance level.

`GeneralizedLinearMixedModel` | `compare` | `fitglme` | `fixedEffects` | `randomEffects`

covarianceParameters

Class: LinearMixedModel

Extract covariance parameters of linear mixed-effects model

Syntax

```
psi = covarianceParameters(lme)
[psi,mse] = covarianceParameters(lme)
[psi,mse,stats] = covarianceParameters(lme)
[psi,mse,stats] = covarianceParameters(lme,Name,Value)
```

Description

`psi = covarianceParameters(lme)` returns the estimated covariance parameters that parameterize the prior covariance of random effects.

`[psi,mse] = covarianceParameters(lme)` also returns an estimate of the residual variance.

`[psi,mse,stats] = covarianceParameters(lme)` also returns a cell array, `stats`, containing the covariance parameters and related statistics.

`[psi,mse,stats] = covarianceParameters(lme,Name,Value)` returns the covariance parameters and related statistics in `stats` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the confidence level for the confidence limits of covariance parameters.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: `single` | `double`

Output Arguments

psi — Estimate of covariance parameters

cell array

Estimate of covariance parameters that parameterize the prior covariance of the random effects, returned as a cell array of length R , such that `psi{r}` contains the covariance matrix of random effects associated with grouping variable g_r , $r = 1, 2, \dots, R$. The order of grouping variables is the same order you enter when you fit the model.

mse — Residual variance estimate

scalar value

Residual variance estimate, returned as a scalar value.

stats — Covariance parameter estimates and related statistics

cell array

Covariance parameter estimates and related statistics, returned as a cell array of length $(R + 1)$ containing dataset arrays with the following columns.

Group	Grouping variable name
Name1	Name of the first predictor variable
Name2	Name of the second predictor variable
Type	<code>std</code> (standard deviation), if Name1 and Name2 are the same
	<code>corr</code> (correlation), if Name1 and Name2 are different
Estimate	Standard deviation of the random effect associated with predictor Name1 or Name2, if Name1 and Name2 are the same
	Correlation between the random effects associated with predictors Name1 and Name2, if Name1 and Name2 are different
Lower	Lower limit of a 95% confidence interval for the covariance parameter
Upper	Upper limit of a 95% confidence interval for the covariance parameter

`stats{r}` is a dataset array containing statistics on covariance parameters for the r th grouping variable, $r = 1, 2, \dots, R$. `stats{R+1}` contains statistics on the residual standard deviation. The dataset array for the residual error has the fields `Group`, `Name`, `Estimate`, `Lower`, and `Upper`.

Examples

Two Random-Effects Terms for Intercept

Load the sample data.

```
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` is the fixed-effects variable, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently. This model corresponds to

$$y_{ijk} = \beta_0 + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + b_{0jk} (S^*T)_{jk} + \epsilon_{ijk},$$

where $i = 1, 2, \dots, 60$ corresponds to the observations, $j = 2, \dots, 5$ corresponds to the tomato types, and $k = 1, 2, 3$ corresponds to the blocks (soil). S_k represents the k th soil type, and $(S^*T)_{jk}$ represents the j th tomato type nested in the k th soil type. $I[T]_{ij}$ is the dummy variable representing the level j of the tomato type.

The random effects and observation error have the following prior distributions: $b_{0k} \sim N(0, \sigma_S^2)$, $b_{0jk} \sim N(0, \sigma_{S^*T}^2)$, and $\epsilon_{ijk} \sim N(0, \sigma^2)$.

```
lme = fitlme(ds, 'Yield ~ Fertilizer + (1|Soil) + (1|Soil:Tomato)');
```

Compute the covariance parameter estimates (estimates of σ_S^2 and $\sigma_{S^*T}^2$) of the random-effects terms.

```
psi = covarianceParameters(lme)
```

```
psi=2x1 cell array
    {[4.2642e-17]}
    {[ 352.8481]}
```

Compute the residual variance (σ^2).

```
[~,mse] = covarianceParameters(lme)
```

```
mse = 151.9007
```

Potentially Correlated Random-Effects Terms

Load the sample data.

```
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a dataset array. Define `Subject` and `Program` as categorical variables.

```
ds = dataset(InitialWeight,Program,Subject,Week,y);
ds.Subject = nominal(ds.Subject);
ds.Program = nominal(ds.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

For 'reference' dummy variable coding, `fitlme` uses Program A as reference and creates the necessary dummy variables $I[\cdot]$. This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i \\ + \beta_5 I[\text{PD}]_i + b_{0m} + b_{1m} \text{Week}_{im} + \epsilon_{im}$$

where i corresponds to the observation number, $i = 1, 2, \dots, 120$, and m corresponds to the subject number, $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing Program B.

The random effects and observation error have the following prior distributions:

$$\begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N\left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix}\right)$$

and

$$\epsilon_{im} \sim N(0, \sigma^2).$$

```
lme = fitlme(ds, 'y ~ InitialWeight + Program + (Week|Subject)');
```

Compute the estimates of covariance parameters for the random effects.

```
[psi,mse,stats] = covarianceParameters(lme)
```

```
psi = 1x1 cell array
      {2x2 double}
```

```
mse = 0.0105
```

```
stats=2x1 cell array
      {3x7 classreg.regr.lmeutils.titledataset}
      {1x5 classreg.regr.lmeutils.titledataset}
```

`mse` is the estimated residual variance. It is the estimate for σ^2 .

To see the covariance parameters estimates for the random-effects terms (σ_0^2 , σ_1^2 , and $\sigma_{0,1}$), index into `psi`.

```
psi{1}
ans = 2x2
    0.0572    0.0490
    0.0490    0.0624
```

The estimate of the variance of the random effects term for the intercept, σ_0^2 , is 0.0572. The estimate of the variance of the random effects term for week, σ_1^2 , is 0.0624. The estimate for the covariance of the random effects terms for the intercept and week, $\sigma_{0,1}$, is 0.0490.

`stats` is a 2-by-1 cell array. The first cell of `stats` contains the confidence intervals for the standard deviation of the random effects and the correlation between the random effects for intercept and week. To display them, index into `stats`.

```
stats{1}
ans =
Covariance Type: FullCholesky

Group      Name1              Name2              Type
Subject    {'(Intercept)'}   {'(Intercept)'}   {'std' }
Subject    {'Week'           }   {'(Intercept)'}   {'corr' }
Subject    {'Week'           }   {'Week'           }   {'std' }

Estimate    Lower    Upper
0.23927     0.14364 0.39854
0.81971     0.38662 0.95658
0.2497      0.18303 0.34067
```

The display shows the name of the grouping parameter (`Group`), the random-effects variables (`Name1`, `Name2`), the type of the covariance parameters (`Type`), the estimate (`Estimate`) for each parameter, and the 95% confidence intervals for the parameters (`Lower`, `Upper`). The estimates in this table are related to the estimates in `psi` as follows.

The standard deviation of the random-effects term for intercept is $0.23927 = \sqrt{0.0527}$. Likewise, the standard deviation of the random effects term for week is $0.2497 = \sqrt{0.0624}$. Finally, the correlation between the random-effects terms of intercept and week is $0.81971 = 0.0490 / (0.23927 * 0.2497)$.

Note that this display also shows which covariance pattern you use when fitting the model. In this case, the covariance pattern is `FullCholesky`. To change the covariance pattern for the random-effects terms, you must use the `'CovariancePattern'` name-value pair argument when fitting the model.

The second cell of `stats` includes similar statistics for the residual standard deviation. Display the contents of the second cell.

```
stats{2}
```

```
ans =
  Group      Name      Estimate      Lower      Upper
  Error      {'Res Std'}  0.10261      0.087882   0.11981
```

The estimate for residual standard deviation is the square root of mse, $0.10261 = \text{sqrt}(0.0105)$.

Two Grouping Variables

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and weight, a potentially correlated random effect for intercept and acceleration grouped by model year, and an independent random effect for weight, grouped by the origin of the car. This model corresponds to

$$\text{MPG}_{imk} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{Weight}_i + b_{10m} + b_{11m} \text{Acc}_i + b_{21k} \text{Weight}_i + \epsilon_{imk}$$

where $m = 1, 2, \dots, 13$ represents the levels for the variable `Model_Year`, and $k = 1, 2, \dots, 8$ represents the levels for the variable `Origin`. MPG_{imk} is the miles per gallon for the i th observation, m th model year, and k th origin that correspond to the i th observation. The random-effects terms and the observation error have the following prior distributions:

$$b_{1m} = \begin{pmatrix} b_{10m} \\ b_{11m} \end{pmatrix} \sim N\left(0, \begin{pmatrix} \sigma_{10}^2 & \sigma_{10,11} \\ \sigma_{10,11} & \sigma_{11}^2 \end{pmatrix}\right),$$

$$b_{2k} \sim N(0, \sigma_2^2),$$

$$\epsilon_{imk} \sim N(0, \sigma^2).$$

Here, the random-effects term b_{1m} represents the first random effect at level m of the first grouping variable. The random-effects term b_{10m} corresponds to the first random effects term (1), for the intercept (0), at the m th level (m) of the first grouping variable. Likewise b_{11m} is the level m for the first predictor (1) in the first random-effects term (1).

Similarly, b_{2k} stands for the second random effects-term at level k of the second grouping variable.

σ_{10}^2 is the variance of the random-effects term for the intercept, σ_{11}^2 is the variance of the random effects term for the predictor acceleration, and $\sigma_{10,11}$ is the covariance of the random-effects terms for the intercept and the predictor acceleration. σ_2^2 is the variance of the second random-effects term, and σ^2 is the residual variance.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Weight];
Z = {[ones(406,1) Acceleration],[Weight]};
```

```

Model_Year = nominal(Model_Year);
Origin = nominal(Origin);
G = {Model_Year,Origin};

```

Fit the model using the design matrices.

```

lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Weight'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'},{'Weight'}},'RandomEffectGroups',{'Model_Year','Origin'});

```

Compute the estimates of covariance parameters for the random effects.

```

[psi,mse,stats] = covarianceParameters(lme)

```

```

psi=2x1 cell array
    {2x2 double }
    {[6.7555e-08]}

```

```

mse = 9.0802

```

```

stats=3x1 cell array
    {3x7 classreg.regr.lmeutils.titledataset}
    {1x7 classreg.regr.lmeutils.titledataset}
    {1x5 classreg.regr.lmeutils.titledataset}

```

The residual variance `mse` is 9.0755. `psi` is a 2-by-1 cell array, and `stats` is a 3-by-1 cell array. To see the contents, you must index into these cell arrays.

First, index into the first cell of `psi`.

```

psi{1}
ans = 2x2

    8.3081    -0.8359
   -0.8359     0.1093

```

The first cell of `psi` contains the covariance parameters for the correlated random effects for intercept σ_{10}^2 as 8.5160, and for acceleration σ_{11}^2 as 0.1087. The estimate for the covariance of the random-effects terms for the intercept and acceleration $\sigma_{10,11}$ is -0.8387.

Now, index into the second cell of `psi`.

```

psi{2}
ans = 6.7555e-08

```

The second cell of `psi` contains the estimate for the variance of the random-effects term for weight σ_2^2 .

Index into the first cell of `stats`.

```

stats{1}
ans =
    Covariance Type: FullCholesky

```

Group	Name1	Name2	Type
Model_Year	{'Intercept' }	{'Intercept' }	{'std' }
Model_Year	{'Acceleration' }	{'Intercept' }	{'corr' }
Model_Year	{'Acceleration' }	{'Acceleration' }	{'std' }

Estimate	Lower	Upper
2.8824	1.1116	7.4738
-0.87704	-0.98411	-0.30222
0.33066	0.18918	0.57796

This table shows the standard deviation estimates for the random-effects terms for intercept and acceleration. Note that the standard deviations estimates are the square roots of the diagonal elements in the first cell of `psi`. Specifically, $2.9182 = \sqrt{8.5160}$ and $0.32968 = \sqrt{0.1087}$. The correlation is a function of the covariance of intercept and acceleration, and the standard deviations of intercept and acceleration. The covariance of intercept and acceleration is the off-diagonal value in the first cell of `psi`, -0.8387 . So, the correlation is $-0.8387 / (0.32968 * 2.92182) = -0.87$.

The grouping variable for intercept and acceleration is `Model_Year`.

Index into the second cell of `stats`.

```
stats{2}
```

```
ans =
```

```
Covariance Type: FullCholesky
```

Group	Name1	Name2	Type	Estimate
Origin	{'Weight' }	{'Weight' }	{'std' }	0.00025991
Lower	Upper			
9.17e-05	0.0007367			

The second cell of `stats` has the standard deviation estimate and the 95% confidence limits for the standard deviation of the random-effects term for `Weight`. The grouping variable is `Origin`.

Index into the third cell of `stats`.

```
stats{3}
```

```
ans =
```

Group	Name	Estimate	Lower	Upper
Error	{'Res Std' }	3.0133	2.8034	3.239

The third cell of `stats` contains the estimate for residual standard deviation and the 95% confidence limits. The estimate for residual standard deviation is the square root of `mse`, $\sqrt{9.0755} = 3.0126$.

Construct 99% confidence intervals for the covariance parameters.

```
[~,~,stats] = covarianceParameters(lme, 'Alpha', 0.01);
stats{1}
```

```
ans =

coxphfit

Cox proportional hazards regression

Syntax

```
b = coxphfit(X,T)
b = coxphfit(X,T,Name,Value)
[b,logl,H,stats] = coxphfit( ___ )
```

Description

`b = coxphfit(X,T)` returns a p -by-1 vector, `b`, of coefficient estimates for a Cox proportional hazards regression on page 32-900 of the observed responses `T` on the predictors `X`, where `T` is either an n -by-1 vector or an n -by-2 matrix, and `X` is an n -by- p matrix.

The model does not include a constant term, and `X` cannot contain a column of 1s.

`b = coxphfit(X,T,Name,Value)` returns a vector of coefficient estimates, with additional options specified by one or more `Name, Value` pair arguments.

`[b,logl,H,stats] = coxphfit(___)` also returns the loglikelihood, `logl`, a structure, `stats`, that contains additional statistics, and a two-column matrix, `H`, that contains the `T` values in the first column and the estimated baseline cumulative hazard, in the second column. You can use any of the input arguments in the previous syntaxes.

Examples

Use Cox Proportional Hazards Regression to Model Lifetime of Light Bulbs

Load the sample data.

```
load('lightbulb.mat');
```

The first column of the light bulb data has the lifetime (in hours) of two different types of bulbs. The second column has the binary variable indicating whether the bulb is fluorescent or incandescent. 0 indicates that the bulb is incandescent, and 1 indicates that it is fluorescent. The third column contains the censorship information, where 0 indicates the bulb was observed until failure, and 1 indicates the bulb was censored.

Fit a Cox proportional hazards model for the lifetime of the light bulbs, also accounting for censoring. The predictor variable is the type of bulb.

```
b = coxphfit(lightbulb(:,2),lightbulb(:,1), ...
'Censoring',lightbulb(:,3))
```

```
b = 4.7262
```

The estimate of the hazard ratio is $e^b = 112.8646$. This means that the hazard for the incandescent bulbs is 112.86 times the hazard for the fluorescent bulbs.

Change Algorithm Parameters for Cox Proportional Hazards Model

Load the sample data.

```
load('lightbulb.mat');
```

The first column of the data has the lifetime (in hours) of two types of bulbs. The second column has the binary variable indicating whether the bulb is fluorescent or incandescent. 1 indicates that the bulb is fluorescent and 0 indicates that it is incandescent. The third column contains the censorship information, where 0 indicates the bulb is observed until failure, and 1 indicates the item (bulb) is censored.

Fit a Cox proportional hazards model, also accounting for censoring. The predictor variable is the type of bulb.

```
b = coxphfit(lightbulb(:,2),lightbulb(:,1),...
'Censoring',lightbulb(:,3))
```

```
b = 4.7262
```

Display the default control parameters for the algorithm `coxphfit` uses to estimate the coefficients.

```
statset('coxphfit')
```

```
ans = struct with fields:
    Display: 'off'
    MaxFunEvals: 200
    MaxIter: 100
    TolBnd: 1.0000e-06
    TolFun: 1.0000e-08
    TolTypeFun: []
    TolX: 1.0000e-08
    TolTypeX: []
    GradObj: []
    Jacobian: []
    DerivStep: []
    FunValCheck: []
    Robust: []
    RobustWgtFun: []
    WgtFun: []
    Tune: []
    UseParallel: []
    UseSubstreams: []
    Streams: {}
    OutputFcn: []
```

Save the options under a different name and change how the results will be displayed and the maximum number of iterations, `Display` and `MaxIter`.

```
coxphopt = statset('coxphfit');
coxphopt.Display = 'final';
coxphopt.MaxIter = 50;
```

Run `coxphfit` with the new algorithm parameters.

```
b = coxphfit(lightbulb(:,2),lightbulb(:,1),...
'Censoring',lightbulb(:,3),'Options',coxphopt)
```

Successful convergence: Norm of gradient less than OPTIONS.TolFun

```
b = 4.7262
```

`coxphfit` displays a report on the final iteration. Changing the maximum number of iterations did not affect the coefficient estimate.

Fit and Compare Cox and Weibull Survivor Functions

Generate Weibull data depending on predictor X.

```
rng('default') % for reproducibility
X = 4*rand(100,1);
A = 50*exp(-0.5*X);
B = 2;
y = wblrnd(A,B);
```

The response values are generated from a Weibull distribution with a shape parameter depending on the predictor variable X and a scale parameter of 2.

Fit a Cox proportional hazards model.

```
[b,logL,H,stats] = coxphfit(X,y);
[b logL]
```

```
ans = 1×2
```

```
0.9409 -331.1479
```

The coefficient estimate is 0.9409 and the log likelihood value is -331.1479.

Request the model statistics.

```
stats
```

```
stats = struct with fields:
    covb: 0.0158
    beta: 0.9409
    se: 0.1256
    z: 7.4889
    p: 6.9462e-14
    csres: [100x1 double]
    devres: [100x1 double]
    martres: [100x1 double]
    schres: [100x1 double]
    sschres: [100x1 double]
    scores: [100x1 double]
    sscores: [100x1 double]
```

The covariance matrix of the coefficient estimates, `covb`, contains only one value, which is equal to the variance of the coefficient estimate in this example. The coefficient estimate, `beta`, is the same as

b and is equal to 0.9409. The standard error of the coefficient estimate, se , is 0.1256, which is the square root of the variance 0.0158. The z-statistic, z , is $\beta/se = 0.9409/0.1256 = 7.4880$. The p-value, p , indicates that the effect of X is significant.

Plot the Cox estimate of the baseline survivor function together with the known Weibull function.

```
stairs(H(:,1),exp(-H(:,2)), 'LineWidth',2)
xx = linspace(0,100);
line(xx,1-wblcdf(xx,50*exp(-0.5*mean(X)),B), 'color','r', 'LineWidth',2)
xlim([0,50])
legend('Estimated Survivor Function','Weibull Survivor Function')
```

The fitted model gives a close estimate to the survivor function of the actual distribution.

Input Arguments

X — Observations on predictor variables

matrix

Observations on predictor variables, specified as an n -by- p matrix of p predictors for each of n observations.

The model does not include a constant term, thus X cannot contain a column of 1s.

If X , T , or the value of 'Frequency' or 'Strata' contain NaN values, then `coxphfit` removes rows with NaN values from all data when fitting a Cox model.

Data Types: double

T — Time-to-event data

vector | two-column matrix

Time-to-event data, specified as an n -by-1 vector or a two-column matrix.

- When T is an n -by-1 vector, it represents the event time of right-censored time-to-event data.
- When T is an n -by-2 matrix, each row represents the risk interval (start,stop] in the counting process format for time-dependent covariates. The first column is the start time and the second column is the stop time. For an example, see “Cox Proportional Hazards Model with Time-Dependent Covariates” on page 14-35.

If X, T, or the value of 'Frequency' or 'Strata' contain NaN values, then `coxphfit` removes rows with NaN values from all data when fitting a Cox model.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Baseline', 0, 'Censoring', censoreddata, 'Frequency', freq specifies that `coxphfit` calculates the baseline hazard rate relative to 0, considering the censoring information in the vector `censoreddata`, and the frequency of observations on T and X given in the vector `freq`.

B0 — Coefficient initial values

0.01/std(X) (default) | numeric vector

Coefficient initial values, specified as the comma-separated value consisting of 'B0' and a numeric vector.

Data Types: double

Baseline — X values at which to compute the baseline hazard

mean(X) (default) | scalar value

X values at which to compute the baseline hazard, specified as the comma-separated pair consisting of 'Baseline' and a scalar value.

The default is `mean(X)`, so the hazard rate at X is $h(t) \cdot \exp((X - \text{mean}(X)) \cdot b)$. Enter 0 to compute the baseline relative to 0, so the hazard rate at X is $h(t) \cdot \exp(X \cdot b)$. Changing the baseline does not affect the coefficient estimates, but the hazard ratio changes.

Example: 'Baseline', 0

Data Types: double

Censoring — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of 'Censoring' and a Boolean array of the same size as T. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed. For an example, see “Cox Proportional Hazards Model for Censored Data” on page 14-31.

Example: 'Censoring',cens

Data Types: logical

Frequency — Frequency or weights of observations

array of 1s (default) | vector of nonnegative scalar values

Frequency or weights of observations, specified as the comma-separated pair consisting of 'Frequency' and an array that is the same size as T containing nonnegative scalar values. The array can contain integer values corresponding to frequencies of observations or nonnegative values corresponding to observation weights.

If X, T, or the value of 'Frequency' or 'Strata' contain NaN values, then `coxphfit` removes rows with NaN values from all data when fitting a Cox model.

The default is 1 per row of X and T.

Example: 'Frequency',w

Data Types: double

Strata — Stratification variables

[] (default) | matrix of real values

Stratification variables, specified as the comma-separated pair consisting of a matrix of real values. The matrix must have the same number of rows as T, with each row corresponding to an observation.

If X, T, or the value of 'Frequency' or 'Strata' contain NaN values, then `coxphfit` removes rows with NaN values from all data when fitting a Cox model.

The default, [], is no stratification variable.

Example: 'Strata',Gender

Data Types: single | double

Ties — Method to handle tied failure times

'breslow' (default) | 'efron'

Method to handle tied failure times, specified as the comma-separated pair consisting of 'Ties' and either 'breslow' (Breslow's method) or 'efron' (Efron's method).

Example: 'Ties','efron'

Options — Algorithm control parameters

structure

Algorithm control parameters for the iterative algorithm used to estimate **b**, specified as the comma-separated pair consisting of 'Options' and a structure. A call to `statset` creates this argument. For parameter names and default values, type `statset('coxphfit')`. You can set the options under a new name and use that in the name-value pair argument.

Example: 'Options',statset('coxphfit')

Output Arguments

b — Coefficient estimates

vector

Coefficient estimates for a Cox proportional hazards regression on page 32-900, returned as a p -by-1 vector.

logl — Loglikelihood

scalar

Loglikelihood of the fitted model, returned as a scalar.

You can use log likelihood values to compare different models and assess the significance of effects of terms in the model.

H — Estimated baseline cumulative hazard

two-column matrix | $(2+k)$ column matrix

Estimated baseline cumulative hazard rate evaluated at T values, returned as one of the following.

- If the model is unstratified, then H is a two-column matrix. The first column of the matrix contains T values, and the second column contains cumulative hazard rate estimates.
- If the model is stratified, then H is a $(2+k)$ column matrix, where the last k columns correspond to the stratification variables using the `Strata` name-value pair argument.

stats — Coefficient statistics

structure

Coefficient statistics, returned as a structure that contains the following fields.

beta	Coefficient estimates (same as b)
se	Standard errors of coefficient estimates, b
z	z-statistics for b (that is, b divided by standard error)
p	p -values for b
covb	Estimated covariance matrix for b
csres	Cox-Snell residuals
devres	Deviance residuals
martres	Martingale residuals
schres	Schoenfeld residuals
sschres	Scaled Schoenfeld residuals
scores	Score residuals
sscores	Scaled score residuals

`coxphfit` returns the Cox-Snell, martingale, and deviance residuals as a column vector with one row per observation. It returns the Schoenfeld, scaled Schoenfeld, score, and scaled score residuals as matrices of the same size as X. Schoenfeld and scaled Schoenfeld residuals of censored data are NaNs.

More About

Cox Proportional Hazards Regression

Cox proportional hazards regression is a semiparametric method for adjusting survival rate estimates to remove the effect of confounding variables and to quantify the effect of predictor variables. The

method represents the effects of explanatory and confounding variables as a multiplier of a common baseline hazard function, $h_0(t)$.

For a baseline relative to 0, this model corresponds to

$$h(X_i, t) = h_0(t) \exp \left[\sum_{j=1}^p x_{ij} b_j \right],$$

where $X_i = (x_{i1}, x_{i2}, \dots, x_{ip})$ is the predictor variable for the i th subject, $h(X_i, t)$ is the hazard rate at time t for X_i , and $h_0(t)$ is the baseline hazard rate function. The baseline hazard function is the nonparametric part of the Cox proportional hazards regression function, whereas the impact of the predictor variables is a loglinear regression. The assumption is that the baseline hazard function depends on time, t , but the predictor variables do not depend on time. See “Cox Proportional Hazards Model” on page 14-26 for details, including the extensions for stratification and time-dependent variables, tied events, and observation weights.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- X can be a single- or double-precision matrix and can be variable-size.
- The value of the 'Ties' name-value pair argument must be a compile-time constant. For example, to use Efron's method to handle tied failure times, include `{coder.Constant('Ties'), coder.Constant('efron')}` in the `-args` value of `codegen`.
- Names in name-value pair arguments must be compile-time constants.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced before R2006a

createns

Create nearest neighbor searcher object

Syntax

```
NS = createns(X)
NS = createns(X,Name,Value)
```

Description

`NS = createns(X)` creates either an `ExhaustiveSearcher` or `KDTreeSearcher` model object using the n -by- K numeric matrix of the training data X .

`NS = createns(X,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify `NSMethod` to determine which type of object to create.

Examples

Train Default Exhaustive Nearest Neighbor Searcher

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n = 150
```

```
k = 4
```

X has 150 observations and 4 predictors.

Prepare an exhaustive nearest neighbor searcher using the entire data set as training data.

```
Mdl1 = ExhaustiveSearcher(X)
```

```
Mdl1 =
    ExhaustiveSearcher with properties:
```

```
    Distance: 'euclidean'
    DistParameter: []
           X: [150x4 double]
```

`Mdl1` is an `ExhaustiveSearcher` model object, and its properties appear in the Command Window. The object contains information about the trained algorithm, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can prepare an exhaustive nearest neighbor searcher by using `createns` and specifying `'exhaustive'` as the search method.

```
Mdl2 = createns(X,'NSMethod','exhaustive')
```

```
Mdl2 =  
    ExhaustiveSearcher with properties:  
  
        Distance: 'euclidean'  
    DistParameter: []  
            X: [150x4 double]
```

Mdl2 is also an ExhaustiveSearcher model object, and it is equivalent to Mdl1.

To search X for the nearest neighbors to a batch of query data, pass the ExhaustiveSearcher model object and the query data to knnsearch or rangesearch.

Grow Default Kd-Tree

Grow a four-dimensional Kd-tree that uses the Euclidean distance.

Load Fisher's iris data set.

```
load fisheriris  
X = meas;  
[n,k] = size(X)
```

```
n = 150
```

```
k = 4
```

X has 150 observations and 4 predictors.

Grow a four-dimensional Kd-tree using the entire data set as training data.

```
Mdl1 = KDTreeSearcher(X)
```

```
Mdl1 =  
    KDTreeSearcher with properties:
```

```
        BucketSize: 50  
        Distance: 'euclidean'  
    DistParameter: []  
            X: [150x4 double]
```

Mdl1 is a KDTreeSearcher model object, and its properties appear in the Command Window. The object contains information about the grown four-dimensional Kd-tree, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can grow a Kd-tree by using createns.

```
Mdl2 = createns(X)
```

```
Mdl2 =  
    KDTreeSearcher with properties:
```

```
        BucketSize: 50  
        Distance: 'euclidean'  
    DistParameter: []
```

```
X: [150x4 double]
```

Mdl2 is also a KDTreeSearcher model object, and it is equivalent to Mdl1. Because X has four columns and the default distance metric is Euclidean, createns creates a KDTreeSearcher model by default.

To find the nearest neighbors in X to a batch of query data, pass the KDTreeSearcher model object and the query data to knnsearch or rangesearch.

Grow Kd-Tree Using Minkowski Distance Metric

Grow a Kd-tree that uses the Minkowski distance with an exponent of five.

Load Fisher's iris data set. Create a variable for the petal dimensions.

```
load fisheriris
X = meas(:,3:4);
```

Grow a Kd-tree. Specify the Minkowski distance with an exponent of five.

```
Mdl = createns(X, 'Distance', 'minkowski', 'P', 5)
```

```
Mdl =
  KDTreeSearcher with properties:
    BucketSize: 50
    Distance: 'minkowski'
    DistParameter: 5
    X: [150x2 double]
```

Because X has two columns and the distance metric is Minkowski, createns creates a KDTreeSearcher model object by default.

Search for Nearest Neighbors of Query Data Using Mahalanobis Distance

Create an exhaustive searcher object by using the createns function. Pass the object and query data to the knnsearch function to find *k*-nearest neighbors.

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng('default');           % For reproducibility
n = size(meas,1);         % Sample size
qIdx = randsample(n,5);   % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Prepare an exhaustive nearest neighbor searcher using the training data. Specify the Mahalanobis distance for finding nearest neighbors.

```
Mdl = createns(X, 'Distance', 'mahalanobis')
```

```
Mdl =
  ExhaustiveSearcher with properties:
    Distance: 'mahalanobis'
    DistParameter: [4x4 double]
    X: [145x4 double]
```

Because the distance metric is Mahalanobis, `createns` creates an `ExhaustiveSearcher` model object by default.

The software uses the covariance matrix of the predictors (columns) in the training data for computing the Mahalanobis distance. To display this value, use `Mdl.DistParameter`.

```
Mdl.DistParameter
```

```
ans = 4x4
    0.6547    -0.0368    1.2320    0.5026
   -0.0368    0.1914   -0.3227   -0.1193
    1.2320   -0.3227    3.0671    1.2842
    0.5026   -0.1193    1.2842    0.5800
```

Find the indices of the training data (`Mdl.X`) that are the two nearest neighbors of each point in the query data (`Y`).

```
IdxNN = knnsearch(Mdl, Y, 'K', 2)
```

```
IdxNN = 5x2
     5     6
    98    95
   104   128
   135    65
   102   115
```

Each row of `IdxNN` corresponds to a query data observation. The column order corresponds to the order of the nearest neighbors with respect to ascending distance. For example, based on the Mahalanobis metric, the second nearest neighbor of `Y(3, :)` is `X(128, :)`.

Input Arguments

X — Training data

numeric matrix

Training data, specified as a numeric matrix. `X` has n rows, each corresponding to an observation (that is, an instance or example), and K columns, each corresponding to a predictor (that is, a feature).

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `NS = createns(X, 'Distance', 'mahalanobis')` creates an `ExhaustiveSearcher` model object that uses the Mahalanobis distance metric when searching for nearest neighbors.

For Exhaustive and Kd-Tree Nearest Neighbor Searchers

NSMethod — Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method used to define the type of object created, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — `createns` creates a `KDTreeSearcher` model object using the Kd-tree algorithm.
- 'exhaustive' — `createns` creates an `ExhaustiveSearcher` model object using the exhaustive search algorithm.

The default value is 'kdtree' when these three conditions are true:

- The number of columns of `X` (K) is less than or equal to 10 (that is, $K \leq 10$).
- `X` is not sparse.
- `Distance` is 'euclidean', 'cityblock', 'chebychev', or 'minkowski'.

Otherwise, the default value is 'exhaustive'.

Example: 'NSMethod', 'exhaustive'

Distance — Distance metric

'euclidean' (default) | character vector or string scalar of distance metric name | custom distance function

Distance metric used when you call `knnsearch` or `rangesearch` to find nearest neighbors for future query points, specified as the comma-separated pair consisting of 'Distance' and a character vector or string scalar of distance metric name or function handle.

For both types of nearest neighbor searchers, `createns` supports these distance metrics.

Value	Description
'chebychev'	Chebychev distance (maximum coordinate difference).
'cityblock'	City block distance.
'euclidean'	Euclidean distance.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.

If `createns` uses the exhaustive search algorithm ('NSMethod' is 'exhaustive'), then `createns` also supports these distance metrics.

Value	Description
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values)
'cosine'	One minus the cosine of the included angle between observations (treated as row vectors)
'hamming'	Hamming distance, which is the percentage of coordinates that differ
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ
'mahalanobis'	Mahalanobis distance
'seuclidean'	Standardized Euclidean distance
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values)

If `createns` uses the exhaustive search algorithm (`'NSMethod'` is `'exhaustive'`), then you can also specify a function handle for a custom distance metric by using `@` (for example, `@distfun`). A custom distance function must:

- Have the form `function D2 = distfun(ZI,ZJ)`.
- Take as arguments:
 - A 1-by- K vector `ZI` containing a single row from X or from the query points Y , where K is the number of columns in X .
 - An m -by- K matrix `ZJ` containing multiple rows of X or Y , where m is a positive integer.
- Return an m -by-1 vector of distances `D2`, where `D2(j)` is the distance between the observations `ZI` and `ZJ(j,:)`.

For more details, see “Distance Metrics” on page 18-11.

Example: `'Distance','minkowski'`

P — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar. This argument is valid only if `'Distance'` is `'minkowski'`.

Example: `'P',3`

Data Types: `single` | `double`

For Exhaustive Nearest Neighbor Searchers

Cov — Covariance matrix for Mahalanobis distance metric

`nancov(X)` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of `'Cov'` and a K -by- K positive definite matrix, where K is the number of columns in X . This argument is valid only if `'Distance'` is `'mahalanobis'`.

Example: `'Cov',eye(3)`

Data Types: `single` | `double`

Scale — Scale parameter value for standardized Euclidean distance metric

`nanstd(X)` (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector of length K , where K is the number of columns in X . The software scales each difference between the training and query data using the corresponding element of `Scale`. This argument is valid only if 'Distance' is 'seuclidean'.

Example: `'Scale', quantile(X,0.75) - quantile(X,0.25)`

Data Types: `single` | `double`

For Nearest Neighbor Searchers Using Kd-Tree

BucketSize — Maximum number of data points in each leaf node

50 (default) | positive integer

Maximum number of data points in each leaf node of the Kd-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer.

This argument is valid only when you create a `KDTreeSearcher` model object.

Example: `'BucketSize', 10`

Data Types: `single` | `double`

Output Arguments

NS — Nearest neighbor searcher

`ExhaustiveSearcher` model object | `KDTreeSearcher` model object

Nearest neighbor searcher, returned as an `ExhaustiveSearcher` model object or a `KDTreeSearcher` model object.

Once you create a nearest neighbor searcher model object, you can find the neighboring points in the training data to the query data by performing a nearest neighbor search using `knnsearch` or a radius search using `rangesearch`.

Introduced in R2010a

crosstab

Cross-tabulation

Syntax

```
tbl = crosstab(x1,x2)
tbl = crosstab(x1,...,xn)
[tbl,chi2,p] = crosstab(____)
[tbl,chi2,p,labels] = crosstab(____)
```

Description

`tbl = crosstab(x1,x2)` returns a cross-tabulation, `tbl`, of two vectors of the same length, `x1` and `x2`.

`tbl = crosstab(x1,...,xn)` returns a multi-dimensional cross-tabulation, `tbl`, of data for multiple input vectors, `x1`, `x2`, ..., `xn`.

`[tbl,chi2,p] = crosstab(____)` also returns the chi-square statistic, `chi2`, and its *p*-value, `p`, for a test that `tbl` is independent in each dimension. You can use any of the previous syntaxes.

`[tbl,chi2,p,labels] = crosstab(____)` also returns a cell array, `labels`, which contains one column of labels for each input argument, `x1 ... xn`.

Examples

Cross-Tabulate Two Data Vectors

Create two sample data vectors, containing three and four distinct values, respectively.

```
x = [1 1 2 3 1];
y = [1 2 5 3 1];
```

Cross-tabulate `x` and `y`.

```
table = crosstab(x,y)
```

```
table = 3×4
```

```
     2     1     0     0
     0     0     0     1
     0     0     1     0
```

The rows in `table` correspond to the three distinct values in `x`, and the columns correspond to the four distinct values in `y`.

Cross-Tabulate Independent Data Vectors

Generate two independent vectors, `x1` and `x2`, each containing 50 discrete uniform random numbers in the range 1:3.

```
rng default; % for reproducibility
x1 = unidrnd(3,50,1);
x2 = unidrnd(3,50,1);
```

Cross-tabulate `x1` and `x2`.

```
[table,chi2,p] = crosstab(x1,x2)
```

```
table = 3×3
```

```
     1     6     7
     5     5     2
    11     7     6
```

```
chi2 = 7.5449
```

```
p = 0.1097
```

The returned `p` value of 0.1097 indicates that, at the 5% significance level, `crosstab` fails to reject the null hypothesis that `table` is independent in each dimension.

Cross-Tabulate Grouped Data

Load the sample data, which contains measurements of large model cars during the years 1970-1982.

```
load carbig
```

Cross-tabulate the data of four-cylinder cars (`cyl4`) based on model year (`when`) and country of origin (`org`).

```
[table,chi2,p,labels] = crosstab(cyl4,when,org);
```

Use `labels` to determine the index location in `table` for the number of four-cylinder cars made in the USA during the late period of the data.

```
labels
```

```
labels=3×3 cell array
    {'Other' }    {'Early'}    {'USA' }
    {'Four'  }    {'Mid' }    {'Europe'}
    {0×0 double}  {'Late' }    {'Japan' }
```

The first column of `labels` corresponds to the data in `cyl4`, and indicates that row 2 of `table` contains data on cars with four cylinders. The second column of `labels` corresponds to the data in `when`, and indicates that column 3 of `table` contains data on cars made during the late period. The third column of `labels` corresponds to the data in `org`, and indicates that location 1 of the third dimension of `table` contains data on cars made in the USA.

Therefore, `table(2,3,1)` contains the number of four-cylinder cars made in the USA during the late period.

```
table(2,3,1)
```

```
ans = 38
```

The data contains 38 four-cylinder cars made in the USA during the late period.

Generate Contingency Table Using `crosstab`

Load the hospital data.

```
load hospital
```

The `hospital` dataset array contains data on 100 hospital patients, including last name, gender, age, weight, smoking status, and systolic and diastolic blood pressure measurements.

To determine whether smoking status is independent of gender, use `crosstab` to create a 2-by-2 contingency table of smokers and nonsmokers, grouped by gender.

```
[tbl,chi2,p,labels] = crosstab(hospital.Sex, hospital.Smoker)
```

```
tbl = 2x2
```

```
    40    13
    26    21
```

```
chi2 = 4.5083
```

```
p = 0.0337
```

```
labels = 2x2 cell
    {'Female'}    {'0'}
    {'Male' }    {'1'}
```

The rows of the resulting contingency table `tbl` correspond to the patient's gender, with row 1 containing data for females and row 2 containing data for males. The columns correspond to the patient's smoking status, with column 1 containing data for nonsmokers and column 2 containing data for smokers. The returned result `chi2 = 4.5083` is the value of the chi-squared test statistic for a Pearson's chi-squared test of independence. The returned value `p = 0.0337` is an approximate *p*-value based on the chi-squared distribution.

Input Arguments

x1 — Input vector

vector of grouping variables

Input vector, specified as a vector of grouping variables. All input vectors, including `x1`, `x2`, ..., `xn`, must be the same length.

Data Types: `single` | `double` | `char` | `string` | `logical`

x2 — Input vector

vector of grouping variables

Input vector, specified as a vector of grouping variables. All input vectors, including x_1 , x_2 , ..., x_n , must be the same length.

Data Types: `single` | `double` | `char` | `string` | `logical`**x1, ..., xn — Input vectors**

vectors of grouping variables

Input vectors, specified as vectors of grouping variables. If you use this syntax to specify more than two input vectors, then `crosstab` generates a multi-dimensional cross-tabulation table. All input vectors, including x_1 , x_2 , ..., x_n , must be the same length.

Data Types: `single` | `double` | `char` | `string` | `logical`**Output Arguments****tbl — Cross-tabulation table**

matrix of integer values

Cross-tabulation table, returned as a matrix of integer values.

If you specify two input vectors, x_1 and x_2 , then `tbl` is an m -by- n matrix, where m is the number of distinct values in x_1 and n is the number of distinct values in x_2 .

If you specify three or more input vectors, then `tbl(i, j, ..., n)` is a count of indices where `grp2idx(x1)` is i , `grp2idx(x2)` is j , `grp2idx(x3)` is k , and so on.

chi2 — Chi-square statistic

positive scalar value

Chi-square statistic, returned as a positive scalar value. The null hypothesis is that the proportion in any entry of `tbl` is the product of the proportions in each dimension.

p — p-Valuescalar value in the range $[0, 1]$

p-value for the chi-square test statistic, returned as a scalar value in the range $[0, 1]$. `crosstab` tests that `tbl` is independent in each dimension.

labels — Data labels

cell array

Data labels, returned as a cell array. The entries in the first column are labels for the rows of `tbl`, the entries in the second column are labels for the columns, and so on, for a multi-dimensional `tbl`.

Algorithms

- `crosstab` uses `grp2idx` to assign a positive integer to each distinct value. `tbl(i, j)` is a count of indices where `grp2idx(x1)` is i and `grp2idx(x2)` is j . The numerical order of `grp2idx(x1)` and `grp2idx(x2)` order rows and columns of `tbl`, respectively.

In this case, the returned value of `tbl(i, j, ..., n)` is a count of indices where `grp2idx(x1)` is `i`, `grp2idx(x2)` is `j`, `grp2idx(x3)` is `k`, and so on.

- `crosstab` computes the p -value of the chi-square test statistic using a formula that is asymptotically valid for a large sample size. The approximation is less accurate for small samples or samples with uneven marginal distributions. If your sample includes only two variables and each has two levels, you can use `fishertest` instead. This function performs Fisher's exact test, which does not depend on large-sample distribution assumptions.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitation:

The fourth output, `labels`, is returned as a cell array containing `M` unevaluated tall cell arrays, where `M` is the number of input grouping variables. Each unevaluated tall cell array, `labels{j}`, contains the labels for one grouping variable.

For more information, see "Tall Arrays for Out-of-Memory Data" (MATLAB).

crossval

Estimate loss using cross-validation

Syntax

```
err = crossval(criterion,X,y,'Predfun',predfun)
err = crossval(criterion,X1,...,XN,y,'Predfun',predfun)
```

```
values = crossval(fun,X)
values = crossval(fun,X1,...,XN)
```

```
___ = crossval( ___,Name,Value)
```

Description

`err = crossval(criterion,X,y,'Predfun',predfun)` returns a 10-fold cross-validation error estimate for the function `predfun` based on the specified `criterion`, either `'mse'` (mean squared error) or `'msc'` (misclassification rate). The rows of `X` and `y` correspond to observations, and the columns of `X` correspond to predictor variables.

In this case, `crossval` performs 10-fold cross-validation as follows:

- 1 Split the observations in the predictor data `X` and the response variable `y` into 10 groups, each of which has approximately the same number of observations.
- 2 Use the last nine groups of observations to train a model as specified in `predfun`. Use the first group of observations as test data, pass the test predictor data to the trained model, and compute predicted values as specified in `predfun`. Compute the error specified by `criterion`.
- 3 Use the first group and the last eight groups of observations to train a model as specified in `predfun`. Use the second group of observations as test data, pass the test data to the trained model, and compute predicted values as specified in `predfun`. Compute the error specified by `criterion`.
- 4 Proceed in a similar manner until each group of observations is used as test data exactly once.
- 5 Return the mean error estimate as the scalar `err`.

`err = crossval(criterion,X1,...,XN,y,'Predfun',predfun)` returns a 10-fold cross-validation error estimate for `predfun` by using the predictor variables `X1` through `XN` and the response variable `y`.

`values = crossval(fun,X)` performs 10-fold cross-validation for the function `fun`, applied to the data in `X`. The rows of `X` correspond to observations, and the columns of `X` correspond to variables.

`crossval` typically performs 10-fold cross-validation as follows:

- 1 Split the data in `X` into 10 groups, each of which has approximately the same number of observations.
- 2 Use the last nine groups of data to train a model as specified in `fun`. Use the first group of data as a test set, pass the test set to the trained model, and compute some value (for example, loss) as specified in `fun`.

- 3 Use the first group and the last eight groups of data to train a model as specified in `fun`. Use the second group of data as a test set, pass the test set to the trained model, and compute some value as specified in `fun`.
- 4 Proceed in a similar manner until each group of data is used as a test set exactly once.
- 5 Return the 10 computed values as the vector `values`.

`values = crossval(fun,X1,...,XN)` performs 10-fold cross-validation for the function `fun`, applied to the data in `X1,...,XN`. Every data set, `X1` through `XN`, must have the same number of observations and, therefore, the same number of rows.

`___ = crossval(___,Name,Value)` specifies cross-validation options using one or more name-value pair arguments in addition to any of the input argument combinations and output arguments in previous syntaxes. For example, `'KFold',5` specifies to perform 5-fold cross-validation.

Examples

Compute Mean Squared Error Using Cross-Validation

Compute the mean squared error of a regression model by using 10-fold cross-validation.

Load the `carsmall` data set. Put the acceleration, horsepower, weight, and miles per gallon (MPG) values into the matrix `data`. Remove any rows that contain NaN values.

```
load carsmall
data = [Acceleration Horsepower Weight MPG];
data(any(isnan(data),2),:) = [];
```

Specify the last column of `data`, which corresponds to MPG, as the response variable `y`. Specify the other columns of `data` as the predictor data `X`. Add a column of ones to `X` when your regression function uses `regress`, as in this example.

Note: `regress` is useful when you simply need the coefficient estimates or residuals of a regression model. If you need to investigate a fitted regression model further, create a linear regression model object by using `fitlm`. For an example that uses `fitlm` and `crossval`, see “Compute Mean Absolute Error Using Cross-Validation” on page 32-919.

```
y = data(:,4);
X = [ones(length(y),1) data(:,1:3)];
```

Create the custom function `regf` (shown at the end of this example). This function fits a regression model to training data and then computes predicted values on a test set.

Note: If you use the live script file for this example, the `regf` function is already included at the end of the file. Otherwise, you need to create this function at the end of your `.m` file or add it as a file on the MATLAB® path.

Compute the default 10-fold cross-validation mean squared error for the regression model with predictor data `X` and response variable `y`.

```
rng('default') % For reproducibility
cvMSE = crossval('mse',X,y,'Predfun',@regf)
```

```
cvMSE = 17.5399
```

This code creates the function `regf`.

```
function yfit = regf(Xtrain,ytrain,Xtest)
b = regress(ytrain,Xtrain);
yfit = Xtest*b;
end
```

Compute Misclassification Error Using Logistic Regression Model and Cross-Validation

Compute the misclassification error of a logistic regression model trained on numeric and categorical predictor data by using 10-fold cross-validation.

Load the `patients` data set. Specify the numeric variables `Diastolic` and `Systolic` and the categorical variable `Gender` as predictors, and specify `Smoker` as the response variable.

```
load patients
X1 = Diastolic;
X2 = categorical(Gender);
X3 = Systolic;
y = Smoker;
```

Create the custom function `classf` (shown at the end of this example). This function fits a logistic regression model to training data and then classifies test data.

Note: If you use the live script file for this example, the `classf` function is already included at the end of the file. Otherwise, you need to create this function at the end of your `.m` file or add it as a file on the MATLAB® path.

Compute the 10-fold cross-validation misclassification error for the model with predictor data `X1`, `X2`, and `X3` and response variable `y`. Specify `'Stratify'`, `y` to ensure that training and test sets have roughly the same proportion of smokers.

```
rng('default') % For reproducibility
err = crossval('mcr',X1,X2,X3,y,'Predfun',@classf,'Stratify',y)

err = 0.1100
```

This code creates the function `classf`.

```
function pred = classf(X1train,X2train,X3train,ytrain,X1test,X2test,X3test)
Xtrain = table(X1train,X2train,X3train,ytrain, ...
    'VariableNames',{'Diastolic','Gender','Systolic','Smoker'});
Xtest = table(X1test,X2test,X3test, ...
    'VariableNames',{'Diastolic','Gender','Systolic'});
modelspec = 'Smoker ~ Diastolic + Gender + Systolic';
mdl = fitglm(Xtrain,modelspec,'Distribution','binomial');
yfit = predict(mdl,Xtest);
pred = (yfit > 0.5);
end
```

Determine Number of Clusters Using Cross-Validation

For a given number of clusters, compute the cross-validated sum of squared distances between observations and their nearest cluster center. Compare the results for one through ten clusters.

Load the `fisheriris` data set. `X` is the matrix `meas`, which contains flower measurements for 150 different flowers.

```
load fisheriris
X = meas;
```

Create the custom function `clustf` (shown at the end of this example). This function performs the following steps:

- 1 Standardize the training data.
- 2 Separate the training data into `k` clusters.
- 3 Transform the test data using the training data mean and standard deviation.
- 4 Compute the distance from each test data point to the nearest cluster center, or centroid.
- 5 Compute the sum of the squares of the distances.

Note: If you use the live script file for this example, the `clustf` function is already included at the end of the file. Otherwise, you need to create the function at the end of your `.m` file or add it as a file on the MATLAB® path.

Create a `for` loop that specifies the number of clusters `k` for each iteration. For each fixed number of clusters, pass the corresponding `clustf` function to `crossval`. Because `crossval` performs 10-fold cross-validation by default, the software computes 10 sums of squared distances, one for each partition of training and test data. Take the sum of those values; the result is the cross-validated sum of squared distances for the given number of clusters.

```
rng('default') % For reproducibility
cvdist = zeros(5,1);
for k = 1:10
    fun = @(Xtrain,Xtest)clustf(Xtrain,Xtest,k);
    distances = crossval(fun,X);
    cvdist(k) = sum(distances);
end
```

Plot the cross-validated sum of squared distances for each number of clusters.

```
plot(cvdist)
xlabel('Number of Clusters')
ylabel('CV Sum of Squared Distances')
```

In general, when determining how many clusters to use, consider the greatest number of clusters that corresponds to a significant decrease in the cross-validated sum of squared distances. For this example, using two or three clusters seems appropriate, but using more than three clusters does not.

This code creates the function `clustf`.

```
function distances = clustf(Xtrain,Xtest,k)
[Ztrain,Zmean,Zstd] = zscore(Xtrain);
[~,C] = kmeans(Ztrain,k); % Creates k clusters
Ztest = (Xtest-Zmean)./Zstd;
d = pdist2(C,Ztest,'euclidean','Smallest',1);
distances = sum(d.^2);
end
```

Compute Mean Absolute Error Using Cross-Validation

Compute the mean absolute error of a regression model by using 10-fold cross-validation.

Load the `carsmall` data set. Specify the `Acceleration` and `Displacement` variables as predictors and the `Weight` variable as the response.

```
load carsmall
X1 = Acceleration;
X2 = Displacement;
y = Weight;
```

Create the custom function `regf` (shown at the end of this example). This function fits a regression model to training data and then computes predicted car weights on a test set. The function compares the predicted car weight values to the true values, and then computes the mean absolute error (MAE) and the MAE adjusted to the range of the test set car weights.

Note: If you use the live script file for this example, the `regf` function is already included at the end of the file. Otherwise, you need to create this function at the end of your `.m` file or add it as a file on the MATLAB® path.

By default, `crossval` performs 10-fold cross-validation. For each of the 10 training and test set partitions of the data in `X1`, `X2`, and `y`, compute the MAE and adjusted MAE values using the `regf` function. Find the mean MAE and mean adjusted MAE.

```
rng('default') % For reproducibility
values = crossval(@regf,X1,X2,y)
```

```
values = 10×2
```

```
319.2261    0.1132
342.3722    0.1240
214.3735    0.0902
174.7247    0.1128
189.4835    0.0832
249.4359    0.1003
194.4210    0.0845
348.7437    0.1700
283.1761    0.1187
210.7444    0.1325
```

```
mean(values)
```

```
ans = 1×2
```

```
252.6701    0.1129
```

This code creates the function `regf`.

```
function errors = regf(X1train,X2train,ytrain,X1test,X2test,ytest)
tbltrain = table(X1train,X2train,ytrain, ...
    'VariableNames',{'Acceleration','Displacement','Weight'});
tbltest = table(X1test,X2test,ytest, ...
    'VariableNames',{'Acceleration','Displacement','Weight'});
mdl = fitlm(tbltrain,'Weight ~ Acceleration + Displacement');
yfit = predict(mdl,tbltest);
MAE = mean(abs(yfit-tbltest.Weight));
adjMAE = MAE/range(tbltest.Weight);
errors = [MAE adjMAE];
end
```

Compute Misclassification Error Using PCA and Cross-Validation

Compute the misclassification error of a classification tree by using principal component analysis (PCA) and 5-fold cross-validation.

Load the `fisheriris` data set. The `meas` matrix contains flower measurements for 150 different flowers. The `species` variable lists the species for each flower.

```
load fisheriris
```

Create the custom function `classf` (shown at the end of this example). This function fits a classification tree to training data and then classifies test data. Use PCA inside the function to reduce the number of predictors used to create the tree model.

Note: If you use the live script file for this example, the `classf` function is already included at the end of the file. Otherwise, you need to create this function at the end of your `.m` file or add it as a file on the MATLAB® path.

Create a `cvpartition` object for stratified 5-fold cross-validation. By default, `cvpartition` ensures that training and test sets have roughly the same proportions of flower species.

```
rng('default') % For reproducibility
cvp = cvpartition(species, 'KFold', 5);
```

Compute the 5-fold cross-validation misclassification error for the classification tree with predictor data `meas` and response variable `species`.

```
cvError = crossval('mcr', meas, species, 'Predfun', @classf, 'Partition', cvp)

cvError = 0.1067
```

This code creates the function `classf`.

```
function yfit = classf(Xtrain, ytrain, Xtest)

% Standardize the training predictor data. Then, find the
% principal components for the standardized training predictor
% data.
[Ztrain, Zmean, Zstd] = zscore(Xtrain);
[coeff, scoreTrain, ~, ~, explained, mu] = pca(Ztrain);

% Find the lowest number of principal components that account
% for at least 95% of the variability.
n = find(cumsum(explained) >= 95, 1);

% Find the n principal component scores for the standardized
% training predictor data. Train a classification tree model
% using only these scores.
scoreTrain95 = scoreTrain(:, 1:n);
mdl = fitctree(scoreTrain95, ytrain);

% Find the n principal component scores for the transformed
% test data. Classify the test data.
Ztest = (Xtest - Zmean) ./ Zstd;
scoreTest95 = (Ztest - mu) * coeff(:, 1:n);
yfit = predict(mdl, scoreTest95);

end
```

Create Confusion Matrix Using Cross-Validation

Create a confusion matrix from the 10-fold cross-validation results of a discriminant analysis model.

Note: Use `classify` when training speed is a concern. Otherwise, use `fitcdiscr` to create a discriminant analysis model. For an example that shows the same workflow as this example, but uses `fitcdiscr`, see “Create Confusion Matrix Using Cross-Validation Predictions” on page 32-2870.

Load the `fisheriris` data set. `X` contains flower measurements for 150 different flowers, and `y` lists the species for each flower. Create a variable `order` that specifies the order of the flower species.

```
load fisheriris
X = meas;
y = species;
order = unique(y)

order = 3x1 cell
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

Create a function handle named `func` for a function that completes the following steps:

- Take in training data (`Xtrain` and `ytrain`) and test data (`Xtest` and `ytest`).
- Use the training data to create a discriminant analysis model that classifies new data (`Xtest`). Create this model and classify new data by using the `classify` function.
- Compare the true test data classes (`ytest`) to the predicted test data values, and create a confusion matrix of the results by using the `confusionmat` function. Specify the class order by using `'Order',order`.

```
func = @(Xtrain,ytrain,Xtest,ytest)confusionmat(ytest, ...
    classify(Xtest,Xtrain,ytrain),'Order',order);
```

Create a `cvpartition` object for stratified 10-fold cross-validation. By default, `cvpartition` ensures that training and test sets have roughly the same proportions of flower species.

```
rng('default') % For reproducibility
cvp = cvpartition(y,'Kfold',10);
```

Compute the 10 test set confusion matrices for each partition of the predictor data `X` and response variable `y`. Each row of `confMat` corresponds to the confusion matrix results for one test set. Aggregate the results and create the final confusion matrix `cvMat`.

```
confMat = crossval(func,X,y,'Partition',cvp);
cvMat = reshape(sum(confMat),3,3)
```

```
cvMat = 3x3
```

```
    50     0     0
     0    48     2
     0     1    49
```

Plot the confusion matrix as a confusion matrix chart by using `confusionchart`.

```
confusionchart(cvMat,order)
```

True Class	setosa	50		
	versicolor		48	2
	virginica		1	49
		setosa	versicolor	virginica
		Predicted Class		

Input Arguments

criteria — Type of error estimate

'mse' | 'mcr'

Type of error estimate, specified as either 'mse' or 'mcr'.

Value	Description
'mse'	Mean squared error (MSE) — Appropriate for regression algorithms only
'mcr'	Misclassification rate, or proportion of misclassified observations — Appropriate for classification algorithms only

X — Data set

column vector | matrix | array

Data set, specified as a column vector, matrix, or array. The rows of X correspond to observations, and the columns of X generally correspond to variables. If you pass multiple data sets X1, . . . , XN to crossval, then all data sets must have the same number of rows.

Data Types: single | double | logical | char | string | cell | categorical

y — Response data

column vector | character array

Response data, specified as a column vector or character array. The rows of **y** correspond to observations, and **y** must have the same number of rows as the predictor data **X** or **X1, . . . , XN**.

Data Types: single | double | logical | char | string | cell | categorical

predfun — Prediction function

function handle

Prediction function, specified as a function handle. You must create this function as an anonymous function, a function defined at the end of the **.m** or **.mlx** file containing the rest of your code, or a file on the MATLAB path.

This table describes the required function syntax, given the type of predictor data passed to **crossval**.

Value	Predictor Data	Function Syntax
@myfunction	X	<pre>function yfit = myfunction(Xtrain,ytrain,Xtest) % Calculate predicted response ... end</pre> <ul style="list-style-type: none"> • Xtrain — Subset of the observations in X used as training predictor data. The function uses Xtrain and ytrain to construct a classification or regression model. • ytrain — Subset of the responses in y used as training response data. The rows of ytrain correspond to the same observations in the rows of Xtrain. The function uses Xtrain and ytrain to construct a classification or regression model. • Xtest — Subset of the observations in X used as test predictor data. The function uses Xtest and the model trained on Xtrain and ytrain to compute the predicted values yfit. • yfit — Set of predicted values for observations in Xtest. The yfit values form a column vector with the same number of rows as Xtest.

Value	Predictor Data	Function Syntax
@myfunction	X1,...,XN	<pre>function yfit = myfunction(X1train,...,XNtrain,ytrain) % Calculate predicted response ... end</pre> <ul style="list-style-type: none"> • X1train,...,XNtrain — Subsets of the predictor data in X1,...,XN, respectively, that are used as training predictor data. The rows of X1train,...,XNtrain correspond to the same observations. The function uses X1train,...,XNtrain and ytrain to construct a classification or regression model. • ytrain — Subset of the responses in y used as training response data. The rows of ytrain correspond to the same observations in the rows of X1train,...,XNtrain. The function uses X1train,...,XNtrain and ytrain to construct a classification or regression model. • X1test,...,XNtest — Subsets of the observations in X1,...,XN, respectively, that are used as test predictor data. The rows of X1test,...,XNtest correspond to the same observations. The function uses X1test,...,XNtest and the model trained on X1train,...,XNtrain and ytrain to compute the predicted values yfit. • yfit — Set of predicted values for observations in X1test,...,XNtest. The yfit values form a column vector with the same number of rows as X1test,...,XNtest.

Example: @(Xtrain,ytrain,Xtest)(Xtest*regress(ytrain,Xtrain));

Data Types: function_handle

fun — Function to cross-validate

function handle

Function to cross-validate, specified as a function handle. You must create this function as an anonymous function, a function defined at the end of the .m or .mlx file containing the rest of your code, or a file on the MATLAB path.

This table describes the required function syntax, given the type of data passed to crossval.

Value	Data	Function Syntax
@myfunction	X	<pre>function value = myfunction(Xtrain,Xtest) % Calculation of value ... end</pre> <ul style="list-style-type: none"> • Xtrain — Subset of the observations in X used as training data. The function uses Xtrain to construct a model. • Xtest — Subset of the observations in X used as test data. The function uses Xtest and the model trained on Xtrain to compute value. • value — Quantity or variable. In most cases, value is a numeric scalar representing a loss estimate. value can also be an array, provided that the array size is the same for each partition of training and test data. If you want to return a variable output that can change size depending on the data partition, set value to be the cell scalar {output} instead.
@myfunction	X1,...,XN	<pre>function value = myfunction(X1train,...,XNtrain,X1test,...,XNtest) % Calculation of value ... end</pre> <ul style="list-style-type: none"> • X1train,...,XNtrain — Subsets of the data in X1,...,XN, respectively, that are used as training data. The rows of X1train,...,XNtrain correspond to the same observations. The function uses X1train,...,XNtrain to construct a model. • X1test,...,XNtest — Subsets of the data in X1,...,XN, respectively, that are used as test data. The rows of X1test,...,XNtest correspond to the same observations. The function uses X1test,...,XNtest and the model trained on X1train,...,XNtrain to compute value. • value — Quantity or variable. In most cases, value is a numeric scalar representing a loss estimate. value can also be an array, provided that the array size is the same for each partition of training and test data. If you want to return a variable output that can change size depending on the data partition, set value to be the cell scalar {output} instead.

Data Types: function_handle

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
crossval('mcr', meas, species, 'Predfun', @classf, 'KFold', 5, 'Stratify', species)
```

specifies to compute the stratified 5-fold cross-validation misclassification rate for the `classf` function with predictor data `meas` and response variable `species`.

Holdout — Fraction or number of observations used for holdout validation

[] (default) | scalar value in the range (0,1) | positive integer scalar

Fraction or number of observations used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1) or a positive integer scalar.

- If the `Holdout` value `p` is a scalar in the range (0,1), then `crossval` randomly selects and reserves approximately $p \times 100\%$ of the observations as test data.
- If the `Holdout` value `p` is a positive integer scalar, then `crossval` randomly selects and reserves `p` observations as test data.

In either case, `crossval` then trains the model specified by either `fun` or `predfun` using the rest of the data. Finally, the function uses the test data along with the trained model to compute either `values` or `err`.

You can use only one of these four name-value pair arguments: `Holdout`, `KFold`, `Leaveout`, and `Partition`.

Example: `'Holdout', 0.3`

Example: `'Holdout', 50`

Data Types: `single` | `double`

KFold — Number of folds

10 (default) | positive integer scalar greater than 1

Number of folds for k-fold cross-validation, specified as the comma-separated pair consisting of `'KFold'` and a positive integer scalar greater than 1.

If you specify `'KFold', k`, then `crossval` randomly partitions the data into `k` sets. For each set, the function reserves the set as test data, and trains the model specified by either `fun` or `predfun` using the other `k - 1` sets. `crossval` then uses the test data along with the trained model to compute either `values` or `err`.

You can use only one of these four name-value pair arguments: `Holdout`, `KFold`, `Leaveout`, and `Partition`.

Example: `'KFold', 5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation

[] (default) | 1

Leave-one-out cross-validation, specified as the comma-separated pair consisting of 'Leaveout' and 1.

If you specify 'Leaveout', 1, then for each observation, `crossval` reserves the observation as test data, and trains the model specified by either `fun` or `predfun` using the other observations. The function then uses the test observation along with the trained model to compute either `values` or `err`.

You can use only one of these four name-value pair arguments: `Holdout`, `KFold`, `Leaveout`, and `Partition`.

Example: 'Leaveout', 1

Data Types: single | double

MCREps — Number of Monte Carlo repetitions

1 (default) | positive integer scalar

Number of Monte Carlo repetitions for validation, specified as the comma-separated pair consisting of 'MCREps' and a positive integer scalar. If the first input of `crossval` is 'mse' or 'mcr' (see `criterion`), then `crossval` returns the mean MSE or misclassification rate across all Monte Carlo repetitions. Otherwise, `crossval` concatenates the values from all Monte Carlo repetitions along the first dimension.

If you specify both `Partition` and `MCREps`, then the first Monte Carlo repetition uses the partition information in the `cvpartition` object, and the software calls the `repartition` object function to generate new partitions for each of the remaining repetitions.

Example: 'MCREps', 5

Data Types: single | double

Partition — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'Partition' and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and test sets.

When you use `crossval`, you cannot specify both `Partition` and `Stratify`. Instead, directly specify a stratified partition when you create the `cvpartition` partition object.

You can use only one of these four name-value pair arguments: `Holdout`, `KFold`, `Leaveout`, and `Partition`.

Stratify — Variable specifying groups used for stratification

column vector

Variable specifying the groups used for stratification, specified as the comma-separated pair consisting of 'Stratify' and a column vector with the same number of rows as the data `X` or `X1, ..., XN`.

When you specify `Stratify`, both the training and test sets have roughly the same class proportions as in the `Stratify` vector. The software treats NaNs, empty character vectors, empty strings, <missing> values, and <undefined> values in `Stratify` as missing data values, and ignores the corresponding rows of the data.

A good practice is to use stratification when you use cross-validation with classification algorithms. Otherwise, some test sets might not include observations for all classes.

When you use `crossval`, you cannot specify both `Partition` and `Stratify`. Instead, directly specify a stratified partition when you create the `cvpartition` partition object.

Data Types: `single` | `double` | `logical` | `string` | `cell` | `categorical`

Options — Options for running in parallel and setting random streams

structure

Options for running computations in parallel and setting random streams, specified as the comma-separated pair consisting of 'Options' and a structure. Create the Options structure with `statset`. This table lists the option fields and their values.

Field Name	Value	Default
<code>UseParallel</code>	Set this value to <code>true</code> to run computations in parallel.	<code>false</code>
<code>UseSubstreams</code>	Set this value to <code>true</code> to run computations in parallel in a reproducible manner. To compute reproducibly, set <code>Streams</code> to a type that allows substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code> .	<code>false</code>
<code>Streams</code>	Specify this value as a <code>RandStream</code> object or a cell array consisting of one such object.	If you do not specify <code>Streams</code> , then <code>crossval</code> uses the default stream.

Note You need Parallel Computing Toolbox to run computations in parallel.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

Output Arguments

err — Mean squared error or misclassification rate

numeric scalar

Mean squared error or misclassification rate, returned as a numeric scalar. The type of error depends on the `criterion` value.

values — Loss values

column vector | matrix

Loss values, returned as a column vector or matrix. Each row of `values` corresponds to the output of `fun` for one partition of training and test data.

If the output returned by `fun` is multidimensional, then `crossval` reshapes the output and fits it into one row of values. For an example, see “Create Confusion Matrix Using Cross-Validation” on page 32-921.

Tips

- A good practice is to use stratification (see `Stratify`) when you use cross-validation with classification algorithms. Otherwise, some test sets might not include observations for all classes.

Alternative Functionality

Many classification and regression functions allow you to perform cross-validation directly.

- When you use fit functions such as `fitcsvm`, `fitctree`, and `fitrtree`, you can specify cross-validation options by using name-value pair arguments. Alternatively, you can first create models with these fit functions and then create a partitioned object by using the `crossval` object function. Use the `kfoldLoss` and `kfoldPredict` object functions to compute the loss and predicted values for the partitioned object. For more information, see `ClassificationPartitionedModel` and `RegressionPartitionedModel`.
- You can also specify cross-validation options when you perform lasso or elastic net regularization using `lasso` and `lassoglm`.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

Set the `'UseParallel'` field of the options structure to `true` using `statset` and specify the `'Options'` name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the `'Options'` name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics

“Selecting Features for Classifying High-dimensional Data”

Introduced in R2008a

crossval

Class: ClassificationDiscriminant

Cross-validated discriminant analysis classifier

Syntax

```
cvmodel = crossval(obj)
cvmodel = crossval(obj,Name,Value)
```

Description

`cvmodel = crossval(obj)` creates a partitioned model from `obj`, a fitted discriminant analysis classifier. By default, `crossval` uses 10-fold cross validation on the training data to create `cvmodel`.

`cvmodel = crossval(obj,Name,Value)` creates a partitioned model with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

CVPartition

Object of class `cvpartition`, created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these options at a time: `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Default: []

Holdout

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. Use only one of these options at a time: `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

KFold

Number of folds to use in a cross-validated classifier, a positive integer value greater than 1.

Use only one of these options at a time: `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Default: 10

Leaveout

Set to 'on' for leave-one-out cross validation.

Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Examples

Create a classification model for the Fisher iris data, and then create a cross-validation model. Evaluate the quality the model using `kfoldLoss`.

```
load fisheriris
obj = fitcdiscr(meas,species);
cvmodel = crossval(obj);
L = kfoldLoss(cvmodel)
```

```
L =
    0.0200
```

Tips

- Assess the predictive performance of `obj` on cross-validated data using the “kfold” methods and properties of `cvmodel`, such as `kfoldLoss`.

Alternatives

You can create a cross-validation classifier directly from the data, instead of creating a discriminant analysis classifier followed by a cross-validation classifier. To do so, include one of these options in `fitcdiscr`: 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

crossval

Cross-validate multiclass error-correcting output codes (ECOC) model

Syntax

```
CVMdl = crossval(Mdl)
CVMdl = crossval(Mdl,Name,Value)
```

Description

`CVMdl = crossval(Mdl)` returns a cross-validated (partitioned) multiclass error-correcting output codes (ECOC) model (`CVMdl`) from a trained ECOC model (`Mdl`). By default, `crossval` uses 10-fold cross-validation on the training data to create `CVMdl`, a `ClassificationPartitionedECOC` model.

`CVMdl = crossval(Mdl,Name,Value)` returns a partitioned ECOC model with additional options specified by one or more name-value pair arguments. For example, you can specify the number of folds or a holdout sample proportion.

Examples

Cross-Validate ECOC Classifier

Cross-validate an ECOC classifier with SVM binary learners, and estimate the generalized classification error.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and standardize the predictors.

```
t = templateSVM('Standardize',true)
```

```
t =
Fit template for classification SVM.
```

```

           Alpha: [0x1 double]
    BoxConstraint: []

    CachingMethod: ''
           ClipAlphas: []
DeltaGradientTolerance: []
           Epsilon: []
           GapTolerance: []
           KKTolerance: []
    IterationLimit: []
    KernelFunction: ''
           KernelScale: []
```

```

        KernelOffset: []
KernelPolynomialOrder: []
        NumPrint: []
          Nu: []
    OutlierFraction: []
RemoveDuplicates: []
    ShrinkagePeriod: []
        Solver: ''
StandardizeData: 1
SaveSupportVectors: []
    VerbosityLevel: []
        Version: 2
          Method: 'SVM'
            Type: 'classification'

```

`t` is an SVM template. Most of the template object properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train the ECOC classifier, and specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{ 'setosa', 'versicolor', 'virginica' });
```

`Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross-validate `Mdl` using 10-fold cross-validation.

```
CVMdl = crossval(Mdl);
```

`CVMdl` is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalized classification error.

```
genError = kfoldLoss(CVMdl)
```

```
genError = 0.0400
```

The generalized classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

Cross-Validate ECOC Classifier Using Parallel Computing

Consider the `arrhythmia` data set. This data set contains 16 classes, 13 of which are represented in the data. The first class indicates that the subject does not have arrhythmia, and the last class indicates that the arrhythmia state of the subject is not recorded. The other classes are ordinal levels indicating the severity of arrhythmia.

Train an ECOC classifier with a custom coding design specified by the description of the classes.

Load the `arrhythmia` data set. Convert `Y` to a `categorical` variable, and determine the number of classes.

```
load arrhythmia
Y = categorical(Y);
K = unique(Y); % Number of distinct classes
```

Construct a coding matrix that describes the nature of the classes.

```
OrdMat = designecoc(11,'ordinal');
nOrdMat = size(OrdMat);
class1VS0rd = [1; -ones(11,1); 0];
class1VSClass16 = [1; zeros(11,1); -1];
OrdVSClass16 = [0; ones(11,1); -1];
Coding = [class1VS0rd class1VSClass16 OrdVSClass16,...
          [zeros(1,nOrdMat(2)); OrdMat; zeros(1,nOrdMat(2))]];
```

Train an ECOC classifier using the custom coding design (Coding) and parallel computing. Specify an ensemble of 50 classification trees boosted using GentleBoost.

```
t = templateEnsemble('GentleBoost',50,'Tree');
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Coding',Coding,'Learners',t,'Options',options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

Mdl is a ClassificationECOC model. You can access its properties using dot notation.

Cross-validate Mdl using 8-fold cross-validation and parallel computing.

```
rng(1); % For reproducibility
CVMdl = crossval(Mdl,'Options',options,'KFold',8);
```

```
Warning: One or more folds do not contain points from all the groups.
```

Because some classes have low relative frequency, some folds do not train using observations from those classes. CVMdl is a ClassificationPartitionedECOC cross-validated ECOC model.

Estimate the generalization error using parallel computing.

```
error = kfoldLoss(CVMdl,'Options',options)

error = 0.3208
```

The cross-validated classification error is 32%, which indicates that this model does not generalize well. To improve the model, try training using a different boosting method, such as RobustBoost, or a different algorithm, such as SVM.

Input Arguments

Mdl — Full, trained multiclass ECOC model

ClassificationECOC model

Full, trained multiclass ECOC model, specified as a ClassificationECOC model trained with fitcecoc.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `crossval(Mdl, 'KFold', 3)` specifies using three folds in a cross-validated model.

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using `'CVPartition', cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', p`, then the software completes these steps:

- 1 Randomly select and reserve $p*100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify `'KFold', k`, then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold', 5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Leaveout', 'on'

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',true)`.

Tips

- Assess the predictive performance of `Mdl` on cross-validated data using the "kfold" methods and properties of `CVMDL`, such as `kfoldLoss`.

Alternative Functionality

Instead of training an ECOC model and then cross-validating it, you can create a cross-validated ECOC model directly by using `fitcecoc` and specifying one of these name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'Leaveout', or 'KFold'.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options', `statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

crossval

Cross validate ensemble

Syntax

```
cvens = crossval(ens)
cvens = crossval(ens,Name,Value)
```

Description

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a classification ensemble. Default is 10-fold cross validation.

`cvens = crossval(ens,Name,Value)` creates a cross-validated ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`ens`

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`cvpartition`

A partition of class `cvpartition`. Sets the partition for cross validation.

Use no more than one of the name-value pairs `cvpartition`, `holdout`, `kfold`, or `leaveout`.

`holdout`

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

`kfold`

Number of folds for cross validation, a numeric positive scalar greater than 1.

Use no more than one of the name-value pairs `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

`leaveout`

If `'on'`, use leave-one-out cross validation.

Use no more than one of the name-value pairs 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

nprint

Printout frequency, a positive integer scalar. Use this parameter to observe the training of cross-validation folds.

Default: 'off', meaning no printout

Output Arguments

cvens

A cross-validated classification ensemble of class `ClassificationPartitionedEnsemble`.

Examples

Cross-Validate Classification Ensemble

Create a cross-validated classification model for the Fisher iris data, and assess its quality using the `kfoldLoss` method.

Load the Fisher iris data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using `AdaBoostM2`.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Create a cross-validated ensemble from `ens` and find the classification error averaged over all folds.

```
rng(10,'twister') % For reproducibility
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L = 0.0467
```

Alternatives

You can create a cross-validation ensemble directly from the data, instead of creating an ensemble followed by a cross-validation ensemble. To do so, include one of these five options in `fitcensemble`: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

See Also

`ClassificationPartitionedEnsemble` | `cvpartition`

crossval

Cross-validated k -nearest neighbor classifier

Syntax

```
cvmodel = crossval mdl
cvmodel = crossval(mdl, Name, Value)
```

Description

`cvmodel = crossval(mdl)` creates a cross-validated (partitioned) model from `mdl`, a fitted KNN classification model. By default, `crossval` uses 10-fold cross-validation on the training data to create `cvmodel`, a `ClassificationPartitionedModel` object.

`cvmodel = crossval(mdl, Name, Value)` creates a partitioned model with additional options specified by one or more name-value pair arguments. For example, specify `'Leaveout'`, `'on'` for leave-one-out cross-validation.

Examples

Cross-Validated k -Nearest Neighbor Model

Create a cross-validated k -nearest neighbor model, and assess classification performance using the model.

Load the Fisher iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create a classifier for nearest neighbors.

```
mdl = fitcknn(X,Y);
```

Create a cross-validated classifier.

```
cvmdl = crossval(mdl)
```

```
cvmdl =
classreg.learning.partition.ClassificationPartitionedModel
  CrossValidatedModel: 'KNN'
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  NumObservations: 150
  KFold: 10
  Partition: [1x1 cvpartition]
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
```

Properties, Methods

Find the cross-validated loss of the classifier.

```
cvmdlloss = kfoldLoss(cvmdl)
cvmdlloss = 0.0467
```

The cross-validated loss is less than 5%. You can expect `mdl` to have a similar error rate.

Input Arguments

mdl — *k*-nearest neighbor classifier model

ClassificationKNN object

k-nearest neighbor classifier model, specified as a ClassificationKNN object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `crossval(mdl, 'KFold', 5)` creates a partitioned model with 5-fold cross-validation.

CVPartition — Cross-validation partition

[] (default) | cvpartition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition object created by the cvpartition function. `crossval` splits the data into subsets with cvpartition.

Use only one of these four options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Holdout — Fraction of data for holdout validation

scalar value in the range (0, 1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0, 1).

Use only one of these four options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'Holdout', 0.3

Data Types: single | double

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

Use only one of these four options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'KFold',3

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Leave-one-out is a special case of 'KFold' in which the number of folds equals the number of observations.

Use only one of these four options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'Leaveout', 'on'

Tips

- Assess the predictive performance of mdl on cross-validated data by using the “kfold” methods and properties of cvmodel, such as kfoldLoss.

Alternative Functionality

You can create a cross-validated model directly from the data instead of creating a model followed by a cross-validated model. To do so, specify one of these options in fitcknn: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Introduced in R2012a

crossval

Class: ClassificationNaiveBayes

Cross-validated naive Bayes classifier

Syntax

```
CVMDL = crossval(MDL)
CVMDL = crossval(MDL, Name, Value)
```

Description

`CVMDL = crossval(MDL)` returns a partitioned naive Bayes classifier (`CVSMdl`) from a trained naive Bayes classifier (`Mdl`).

By default, `crossval` uses 10-fold cross validation on the training data to create `CVMDL`.

`CVMDL = crossval(MDL, Name, Value)` returns a partitioned naive Bayes classifier with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify a holdout sample proportion.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using `'CVPartition', cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: double | single

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k , then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold', 5

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout', 'on'

Output Arguments

CVMDL — Cross-validated naive Bayes classifier

ClassificationPartitionedModel model

Cross-validated naive Bayes classifier, returned as a ClassificationPartitionedModel model.

Examples

Cross Validate a Naive Bayes Classifier Using crossval

Load the ionosphere data set.

```
load ionosphere
X = X(:,3:end); % Remove first two predictors for stability
rng(1);        % For reproducibility
```

Train a naive Bayes classifier. It is good practice to define the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'});
```

Mdl is a trained ClassificationNaiveBayes classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier using 10-fold cross validation.

```
CVMDL = crossval(Mdl)
```

```
CVMDL =
classreg.learning.partition.ClassificationPartitionedModel
  CrossValidatedModel: 'NaiveBayes'
  PredictorNames: {1x32 cell}
  ResponseName: 'Y'
  NumObservations: 351
  KFold: 10
  Partition: [1x1 cvpartition]
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
```

Properties, Methods

```
FirstModel = CVMDL.Trained{1}
```

```
FirstModel =
classreg.learning.classif.CompactClassificationNaiveBayes
  ResponseName: 'Y'
  CategoricalPredictors: []
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
  DistributionNames: {1x32 cell}
  DistributionParameters: {2x32 cell}
```

Properties, Methods

`CVMDL` is a `ClassificationPartitionedModel` cross-validated classifier. The software:

- 1 Randomly partitions the data into 10, equally sized sets.
- 2 Trains a naive Bayes classifier on nine of the sets.
- 3 Repeats steps 1 and 2 $k = 10$ times. It excludes one partition each time, and trains on the other nine partitions.
- 4 Combines generalization statistics for each fold.

`FirstModel` is the first of the 10 trained classifiers. It is a `CompactClassificationNaiveBayes` model.

You can estimate the generalization error by passing `CVMDL` to `kfoldLoss`.

Specify a Holdout-Sample Proportion for Naive Bayes Cross Validation

By default, `crossval` uses 10-fold cross validation to cross validate a naive Bayes classifier. You have several other options, such as specifying a different number of folds or holdout-sample proportion. This example shows how to specify a holdout-sample proportion.

Load the `ionosphere` data set.

```
load ionosphere
X = X(:,3:end); % Remove first two predictors for stability
rng(1);        % For reproducibility
```

Train a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to define the class order.

```
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'});
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier by specifying a 30% holdout sample.

```
CVMDL = crossval(Mdl,'Holdout',0.30)
```

```
CVMDL =
classreg.learning.partition.ClassificationPartitionedModel
  CrossValidatedModel: 'NaiveBayes'
  PredictorNames: {1x32 cell}
  ResponseName: 'Y'
  NumObservations: 351
  KFold: 1
  Partition: [1x1 cvpartition]
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
```

Properties, Methods

```
TrainedModel = CVMdl.Trained{1}

TrainedModel =
  classreg.learning.classif.CompactClassificationNaiveBayes
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    DistributionNames: {1x32 cell}
    DistributionParameters: {2x32 cell}
```

Properties, Methods

CVMdl is a `ClassificationPartitionedModel`. `TrainedModel` is a `CompactClassificationNaiveBayes` classifier trained using 70% of the data.

Estimate the generalization error.

```
kfoldLoss(CVMdl)
```

```
ans = 0.2571
```

The out-of-sample misclassification error is approximately 2.6%.

Tips

Assess the predictive performance of `Mdl` on cross-validated data using the “`kfold`” function and properties of `CVMdl`, such as `kfoldLoss`.

Alternatives

Instead of creating a naive Bayes classifier followed by a cross-validation classifier, create a cross-validated classifier directly using `fitcnb` and by specifying any of these name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'Leaveout', or 'KFold'.

crossval

Cross-validate support vector machine (SVM) classifier

Syntax

```
CVSVMMModel = crossval(SVMMModel)
CVSVMMModel = crossval(SVMMModel,Name,Value)
```

Description

`CVSVMMModel = crossval(SVMMModel)` returns a cross-validated (partitioned) support vector machine (SVM) classifier (`CVSVMMModel`) from a trained SVM classifier (`SVMMModel`). By default, `crossval` uses 10-fold cross-validation on the training data to create `CVSVMMModel`, a `ClassificationPartitionedModel` classifier.

`CVSVMMModel = crossval(SVMMModel,Name,Value)` returns a partitioned SVM classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the number of folds or holdout sample proportion.

Examples

Cross-Validate SVM Classifier

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Standardize the predictor data and specify the order of the classes.

```
SVMMModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

`SVMMModel` is a trained `ClassificationSVM` classifier. 'b' is the negative class and 'g' is the positive class.

Cross-validate the classifier using 10-fold cross-validation.

```
CVSVMMModel = crossval(SVMMModel)
```

```
CVSVMMModel =
  classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'SVM'
      PredictorNames: {1x34 cell}
      ResponseName: 'Y'
    NumObservations: 351
      KFold: 10
      Partition: [1x1 cvpartition]
      ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
```

Properties, Methods

```
FirstModel = CVSVMModel.Trained{1}

FirstModel =
  classreg.learning.classif.CompactClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
          Alpha: [78x1 double]
          Bias: -0.2209
  KernelParameters: [1x1 struct]
      Mu: [1x34 double]
      Sigma: [1x34 double]
  SupportVectors: [78x34 double]
  SupportVectorLabels: [78x1 double]
```

Properties, Methods

`CVSVMModel` is a `ClassificationPartitionedModel` cross-validated classifier. During cross-validation, the software completes these steps:

- 1 Randomly partition the data into 10 sets of equal size.
- 2 Train an SVM classifier on nine of the sets.
- 3 Repeat steps 1 and 2 $k = 10$ times. The software leaves out one partition each time and trains on the other nine partitions.
- 4 Combine generalization statistics for each fold.

`FirstModel` is the first of the 10 trained classifiers. It is a `CompactClassificationSVM` classifier.

You can estimate the generalization error by passing `CVSVMModel` to `kfoldLoss`.

Specify Holdout Sample Proportion for SVM Cross-Validation

Specify a holdout sample proportion for cross-validation. By default, `crossval` uses 10-fold cross-validation to cross-validate an SVM classifier. However, you have several other options for cross-validation. For example, you can specify a different number of folds or holdout sample proportion.

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

`SVModel` is a trained `ClassificationSVM` classifier.

Cross-validate the classifier by specifying a 15% holdout sample.

```

CVSVMModel = crossval(SVMModel, 'Holdout', 0.15)

CVSVMModel =
    classreg.learning.partition.ClassificationPartitionedModel
        CrossValidatedModel: 'SVM'
        PredictorNames: {1x34 cell}
        ResponseName: 'Y'
        NumObservations: 351
        KFold: 1
        Partition: [1x1 cvpartition]
        ClassNames: {'b' 'g'}
        ScoreTransform: 'none'

```

Properties, Methods

CVSVMModel is a ClassificationPartitionedModel.

Display properties of the classifier trained using 85% of the data.

```
TrainedModel = CVSVMModel.Trained{1}
```

```

TrainedModel =
    classreg.learning.classif.CompactClassificationSVM
        ResponseName: 'Y'
        CategoricalPredictors: []
        ClassNames: {'b' 'g'}
        ScoreTransform: 'none'
        Alpha: [74x1 double]
        Bias: -0.2952
        KernelParameters: [1x1 struct]
        Mu: [1x34 double]
        Sigma: [1x34 double]
        SupportVectors: [74x34 double]
        SupportVectorLabels: [74x1 double]

```

Properties, Methods

TrainedModel is a CompactClassificationSVM classifier trained using 85% of the data.

Estimate the generalization error.

```
kfoldLoss(CVSVMModel)
```

```
ans = 0.0769
```

The out-of-sample misclassification error is approximately 8%.

Input Arguments

SVMModel — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with fitcsvm.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `crossval(SVMModel, 'KFold', 5)` specifies using five folds in a cross-validated model.

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using `'CVPartition', cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', p`, then the software completes these steps:

- 1 Randomly select and reserve $p*100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify `'KFold', k`, then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold', 5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Tips

Assess the predictive performance of `SVMModel` on cross-validated data by using the “kfold” methods and properties of `CVSVMModel`, such as `kfoldLoss`.

Alternative Functionality

Instead of training an SVM classifier and then cross-validating it, you can create a cross-validated classifier directly by using `fitcsvm` and specifying any of these name-value pair arguments: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'Leaveout'`, or `'KFold'`.

Introduced in R2014a

crossval

Class: ClassificationTree

Cross-validated decision tree

Syntax

```
cvmodel = crossval(model)
cvmodel = crossval(model,Name,Value)
```

Description

`cvmodel = crossval(model)` creates a partitioned model from `model`, a fitted classification tree. By default, `crossval` uses 10-fold cross validation on the training data to create `cvmodel`.

`cvmodel = crossval(model,Name,Value)` creates a partitioned model with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`model`

A classification model, produced using `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` object created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these four options at a time: `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Holdout — Fraction of data for holdout validation

scalar value in the range $(0,1)$

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range $(0,1)$.

Use only one of these four options at a time: `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Example: `'Holdout',0.3`

Data Types: `single` | `double`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

Use only one of these four options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'KFold',3

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Leave-one-out is a special case of 'KFold' in which the number of folds equals the number of observations.

Use only one of these four options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'Leaveout', 'on'

Output Arguments

cvmodel — Partitioned model

ClassificationPartitionedModel object

Partitioned model, returned as a ClassificationPartitionedModel object.

Examples

Create a Cross-Validation Model

Create a classification model for the ionosphere data, then create a cross-validation model. Evaluate the quality the model using `kfoldLoss`.

```
load ionosphere
tree = fitctree(X,Y);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)
```

```
L = 0.1111
```

Tips

- Assess the predictive performance of `model` on cross-validated data using the “kfold” methods and properties of `cvmodel`, such as `kfoldLoss`.

Alternatives

You can create a cross-validation tree directly from the data, instead of creating a decision tree followed by a cross-validation tree. To do so, include one of these five options in `fitctree`: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

See Also

`crossval` | `fitctree`

crossval

Cross validate ensemble

Syntax

```
cvens = crossval(ens)
cvens = crossval(ens,Name,Value)
```

Description

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a regression ensemble. Default is 10-fold cross validation.

`cvens = crossval(ens,Name,Value)` creates a cross-validated ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`ens`

A regression ensemble created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`cvpartition`

A partition of class `cvpartition`. Sets the partition for cross validation.

Use no more than one of the name-value pairs `cvpartition`, `holdout`, `kfold`, and `leaveout`.

`holdout`

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

`kfold`

Number of folds for cross validation, a positive integer value greater than 1.

Use no more than one of the name-value pairs `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

`leaveout`

If `'on'`, use leave-one-out cross-validation.

Use no more than one of the name-value pairs 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

nprint

Printout frequency, a positive integer scalar. Use this parameter to observe the training of cross-validation folds.

Default: 'off', meaning no printout

Output Arguments

cvens

A cross-validated classification ensemble of class `RegressionPartitionedEnsemble`.

Examples

Create Cross-Validated Regression Model

Create a cross-validated regression model for the `carsmall` data, and evaluate its quality using the `kfoldLoss` method.

Load the `carsmall` data set and select acceleration, displacement, horsepower, and vehicle weight as predictors.

```
load carsmall;  
X = [Acceleration Displacement Horsepower Weight];
```

Train a regression ensemble.

```
rens = fitensemble(X,MPG);
```

Create a cross-validated ensemble from `rens` and find the cross-validation loss.

```
rng(10,'twister') % For reproducibility  
cvens = crossval(rens);  
L = kfoldLoss(cvens)
```

```
L = 30.8569
```

Alternatives

You can create a cross-validation ensemble directly from the data, instead of creating an ensemble followed by a cross-validation ensemble. To do so, include one of these five options in `fitensemble`: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

See Also

`RegressionPartitionedEnsemble` | `cvpartition` | `kfoldLoss`

crossval

Class: RegressionGP

Cross-validate Gaussian process regression model

Syntax

```
cvMdl = crossval(gprMdl)
cvmdl = crossval(gprMdl,Name,Value)
```

Description

`cvMdl = crossval(gprMdl)` returns the partitioned model, `cvMdl`, built from the Gaussian process regression (GPR) model, `gprMdl`, using 10-fold cross validation.

`cvmdl` is a `RegressionPartitionedModel` object, and `gprMdl` is a `RegressionGP` (full) object.

`cvmdl = crossval(gprMdl,Name,Value)` returns the partitioned model, `cvmdl`, with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the number of folds or the fraction of the data to use for testing.

Input Arguments

gprMdl — Gaussian process regression model

`RegressionGP` object

Gaussian process regression model, specified as a `RegressionGP` (full) object. You cannot call `crossval` on a compact regression object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.
